Adversities in childhood and their impact on mental health across the life course

S. Pollak

University of Wisconsin,

Psychology-Pediatrics-Psychiatry-Neuroscience, Madison, USA

How is the brain shaped and refined by children's early social and emotional experiences? In this colloquium, I will focus on the development of children who have endured environments marked by toxic levels of stress early in their development. These children are known to be at increased risk for a variety of health, academic, and social problems. Some of these problems appear immediately, but others may not manifest themselves until much later in development. I will highlight ways in which we can address central

issues in human development by studying the quality and timing of children's social experiences. To do so, I will describe recent research involving children who have experienced child abuse and neglect, children raised in poverty, children raised in institutional settings, children who have endured traumatic life experiences, and typically developing children. Through these studies, I will highlight new insights about the developmental processes underlying children's sensitivity to their social environments as a way to understand the emergence of both adaptive and maladaptive human emotional behavior. Defining and specifying ways in which the environment creates long-term effects on brain and behavior holds tremendous promise for improving the health and well-being of children.

Debate: Suicide risk can be predicted

D01

Debate: Can suicide be prevented?

D. Wasserman

Karolinska Institute, National Centre for Suicide Research and Prevention of Mental ill-Health NASP, Stockholm, Sweden

Suicidal behaviour is the most common life-threatening psychiatric emergency. Reliable and precise tools to predict suicidal behaviours and to get support in the clinical practice are frequently requested. Several measurement tools for suicide risk assessment, both psychometric and biological have been studied. However, the low precision of the predictions make these tools insufficient from the clinical perspective. To date, the same applies to the search of genetic predictors. The best information is gained in a standard clinical evaluation, which puts focus on the need of acquiring the best possible knowledge and skills by practicing clinicians. The European Psychiatric Association (EPA) issued a guidance paper on suicide treatment and prevention, which was published in the European Psychiatry in 2012 [1]. This guidance paper elucidates the process of systematic evaluation of suicidal risks in the

clinical interview, an overview of the best treatment possibilities and strategies for follow-up. As psychiatric patients constitute the majority of people who commit suicide, the adequate treatment of depression, substance use disorders, schizophrenia and other psychiatric diseases is a must.

We will probably never be able to have perfect measurements to predict if an individual will or will not commit suicide, due to the complexities of human behaviour. However, with a good clinical praxis, suicide is an unnecessary death [2].

21st century psychiatry: The need for a unitary framework

M. Maj

University of Naples SUN, Department of Psychiatry, Naples, Italy

While the plurality of approaches is a richness of psychiatry, we need today a unitary framework in which the vast majority of psychiatrists are able to place and recognize themselves. An essential component of this framework should be the awareness that a major outcome of research efforts of the past thirty years is the notion that a simple deterministic etiological model cannot be applied to mental disorders, which instead represent the product of the complex interaction of a multiplicity of vulnerability and protective factors of different nature (biological, intrapsychic, interpersonal, psychosocial). Most current significant etiological research in psychiatry can be accommodated within this framework, thus appearing much less chaotic, inconsistent and fragmentary. This first level of the framework affects in a probabilistic, not a deterministic, way the second one, that of neurobiological, cognitive and psychological intermediate processes. It is unavoidable that different languages be used to describe these processes, but these languages may be translatable into each other to some extent. Furthermore, comprehensive pathogenetic models usually require the integration of different languages. This second level leads, again in a probabilistic way, to the third level, that of symptoms, signs, cognitive dysfunctions and psychopathological dimensions. These are the elements composing the fourth level, the syndromal one. The ICD/DSM formulation of this fourth level is not optimal, but it is the best we have at the moment. Certainly, the fact that two major diagnostic systems exist in psychiatry adds to the confusion and the uncertainty, and should be overcome in the future.

EF02

Outcomes of promotion, prevention, treatment and care

M. Muijen

WHO European Office for Europe, Mental Health, Copenhagen, Denmark

The WHO European Mental Health Action Plan encompasses promotion, prevention, treatment and recovery, within the context of

a model of mental health that proposes a set of socio-economic and biological determinants that predispose to vulnerabilities and increase the risk of disorders. These determinants also negatively affect access to and quality of care. Such risk factors are shared with common non-communicable disorders, increasing the risk of morbidity and early mortality for people with mental disorders.

Mental health promotion and prevention actions should therefore be addressing determinants such as alcohol and smoking. However, such determinants are not equally distributed in the population, but cluster among vulnerable groups, such as those with a low income, the unemployed and minority groups. These groups overlap with the populations services struggle to reach. In addition, both primary care and specialist mental health services struggle to identify and treat people with co-morbidities. This suggests that connections need to be established between public health, primary care and specialist mental health services.

WHO is focussing on the strengthening of primary care and the interface with mental health services. In particular, there is an urgent need to screen people who present with symptoms of NCDs or mental disorders for common determinants and co-morbidities. Effective health promotion activities need to be offered to populations at risk, in addition to universal health promotion interventions such as taxation or advertising bans. Some examples will be presented.

EF03

Human rights and mental health care – Can we find a common ground?

D. Pūras

Vilnius university, Department of Psychiatry, Vilnius, Lithuania

Future of psychiatry is discussed in the context of modern human rights principles, evidence-based policies and sustainable development goals.

After international community agreed on sustainable development goals to be reached by 2030, there is a good opportunity to address mental health as a priority and to substantially invest in promotion of mental health and emotional well-being.

Psychiatry, as an influential specialty, needs to reconsider its strategy in this context, and to rethink strengths and weaknesses of its role and image.

Protection of dignity and human rights of persons with psychosocial disabilities, in the post-CRPD framework, should become

a priority for psychiatry. Common ground for search of a new consensus between different views on non-consensual treatment in psychiatry could be equilibrium within the principles of “first, do no harm”, “right to treatment” and “no hierarchy within human rights”. For mental healthcare practice, this would mean that good intentions to provide evidence-based interventions do not justify the use of force and deprivation of liberty which threatens dignity and universal human rights principles.

Psychiatry, while rethinking future directions, should critically reconsider its current focus on neurobiological paradigm and tradition of using force in the name of medicine and social control. These

two paradigms, traditionally perceived as strengths of psychiatry and sources of its power, are now too often misused and increasingly discussed as lacking evidence, ignoring human rights and thus threatening image of psychiatry. Instead, psychiatry could consider accepting post-CRPD challenge as a unique opportunity for change, through strengthening strategic alliance with human rights mechanisms, social sciences, general and community medicine, modern public health approach and users' perspective.

Symposium: choosing wisely – prioritization in mental health care?

CS01

Making mental health part of the solution for reducing the negative impact of austerity – a perspective from England

S. Bailey

The Royal College of Psychiatrists, London, United Kingdom

This paper will describe four initiatives in England to protect the mental health of the population.

1. Lobbying government – presenting the evidence about how mental health services can reduce the impact of austerity on families and communities.
2. Building psychosocial resilience in schools through well being programmes and through “enabling environments” in the workplace.
3. Delivering sustainability in mental and physical healthcare:
 - prevention – don’t get ill in the first place;
 - patient empowerment – if unwell patient to self manage where possible;
 - lean service design – if healthcare services necessary, these should be efficient and high value;
 - low carbon – reducing carbon footprint and waste.
4. Working across medicine – choosing wisely:
 - promoting conversations between doctors and patients to choose care that is:
 - supported by evidence,
 - not duplicative of other tests of procedures already received,
 - free from harm,
 - truly necessary.

Disclosure of interest The author has not supplied his declaration of competing interest.

Choosing wisely in Germany – adapting an international initiative to a national healthcare agenda

D. Klemperer

Ostbayerische Technische Hochschule Regensburg, Faculty of Social and Health Care Sciences, Regensburg, Germany

Overuse and underuse in healthcare is a chronic problem in most healthcare systems. Inspired by the North American Choosing Wisely Initiative, the Association of Scientific Medical Societies in Germany (AWMF), which actually counts 173 member organisations, decided to address the problem. The aim of the German “Gemeinsam klug entscheiden” (deciding together wisely)-initiative is to reduce overuse, underuse and misuse of health interventions in areas where recommendations of clinical practice guidelines (CPG) are not adequately implemented or missing. Starting point are the positive and negative recommendations of the CPGs, which the AWMF-member societies have developed for more than 20 years, following the manual and rules set up by AWMF. To identify and select recommendations methodological criteria have been developed by a working group in a consensus-based process. The development of AWMF-CPGs follows a methodology that aims to ensure the full integration of evidence, an interdisciplinary and interprofessional perspective, the prevention of bias as a consequence of conflicts of interest and full transparency of the development process.

Choosing wisely – the viewpoint and experiences of the American Psychiatric Association

J. McIntyre

University of Rochester, Psychiatry, Rochester, NY, USA

Choosing wisely, a program developed by the American Board of Internal Medicine in 2012, is advancing a national dialogue on avoiding wasteful or unnecessary medical tests, treatments or procedures. Recommendations are chosen that have a strong evidence base. There are now over seventy specialty society partners including the American Psychiatric Association. The program attempts to involve patients in the dialogue and an important partner in the program is consumer reports. In this presentation, information about the origins of the program, its development and the impact it has on the practice of medicine will be reviewed. Also the measures developed and submitted by the American Psychiatric Association will be discussed and potential additional psychiatric measures will be discussed. The strengths and weaknesses of the program will be identified.

Disclosure of interest The author has not supplied his declaration of competing interest.

CS04
Prioritization in medicine – a special role for mental healthcare?

T. Meyer
 Hannover Medical School, Institute for epidemiology – social medicine and health system research, Hannover, Germany

The international debate on priority setting in health care has been around for more than 30 years now, Denmark, Norway, the US state of Oregon, Sweden, UK and the Netherlands being among their vanguards. From the beginning, the debate has been related to – or was even seen as identical to – the discourse on rationing in health care. Based on these international debates, the presentation will introduce different understandings and characteristics of the priority-setting concept in health care and will argue for a clear distinction between priority setting and rationing. Different ways of implementing priority setting, i.e., by means of guidelines or ethical frameworks, will be introduced to set the frame for the current choosing-wisely initiative. It will be argued that priority setting is important for the organisation of mental health care, as it is for health and social care of different chronic disorders.

Disclosure of interest The author has not supplied his declaration of competing interest.

Symposium: psychosocial rehabilitation and mental health

CS05
Evidence-based psychosocial measures in rehabilitation

T. Becker^{1,*}, U. Guehne², S. Riedel-Heller³
¹ Günzburg, Germany
² Universität Leipzig, Selbständige Abteilung für Sozialmedizin, Leipzig, Germany
³ Universität Leipzig-Medizinische Fakultät, Institut für Sozialmedizin- Arbeitsmedizin und Public Health, Institut für Sozialmedizin- Arbeitsmedizin und Public Health, Germany
 * Corresponding author.

Background Psychosocial interventions are essential tools in mental health care and rehabilitation. A range of interventions relevant to rehabilitation that are covered in a German DGPPN S3 guideline on psychosocial interventions are discussed.

Methods Literature search and (mostly) systematic reviews were performed for a range of psychosocial interventions.

Findings Milieu therapy (MT) includes measures that impinge on therapeutic milieu/atmosphere in joint professional/user groups in the course of treatment. MT provides a context in which psychosocial interventions can be implemented. There is evidence of its effectiveness in improving mental health outcomes. Peer involvement (PI) and peer support are supported by promising evidence as innovative interventions in mental health care. Findings on case management (CM) are inconsistent. There

are difficulties in defining CM. CM strengths include treatment satisfaction and continuity of care. With respect to integration in the labour market for people with severe mental illness supported employment (SE) has been shown to be more effective in achieving job placement. A proportion of SE users fail to find jobs on the general labour market. Other types of work rehabilitation are required, and there is room for pre-vocational training interventions.

Discussion Psychosocial interventions are strong interventions. The strength of the evidence is varied. The use of psychosocial interventions rests on experience, evidence and ethics.

Conclusions Psychosocial interventions are indispensable in building mental health care systems. Vocational interventions and residential services are mandatory. Peer involvement could help in moving mental health services forward.

Disclosure of interest The authors have not supplied their declaration of competing interest.

CS06
Quality assessment of mental health rehabilitation services

H. Killaspy
 University College London, London, United Kingdom

Objectives Providing good quality mental health care is vital to achieve better outcomes but service quality is a complex, multidimensional construct that extends beyond the delivery of specific evidence based treatments and interventions. This makes it difficult to operationalize and measure, particularly at the international level where different socioeconomic and political contexts impact. Mental health rehabilitation services focus on people with severe and complex psychosis. This group are one of the most socially excluded in society and are vulnerable to exploitation and abuse. They are also, by definition, difficult to treat and, historically, have often been institutionalised in hospital or community facilities.

Aims This presentation will report on the development and application of an internationally validated quality assessment tool for longer term mental health care facilities, the Quality Indicator for Rehabilitative Care (QuIRC).

Methods The content of the QuIRC was derived from a systematic literature review, international Delphi exercise and review of care standards in ten European countries. Its psychometric properties were assessed in over 200 longer-term mental health facilities across Europe involving validation with over 1750 service users. It has subsequently been used in a national programme of research into inpatient mental health rehabilitation services in England which will also be briefly described.

Results The QuIRC has excellent inter-rater reliability and validity. Specific aspects of care assessed by the QuIRC have been found to be associated with successful community discharge from inpatient mental health rehabilitation services.

Conclusions The QuIRC is a free to use, standardised and validated on-line international quality assessment benchmarking and research tool, available in ten European languages.

Disclosure of interest The author has not supplied his declaration of competing interest.

Symposium: mental health in young women: are they more at risk in the 21st century?

CS07

Why mental health in young women is more at risk in the 21st century

H. Herrman

Orygen – The National Centre of Excellence in Youth Mental Health and The University of Melbourne, Centre for Youth Mental Health, Melbourne, Australia

The mental health of women and girls is endangered when they experience violence and gender-based discrimination, including poor access to education and lack of autonomy in the family and broader community. The conditions of conflict and poverty that foster violence against women, including systematic sexual violence, are growing across some world regions including parts of Africa and Asia, even while women are becoming more empowered in others. The prevalence of abuse of women at home appears to be high across the regions, and the widespread nature of other forms of violence such as genital mutilation and trafficking is increasingly recognised.

The psychological consequences of violence increase the risk of mental illnesses such as depression and anxiety, including the risk of these conditions in the perinatal period. The services provided for women with mental ill health in primary health care, maternal and child health services, community mental health services or hospital settings do not in many places respond adequately to their needs. The inadequacies in response can reproduce or amplify the difficulties and injustices that women face in their lives, especially maltreatment as girls and intimate partner violence as adults.

The World Psychiatric Association aims to increase awareness of the need for improved mental health of women and girls worldwide, especially in settings of disadvantage, conflict and adversity. It is also aiming to work in partnership with other health and non-health organisations to develop a platform for action to respond to the need – for health promotion, risk reduction and access to prevention and treatment services.

Disclosure of interest The author has not supplied his declaration of competing interest.

CS08

Early psychosis in young women

A. Riecher-Rössler

University of Basel Psychiatric Clinics, Center for Gender Research and Early Detection, Basel, Switzerland

Introduction It is well known that young women are at lower risk for schizophrenic psychoses than young men. However, little is known about the peculiarities of emerging psychosis in young women.

Objectives To describe characteristics of emerging psychosis in women.

Methods Within the FePsy (Früherkennung von Psychosen=early detection of psychosis) study at the University of Basel Psychiatric Clinics we have examined consecutively all patients with a first episode of psychosis (FEP) or an at-risk mental state (ARMS) referred to us between 2000 and 2015.

Results Women did not significantly differ from men regarding psychopathology, neither in the ARMS nor in the FEP group. This was true for positive as well as negative symptoms and basic symptoms. Interestingly, women had a higher correlation of self-rating with observer-rating regarding psychotic symptoms. Duration of untreated psychosis was significantly lower in women than in men. Women seek help more quickly than men and their first contact is more often their partner.

Regarding neurocognition women showed a slightly better performance in verbal tasks. They also had higher prolactin levels and larger pituitary volumes, even when drug-naïve. Transition to psychosis occurred as often and as quickly in women as in men.

Conclusions There are only few gender differences in patients with emerging psychosis, which resemble mainly those found in the general population, with women showing a better help-seeking behavior, being more partner-oriented, having a better verbal performance and potentially also a higher stress reactivity [1].

Disclosure of interest The author has not supplied his declaration of competing interest.

Symposium: brain plasticity in psychiatry

CS09

Relevance of brain plasticity to neuroprogression and staging of bipolar disorders – opposing effects of illness burden and lithium treatment

T. Hajek^{1,2,*}, M. Kopecek², M. Alda¹

¹ Department of Psychiatry, Dalhousie University, Halifax, Canada

² National Institute of Mental Health of Czech Republic, Psychiatry, Klecany, Czech Republic

* Corresponding author.

Introduction Brain changes in bipolar disorders (BD) may represent inherited risk factors or consequences of the illness (brain plasticity). Neuroanatomical changes, which predispose for BD could aid in early diagnosis, whereas the neuronal sequelae of BD could yield biological outcome measures for prevention and treatment.

Methods To separate neuroanatomical changes into those that increase the risk of BD versus those that result from it, we acquired MRI/clinical data from participants at different stages of BD, including: (1) affected and unaffected offspring of bipolar parents ($n = 86$); (2) participants with substantial illness burden who had had at least 2 years of current Li treatment ($n = 37$) or were Li naïve ($n = 19$). We also recruited 99 healthy controls matched to the above-mentioned cohorts by age and sex.

Results Relative to controls, both the affected and unaffected offspring of bipolar probands showed increased right inferior frontal gyrus (rIFG) volume, but comparable hippocampal volumes and prefrontal N-acetyl aspartate (NAA) levels. Larger rIFG volume was associated with an increased risk of conversion to psychiatric disorders within 4 years following the MRI scanning (hazard ratio = 4.5). In contrast, Li naïve patients with substantial illness burden had smaller rIFG, hippocampal volumes and prefrontal NAA levels than controls, who were comparable in these indices to the Li treated subjects with substantial illness burden.

Conclusions Brain structural changes in BD may not be static, but may instead result from an interplay between illness burden and compensatory processes. This illness related brain plasticity may be modulated by lithium treatment.

24th European Congress of Psychiatry Joint symposium

Symposium: Europe meets Asia – commonalities, differences and future perspectives on postgraduate training in psychiatry – Joint symposium with AFPA

JS01

The Asian perspective

S. Kanba

Kyushu University, Neuropsychiatry, Fukuoka, Japan

The 1990s saw an inexorable wave of globalization. This came as a massive jolt to the culture of Japan, which until then had been in a state of balance and stability. However, unlike the West, in Japan this economic globalization is not a manifestation born of individualistic value systems and socioeconomic systems that had previously been in place. The spirit that was imported together with economic globalization was not mature individualism. At the risk of overstating the case, Japan went too far in ripping apart the complex, intricate interpersonal relations that had been in place and moving toward the individualism.

I will explain that the relationship between culture and the mind takes the form of a cooperative organization. The relationship between culture and the brain therefore also takes the form of a cooperative organization. Culture has a top-down influence even on simple visual perception.

I will state that the phenomenon of the depressive state generally known as “modern depression” occurring in epidemic proportions can be explained in terms of a loss of etiquette due to cultural intermingling as well as cultural affordance. Public opinion tends toward the argument of whether or not those who have sunk into this depressive state simply want to slack off. However, from the point of view of psychiatry, it is more important to consider the fact that while manifestations and popular names may differ, mental disorders will continue to develop in the future, regardless of the era, and we need to cultivate a better understanding of their structure. The essential challenge in this respect is the merging of cultural psychology and cultural neuroscience.

The trainee perspective

M. Phanasathit

Department of Psychiatry, Thammasat University, Pathumthani, Thailand

In Asia, while the postgraduate training in psychiatry employs the World Psychiatric Association (WPA) core training curriculum for psychiatry as a standard course, some adjustment to the course is required for the unique demographic and sociocultural characteristics of its region.

From the small group work in the 14th course for the academic development of psychiatrists (CAD), organized by the Japan Young Psychiatrists Organization (JYPO) in 2015, young psychiatrists from Indonesia, Japan, Philippines, South Korea, Taiwan and Thailand agreed that the core psychiatric curriculum must include both general and psychiatric knowledge which are fundamental to clinical practice and continuous learning. General knowledge consists of knowledge management, academic skills, epidemiology, research methodology and statistics, evidence-based medicine, bio-ethic and medicolegal issues, professionalism, and medical anthropology, while psychiatric knowledge incorporates basic science, diagnostic assessment skills, etiopathogenesis, pharmacological and non-pharmacological treatments, disease prognosis, and mental health promotion and prevention. Moreover, the curriculum for junior psychiatric residents has to be composed of courses from various departments that encourage them practice in holistic care and multidisciplinary approach including emergency medicine, internal medicine, neurology, pediatrics, community based medicine, anesthesiology, radiology and palliative care. For senior psychiatric residents, the training program should consist of in-depth psychiatric knowledge, general psychotherapy concept and basic skills, and free elective subjects.

Since Asia is different from Europe in terms of large population, shortage of psychiatrists, aging society, racial and cultural diversity, and high risk of natural disasters; the postgraduate training in psychiatry in Asia should focus on the subjects regarding health economy, geriatric psychiatry, cultural and trans-cultural psychiatry, ethnopsychopharmacology, disaster psychiatry and mental health. Furthermore, the cooperation among Asian countries should be promoted in order to initiate knowledge exchange and research collaboration. These could contribute to the sustainable advancement of Asian psychiatry and mental health in the future.

Internally displaced persons in Ukraine

V. Korostiy

Kharkiv national medical university, Psychiatry – narcology and medical psychology, Kharkov, Ukraine

As of May 21, 2015 UNHCR has information about 1,299,800 IDPs, the data provided by the Ministry of Social Policy of Ukraine. Since the process of establishing a centralized system for registration is still pending, the actual number of persons displaced within the country may be higher.

We have a complex psychopathological and clinical research psychodiagnostic 97 internally displaced people in volunteer center, located at the central train station in Kharkiv to study the clinical features of neurotic disorders.

The results showed that 75.9% of IDPs observed have violations of adaptation: long-term depressive reaction (F 43.21) and predominant disturbance of other emotions (F 43.23). The clinical picture is dominated by the depression, anxiety, inner tension, inability to relax, asthenic symptoms, various fears and paroxysmal autonomic instability.

The results of the diagnostic psychological studies have found that men reactive alarm indicators (average – $37,7 \pm 3,0$) were higher than trait anxiety (average – $32,6 \pm 2,9$). On the contrary, women figures trait anxiety (average – $38,6 \pm 2,9$) were higher than reactive anxiety (average – $34,7 \pm 3,0$). Severity of depressive symptoms also slightly prevailed in women. The mean score on the Hamilton scale for men was $17,0 \pm 2,3$ points, women – $18,0 \pm 2,3$ points.

A new humanitarian emergency: Refugees and mental health in Turkey

L. Küey

Psychology Department, Istanbul Bilgi University, Istanbul, Turkey

Warfare in different parts of the world has led to a humanitarian emergency: forced displacement of millions of people. Global forced displacement in 2014 was the highest displacement on record since WW 2. By the end-2014, 59.5 million individuals forcibly displaced worldwide, as a result of persecution, armed conflicts, general violence, wars, or human rights violations. The number of individuals forced to leave their homes per day reached to 42,500 in 2014, hence, increased 4 times in the last 4 years. Top five refugee hosting countries are Turkey, Pakistan, Lebanon, Iran, Ethiopia and Jordan. While Turkey hosted 1.6 million forced displaced people in 2014; it is estimated that this number reached 2.5 million by the end of 2015.

Forced displacement of people due to warfare may be considered as a psychosocial earthquake. Especially after the deaths of thousands of them in the Mediterranean in the last couple years has brought this issue sharply into the focus of the whole world. While the deaths of the forced displaced people on across the borders of the whole world in the first nine months of 2014 were slightly over 4000; it reached the same number of human loss only in the Mediterranean region in 2015.

Refugees fleeing with few possessions leading to neighboring or more developed countries face many life-threatening risks on the way, as they have nowhere to turn. A refugee is a person who has lost the past for an unknown future. Experiences of loss and danger

are imprinted in their selves. It is shown that, in the short/medium term, 60% suffer from mental disorders, e.g., posttraumatic stress disorder (PTSD), depressive disorders, anxiety disorders, psychosis, and dissociative disorders. In the long term, existing evidence suggests that mental disorders tend to be highly prevalent in war refugees even many years after resettlement. This increased risk may not only be a consequence of exposure to wartime trauma but may also be influenced by post-migration socioeconomic factors. In fact, “we are seeing here the immense costs of not ending wars, of failing to resolve or prevent conflicts.” Once more, psychiatry and mental health workers are facing the mental health consequences of persecution, general violence, wars, and human rights violations caused by the current prevailing economy-politics and socio-politics. So, a serious challenge here is avoiding the medicalization of social phenomena. This presentation will discuss the issue of forced displaced people considering it as a humanitarian tragedy with some examples of its mental health consequences from Turkey.

Symposium: advancing implementation – Joint symposium with European mental health programmes

JS06

Implementing the mental health action plan – experiences and challenges

M. Muijen

WHO Regional Office for Europe, Mental Health, Copenhagen, Denmark

The WHO European mental health action plan was adopted by all countries in the European region in Izmir in September 2013. Its 6 objectives cover promotion and prevention, human rights, services and partnerships. Since its adoption, the WHO mental health programme is working in some 25 countries, supporting policy development and implementation. Priorities are the introduction of health promotion programmes for vulnerable groups; the competence of primary care to identify, diagnose and treat people with mental disorders; and the implementation of community-based service models sensitive to the culture and resources of countries. Particularly successful have been countries where a consensus was established between policymakers and professional leaders, and where different levels of government worked together. Obstacles

experiences have been funding cuts and lack of incentives. Some examples will be presented.

Disclosure of interest The author has not supplied his declaration of competing interest.

Can ecstasy treat the agony of PTSD?

M. Mithoefer

Department of Psychiatry and Behavioral Sciences, Medical University of South Carolina, Charleston, USA

Introduction Two serotonin reuptake inhibitors (SSRIs) have received FDA indication for treatment of PTSD, however the effectiveness of pharmacotherapy for PTSD is limited. Psychotherapy, including several well established evidence based methods, is the mainstay of PTSD treatment. Despite advances in this area, a significant percentage of PTSD patients are refractory to existing treatments. Recent research has explored the possibility that certain drugs could increase the effectiveness of psychotherapy when administered intermittently in conjunction with psychotherapy sessions. The most robust published. Results to date using this approach have been in early clinical trials of \pm 3,4-methylenedioxymethamphetamine (MDMA)-assisted psychotherapy. These studies primarily involved civilians with treatment-resistant, crime-related PTSD. A more recent phase 2 trial, completed in 2015 yielded equally promising. Results in a cohort of military veterans, police officers and firefighters, mostly veterans from the wars in Iraq and Afghanistan.

Methodology In these double blind controlled trials subjects with PTSD refractory to prior treatment are randomized to an active dose of MDMA or an active or inactive placebo administered to each individual on only two or three occasions during eight-hour psychotherapy sessions one month apart, in conjunction with preparatory and follow-up psychotherapy sessions. Outcome measures are repeated one or two months after the second MDMA-assisted session before the blind is broken. Subjects who were randomized to full dose MDMA are then eligible for one additional, open label, MDMA-assisted session. Those randomized to placebo or a lower dose of MDMA are eligible for three open-label full dose sessions. Outcome measures are repeated two months following the third MDMA-assisted session. The primary outcome measure is the Clinician Administered PTSD Scale (CAPS). Additional measures include the Beck Depression Inventory-II (BDI-II), Global Assessment of Functioning (GAF), Pittsburgh Sleep Quality Index (PSQI) and Posttraumatic Growth Inventory (PTGI).

Results In the original study comparing MDMA with inactive placebo along with the same psychotherapy PTSD was resolved in 83% of the MDMA group vs. 25% of the placebo group receiving the same therapy. Improvement was maintained for at least 74% of subjects at long-term follow-up a mean of 45 months later. In a more recent, unpublished, study both the high dose and the medium dose of MDMA showed large effect sizes in reducing CAPS scores, and improvements in secondary measures: and BDI-II, PSQI, GAF and PTGI.

Conclusion Evidence in phase II trials suggest that MDMA-assisted psychotherapy is effective in treating PTSD in both civilians and veterans who have not responded to established treatments. Phase III trials are necessary to definitively establish safety and efficacy of MDMA-assisted psychotherapy for PTSD.

Treatment of heroin dependence with ibogaine

A. Schellekens^{1,*}, T. Oosteren², T. Knuijver², R.J. Verkes¹, M. Belgers²

¹ Radboud University Medical Centre, Donders Centre for Neuroscience- department of Psychiatry – Nijmegen Institute for Scientist Practitioners in Addiction, Nijmegen, Netherlands

² IrisZorg, addiction care, Arnhem, Netherlands

* Corresponding author.

Background The use of the hallucinogen ibogaine as an anti-addiction agent has been described in several case reports, dating back to the eighties. The anti-addiction properties of ibogaine have been confirmed in a large body of animal work. Ibogaine has been shown to be effective in reducing withdrawal severity and substance use for a variety of substances, including cocaine and opiates. Animal studies also show some potentially dangerous adverse reactions, including cerebellar toxicity and potential cardiac effects. While pharmacological treatment options for opiate and cocaine dependence are still limited, ibogaine assisted treatment might be a promising new option. Therefore more systematic studies on its toxicity and efficacy are warranted. In our studies we address these two research questions: is ibogaine treatment for opiate dependence safe and effective for treating opiate withdrawal and relapse prevention? A secondary objective is to explore the pharmacokinetic properties of ibogaine.

Methods Animal work: first we performed a systematic review and meta-analysis of animal studies on ibogaine. Thirty studies were included in the systematic review, of which 27 could be analyzed in meta-analysis. Human studies: fifteen opiate dependent patients will be treated with ibogaine (10 mg/kg), on top of treatment as usual. Ibogaine toxicity will be assessed through close monitoring with electrocardiography, with QTc prolongation as main outcome measure, repeated assessments of ataxia using the (SARA) and observation of psychotic symptoms by using the Delirium Observations Scale (DOS). Ibogaine efficacy will be measured, using repeated evaluations of opiate withdrawal severity (Subjective Opiate Withdrawal Scale: SOWS; Objective Opiate Withdrawal Scale: OOWS), craving intensity (using a Visual Analogue Scale) and substance use, with a six-month follow-up. Clinical observations in ibogaine treated individuals will be compared with a cohort of opiate dependent patients treated with a rapid detoxification procedure. Both acute and long-term effects will be linked with serum ibogaine and noribogaine levels.

Results Animal work: overall, ibogaine reduced drug self-administration, particularly during the first 24 hours after administration. Ibogaine had no effect on drug-induced conditioned place preference. Ibogaine administration resulted in motor impairment in the first 24 hours after supplementation, and cerebral cell loss even weeks after administration. Data on ibogaine effect on cardiac rhythm as well as on its neuropharmacological working mechanisms are limited. Human studies: human data are still being collected. Treatment of the first patients confirmed strong effects of ibogaine on heart rhythm (QTc prolongation) and ataxia, while the opiate withdrawal symptoms were relatively mild. The first observations on the clinical effect of ibogaine on craving and substance use will also be shared.

Conclusions Based on our meta-analysis of animal data, there is strong evidence that ibogaine is effective in reducing drug self-administration in animals. This warrants further studies into the clinical efficacy of ibogaine in substance dependent patients in reducing craving and substance use. Our first clinical experiences in

a limited number of patients confirm that ibogaine treatment may be effective in reducing opiate withdrawal, but can potentially have transient cardiac and cerebellar toxicity.

Symposium: world psychiatry in 2020 – where we are and where we need to go – Joint symposium with the WPA

JS09

Social psychiatry in a global perspective

T. Jamieson-Craig

King's College London- Institute of Psychiatry Psychology and Neuroscience, Health Service and Population Research, London, United Kingdom

Social psychiatry starts from the position that as social animals, the cause, course and response to treatment of mental health problems are powerfully determined by the social environment. For example, childhood trauma within the home and bullying at school is associated with both internalizing and externalizing disorders and exerts its influence through life-long impacts on the individual's ability to form supportive relationships with others, their self-esteem and their resilience in the face of future adversity. Difficulties forming and sustaining personal relationships are intensified by the emergence of illness, consequent social exclusion and discrimination that in turn intensifies damaging beliefs of low self-worth and rejection. In contrast, we have considerable evidence for the “therapeutic” value of good relationships, notably the role of family and social support in the remarkable resilience shown by those who have come through the most appalling environmental and personal crises. It is therefore surprising that the balance of psychiatric therapeutic effort is stubbornly focused on the individual patient as the problem with less attention paid to developing and implementing social interventions targeted at the family and wider social network to prevent and alleviate mental illness. In this presentation I will argue that psychiatrists should be more active in developing and leading interventions that focus on the social and interpersonal networks of their patients with illustrations from past and ongoing efforts to this end.

Symposium: development of a European training curriculum on psychiatry – Joint symposium with hosting NPA

JS10

Psychiatric trainees' view on a European curriculum of psychiatry

M. Pinto da Costa

Psychiatry Department of Porto, Hospital de Magalhães Lemos, Porto, Portugal

The European Federation of Psychiatric Trainees (EFPT) represents the consensus of psychiatry trainees associations across more than 30 European countries, advocating for the improvement and harmonization of psychiatry training across Europe. This federation has as priority to get direct feedback from psychiatry trainees, analyzing the concerns related to psychiatry and training in Europe, collaborating with other national and international partners to translate trainees' views into action, while offering trainees several opportunities.

Surveys of psychiatry trainees show that the main concerns around Europe revolve around differences of duration of training in the different countries, the discrepancies between the European training standards, the national programmes and the real experience of trainees. Likewise, levels of recruitment into psychiatry and inadequate working conditions also concern trainees, especially at the current times of economic challenge, where the choice to migrate abroad is quite frequent. Nevertheless, the involvement of psychiatry trainees in the development of national programmes and in the quality assurance of training varies significantly around Europe.

This presentation will highlight the current differences observed in the structure, content and duration of psychiatry training programs in Europe, reporting trainees' views on a European curriculum of psychiatry, and exploring mechanisms to evaluate and harmonize the postgraduate training in Europe.

Psychosocial intervention in schizophrenia

T. Wykes

Institute of Psychiatry – Psychology and Neuroscience – KCL, Psychology, London, United Kingdom

Psychological treatments aimed at symptoms or behaviours that impede recovery now have a relatively strong database but it is not clear which treatments are more effective and when they should be applied. For large-scale roll out we need to consider which are the most helpful and cost-effective at which stage of the illness and to which individuals. This requires knowledge of how service users ascribe value to different outcomes and treatments as well as which individuals are likely to benefit the most from different treatments to produce a coherent mental health recovery programme. Tailoring treatment requires an understanding of adherence requirements as well as therapeutic interactions to explain how therapy fits with the service users' personal goals. Not all information for making these clinical decisions is embedded in any database so the burden on research is to provide enough information to signal to health professionals the best course of action. More research on dissemination of treatment approaches as well as training and supervision requirements is needed in the form of dissemination science if patients with a diagnosis of schizophrenia are to receive the best intervention programme.

Nutrition, sleep, physical exercise: Impact on mental health

W. Rössler

University of Zurich, Psychiatric University Hospital, Zürich, Switzerland

Until recently nutrition and various other lifestyle factors were predominantly in the focus of medical disciplines like cardiology, endocrinology or gastroenterology. As mental disorders are multifactorial diseases and as such are complex, emerging evidence suggests that nutrition, exercise and sleep also play an important role in the aetiology, progression and treatment of mental disorders. In this regard research has mostly focused on depression and anxiety, but there is also evidence for other mental disorders like schizophrenia or autism. Some details concerning the relationship

between diet and sleep on neuro-transmitter processes, immune-inflammatory pathways or oxidative stress will be demonstrated. Modifications of life style factors and diet are increasingly recognized as potential therapeutic options. Mostly used are nutrient-based supplements and essential elements in combination. But also healthy diet patterns with a high intake of vegetable, fruits and fish have proven beneficial in the treatment. If we better understand the microbiota-gut-brain axis and its impact on behavior, mood and cognitive processes, diet and lifestyle factors can not only contribute to the treatment but also to the prevention of mental disorders.

Drinking patterns we should accept while reducing harmful alcohol consumption

SA03

Can alcohol-dependent patients really reduce their alcohol consumption over time?

K. Mann

Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Addiction Research, Mannheim, Germany

Introduction Treatment of alcohol dependent patients is moderately successful but it only reaches about 10% of the population in need. A new harm reduction strategy aims at abstinence in the long run but claims to benefit patients already early on by reducing their alcohol consumption.

Objectives A brief outline of the debate on abstinence versus controlled drinking will be followed reporting several RCTs striving for reduced drinking in alcohol dependent patients.

Aims The participant will find guidance whether and how to treat patients following this new approach.

Results Studies testing behavioural treatments and counselling (MATCH, UKATT) indicate that a reduction over time is possible. Using nalmefene (a mu and delta opioid antagonist and a partial agonist) RCTs with more than 2500 patients were performed showing a benefit over placebo. On this basis the EMA approved this drug for the reduction of alcohol consumption in alcohol dependent

patients. Other compounds such as naltrexone showed similar effects in smaller trials but are not approved for reduction. More studies testing further compounds are underway.

Conclusions This new approach has the potential to lower the barriers which to date prevent many patients from accepting treatment for their alcohol problems. Two research questions warrant further study: (1) does the reduction in alcohol consumption

translate into health and other benefits, and (2) are there specific subgroups of patients who benefit more than others. Preliminary answers will be given in the lecture.

Early career psychiatrists programme

Conversations – the political and social mission of psychiatry

EECP 01

The political and social mission of psychiatry

S. Priebe

Unit for Social and Community Psychiatry, Queen Mary – University of London, London, United Kingdom

Psychiatry is based on values and scientific evidence. The presentation will argue that both bases come with a social and political mission.

The values require a commitment to help those in need of support, which cannot be fully achieved without social and political action. The scientific evidence points to the central role of societal factors, such as inequality and poverty, for the development of mental disorders. Influencing these factors requires political decisions.

It will be concluded that taking up the social and political mission is a moral imperative for both psychiatrists as a professional group and individual psychiatrists, and may make the profession more relevant in society, more attractive to medical students, and more effective in helping patients with mental distress.

The discussion will address the challenges and practical options for such a mission.

<http://dx.doi.org/10.1016/j.eurpsy.2016.01.807>

Contemporary approaches to medical education emphasize the importance of doctors in training demonstrating the acquisition of competencies. This approach to educating doctors has been criticized on a number of grounds, not least because a solely behavioural focus risks trivializing medical professionalism. An alternative approach is to look at the formation of professional identity as a legitimate goal of training.

In this presentation, I will describe the behavioural and constructionist approaches to medical education and their implications for psychiatry training. I will make a plea for psychiatry training to renegotiate the balance between the two approaches.

Addiction medicine/psychiatry, a medical subspecialty founded on October 1991 by the American Board of Psychiatry and Neurology, was granted as subspecialty within psychiatry. It mainly deals with medical assessment, diagnosis and treatment of subjects who suffer from an addiction (i.e. drug and/or alcohol addiction; gambling; sexual addiction; game addiction; and so on). Addiction psychiatry also deals with subjects in dual diagnosis, i.e. individuals with addiction issues along with co-occurring psychiatric disorders. However, despite its well established “dignity” to be part of psychiatry, most mental health's professionals believe that it is not a primarily psychiatric field due to the frequent co-occurrence of internistic/medical issues. In addition, the situation of psychiatric training specifically addressed to addiction is widely diversified across the European countries. Therefore, most psychiatrists do not possess specific qualifications and formation on this increasing field of psychiatry. The present lecture aims at providing an insight into the issues related to the diatribe between psychiatry and medicine on addiction medicine/psychiatry, specifically focusing on differences across European countries.

Purpose It is widely recognised that people with intellectual disabilities receive a poorer quality of healthcare than their non-disabled counterparts. Training for healthcare professionals in intellectual disability is often scant or non-existent. The purpose of this work is to explore the usefulness of employing actors with intellectual disabilities as simulated patients in the assessment of trainee psychiatrists.

Design/methodology/approach The development of a structured clinical exam “station” designed to assess the ability of trainee psychiatrists to communicate with a simulated patient played by an actor with an intellectual disability is described. The paper also assesses the potential benefits of this kind of assessment and the experience of actors and examiners taking part in this process.

Findings The station was found to perform well in discriminating between candidates of various abilities and was well received by actors, examiners and observers. The station is now routinely used in the formal assessment of trainee psychiatrists in the UK.

Practical implications The use of people with intellectual disabilities in training and assessment appears to be advantageous in terms of improving knowledge, attitudes and skills amongst healthcare professionals and gives increased opportunities for people with intellectual disabilities to undertake valued social roles.

Originality/value Few institutions currently employ actors with intellectual disabilities as simulated patients as part of their training programmes and as a result there is little in the way of literature on this subject. This paper describes an alternative approach to teaching and assessment which falls in line with recommendations from the UK Department of Health to involve service users in the training of healthcare professionals.

Training workshop – Dissociative symptoms, how to recognise and treat them

EECP 07

Discussion

G. Stanghellini

“G. d’Annunzio” University, Department of Psychological – Humanistic and Territorial Sciences, Chieti, Italy

The concept of “dissociation” covers a rather wide array of psychopathological conditions, ranging from dissociation of consciousness (e.g., post-traumatic conditions), to dissociation of personality, (i.e., multiple personality disorder) and dissociation of

the basic structures of the pre-reflexive self (as it is the case with schizophrenic abnormal experiences). I will focus on this last issue and describe the dissociation of time experiences in people with schizophrenia as a characterizing feature of this condition.

Schizophrenic persons often describe their sense of temporal reality as: “things to a standstill”, “immobility, but not calm”, “time going back to same moment over and over”, “people like statues”, “frozen moment”, “out of time”, “marmoreal”, “unreal stillness”. Time is fragmented, there is a breakdown in time Gestalt, and an itemization of now-moments. The mere succession of conscious moments as such cannot establish the experience of continuity. Another typical phenomenon is that a revelation is on the verge to happen, the world is on the verge of ending, a new world is coming, one’s own life is on the point of undergoing a radical change. The schizophrenic mood can be characterized as the dawn of a new reality, an eternally pregnant now in which what is most important is not present, what is really relevant is not already there, but is forever about to happen. Time in the schizophrenic mood is “a state of suspense”, “pregnant now”, “being is hanging”, “something imminent”, “something... I didn’t know what... was going to happen... between inspiration and expiration”. The main feature of abnormal time experience in schizophrenia is disarticulation – a breakdown of the synthesis of past, present and future. This includes four subcategories: disruption of time flowing, “dèjà vu/véçu”, premonitions about oneself and the external world. The integrity of time consciousness is the condition of possibility of the identity through time of an object of perception as well as of the person who perceives it. Abnormal time experience may be related to the manifold of other schizophrenic subjective abnormal experiences and symptoms, including anomalies of phenomenal consciousness (e.g., disintegration of the appearance of external objects and itemization of external world experience), selfhood (e.g., disruption of the implicit sense of being a unified, bounded and incarnated entity), and sociality (e.g., breakdown of one’s sense of being naturally immersed in a meaningful flow of social interactions with others).

Disarticulation of time experience includes four subcategories. Disruption of time flowing: Patients live time as fragmented. Past, present and future are experienced as disarticulated. The intentional unification of consciousness is disrupted. The present moment has no reference to either past or future. The external world appears as a series of snapshots. Dèjà vu/véçu: Patients experience places, people and situations as already seen and the news as already heard. This abnormal time experience entails a disarticulation of time structure as the past is no more distinguishable from the present moment. The already-happened prevails. Premonitions about oneself: patients feel that something is going to happen to them or that they are going to do something. This abnormal time experience entails a disarticulation of time structure as the immediate future intrudes into the present moment. The about-to-happen prevails. Premonitions about the external world: patients feel that something is going to happen in the external world. As the previous one, this abnormal time experience entails a disarticulation of time structure as the immediate future intrudes into the present moment. The about-to-happen prevails.

* Corresponding author.

Established in 2008, the Research Working Group of the European Federation of Psychiatric Trainees (EFPT) creates a platform for trainee-led collaborative studies. Several large-scale transnational studies on training-related subjects have been initiated and carried out, driven by psychiatry trainees. Examples of recent and ongoing projects are the Brain Drain study, which investigated migratory experiences and attitudes among trainees in Europe, and the TEO-PC project, which aims to raise awareness on UEMS Psychiatric competencies as well as to compile data on trainees' experiences and satisfaction with their national training programs.

Earlier projects leading to publications have looked into drug prescription habits of trainees [1,2] and the interactions trainees with pharmaceutical industry [3]. Besides these projects, EFPT yearly gathers reports from the representatives of the national trainees associations on the structure, content and conditions of psychiatry training in all member countries. The information obtained through these channels is used actively to guide and influence policy related to psychiatry training, through collaboration with relevant organizations involved in the creation of guidelines, and through the EFPT statements, which serve to empower trainees themselves.

EECP 09

Brain Drain Project

M. Pinto da Costa

Psychiatry Department of Porto, Hospital de Magalhães Lemos, Porto, Portugal

Despite the ongoing reality of workforce migration, information on medical migration is missing, with lack of detailed evidence of transnational migrations within Europe, obscuring the extent of how migration occurs amongst the different medical specialties. The European Federation of Psychiatric Trainees (EFPT) has been pioneer in researching workforce migration in junior doctors, conducting the EFPT Brain Drain study, which explored the reasons and patterns of mobility and migration in 33 European countries among junior doctors training in psychiatry.

The intention has been to better understand the migration phenomena, its reasoning and effects in order to give practical proposals to improve education, training and work conditions and ultimately the health care itself in both donor and host countries. Migration among medical professionals can take place throughout the career: before, during or after training. Exploring attitudes towards migration among junior doctors can help to understand the factors that shape the decision-making processes related to migration in future specialists.

These findings provide objective data that can assist policy makers, providing instruments to address the critical conditions leading to migration from at-risk countries, adjusting the pull factors and improving the standards of education, work and salaries.

Future studies should explore whether the presented results differ for junior doctors in other medical disciplines, as well as physicians in general and psychiatric consultants in Europe and in other areas of the world. Furthermore, the follow up of the respondents from this study could assess to what extent the migratory tendency and intention predicts the future migration itself.

Addictions and addictive behaviours: Psychopathological, philosophical and ethical reflections

S01

The synthetic psychosis substances induced: A clinical case study

G. DiPetta (Neuropsychiatrist, Addiction Center Consultant)
 Department of Mental Health, Naples, Italy

The presentation intends to examine a new kind of clinical psychiatric syndrome, called by the author “synthetic psychosis”, which can occur in people who abuse novel psychoactive substances (NPS). This syndrome will be considered from both a psychopathological and a phenomenological perspective. The contemporary trend of poly-abuse of NPS in young people can lead to a sort of very intense paraphrenic state characterised by continuous hallucinations and formed by a mental automatism syndrome and by secondary (interpretative) delusions. The clinical case of G., discussed in this paper, is an exemplary case of this synthetic psychosis. The psychopathological understanding of the core symptomatology of the patient examined has been fundamental for the successive therapeutic approach. If this attempt at understanding is ineffective, the frequent consequences include: the worsening of the psychopathology and addiction; the patient’s admission into a psychiatric hospital; his/her arrest for crimes related to antisocial behaviour; a diffusion of infective diseases commonly found in addicts; more frequent overdoses; aggressive behaviour; an increase in the costs of public health system and, finally, the suicide of the patient [1].

* Corresponding author.

Introduction Corollary discharges (CDs) are the reason most people cannot tickle themselves. They are the brain’s way of distinguishing whether a stimulus is associated with one’s own actions or something else. In neural terms, CDs are copies of motor plans that are propagated to sensory cortex where they can be compared with inputs. A range of phenomena associated with schizophrenia from auditory hallucinations to visual processing difficulties to the ability of patients to tickle themselves can be explained as pathologies in CD mechanisms. Auditory hallucinations for example involve patients failing to perceive themselves as the author of their own inner speech.

Objectives and aims To test whether schizophrenia is associated with a structural network disruption that could impair CD signals involved in language processing, adolescents with schizophrenia were examined using magnetic resonance imaging and compared to healthy controls.

Methods A graph theoretical approach was used to analyse the connectivity in networks centered on:

- Broca's area;
- Wernicke's area.

Connectivity information was acquired using diffusion tensor imaging (DTI).

Results Compared to healthy controls, adolescents with schizophrenia displayed a lower average degree of connectivity with the left inferior frontal gyrus (Broca's area). No significant differences were found in the degree of connectivity with the right inferior frontal gyrus and the superior temporal gyrus bilaterally (Wernicke's area).

Conclusions The results suggest a link between schizophrenia and impairment to areas where CDs associated with inner speech plausibly originate.

GRIN2B mediates susceptibility to affective problems in children and adolescents

M. Nobile

Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy

Objectives Association studies have implicated the N-methyl-D-aspartate receptor 2B subunit gene (*GRIN2B*) as candidate for different brain illnesses, also including both internalizing and externalizing disorders. Here, we explored the association between selected SNPs of *GRIN2B* (rs5796555-/A; rs1012586C/G; rs2268119A/T; rs2216128A/G; rs11609779C/T; rs2192973G/A) and attention problems in children and adolescents as assessed by CBCL 6/18 (Achenbach and Rescorla, 2001).

Methods In a large cohort of 320 Italian nuclear families selected from an ongoing comprehensive project on child and adolescent psychopathology performed at two sites of our Institutes (BP and UD), we performed a family-based association study to determine whether the *GRIN2B* gene influence and/or mediates susceptibility to attention problems through time. Genetic association was investigated by the quantitative transmission disequilibrium test (QTDT, version 2.5.1; Abecasis et al., 2000). Quantitative traits were analyzed using the '-wega' and the '-ao' options. Empirical *P*-values were computed from 10,000 Monte-Carlo permutations, and the significance levels were adjusted by the false discovery rate method (Storey, 2002) applied to the tests performed for each marker (i.e., 8 phenotypes) at two different point times. Latent profile analysis was performed to assess the effect of gene on different trajectories over time. The effect of environmental determinants was also evaluated.

Results Evidence for significant association of *GRIN2B*-rs5796555-/A was found with attention problems both at first and second evaluation. Latent profile analysis suggested significant association with specific trajectories and specific environmental factors.

Conclusions These results provide preliminary evidence of an association between the *GRIN2B* polymorphism and continuity of attention problems throughout adolescence within an Italian population of referred children and adolescents, suggesting that the *GRIN2B* genes could play a role in susceptibility to attention problems during developmental age.

Biological markers of short-term and long-term treatment outcome in mental disorders

S04

Brain glutamate levels and antipsychotic response in schizophrenia

A. Egerton

Department of Psychosis Studies, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

There is considerable interest in identifying biomarkers of antipsychotic response in schizophrenia. Glutamate is one key candidate. The development of brain imaging techniques for measuring brain glutamate levels has allowed this hypothesis to be tested directly in patients. This talk will present our ongoing research examining the relationship between brain glutamate levels and antipsychotic response in first-episode psychosis and in treatment-resistant schizophrenia. I will summarise our results from both our completed and ongoing studies, to consider whether glutamate imaging might be useful in the future to identify patients who would benefit from non-dopaminergic antipsychotic drugs and inform novel, glutamate-based, treatment strategies.

Biochemical and genetic markers in patients with alcohol dependence and affective disorders and their correlation with alcohol intake

U. Preuss^{1,*}, F. Wurst²

¹ Martin-Luther University, Halle-Wittenberg, Department of Psychiatry, Psychotherapy and Psychosomatics, Germany

² Paracelsus University Salzburg, Psychiatry, Salzburg, Austria

* Corresponding author.

Rates of comorbid affective disorders in alcohol-dependent individuals are significant. Biomarkers of alcohol use may support the diagnosis of high and frequent alcohol use in these individuals. The aim of these analyses of the WHO-ISBRA Study on State and Trait Markers of Alcohol Use and Dependence is to compare biomarkers of alcohol use across individuals with and without comorbid alcohol dependence and affective disorders. Significantly, higher values of these biomarkers are hypothesized in individuals with comorbid disorders compared to alcohol dependence only. Assessment of Alcohol dependence and comorbid depression and bipolar disorders were conducted using an adapted version of the Alcohol Use Disorder and Associated Disabilities Interview Schedule (AUDADIS). Altogether, *n* = 1863 individuals were included into the analyses, of whom *n* = 299 had a lifetime history of depression and *n* = 20 a bipolar disorder. Clinical characteristics like mean alcohol intake last month and biomarkers including ASAT, GGT, CDT, 5-HTOL/5-HIAA ratio and MAO-Activity were included into the analyses. Results indicate that AD only subjects had higher measures of all biomarkers compared to comorbid bipolar and depression subjects, while the latter had a higher alcohol intake during last month.

Since this is a cross-sectional study, conducted in emergency rooms of several countries, this allegedly divergent result in alcohol intake in comorbid subjects compared to higher biomarkers in AD only subjects may indicate that drinking is more frequent in alcohol-dependent individuals while bipolar and depressed subjects may have more episodic pattern of alcohol intake. The latter may lead to shorter periods of intake compared to the chronic and frequent

use of this substance in alcohol-dependent individuals and higher biomarkers of alcohol use.

S06

Potential relationship between inflammatory markers, neuroimaging findings and treatment response in depression

A. Szulc

Medical University of Warsaw, Department of Psychiatry, Pruszkow, Poland

Pharmacological therapy in mental disorders is usually effective in 60–70%, the treatment reaction is worsening with the disease progression, and proper medication and early treatment regimen choice is crucial. Research showed that specific brain changes (structural and functional) are present in depressed patients. These abnormalities are probably linked to neurodegeneration. There is also an evidence that inflammation contributes to the depression pathophysiology, and both these processes – neurodegeneration and inflammation are related.

Novel biological markers allow us to better understand the individual mechanisms of treatment response in depression. Recently, several biological measures have been proposed, amongst them – neuropsychological dysfunction, decreased GABA level in proton magnetic resonance spectroscopy (¹H MRS), body weight, genetic factors and peripheral inflammatory markers. Latest research found that brain changes assessed with neuroimaging methods (including ¹H MRS, e.g. glutamatergic system abnormalities), correlate with peripheral inflammatory markers. Furthermore, both these factors taken together may serve as one integrated treatment prediction marker in depressed patients.

Bipolar disorders: From detection to intervention

S07

Developmental trajectories to bipolar disorder

S. Frangou

Icahn School of Medicine at Mount Sinai, Psychiatry, New York, USA

Background Childhood subclinical phenotypes have been informative for etiological research and as a target for preventative interventions. Using a prospective longitudinal general population cohort we investigated whether childhood manic symptoms predicted a diagnosis of bipolar disorder (BD) or other psychiatric disorders by early adulthood.

Methods Subthreshold manic symptoms at age 11 years ($n = 1907$) and clinical outcomes by age 19 years ($n = 1584$) were ascertained in the TRacking Adolescents' Individual Lives Survey (TRAILS), a prospective Dutch community cohort. We used latent class analysis to stratify TRAILS participants at age 11 years into distinct classes based on the pattern and severity of childhood manic symptoms. We then determined the association between class membership and clinical diagnoses by age 19 years.

Results At age 11 years, we identified a normative class with negligible symptoms ($n = 862$), a mildly symptomatic ($n = 846$) and a highly symptomatic class ($n = 199$). The risk of BD was

moderately increased in individuals in the mildly symptomatic class (OR = 2.65, 95% CI 1.41–5.01), and substantially increased in the highly symptomatic class (OR = 7.08, 95% CI = 3.32–15.11). Children in the highly symptomatic class were additionally characterized by lower IQ and socioeconomic status, greater family dysfunction and increased rates of parental psychiatric morbidity. Class membership did not show significant associations with depressive, anxiety and substance abuse disorders by age 19 years.

Conclusions The results provide support to developmental models of BD, and suggest that manic symptoms in childhood may be a marker for adult disorders and therefore potentially useful for early identification of at risk individuals.

Protecting the cardiometabolic health of young people experiencing psychosis

D. Shiers (Honorary Reader in Early Psychosis)

School of Psychological Sciences, University of Manchester, United Kingdom

This presentation will highlight how the early phase of major mental illness may provide a critical window of opportunity in which to prevent future life-restricting and life-shortening physical comorbidities.

Despite many recent advances in our understanding of severe mental illnesses, those affected still lose 15–20 years of life on average compared to the general population. Most premature deaths arise from the same common disorders that affect the general population such as cardiovascular disease, infections and cancers. Of these cardiovascular diseases is now the single biggest cause, far greater than suicide. Shockingly the mortality gap is still widening as the reduction in CVD morbidity and mortality seen in the general population over the last three decades continues to elude people with severe mental illnesses, for whom the prevalence of CVD, obesity and diabetes are now of epidemic proportion.

And yet, much of this epidemic can be predicted. High rates of tobacco use, physical inactivity and poor nutrition point to underlying health inequalities. Furthermore, initiation of antipsychotic treatment is associated with aggressive weight gain and metabolic disturbance from the early phase of psychosis, and yet often these adverse effects remain unmonitored and untreated.

This presentation will argue that these potentially modifiable risk factors provide natural targets for prevention from the onset of psychosis and its treatment. Extending the early intervention paradigm to embrace a far more holistic body & mind approach is overdue.

Implementing the clinical standards of the National Institute for Health and Care Excellence (NICE) bipolar clinical guideline

M. Tremblay^{1,2,*}, S. Palin¹

¹ Cheshire and Wirral Partnership NHS Foundation Trust, Mental Health, Winsford, United Kingdom

² Fellow of NICE (2012–2015)

* Corresponding author.

In the UK, the National Institute for Health and Care Excellence (NICE) sets standards for interventions to drive improvement in the quality of services delivered. The actual update of clinical guidelines remains patchy and difficult to ascertain.

NICE most recent guideline on the management of bipolar disorder in adults will be reviewed. A concept tool to facilitate adherence to NICE clinical standards will be presented along with detailed outcomes of its pilot application in a naturalistic treatment setting, which drove the average concordance from 32% for a team providing treatment as usual, to 92% for a team supporting their practice with the tool. This presentation will also address additional impacts of its use including allowing drawing key clinical characteristics of an index population of individuals suffering from bipolar disorder, supporting education and auditing the actual service delivery. The usefulness of the tool to shape clinical practice according to NICE evidence-based standards will be outlined. Its versatility and limitations will be debated. The discussion of the findings will include epidemiological considerations as well as implications for mental and physical well-being.

Co-occurring psychiatric and substance use disorders: Impact on illness course and recovery

S10

Alcohol and aggression

A. Heinz*, U. Kluge, M. Schouler-Ocak, A. Beck
Charité, Universitätsmedizin Berlin, Department of Psychiatry and Psychotherapy, Campus Charité Mitte, Berlin, Germany

* Corresponding author.

About half of all murders are committed in Western industrialized countries by subjects under the influence of alcohol. Chronic alcohol use also increases the rate of violent attacks. These findings appear to be due to an interaction between acute and chronic environmental effects (acute alcohol consumption and chronic social isolation stress) on the one hand and limbic processing of aversive stimuli modulated by neurotransmitter systems such as dopamine and serotonin on the other. Animal experiments showed that early social isolation stress can induce serotonin dysfunction and appears to predispose individuals towards increased threat perception. Studies in humans revealed that depending on serotonergic neurotransmission and serotonin transporter genotype, some individuals are prone to show elevated functional activation elicited by aversive and threatening cues. Previous experience with alcohol-related aggression seems to further predispose an individual towards a “fight vs. flight” reaction when confronted with perceived threat during alcohol intake. Together, these findings point to complex gene-environment interactions and a specific role of social isolation stress in the development of alcohol-related aggression.

Multi-morbidity: Psychosis early childhood adversity and substance use within homeless people

M. Krausz
Institute of Mental Health at UBC, Vancouver, BC, Canada

Homelessness is the most visible indicator for social marginalization and vulnerability. It is a risk factor for subsequent health threats and especially individuals with a history of trauma,

substance use and severe persistent mental illness are at high risk to lose their homes, jobs and social networks.

The Canadian At Home/Chez Soi study aimed to better understand the entanglement of homelessness and mental illness and possible strategies to provide care to the most vulnerable. In 5 Canadian centers, over 2000 patients were included and randomized to different intervention arms based on a housing first approach.

Early trauma and foster care were as rampant as poly substance use, which explains a significant increase in mortality too.

Disclosure of interest The author has not supplied his declaration of competing interest.

S12

Are attention-deficit/hyperactivity disorder symptoms associated with a more severe course of substance use? A longitudinal study with young Swiss men

F. Moggi

University Hospital of Psychiatry and Psychotherapy, University of Bern, Bern, Switzerland

Introduction Adults with attention-deficit/hyperactivity disorder (ADHD) symptoms show higher prevalence rates for substance use disorders (SUD).

Objectives Few longitudinal studies have been conducted to observe the course of substance use among adults with ADHD.

Aims This study examined the predictive value of ADHD symptoms during the course of substance use in a population sample.

Methods In two waves data from a representative sample of 5103 Swiss men in their early 20s were collected (baseline and 15-month follow-up) in the longitudinal “Cohort Study on Substance Use Risk Factors” (C-SURF). ADHD symptoms and substance use were assessed using the adult ADHD Self-Report Scale (ASRS-v1.1) and self-administered SUD questionnaires, respectively. Individuals who screened positive for ADHD (ADHD+) were compared to those who screened negative (ADHD-).

Results At baseline, the 215 individuals in the ADHD+ group (4.2%) showed considerably higher prevalence and frequency of substance use and prevalence of alcohol, tobacco, and cannabis use disorders relative to the ADHD- group. While alcohol, tobacco, cannabis, and heroin use remained stable from baseline to follow-up, the ADHD+ group was more likely to begin using illicit drugs (i.e. amphetamines, speed, ecstasy, hallucinogens, and cocaine) and initiate nonmedical use of prescription drugs (i.e. stimulants/amphetamines, hypnotics, and tranquilizers) relative to the ADHD- group.

Conclusions Young men with ADHD symptoms displayed more severe substance use patterns and were at a high risk of initiating drug use within 15 months. The identification of ADHD symptoms during early adulthood may be relevant in early interventions to lower the risk of drug use.

Disclosure of interest The author has not supplied his declaration of competing interest.

Autism and substance use comorbidity: Screening, identification and treatment

P.J.M. van Wijngaarden-Cremers

Dimence, Centre for Developmental Disorders, Zwolle, Netherlands

Objective Autism spectrum disorders (ASD) are well-known for high prevalences of comorbid conditions especially anxiety, obsessions, depression, challenging behaviours.

In this presentation, we will consider the evidence for comorbidity between ASD and addiction [substance use disorders (SUD)] and explore the possible underlying explanations.

Methods A literature study on similarities between addiction and ASD (at a phenotypical and neurobiological level) as well as a case note review on a year cohort of 120 consecutive admissions in an adult addiction psychiatry unit and 120 admissions in an adult ASD unit.

Results In our addiction psychiatry cohort, 8 (men) on 118 patients were diagnosed with autism spectrum disorder. This is much higher than in the general population (1%). In the ASD cohort, the results are measured at the moment and the results will be presented in the presentation.

Autism spectrum disorders and addiction can both be perceived as developmental disorders in which a genetic predisposition and vulnerability interact with environmental factors. They can be induced by early stress thus affecting the proper functioning of the cortico-striatal dopaminergic regulation systems (and also the HPA axis). In “pure” ADHD this is attributed to a deregulation in the cognitive loops and the “impulsivity” endophenotype. Whereas in cases of ASD without an ADHD component the limbic and sensimotore cortico-striatal regulations loops are also involved.

Conclusions There are clear indications that a possible comorbidity of substance abuse disorder should be considered in cases of individuals with autism spectrum disorders. This finding is important for clinicians to take into account in assessing patients with addiction problems and ASD.

Disclosure of interest The author has not supplied his declaration of competing interest.

Coercion in psychiatry: Challenges and perspectives

S14

Ethical challenges in the use of coercion

M. Kastrup (Speciallæge i psykiatri)
Copenhagen, Denmark

The use of coercive measures remains one of the great challenges in psychiatry.

Increased focus on patient rights and autonomy, concern from user and relatives organizations as well as from human rights organizations all have contributed to that the use of all kinds of coercion is high on the agenda. And yet, we are still faced with that a number of psychiatric patients will experience that coercive measures are used as part of their treatment.

The EPA Ethical Committee carried out a survey comprising the European associations of psychiatry in which a questionnaire was circulated regarding what the different associations found were the major ethical challenges in their respective countries.

Among the issues that have given rise to particular concern are the use of physical restraints including why some countries avoid physical restraints while other – e.g. Denmark – use it extensively. Why do we find such large differences? Is this due to different approaches to coercion, different traditions? Shortage of resources? Another concern is that certain groups seem more likely to be subject to coercion compared to others. Thus, it has been demonstrated that patients belonging to ethnic minority groups are more likely to experience this.

The paper will focus on ethical problems and issues of concern related to the use of coercion. The focus will be on facets of international relevance with the aim to remain critical towards the use and when needed to strengthen the quality of coercive treatment care.

S15

Does the use of coercion improve the outcome of patients with severe mental disorders?

M. Luciano

University of Naples SUN, Department of Psychiatry, Naples, Italy

Coercive measures have always been part of the psychiatric armamentarium; however, the clinical and ethical dilemma between the use of a “therapeutic” coercion and the loss of patients’ dignity is one of the most controversial issues in mental health practice. According to International guidelines, coercive measures should be adopted only when all the other less restrictive approaches failed and should be considered as the “last restrictive alternative”. Although coercive measures are frequently used to manage patients’ aggressive behaviors and self-harm, refusal of medication and impulsivity, their effect on patients’ outcome is not clear. In fact, the use of coercive measures can reduce patients’ aggressiveness and improve psychiatric symptoms, but can also have a negative impact in terms of therapeutic relationship, engagement with mental health services and self-stigma, arising negative feelings on patients and on mental health professionals. International attempts have been made to improve and harmonize the use of involuntary treatments. Recommendations of good clinical practice on the use of coercive involuntary treatments and forced medications have been proposed by the EUNOMIA consortium, and the effect of coercion on the outcome of patients with severe mental disorders have been described. Results of this study will be reported as well as lessons learnt from other international experiences.

Considering pain to better understand the suicidal process

S16

Psychological pain and interpersonal theory of suicide

A. Apter

Schneiders Childrens Medical Center of Israel, Petach Tikva, Israel

Psychological pain is an important variable in the understanding of suicidal individual.

This presentation describes the how psychological pain interacts with problems in communication to set up risk for serious suicidal behavior and describes some empirical studies supporting a model for using this concept in suicide prevention strategies.

S17

Pain perception in self-injurious behaviours

C. Schmahl

Central Institute of Mental Health, Psychosomatic Medicine and Psychotherapy, Mannheim, Germany

Borderline personality disorder (BPD) is characterized by affective dysregulation and non-suicidal self-injurious behaviour (NSSI), which is closely linked with reduced pain perception. Several experimental studies revealed reduced pain sensitivity in BPD as well as significant correlations between pain perception, aversive inner tension and dissociation. Psychophysiological experiments revealed no deficit in the sensory-discriminative pain component in BPD. However, neurofunctional investigations point at alterations of the affective-motivational and the cognitive pain component in BPD. Preliminary evidence suggests that disturbed pain processing normalizes when patients stop NSSI after successful psychotherapeutic treatment. We could demonstrate that pain leads to a decrease in affective arousal and amygdala activity in patients with BPD and to an increase in amygdala-prefrontal connectivity. We are currently investigating the role of seeing blood and the importance of self-infliction of pain in the context of NSSI.

S18

Neural pathways of the association between pain and suicide

K. van Heeringen

Unit for Suicide Research, Department of Psychiatry and Medical Psychology, Ghent University, Gent, Belgium

Physical pain and psychological pain are risk factors for suicidal behaviour, and understanding of the neural pathways linking pain and suicide may contribute to suicide prevention. Neuroimaging studies have shown changes in association with physical and psychological pain and with suicidal behaviour. Psychological stressors such as social exclusion may trigger emotional pain that is associated with functional changes in the prefrontal cortex, cingulate cortex, thalamus, and parahippocampal gyrus. This functional network shows considerable overlap with brain areas involved in physical pain and suicidal behaviour. Changes in the brain motivation-valuation circuitry may predict pain persistence and thus contribute to the development of suicidal thoughts and behaviours.

Culture-society bound psychopathology

S19

Hikikomori and modern-type depression in Japan

T. Kato

Kyushu University, Department of Neuropsychiatry, Fukuoka, Japan

Maladaptive social interaction and its related-psychopathology have been highlighted in psychiatry especially among younger generations. “Hikikomori” defined as a syndrome with six months or longer of severe social withdrawal was initially reported in Japan, and the prevalence rate has been reported as 1.2% in Japanese population. The majority of hikikomori patients are adolescents and young adults who become recluses in their parents’ homes for months or years. They withdraw from contact with family, rarely have friends, and do not attend school or hold a job. An international vignette-used questionnaire survey indicates the spread of hikikomori in many other countries (Kato et al. *Lancet*, 2011; Kato et al. *Soc Psychiatry Psychiatr Epidemiol*, 2012).

In addition, our international clinical studies have revealed the prevalence of hikikomori outside Japan (Teo et al., 2015). On the other hand, a novel form of maladaptive psychopathology, called modern-type depression has emerged in Japan (Kato et al. *J Affect Disord*, 2011; Kato et al. *Psychiatry Clin Neurosci*, 2016).

In this presentation, I will introduce “Hikikomori” and “modern-type depression” in Japan, and also propose novel diagnostic/therapeutic approach against them.

S20

International research on social withdrawal

A.R. Teo

VA Portland Health Care System, Center to Improve Veteran Involvement in Care, Portland, USA

Introduction Since the 1990s the term “Hikikomori” has emerged as a way to describe a modern form of severe social withdrawal first described in Japan. Recently, there have been increasing reports of Hikikomori around the globe.

Objectives To describe operationalized research criteria for Hikikomori, as well as epidemiologic, diagnostic, and psychosocial features of the Hikikomori in international settings.

Methods Participants were recruited from sites in India, Japan, Korea, and the US. Hikikomori was defined as a six-month or longer period of spending almost all time at home and avoiding social situations and social relationships, associated with significant distress/impairment. Lifetime history of psychiatric diagnosis was determined by the Structured Clinical Interview for the DSM-IV Axis-I and Axis-II Disorders. Additional measures included the Internet Addiction Test, UCLA Loneliness Scale, Lubben Social Network Scale (LSNS-6), and Sheehan Disability Scale (SDS).

Results Thirty-six participants meeting diagnostic criteria for Hikikomori were identified, with cases detected in all four countries. Avoidant personality disorder (41%), major depressive disorder (32%), paranoid personality disorder (32%), social anxiety disorder (27%), posttraumatic stress disorder (27%), and depressive personality disorder (27%) were the most common diagnoses. Sixty-eight percent had at least two psychiatric diagnoses. Individuals with Hikikomori had high levels of loneliness (UCLA Loneliness Scale $M = 55.4$, $SD = 10.5$), limited social networks (LSNS-6 $M = 9.7$, $SD = 5.5$), and moderate functional impairment (SDS $M = 16.5$, $SD = 7.9$).

Conclusions Hikikomori exists cross-nationally and can be assessed with a standardized assessment tool. Individuals with Hikikomori have substantial psychosocial impairment and disability, and a history of multiple psychiatric disorders is common.

Diagnostic process in psychiatry

S21

Transcultural issues in diagnostic process

M. Kastrup (Speciallæge i psykiatri)

Copenhagen, Denmark

Diagnostic systems and methods must respond to patients’ diversity in expressions of mental distress, social and cultural context

and the meanings given to illness. Due to increasing migration and globalisation the challenge of considering diagnosis in the context of culture has become increasingly significant in Europe. And globalization has further led to changes in value systems and our awareness of patients with ethnic minority background.

Over recent decades, there has been an increasing development of psychiatric diagnosing with nosological categorisation combined with multi-axial schemas. Diagnosis, besides identifying a disorder and distinguishing one disorder from another disorder - differential diagnosis, has also an aim to include an overall understanding of the patient's situation.

We witness an upsurge in the attention paid to the cultural limitations to psychiatric diagnostic practice and treatment modalities. Guidelines for the psychiatric profession are in critical focus from a transcultural perspective. Some claim their universality independent of cultural context; others find cultural adaptation useful and necessary.

Do the diagnoses and clinical and ethical guidelines give meaning in the cultural setting? Are they compatible with the cultural values of the therapist and those of the patient and the family? Several sources claim the biomedical paradigm for being Western with insufficient consideration of the socio-political context.

The cultural formulation developed as part of DSM-IV and now DSM-5 is one model to support a systematic review of culture and context in psychiatric diagnosing.

The paper will discuss the advantages and shortcomings of current diagnostic categories and guidelines vis-à-vis the universe of traumatized refugees with other ethnic backgrounds.

Interview and therapeutic rapport in diagnostic process

L. Küey

Istanbul Bilgi University, Department of Psychology, Istanbul, Turkey

Diagnostic assessment in psychiatry, as a formulation and as a joint re-construction process between the clinician and the patient, is essential in clinical care. Clinical interview is the crucial tool of the clinician in this process. Accordingly, a two-fold task is faced. On one hand, the clinician is in need of making a comprehensive diagnostic assessment to construct a valid and working formulation of the patient's situation and a treatment plan.

On the other hand, the bases for a psychotherapeutic alliance and rapport should be established. A comprehensive diagnostic assessment aims to bridge the current scientific evidence and knowledge with the uniqueness of the specific person who presents for care. The clinician facing the complexities of the human existence in health and ill mental health constructs working hypotheses in the context of the interview, to understand and formulate the psychopathological state. Clinical interview serving as a practical channel in constructing these hypotheses, also serves as the main tool in establishing a therapeutic alliance. The theory and practice of different schools of psychotherapies offer considerable contributions to the clinician in managing these tasks.

Understanding the meaning of the human suffering through empathy in a judgment free milieu is essential in the establishment of rapport, compliance and a better clinical outcome. This presentation will discuss the complexity of diagnostic process in psychiatry and emphasize the contributions of psychotherapeutic theory and skills and humanistic approaches in this process. Brief clinical vignettes from the authors' clinical practice will be used to broaden the scope of discussion.

Depression is a complex, heterogeneous psychiatric disorder with multifactorial aetiology. Substantial evidence indicates that depressive episodes are associated not only with changes in neurotransmission in the central nervous system (CNS), but also may lead to structural changes in the brain through neuroendocrine, inflammatory, and immunological mechanisms. Among the factors deserving special attention connected with developing systematic inflammation are altered intestinal permeability, IgG food intolerance, and changes in gut microbiota.

We present a possible scenario of the development of depression, linking elevated zonulin production, loosening of the tight junction barrier, an increase in permeability of the gut wall, and the passage of macromolecules, normally staying the gut, into the bloodstream, with the immuno-inflammatory cascade and induction of IgG-dependent food sensitivity. Alterations in bidirectional signaling between the gastrointestinal tract and the brain, so called "microbiota-gut-brain axis", may be normalized by dietary immunomodulating factors, including prebiotics and probiotics. In the case of increased IgG concentrations, the implementation of an elimination-rotation diet may prove to be an effective method of reducing inflammation and, in this way, alleviating depressive symptoms.

Given complexity and variety of mood disorders, it is necessary to develop improved integration models. Preliminary study results raise hope that the new methods mentioned above, i.e. psychobiotics, prebiotics, an elimination-rotation diet, may be an important addition to the psychiatrist's armamentarium as therapeutic agents improving the efficacy of the treatment for affective disorders [1–3].

S24

Can the pathophysiology of autism be explained by the nature of the discovered urine peptides and dietary antigens?

K.L. Reichelt

Oslo University, Blindern, Oslo and lab 1, Sandvika, Norway

Purpose A: 1. To develop the urine analysis for exorphins for routine use in blood and cerebrospinal fluid (CSF).

2. Disorders where patient related validation must be carried out: schizophrenia, depression (uni- and bipolar) and autism.

Method A: HPLC-MS/MS (fragmentation mass spectrometry) technology.

With both a specific HPLC retention time and MS/MS (fragmentation) this method is close to an absolute technique for peptide recognition.

B: ELISA against specific proteins (gliadin, gluten and casein and transglutaminase 6) (Table 1 og 2).

Background A: schizophrenia: increased opioid peptide levels have been found in Schizophrenia using HPLC, immune assay and behavioral tests. [1–6] as part of a general peptide increase in urine. Since peptides are signaling compounds inhibition of peptidases during transport and work up of samples is critical to prevent break down, which is as expected fast at room temperature.

Strongly supporting this view is the data on postpartum psychoses (a very symptom rich psychosis) where also amino acid sequence of human casomorphin found increased, has been done [7–8]. The opioids can explain most of the symptoms of the psychotic schizophrenic state [6]. It is of paramount importance then to measure these peptides in carefully diagnosed patients on and without medication, in urine, blood and spinal fluid.

As can be seen in Table 1, it is important to measure IgA and IgG antibodies against the precursor proteins for the exorphins, which are found increased by several groups, and also have direct effects on the nervous system [9].

B. In depression increase levels of peptides has been found [18,28,29] and also opioid levels measured as opium receptor binding peptides [28]. In schizoaffective psychosis MS/MS exact detection of exorphins have been published [6]. Also in this syndrome it is critical to be able to measure the exorphins in blood and CSF, especially since the peptidases involved in break down of exorphins are decreased in depressions [30,31]. Inflammatory interleukins are also increased in depressions both uni- and bipolar [32] indicative of inflammatory processes probably in the gut. Inflammatory interleukins increase the permeability of epithelial membranes [33].

C. Autism. Considerable work has been done using HPLC with UV detection and co-chromatography [12,34–40]. However, with HPLC-MS/MS we can ensure that we are measuring only the exorphins and not chromatographically similar peaks that hide inside the main peak [41–43]. We therefore need to validate the new method in autism for both urine, blood and CSF (CSF collected only when spinal tap has to be done in any case).

Inhibition of break down in urine, blood and cerebrospinal fluid (CSF) After extensive testing we have been left with three inhibitors. Citric acid 0.2 M; acetic acid 0.2 M and aprotinine [44,45].

These body fluids will be provided by Prof Dr E. Severance and Prof Dr R. Yolken (Johns Hopkins Univ.) and Prof Dr. Cunningham

(Uppsala Univ. Sweden). Lab 1 provides monovettes with citric acid as peptidase inhibitor for urine collection. Blood will be collected in EDTA – aprotinin vacuum test tubes (Vacutainer) as will be CSF. HPLC and MS/MS detection.

The amount of urine analyzed on the HPLC after work up = 250 nanomoles creatinine. To pick out generally active peptides in any one disorder, five and five autistic children or schizophrenic derived and depressive derived urines are mixed, creatinine re-determined and rerun. Peaks that are common to all patients increase or remain the same, while individual peaks of material on the HPLC runs are diluted out.

The complete procedure is published in detail [48]. If we use reporter ions we do not have to match all the peaks as shown in attached figures. On Fig. 1, synthetic bovine β -casomorphine 1-4 (Y-P-F-P) is compared to biologically isolated compound from a batch of five autistic children. On Fig. 2, the faster routine analysis using reporter ions is shown for bovine β -casomorphine 1-4. Top trace is synthetic casomorphin 1-4 and bottom trace is biologically isolated compound. The complete analysis for a series of opioids is published [48].

Program is then in sequence:

– A: further validation of method for urine in the different disorders;

– B: validation of method for blood in the same disorders;

– C: validation of method for CSF (spinal fluid) in schizophrenics and depressive patients.

NB.

To avoid overlooking new compounds a complete HPLC run with UV 215 nm (peptide bonds); 280 nm (aromatic groups) and 325 nm (Indolyl-acryloid) shall be run for urines. If sufficient serum is available and spinal fluid these will also be run on HPLC in addition to MS/MS detection.

Antibody assays will be done at Johns Hopkins using ELISA, Transglutaminase 6 antibodies at Lab 1 also using ELISA assay.

Gastroenterology issues in schizophrenia: Why the gut matters

E. Severance

Johns Hopkins University School of Medicine, Department of Pediatrics, Baltimore, MD, USA

Numerous risk factors for schizophrenia can be reconciled through a common enteric source. These risk factors include systemic

and localized inflammation, compromised endothelial barriers, IgG sensitivities to food antigens, exposure to viral and parasitic pathogens, and autoimmunity. The gut in a homeostatic state equates with a functional digestive system, cellular barrier stability and properly regulated recognition of self and non-self antigens, as managed by a complex community of resident microbes. Our studies address how environmental and genetic factors relate to GI dysfunction, impact the resident gut microbiota and result in dysregulation of processes in the host central nervous system. We hypothesize that disturbance to GI equilibria activates peripheral immune factors including complement pathway components that function in synaptic pruning. We evaluate these issues with peripheral immune biomarkers and deep sequencing in a number of case-control psychiatric cohorts that include antipsychotic-naïve individuals. Although certain medications and lifestyle factors might affect GI functioning, our findings support a GI pathology inherent to the schizophrenia disease process and a role for the gut-brain axis in complex brain disorders. The identification of those individuals affected by GI-related risk factors will enable appropriate and individualized treatments to be designed and tested for efficacy of both gut and brain-related symptoms.

* Corresponding author.

Introduction Novel research concepts based on therapies aiming to modulate intestinal microbiota are emerging. The evidence is mounting that gut-brain axis plays an important role in the development of mood and depressive disorders [1]. The similarities between blood brain barrier (BBB) and gut vascular barrier (GVB) and their role in chronic diseases have been recently unraveled [2]. Especially convincing data come from animal models, where administration of probiotics and antibiotics in germ and pathogen free mice showed beneficial role in the regulation of behavior, cognition, pain, anxiety and mood.

Aims and results Based on available data as well as on studies looking at the effect of multispecies probiotics (Ecologic® Barrier containing *B.bifidum*W23, *B.lactis*W52, *L.acidophilus*W37, *L.brevis*W63, *L.casei*W56, *L.salivarius*W24, *L.lactis*W19, *L.lactis*W58) on cognitive reactivity to sad mood in healthy volunteers [3] we designed the human trial aiming to compare microbiome alterations and response to therapy in patients with depression and schizophrenia. Moreover, in vitro and in vivo data support the notion that multispecies probiotics are capable of improving gut barrier function [4] and may alleviate disorders affecting mood and depressive-like behavior. We postulate that therapies modulating the microbiome-gut-brain axis warrant further investigations.

Conclusion Multispecies probiotics have the potential to influence the gut-brain axis and alleviate mental disorders. Ongoing clinical study in patients with depression and schizophrenia will help to further unravel the role of gut-brain axis in the treatment of patients with psychiatric disturbances.

E-mental Health: Updates on recent achievements and pitfalls

S27

E-Mental Health and models of care: The evidence base and feasibility of picking one vs. another?

D. Hilty

Keck School of Medicine at USC and LAC + USC Medical Center, Los Angeles, USA

The patient-centered care features quality, affordable, and timely care in a variety of settings – technology is a key part of that – particularly among younger generations and child and adolescent patients. The consumer movement related to new technologies is nearly passing clinicians by, as new ways of communicating with others (text, email, Twitter, Facebook) revolutionizes how we experience life and access healthcare. This paper explores a continuum with healthy, innovative behavior on one end (e.g., social media) and pathological Internet use on the other end—and the range of self-help and e-mental healthcare options being used. Specifically, it focuses on how social media adds to, yet may complicate healthcare delivery, such that clinicians may need to adjust our approach to maintain therapeutic relationships, interpersonal/clinical boundaries, and privacy/confidentiality. We suggest planning ahead to discuss expectations about online communication between doctors and patients as part of the informed consent process, offer other do's and don'ts for patients and clinicians, and review applicable guidelines. More research is needed on consumer and patient use of technology related to healthcare, as is an approach to basic and advanced measurement of outcomes.

Disclosure of interest The author has not supplied his declaration of competing interest.

S28

After all, is E-Mental Health capable of making a paradigm shift?

M. Krausz

Institute of Mental Health at UBC, Vancouver, BC, Canada

Only a very small percentage of adolescents and young adults with mental challenges is able to access specialized care. Access is

limited due to a lack of capacity but also internal hurdles and stigma especially among young males. The web creates a new environment for them, which is defining a new culture of communication and interaction. The majority is using smart phones to access the Internet and make that their main communication device.

Walkalong is a web-based platform, which aims to provide a range of opportunities and tools for youth with especially mood challenges. These tools include screening and assessment, online resources and all kind of orientation and interaction for informed decision-making.

We are working on that to develop a framework for better online-based mental health care including useful tools beyond crisis based on the principles of empowerment and strength based approaches.

⁴ Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

* Corresponding author.

Relapses, deterioration of cognitive functioning, negative symptoms, neuroleptic resistance are the examples of many consequences of noncompliance in schizophrenia. In order to improve the compliance, schizophrenic patients treated in an outpatient department in a traditional way have been given an additional possibility of contacting their doctors with the use of a special application on a portable electronic device. Other functions of this application are possibilities of PANSS, Calgary and CGI measurements and cognitive trainings for the patients. This type of a remote contact with patients can be an effective tool in the work in an outpatient setting. The compliance was assessed using a telepsychiatric system, sending reminders: 1 hour before the planned dose to remind them that drug intake is approaching, and at the moment of intake to check if they took the drug. In general the compliance in the group of schizophrenic patients in remission is very low, however the telemedicine system improves the compliance in this group of patients, in which the compliance is the worst.

E-psychiatry: From acceptability to effectiveness!

S30

A study on the effectiveness of E-Mental Health in the treatment of psychosis: Looking to recovery

F. Gucci*, F. Marmo
Clinica Villa Camaldoli, Naples, Italy

* Corresponding author.

Introduction An integrated program (Institutional Psychiatric Open Light Treatment) for psychosis and personality disorder was enriched with audiovisual functions provided through a dedicated website.

The aim of the present study was to observe how and if these added functions support the patients in their daily living, influencing the quality of the recovery process.

Recent studies highlighted how telemental health services are effective to provide access, improve basic outcome, facilitate empowerment of patients and be well-accepted (Hilty, 2013; Hailley, 2008) and how integrated community-based treatment, such as Community-Based Psychodynamic Treatment Program (Chiesa and Fonagy, 2009) or Assertive Community Treatment (Veldhuizen and Bahler, 2013) are effective in SMI.

Telemental health services may become factors improving real-life functioning, integrating community-based treatment for psychosis and bettering social cognition, functional capacity, resilience, internalized stigma and engagement with mental health services, so positively affecting outcomes of psychosis treatment.

Methods All patients admitted (May 2010–April 2015) were included. Aged between 18 and 65, with schizophrenia, psychosis, schizoaffective disorder, bipolar disorder, personality disorder.

Some troubles with the website use (Voice2Voice) led to a second version, more friendly and simple to use (app2gether).

App2gether provided several functions: audio/video conference rooms for patients or family (synchronous virtual space to interact, at scheduled time, with a psychologist, a psychiatrist or a peer support worker, in free groups); chat (asynchronous virtual space for any question or information).

We considered primary outcomes proposed by Cochrane Collaboration (Shek, 2010): hospital admissions, days of hospitalization, day-hospital admissions, day-program attendance (e.g. weekly), treatment compliance (voluntary discharge or missing scheduled date).

We considered, as secondary outcomes, variables closely associated with real-life functioning (Galderisi, 2015): global functioning (Italian translation of Global Assessment of Functioning Scale), quality of life (Short Form 36 item), social relationships (Personal and Social Performance), internalized stigma (Internalized Stigma Mental Illness Inventory), empowerment (Empowerment Scale).

Patients were divided into four cohorts:

- 1-using “app2gether” functions in the follow-up, attending day treatment program ($n = 35$);
- 2-attending day treatment program ($n = 52$);
- 3-attending transitional day-hospital program ($n = 171$);
- 4-not included in the IPOLT-program ($n = 188$).

Patients were included in the first group only based on their basic computer skills and fast Internet availability.

Results At first, we compared (2) and (3) with (4), as control group. For each patient, we considered an identical observation period before and after day-hospital admission (ANOVA, $P < 0.05$). We found a significant improvement in primary outcomes and global functioning, but not in other secondary outcomes, for the groups (2) and (3) compared with (4).

Over 6-months observation, patients using “app2gether” functions in the follow-up showed:

- a significantly decrease in hospital admissions and hospitalization length, compared to non-IPOLT-program group;
- a reduction in day-hospital admissions and day-hospital attendance, compared to (2) and (3) groups;
- a notable effect on secondary outcomes, compared to all other groups.

Conclusion A dedicated website in the IPOLT-program supports patients in their living's place, does not interfere with daily activities, decreases social costs, encourages community integration and reduces stigma.

Synchronous telepsychiatry allow a professionally modulated intervention in “here and now”; asynchronous contacts with specialists combine professional intervention with chances of

autonomy and autoregulation. These services reduce costs, in terms of FTE (Full Time Equivalent), but not the efficacy. Future advances in the websites should be designed, simplifying the contact surface with the treating-team and reducing the social impact of therapeutic practice.

A better understanding of the complex variables influencing real-life functioning and new sensitive tools to detect it are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The impact of E-Mental Health on prevention and early detection of illness

D. Hilty

Keck School of Medicine at USC and LAC + USC Medical Center, Los Angeles, USA

Our current healthcare system in the United States is characterized by problems with access to timely and evidence-based care, particularly for mental disorders. Telemental health improves access to care regardless of the point-of-service or barriers involved. Its effectiveness across age, population and disorders is as good as in-person care, though adjustments for some populations in the approach is necessary. Early intervention is an example of “Cadillac” care or a best evidence-based approach that is easier to distribute via telemedicine. Cadillac care delivered via TMH has the potential to bring evidence-based early intervention modalities to very young children and their families. However, early access to care is also critical for all populations, particularly those with cultural or medical disadvantages. It appears that telemental health may be preferable or better than in-person care in some instances.

The acceptability of web-care for patients with major depressive disorder

M. Ladea*, M. Bran

University of Medicine and Pharmacy “Carol Davila”, Psychiatry, Bucharest, Romania

* Corresponding author.

Introduction With the extraordinary rate of development of E-health and widespread internet access in Romania, Inomedica decided to create a platform dedicated primarily to the patients and their families: depresiv.ro. According to Internet Live Stats there were 11,178,477 Internet users in Romania (representing 51.66% of the population) in 2014. Inomedica is a non-governmental organization founded by a multidisciplinary team (psychiatrists, sociologists, IT specialists).

The platforms provide rigorous and quality online information about depression as well as self-assessment tools and Q&A section. The presentation will explore the development and effects of the first 16 months of operation of a web platform about depression.

Methods The depresiv.ro platform design is simple and user friendly. Mental health specialists contributed to the development of the content, which is easy to access and understand.

The platform also provides access to a self-evaluation tool, the Hospital Anxiety and Depression Scale (HADS), and thus helps the users identify possible problems and encourage them to seek professional help. The web application also included a demographic questionnaire, and a medical history questionnaire. A native iOS version of the application is available to download free on AppStore. The platform is supported by a Google grant program.

Results The platform traffic increased from a few users per day at launch to more than 1000 unique visitors per day. Since 1st January 2015, about 178,000 unique visitors accessed the platform. All the metrics improved significantly during the last months: bounce rate (66.3%), average session duration (02:17 minutes), number of pages per session (2.4).

About 25,000 users accessed the HADS application since its release, from August 2014 until September 2015, showing the increasing need for free online self-evaluation tools.

The Q&A section is one of the most visited on the platform since many users try to find answers for their questions regarding depressive or anxiety symptoms.

Conclusions As new technologies are introduced and become more accessible, mental health specialists are developing new ways of providing services and collecting data. The traffic data/usage for both the depresiv.ro platform and the app are evidence for the widespread acceptability of web-based delivery methods.

Digital healthcare: Fools gold or a promised land?

M. Wise

Wiser Minds Ltd, Adult, London, United Kingdom

Digital healthcare is the use of technology to deliver healthcare. There are many facets of it. The paradigm of care at a distance e.g. a live interface is the most understood, whether it is the old fashioned analog phone call or that of today's Millennial who ‘get’ Skype or see video calling as a day to day reality.

This has moved to non-live uses, asynchronous, the modern version of written communication, email, videomessage, Instagram, twitter or any one of a multitude of social media.

It has progressed beyond that though to a plethora of devices, apps and cross breeds that promise to maximise your patients health, and often your practice income! Grand claims, if not ones supported by the evidence.

They have broadened the range of providers from the plain vanilla (group) therapist to the Cyber support groups; from patient information sheets, to sophisticated hyperlinked, video embedded ‘hope box’, or manual on your phone. They have changed in vivo exposure from what was limited by travel time, to what is limited by the programmers imagination.

Telemedicine can connect patients and providers worldwide – how can that not be an amazing promise, today's truly outstanding goal – tomorrow commonplace event.

The promise of near infinite data; if only we can measure enough, we can treat better, may hold true for a physical paradigm such as mobile ECG or BP monitoring, but is it true for mental health?

Science is not a door to infinite wisdom, but a rescue from unending ignorance. The evidence is that technological innovations are not a magic solution but tools widening access, they are to travel what the motorway is to the dust track. They are an equaliser in that more people can be reached than ever before—but they do not replace human skill and ability.

By December 2015, 500 million smartphone users worldwide will be estimated to be using a health care application. Yet, there is no evidence of a systematic evaluation of a fraction of these apps. They may not be snake oil salesman, but has the placebo effect graduated from molecules to ones and zero's?

We will explore the evidence to understand some of the promises and the realities of what was once Tomorrows World, here today.

Engaging students with psychiatry: Why, how, and where are we now

S34

Medical students choice of psychiatry – an international survey

D. Bhugra (President)

World Psychiatric Association, London, United Kingdom

The appeal of psychiatry as a speciality varies around the globe for a number of reasons. In a majority of countries, medical students are reluctant to choose psychiatry and this has become a much more evident matter of concern in the past three decades. The factors, which affect the choice of psychiatry as a specialty by medical students include external and internal stigma, quality of teaching of the subject as well as research exposure and clinical experience during placements. In many countries, a placement may last only two weeks and the exposure is to patients in asylums, whereas a majority of psychiatric conditions are treated in primary care. In addition, personal factors such as the ability to deal with openness and ambiguity play a role in the choice of speciality. A study in 19 countries to explore factors prior to entering medical school, experiences in medical school and postgraduate in the choice of the subject showed that those medical students who are likely to choose psychiatry fall into three major categories:

- those who had decided prior to joining medical school that they wanted to choose psychiatry;
- those who decide during medical school placements and, finally;
- those who select the speciality after having finished their medical school training.

The latter group has two further subgroups: one, which falls passively into psychiatry and another who make an active choice to take it up. Among 2198 students who participated, 4.5% of the sample planned to become psychiatrists, with a further 15% considering it as a possible career. Women (21%) were more likely to consider psychiatry than men (16%). Key factors associated with choosing psychiatry were personal as well as based on teaching/learning experiences. In order to recruit into psychiatry, better teaching, exposure to common mental disorders and small research projects may prove to be helpful.

Papageno program: When learners collaborate for a safer coverage of suicide

C.E. Notredame

Regional Medical Center of Lille, Child and adolescent psychiatry, Lille, France

Media coverage of suicide has been repeatedly shown to influence suicide rates. The Werther Effect (WE) qualifies the propensity of suicide stories to prompt imitative behaviors. By contrast, the Papageno effect (PE) was more recently identified as a way for journalists to contribute to suicide prevention through their productions. Crucially, both WE and PE depend on the quantitative (audience, redundancies, size of articles, etc.) and qualitative (type of story, editorial style, content, etc.) properties of the coverage.

In order to promote the PE and limit the WE, the World Health Organization (WHO) have edited a guideline for media professionals. For instance, journalists are advised to prohibit sensationalism, avoid pictures or details about the suicide method, and show due respect to the bereaved relatives. However, it is now clear that the only chance for these recommendations to be applied is to integrate

their diffusion into a more general effort toward collaboration with journalists.

Papageno is a French national suicide prevention program that fully relies on learners to rise awareness about suicide and its coverage. It mainly consists in pair-meetings between psychiatry trainees and journalism students. Such an innovative formula breaks with the old top-down knowledge transmission model in order to foster personalized and sustainable sensitization. It aims at growing up a new generation of journalists who would be more aware of their responsibility concerning suicide and would more spontaneously resort to the WHO guidelines. Ultimately, the Papageno program strives for the creation of a new culture where journalists and psychiatrist would collaborate for a safer media coverage of suicide.

Youth leadership in mental health: Views from EFPT and IFMSA

M. Pinto da Costa¹, D. Silva^{2,*}, S. Essafi³, E. Frau⁴, V. Berquist⁵, K. Maceviciute⁶¹ Hospital de Magalhães Lemos, Psychiatry Department of Porto, Porto, Portugal² University of Porto, Faculty of Medicine, Porto, Portugal³ University of Sousse, Medical School, Sousse, Tunisia⁴ University of Fribourg, Faculty of Medicine, Fribourg, Switzerland⁵ Monash University, Faculty of Medicine, Melbourne, Australia⁶ Vilnius University, Faculty of Medicine, Vilnius, Lithuania

* Corresponding author.

The world today is more challenging than ever before. Discrimination, stigma, and ever-changing lifestyles are just a few examples of elements that have a profound impact on the mental health status of our global population. Even though the burden of mental illness is well documented and increasing, mental health remains a neglected area of health worldwide.

Youth Associations, like the International Federation of Medical Students' Associations (IFMSA) and the European Federation of Psychiatric Trainees (EFPT) recognize the importance of tackling this problem, taking an active role on promoting education in our communities, tackling stigma and advocating for more action. Medical students worldwide, from Slovenia, Australia, Lebanon, Brazil, Quebec and Grenada – among at least 42 other countries, organise expansive, creative and engaging mental health projects.

With particular interest we can mention the winner of the last Rex Crossley Award, attributed to a Slovenian project 'in Reflection': a suicide prevention project, which tackles the different factors associated with vulnerable groups through a series of workshops and campaigns that seek to destigmatize the mental health problems and offer the opportunity to high school students to get the help they need.

This talk will give an insight into strengths, weaknesses and challenges faced by youth in tackling mental health, specially in the role of the IFMSA, displaying some of our most interesting and innovative projects from future mental health leaders around the world, together with the initiatives of EFPT.

Epigenetic discoveries in psychiatric disorders

S38

Methylome modifications in monozygotic twins and in depression

L. Fañanás*, A. Córdova-Palomera
University of Barcelona, Animal Biology, Barcelona, Spain

* Corresponding author.

Epigenetics is the study of gene expression changes that are produced by heritable, though potentially reversible, modifications of chromatin structure or DNA methylation. DNA methylation is interesting in epidemiological studies, due to its accessibility and since previous evidence indicates that large inter-individual differences in methylation levels at some loci may correlate with phenotypic plasticity in changing environments.

Prior genome-wide methylomic research on depression has suggested that, together with differential DNA methylation changes, affected co-twins of monozygotic twin pairs have increased DNA methylation variability, probably in line with theories of epigenetic stochasticity. However, the putative biological roots of this variability remain largely unexplored.

This study evaluate whether DNA methylation differences within MZ twin pairs were related to differences in their depressive status. Genome-wide DNA methylation levels were measured in peripheral blood of 34 twins (17 MZ pairs) using Illumina Infinium Human Methylation450 Beadchip. Two analytical strategies were used

to identify differentially methylated probes (DMPs) and variably methylated probes (VMPs).

The majority of the DMPs were located in genes previously related to neuropsychiatric phenotypes, such as WDR26, a GWAS hit for MDD whose expression levels have been found altered in blood of depressed individuals.

VMPs were located in genes such as *CACNA1C*, *IGF2* and the p38 MAP kinase *MAPK11*, showing enrichment for biological processes such as glucocorticoid signaling.

The findings expand on previous research to indicate that both differential and variable methylation may play a role in the etiopathology of depression, and suggest specific genomic loci of potential interest in the epigenetics of depression.

Longitudinal study of methylome profiles in subjects with psychosis and/or schizophrenia

O. Kebir*, B. Chaumette, M.O. Krebs

Inserm U894, Centre of Psychiatry and Neurosciences, Paris, France

* Corresponding author.

Background Schizophrenia is a complex disorder involving both genetic and environmental factors. Epigenetic is a growing theory to explain these interactions at a molecular level. It is well-known that schizophrenia begins with prodromal symptoms and patients undergoing subthreshold symptoms are named ultra-high risk (UHR) subjects. Therapeutic and prognostic attitude remain challenging for this population. According to the model of the gene-environment interactions, the psychotic transition in adolescence could be related to epigenetic changes during the psychotic transition.

Methods We designed and performed the first longitudinal study about whole-genome DNA methylation changes. Thirty-nine UHR patients were recruited in specialized center C'JAAD - Centre Hospitalier Ste Anne - Paris (France). During follow-up, 14 of them became psychotic (converters) according to the validated scale CAARMS. Initial and final methylation were investigated by Infinium Human Methylation450 BeadChip for 450,000 CpG after bisulfite conversion.

Results The psychotic transition was not associated with global methylation changes. Linear models failed to identify CpG and genes significantly associated with psychotic transition after Bonferroni correction. Analyses of the top results provided a cluster, which could classify perfectly converters and non-converters. These genes of interest are over-represented in biological pathways with relevance for psychotic physiopathology. Individual analyses highlighted the biological heterogeneity of the psychotic transition.

Conclusion Improving physiopathological understanding of psychotic transition is a current challenge to identify biomarkers and to develop targeted preventive interventions available in clinical practice for UHR subjects. The epigenetic processes and in particular DNA methylation could be interesting factors.

Epigenetic modifications in anorexia nervosa patients and remitters compared to healthy control women

N. Ramoz^{1,*}, J. Clarke^{1,2}, P. Gorwood^{1,3}

¹ Inserm U894, Centre de Psychiatrie et Neurosciences, Paris, France

² Hôpital R.-Debré, Psychiatrie de l'enfant et de l'adolescent, Paris, France

³ Hôpital Sainte-Anne, CMME, Paris, France

* Corresponding author.

Introduction Anorexia nervosa (AN) is the most severe in terms of morbidity psychiatric illness with the highest mortality rate increased by 23 fold. Treatments are limited effectiveness. AN has a strong genetic component with heritability at 70% but despite ~200 studies no major gene was identified. Epigenetics, such as DNA methylation, is another component of heritability that could explain the high heritability. Methylation is poorly studied in AN from small samples, and is focused on few candidate genes among publications. Under publication, a first genome-wide methylation study investigated 10 restrictive type AN patients, 19 bingeing/purging type of AN patients and 15 normal eaters using DNAs from whole blood (Booij, 2015). Of the 480K CpG sites that can be methylated of Infinium Human Methylation450 BeadChip Kit, authors focused on 24,000 sites located close to genes and they identified candidate genes with a different profile of methylation between AN and controls.

Objectives Our work is to replicate the results of Booji and also to investigate the AN remitters.

Aims Our goal is to identify epigenetic signatures of the AN disorder and the prognostic of remission.

Methods Twenty-four AN patients, 24 AN remitters will be compared to 48 healthy control women for methylation using the Infinium Human Methylation450.

Results As Booji et al., we will compare methylation for 24,000 sites located close to genes for 24 AN, 24 remitters and 48 controls.

Conclusions We expected to replicate the published results of Booji and to identify genes with a methylation signature specific of the AN remission.

³ University of Montpellier, Department of mental health and psychiatry, Montpellier, France

⁴ University Hospitals of Geneva, Department of mental health and psychiatry, Geneva, Switzerland

⁵ University Hospital of Geneva, Department of mental health and psychiatry, Geneva, Switzerland

* Corresponding author.

Early life adversity plays a critical role in the emergence of borderline personality disorder (BPD) and this could occur through epigenetic programming. In this perspective, we aimed to determine whether childhood maltreatment could durably modify epigenetic processes by the means of a whole-genome methylation scan of BPD subjects. Using the Illumina Infinium[®] Human Methylation450 BeadChip, global methylation status of DNA extracted from peripheral blood leucocytes was correlated to the severity of childhood maltreatment in 96 BPD subjects suffering from a high level of child adversity and 93 subjects suffering from major depressive

disorder (MDD) and reporting a low rate of child maltreatment. Several CpGs within or near the following genes (*IL17RA*, *miR124-3*, *KCNQ2*, *EFNB1*, *OCA2*, *MFAP2*, *RPH3AL*, *WDR60*, *CST9L*, *EP400*, *A2ML1*, *NT5DC2*, *FAM163A* and *SPSB2*) were found to be differently methylated, either in BPD compared with MDD or in relation to the severity of childhood maltreatment. A highly relevant biological result was observed for cg04927004 close to *miR124-3* that was significantly associated with BPD and severity of childhood maltreatment. *miR124-3* codes for a microRNA (miRNA) targeting several genes previously found to be associated with BPD such as *NR3C1*. Our results highlight the potentially important role played by miRNAs in the etiology of neuropsychiatric disorders such as BPD and the usefulness of using methylome-wide association studies to uncover such candidate genes. Moreover, they offer new understanding of the impact of maltreatments on biological processes leading to diseases and may ultimately result in the identification of relevant biomarkers.

The community-based 4-level-intervention concept developed within the “European Alliance against Depression” (<http://www.eaad.net/>) combines two important aims: to improve the care and treatment of patients with depression and to prevent suicidal behavior. It has been shown to be effective concerning the prevention of suicidal behavior [1–4] and is worldwide the most broadly implemented community-based intervention targeting depression and suicidal behavior. The 4-level intervention concept comprises training and support of primary care providers (level 1), a professional public relation campaign (level 2), training of community facilitators (teacher, priests, geriatric caregivers,

pharmacists, journalists) (level 3), and support for self-help of patients with depression and for their relatives (level 4). In order to deepen the understanding of factors influencing the effectiveness of the intervention, a systematic implementation research and process analysis was performed within the EU-funded study “Optimizing Suicide Prevention Programs and Their Implementation in Europe” (<http://www.ospi-europe.com/>; 7th Framework Programme) [5]. These analyses were based on data from four intervention and four control regions from four European countries. In addition to intervention effects on suicidal behaviour, a variety of intermediate outcomes (e.g. changes in attitude or knowledge in different populations) were considered. Strong synergistic as well as catalytic effects were identified as a result of being active simultaneously at four different levels. Predictable and unpredictable obstacles to a successful implementation of such community-based programs will be discussed. Via the EAAD, the intervention concept and materials (available in eight different languages) are offered to interested region in and outside of Europe.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Hallucinations and delusions in schizophrenia: From phenomenology to neurobiology

S43

Hallucinations without delusions in patients with first-episode psychosis: Clinical correlates and implications for pathophysiological models

I. Melle

NORMENT Centre for Psychosis Research, Division of Mental Health and Addiction, Institute of Clinical Medicine, University of Oslo and Oslo University Hospital, Oslo, Norway

Introduction The symptomatic distribution in schizophrenia spectrum disorder is heterogeneous. Patients may experience hallucinations, delusions and combinations thereof, in addition to disorganized and negative symptoms. We have previously found that patients with monosymptomatic hallucinations exhibited a different clinical profile than patients with monosymptomatic delusions or combinations of the two; with an earlier age at onset and more suicidal symptoms.

Aims To replicate findings in a new group of patients with schizophrenia spectrum disorders.

Methods A total of 421 consecutive patients with schizophrenia spectrum disorders were included into the study. They were comprehensively assessed by specifically trained psychiatrists or clinical psychologists; using the SCID for DSM-IV for diagnostic purposes, the PANSS to assess current clinical symptoms and CDSS to assess current depression. Lifetime presence of different symptom types was ascertained during the diagnostic interview.

Results A total of 346 (82%) had experienced both hallucinations and delusion, 63 (15%) had experienced delusions without hallucinations, 10 (2.5%) had experienced hallucinations without delusions and 2 patients (0.5%) had neither but experienced negative and severely disorganized symptoms. Contrary to hypothesis,

we did not find any statistically significant differences in age at onset and in clinical symptoms (including suicidality) between these groups. We also did not find any differences in the type of hallucinatory experiences between hallucinating groups.

Conclusions In a new sample of patients, we did not replicate previous findings of a different clinical profile in patients with monosymptomatic hallucinations. This type of psychotic disorder is relatively rare, which might pose a problem concerning statistical strength.

Abnormal time experience, bizarre delusions and verbal-acoustic hallucinations in schizophrenia

G. Stanghellini

“G. d’Annunzio” University, Department of Psychological, Humanistic and Territorial Sciences, Chieti, Italy

The integrity of time consciousness is the condition of possibility of the identity through time of an object of perception as well as of the person who perceives it. I will present our findings about abnormal time experience (ATE) in people with schizophrenia. These data may support the following hypothesis: if the continuity of temporal experience disintegrates (of which ATE are experiential manifestations), overarching meaningful units are no longer available, thereby creating temporal gaps, e.g., in one’s stream of consciousness. In some cases, thoughts that are no longer experienced as embedded in one’s stream of thoughts are experienced as, e.g., thought interferences, blockages, insertion or withdrawal. These symptoms cannot be explained as a mere disturbance of attention or comprehension at the level of semantic combinations. Rather, the disturbance could be searched for at a more basic level where the temporal coherence of conscious awareness is constituted. A failure of the constitutive temporal synthesis may create micro-gaps of conscious experience. In the most severe cases, thoughts or other mental phenomena that are no longer embedded in the continuity of basic self-experience may appear in consciousness as “erratic blocks” and experienced as being inserted, or, if further externalized, as auditory hallucinations (“voices”). This coheres with the hypothesis that a breakdown of temporality may be bound up with the breakdown of prereflexive self-awareness.

Value-based healthcare delivery in the digital era

G. Seara^{1,*}, A. Payá², J. Mayol³

¹ Hospital Clínico San Carlos, Innovation Unit, Madrid, Spain

² Servicio Madrileño de Salud SERMAS, Dirección General de Sistemas de Información Sanitaria, Madrid, Spain

³ Hospital Clínico San Carlos, Universidad Complutense, Innovation Unit, Department of Surgery, Madrid, Spain

* Corresponding author.

Introduction Mental disorders are a major cause of disability in Europe [1]. However, organizational structures and information systems are focused on delivery of care, rather than providing value [2]. In the digital era, we have the capacity to change priorities through the analysis of heterogeneous databases that could support patients' and professionals' decisions.

Objectives to analyse the contradictions between the design and the theoretical structure of mental health services and the possibilities to evaluate the actual value of the delivered care.

Aims To reflect on changing the trend using a different conceptualization of objectives and evaluating methods.

Methods We used a tool provided to clinicians by the Madrid's Regional Health Service SERMAS ('ConsultaWeb') combining primary care, pharmacy and hospital data ($n = 395,073$ patients for the catchment area), and a set of hospital-based data (patients attended by psychiatrists at the ER, $n = 13,877$, and patients admitted to the Psychiatric Inpatient unit $n = 3318$), to explore some of the present professional information resources.

Results Currently used healthcare databases only describe the diagnostic or therapeutic categories of patients and might be used to detect abnormal behaviours. However, they are neither able to show the functional status of patients nor designed to predict their clinical course.

Conclusions A clearer definition of value in patient outcomes is needed. This might help to organize the healthcare delivery and to create a new information system that would allow to assess health outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

New platform of data analytics for mental health

K. Suzuki

Fujitsu Spain, Department of Innovation, Madrid, Japan

Introduction Mental disorder is a key public health challenge and a leading cause of disability-adjusted life years (DALYs) due to its high level of disability and mortality. Therefore, a slight improve-

ment on mental care provision and management could generate solid benefits on relieving the social burden of mental diseases.

Objectives This paper presents a long-term vision of strategic collaboration between Fujitsu Laboratories, Fujitsu Spain, and Hospital Clínico San Carlos to generate value through predictive and preventive medicine improving healthcare outcomes for every clinical area, benefiting managers, clinicians, and patients.

Aims The aim is to enable a data analytic approach towards a value-based healthcare system via health informatics. The project generates knowledge from heterogeneous data sources to obtain patterns assisting clinical decision-making.

Methods This project leverages a data analytic platform named HIKARI ("light" in Japanese) to deliver the "right" information, to the "right" people, at the "right" time. HIKARI consists of a data-driven and evidence-based Decision Support and Recommendation System (DSRS), facilitating identification of patterns in large-scale hospital and open data sets and linking data from different sources and types.

Results Using multiple, heterogeneous data sets, HIKARI detects correlations from retrospective data and would facilitate early intervention when signs and symptoms prompt immediate actions. HIKARI also analyses resource consumption patterns and suggests better resource allocation, using real-world data.

Conclusions With the advance of ICT, especially data-intensive computing paradigm, approaches mixing individual risk assessment and environmental conditions become increasingly available. As a key tool, HIKARI DSRS can assist clinicians in the daily management of mental disorders.

Is schizophrenia a disorder of brain connectivity?

S48

Disintegration of sensorimotor brain networks in schizophrenia

T. Kaufmann*, K.C. Skåtun, D. Alnæs, C.L. Brandt, N.T. Doan,

I. Agartz, I.S. Melle, O.A. Andreassen, L.T. Westlye

* Corresponding author.

A large body of literature reported widespread structural and functional abnormalities throughout the brain in schizophrenia spectrum disorders (SZ). Corresponding with the typical symptomatology in SZ where sensory dysfunctions contribute to the core social and cognitive impairment, converging evidence suggests a disturbed interplay between higher-order (cognitive) and lower-order (sensory) regions. This talk will discuss the results of several recent studies, investigating brain connectivity in SZ using functional magnetic resonance imaging data from large samples. Within-network sensorimotor as well as sensorimotor-thalamic aberrations in SZ robustly appear among the core findings across studies, both during performance of cognitive tasks and during rest. We utilized machine learning to distinguish SZ from healthy controls based on connectivity profiles. When classifying on sensorimotor connections alone, not only can we reach accuracies largely above chance but also, these accuracies are as good as when incorporating whole brain connectivity in the classification. Whereas the overall accuracy levels in distinguishing SZ from controls are not useful in a clinical context, these results underline the robustness of the sensorimotor findings on the individual subject level. Targeting the sensory and perceptual domains may thus be key for

future research to get a better understanding of the heterogeneity of clinical manifestations in severe mental disorders and to map clinical symptoms to imaging phenotypes.

Introduction Several lines of evidence suggest that cognitive deficits represent a core feature of schizophrenia.

Objectives The concept of “cognitive dysmetria” has been introduced to characterize disintegration at the system level of frontal-thalamic-cerebellar circuitry which has been regarded as a key network for a wide range of neuropsychological symptoms in schizophrenia.

Aims The present multimodal study aimed at investigating effective and structural connectivity of the frontal-thalamic circuitry in schizophrenia.

Methods Univariate fMRI data analysis and effective connectivity analysis using dynamic causal modeling (DCM) were combined to examine cognitive control processes in 40 patients with schizophrenia and 40 matched healthy controls. BOLD signal and parameters of effective connectivity were related to parameters of corresponding white matter integrity assessed with diffusion tensor imaging (DTI).

Results In the DTI analysis, significantly decreased fractional anisotropy (FA) was detected in patients in the right anterior limb of the internal capsule (ALIC), the right thalamus and the right corpus callosum. During Stroop task performance patients demonstrated significantly lower activation relative to healthy controls in a predominantly right lateralized frontal-thalamic-cerebellar network. An abnormal effective connectivity was observed in the right lateralized connections between thalamus, anterior cingulate and dorsolateral prefrontal cortex. FA in the right ALIC was significantly correlated with the fronto-thalamic BOLD signal, effective connectivity and cognitive performance in patients.

Conclusions Present data provide evidence for the notion of a structural and functional defect in the prefrontal-thalamic-cerebellar circuitry, which seems to be the basis of the cognitive control deficits in schizophrenia.

Motor symptoms and altered connectivity in schizophrenia

S. Walther*, K. Stegmayer, B. Tobias, A. Federspiel
University Hospital of Psychiatry, Translational Research Center,
Bern, Switzerland

* Corresponding author.

Schizophrenia spectrum disorders are frequently associated with motor abnormalities. Aberrant motor function can be observed in patients throughout the course of the disorder, in subjects at high

clinical risk and in unaffected first-degree relatives. Schizophrenia is further characterized by white matter abnormalities in multiple fiber tracts and aberrant resting state cerebral perfusion. In a series of studies, we investigated the association of objectively measured motor behavior in terms of activity levels with white matter microstructure and cerebral perfusion at rest. Patients were less active than controls at the behavioral level. In the associations with neuroimaging techniques, we detected that unlike controls, patients' activity levels were linked to structure and perfusion of cortical motor areas as well as the connecting white matter. In controls instead, motor activity relied on the association of cortico-subcortical motor loops. Thus, some of the motor signs in schizophrenia may result from ineffective coupling between cortical and subcortical motor areas. Finally, preliminary data from functional connectivity analyses support this notion.

Antipsychotic medication and outcomes in schizophrenia from a lifespan perspective

H. Koponen

Helsinki University and Helsinki University Hospital, Department of Psychiatry, Helsinki, Finland

Introduction Antipsychotic medications play an important role in schizophrenia, and their efficacy in the relapse prevention and treatment of acute psychotic symptoms is clear-cut.

Objectives Data on the long-term use of antipsychotics and impact on prognostic issues is limited, although some previous studies noted a high risk of relapse during the first two years after the first acute psychosis.

Aims Our aim was to study the characteristics and clinical course of medicated and unmedicated schizophrenia patients.

Methods The study population consisted of schizophrenia patients from the Northern Finland 1966 Birth Cohort ($n = 70$). Use of antipsychotics was examined in the follow-up interview by asking about the subjects' medication history during the previous three months. The sample was divided into a non-medicated group ($n = 24$) and a medicated group ($n = 46$).

Results Relapses during the follow-up were equally frequent between non-medicated and medicated subjects (47% vs. 53%). Not having been hospitalised during previous five years, but not previous two years, before the interview predicted long-term successful antipsychotic withdrawal without relapse. Fifteen of the subjects in the non-medicated group (63%) and 9 in the medicated group (20%) were in remission.

Conclusions The present results imply that there are some individuals with schizophrenic psychoses not using antipsychotic medication whose psychotic illness and clinical course are so favourable that they do not necessarily need medication permanently. Changes in the antipsychotic dosing should not be made too fast and the patient and relatives should be able to contact without delay if exacerbation of psychotic symptoms is suspected.

A life course perspective on familial and environmental risks for schizophrenia using a western Australian E-cohort

V. Morgan*, P. Di Prinzio, G. Valuri, M. Croft, S. Shah, T. McNeil, A. Jablensky

The University of Western Australia, School of Psychiatry and Clinical Neurosciences, Perth, Australia

* Corresponding author.

Introduction Familial risk for psychosis may interact with environmental risk factors.

Objectives We are studying a large birth cohort of children of mothers with psychotic disorders, themselves at high risk of developing a psychotic illness, to understand the developmental aetiology of psychotic illness.

Aims Our aim is to examine whether exposure to environmental stressors in childhood, including timing of exposure, is a risk factor for psychotic illness, independent of familial liability. Specificity to maternal schizophrenia is explored.

Methods We used record-linkage across state-wide registers (midwives, psychiatric, child protection and mortality, among others) to identify 15,486 offspring born in Western Australia 1980–2001 to mothers with a lifetime history of psychotic illness (case children) and compared them with 452,459 offspring born in the same period to mothers with no known psychiatric history (comparison children).

Results A total of 4.1% of case children had developed a psychotic illness compared to 1.1% of comparison children. Exposure to environmental risk factors including obstetric complications, aboriginality, lower socioeconomic status, discontinuity in parenting and childhood abuse significantly increased risk of psychotic illness in offspring. Length and age at time of discontinuity in parenting impacted on risk. At the same time, case children were also significantly more likely than comparison children to be at risk of experiencing these adverse life events.

Conclusions Exposure to environmental stressors is associated with psychotic illness, and timing of exposure is important. However, children already at increased familial risk for psychotic illness are also at increased risk of experiencing these environmental stressors.

Treatment-resistant schizophrenia during life span : Epidemiology, outcomes and innovative M-Health treatments within M-RESIST Project

K. Rubinstein^{1,2,3,*}

¹ Sheba Medical Center, Department of Psychiatry, Tel HaShomer, Israel

² Tel-Aviv University, Sackler School of Medicine, Tel Aviv, Israel

³ Gertner Institute of Epidemiology and Health Policy Research, Tel Aviv, Israel

* Correspondence.

Treatment-resistant symptoms of schizophrenia (TRS) complicate the clinical course of the illness, and a large proportion of patients do not reach functional recovery (Englich and Zink, 2012). Out of the estimated 5 million people (0.2–2.6 %) suffering from psychotic disorders in the European Union, 30–50 % can be considered resistant to treatment, and 10–20 % ultra-resistant (Essock et al., 1996 ; Juarez-Reyes et al., 1995). The complexity of standard intervention within this population, along with the presence of persistent posi-

tive symptomatology, extensive periods of hospital care and greater risk of multi-morbidity, lead to a high degrees of suffering for the patients, family and social environment, and a high proportion of costs to the healthcare system (Kennedy et al., 2014).

At present, a uniform definition of treatment resistance in the pharmacotherapy of schizophrenia is not available (Suzuki et al., 2011), as well as generally recommendable evidence-based treatment methods (Dold and Leucht, 2014).

A recent systematic review on the topic showed that TRS is poorly a studied and understood condition, contrasted to its high prevalence, clinical importance and poor prognosis. There is lack of studies on epidemiology and risk factors of this disorder, as well as on outcomes and longitudinal course. Most of the available literature focuses on medication treatments, while very few examine efficacy of adjunctive therapeutic options (Seppala et al., in preparation).

Treatments based on information and communication technology (ICT) present novel possibilities to improve the outcomes of schizophrenia. Previous studies have indicated suitability and promising results of such intervention techniques (Granhm et al., 2012 ; Ben-Zeev et al., 2013). m-RESIST is an innovative project aimed to empower patients with resistant schizophrenia, to personalize treatment by integrating pharmacological and psychosocial approaches, and to further develop knowledge related to the illness using predictive models designed to exploit historical and real-time data based on environmental factors and treatment outcomes.

⁵ Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom

* Corresponding author.

Background Studies mainly relied on hospital or case-control data have well documented that individuals with psychoses, and especially with schizophrenia have increased rates of physical illnesses. They have two to four-fold higher mortality risk, and about 10 to 25 years shorter life expectancy compared with the general population. The aim of this study is to evaluate the prevalence of physical illnesses in individuals with schizophrenia or with other psychoses and among people without psychoses until the age of 46 years using complete outpatient and inpatient data from birth cohort.

Methods The study is based on The Northern Finland 1966 Birth Cohort (NFBC, 1966), which is a population-based prospective cohort concerning 12,058 live-born children in 1966 in the provinces of Lapland and Oulu.

The study population consisted of 10,933 individuals, who were alive at the age of 16-years, and followed serially until the age of 46-years. The study population was divided into three groups: those having schizophrenia ($n=228$) and those with other psychoses ($n=240$) while individuals without psychosis ($n=10,465$)

formed the control group. The data was obtained from various national registers.

Results Diseases of the blood and blood forming organs (prevalence in SCZ was 17% versus 10% in controls, $P < 0.001$), endocrine, nutritional and metabolic diseases (45% vs. 27%, $P < 0.001$), diabetes mellitus (7% vs. 3%, $P < 0.001$) and nervous diseases (33% vs. 25%, $P = 0.018$) were more common among individuals with SCZ compared with controls. Diseases of musculoskeletal system and connective tissue were less common in SCZ than among controls (28% vs. 41%, $P < 0.001$).

People with other psychoses than SCZ had statistically significant association with all the diagnostic groups classified in ICD-10 except with neoplasms. Infections and parasitic diseases (prevalence in other psychoses was 44% versus 32% in controls, $P < 0.001$), diseases of the blood and blood forming organs (18% vs. 10%, $P < 0.001$), endocrine, nutritional and metabolic diseases (42% vs. 27%, $P < 0.001$) including diabetes mellitus (9% vs. 3%, $P < 0.001$), nervous diseases (40% vs. 25%, $P < 0.001$), diseases of the eye and adnexa (32% vs. 21%, $P < 0.001$), diseases of the ear and mastoid process (58% vs. 44%, $P < 0.001$), diseases of circulatory (50% vs. 37%, $P < 0.001$), respiratory (70% vs. 60%, $P < 0.001$) and digestive system (77% vs. 68%, $P = 0.004$), diseases of skin and subcutaneous tissue (23% vs. 16%, $P = 0.006$), diseases of musculoskeletal system and connective tissue (51% vs. 40%, $P = 0.004$) and diseases of genitourinary system (41% vs. 31%, $P = 0.003$) were more common among people with other psychoses than SCZ compared with controls.

Discussion A new finding is that not only people with schizophrenia but especially those with other psychoses show a greater occurrence of somatic diseases compared with those without psychosis. The increased occurrence of somatic comorbidity in other psychoses should be noted by medical professional, and further longitudinal studies are warranted to study its possible risk factors during lifespan.

Market economy and its consequences for mental health

S55

Overview of the EPA guidance paper

M.M. Carrasco

Instituto de Investigaciones Psiquiátricas, Fundación M^a Josefa Recio Hermanas Hospitalarias, Bilbao, Spain

After several decades of Market Faith in Western societies and the most severe financial crash several generations has known, there has not really been a serious re-examination of the role of markets and money in our society. A market economy may be a valuable and effective tool for organizing productive activity. The problem is whether we have become a “market society”. That is, if the economic values have been transplanted to the whole of society – not only economic life – and we have become a monetized society: a society where just about everything is up for sale. That’s to say, a way of life where market relations and market incentives and market values come to dominate all aspects of life. Paradoxically, it is possible that the economic crisis has only increased this trend. Administrations at different levels – European, States, Local... – have demanded tremendous sacrifices from the population intended to save the financial system, but on the way sacrificing a Welfare state that took decades to build. In this presentation, we will review the mental health consequences of the current economic crisis. Also it examines how the change in social values and

sweeping assertion of economic values can affect the way we think about Mental Health and Psychiatric Care.

Discussant: Ethical challenges

M. Kastrup

Own firm, Copenhagen, Denmark

Europe has undergone considerable economic changes that have an impact on mental health of its citizens; have consequences for the organization of mental health services; and raise ethical issues, such as the distribution of wealth, and equity in access to care. Furthermore, Europe is current undergoing serious economic problems that will produce adverse effects on the mental health of its citizens, among them increase in substance abuse related disorders as well as an increase in suicide.

The consequences that economic changes have on mental health relate to the conditions of the particular country, as countries with better health security nets would be less likely to experience adverse effects. Different policy measures may reduce the impact on mental health not only within the health sector, but other sectors of society have to be engaged in the process.

The symposium will consider these problems from different selected perspectives.

An overview of the impact of economic policies on health services will be followed by a presentation of the important role of international organizations like EPA in outlining the problem and finally a presentation of the initiative Choosing Wisely that focuses on communication between health professionals and patients with recommendations of decisions about the most appropriate care based on the patient’s individual situation.

Mental health in context. Impact of economic policies on health services

N. Sartorius (President)

Association for the Improvement of Mental Health Programs, Geneva, Switzerland

The impact of economic policies on mental health services – and with some differences also on general health services – will be exemplified by an analysis of the current trend of governments’ withdrawal from funding the mental health services it provided until now and the replacement of the government funded services by privately owned services. The analysis will be made on the background of the current worldwide tendency of commoditification, which posits that health care should be considered a commodity and judged using indicators, which have proven their value in commerce and handling of commodities. The analysis leads to the conclusion that the both tendencies – of commoditification and of increasing involvement of private capital in running health care services are likely to lead to a deterioration of care for people with mental illness.

Mental health in nursing homes: Current best practice

S58

Organizing mental health care in nursing homes: How, by whom and what for?

C.A. de Mendonça Lima (Head)

Unity of Geriatric Psychiatry, Centre Les Toises, Lausanne, Switzerland

Though care should be provided in patients' homes for as long as possible, it must be recognised that care in an alternative residential setting may be the only way of meeting some patients' needs effectively or avoiding intolerable carer burden. Such care will always be necessary, for people who have no relatives available. The residential care may be useful for respite care including a range of time limited services, to support the carers. Residential care should also be available for those patients whose physical, psychological, and/or social dependencies make living at home no longer possible. This provision includes a range from supported accommodations with low level supervision, medium level care facilities and full nursing facilities. There is a high prevalence of mental disorders in nursing homes and very often the staff is not adequately educated, trained and supported to care these individuals. Psychiatric consultation liaison services should be provided not only for residents but also to support the staff of these facilities. The most recent international documents point out the necessity to offer the best available care [1] for these vulnerable persons in the deep respect of their dignity [2]. It becomes urgent to launch a deep debate on this subject in order to recommend to authorities the best guidelines to support policies to be adopted in this field.

Treating chronically psychotic patients in nursing homes

J. Gaillard

Centre d'action sociale de la ville de Paris, Unité de Liaison Psychiatrique, Paris, France

The increase of aging patients with schizophrenia becomes a public health issue. The exponential demography of the elderly, the improvement of cares associated with better physical follow-up directly impact the number of old patients with chronic psychiatric disease. Deinstitutionalization associated with a dramatic enhancement of ambulatory and community cares has led to a reduction of beds in psychiatric hospitals. When dependency occurs, due to physical comorbid illness or a worsening of the negative symptoms, psychiatric teams should find appropriate housing and no longer the psychiatric hospital. Nursing home and sheltered housing for the elderly dependent persons become a solution, but geriatric staffs are not always prepared to receive resident with schizophrenia and other psychotic disorders. They often are at a loss when faced with the expression of psychiatric symptoms or with the specificity of caring for often-younger patients whose behavior is different from older people with neurodegenerative disorders. How psychiatric teams could long-term assist the sheltered housing and nursing home and bring a psychiatric know-how within

staffs often reluctant to deal with psychotic patients who could burden caregivers. How could they be trained to cope with complex cognitive functions impairments of schizophrenia, far from cognitive impairments of Alzheimer dementia? How to change the representation of psychiatric illness, which often leads to a double stigmatization (old age and madness)? Improving the quality of life of aging patients with severe chronic mental illness in homes for seniors is a great challenge for psychiatric teams in collaboration with geriatric caregivers.

Modell Donaustadt: A best practice example for treatment of mental and physical comorbidity in long-term care

B. Hobl*, B. Schreiber

Haus der Barmherzigkeit, Geriatric Psychiatry, Vienna, Austria

* Corresponding author.

Evidence consistently demonstrates that people with long-term mental health conditions develop serious physical comorbidities at an earlier age than the average population. These physical comorbidities are often exacerbated because long-term psychiatric conditions reduce the patient's ability to manage somatic symptoms effectively, thus hindering treatment. This highlights the critical importance of continuous support by primary care physicians and nursing staff. People with persistent mental illnesses typically require long-term care significantly earlier than people without mental illness.

As a consequence, elderly patients with chronic mental illnesses who are essentially unable or unprepared to function in the outside world or are in need of constant medical attention are typically placed into long-term care facilities and nursing homes geared to serving physically disabled elderly.

These LTC institutions have no capacity to provide specific care for mentally ill patients. Difficulties in treating psychiatric patients in these LTC facilities often result in transfers to and repeated admissions in acute psychiatric hospitals.

In an effort to resolve the "revolving-door" situation of these patients and reduce the rates of re-admission to acute psychiatric hospitals, Modell Donaustadt was developed. In the talk, Modell Donaustadt will be presented as a best practice example for the treatment of mental and physical comorbidities in long-term care.

Offenders with intellectual disability: Best practice update

S61

Sex offenders and intellectual disability

K. Goethals

University Forensic Centre, Antwerp University Hospital, Edegem, Belgium & CAPRI, University of Antwerp, Belgium

Ethical controversies in patients with intellectual disability who are sex offenders.

Patients with an intellectual disability (ID) have a disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social, and practical domains (according to the DSM-5). These deficits in adaptive functioning result in failure to meet developmental and sociocultural standards for personal independence and social responsibility. Without ongoing support, the adaptive deficits limit functioning in one or more activities of daily life. Therefore, it is not surprising that these patients cross physical/sexual boundaries quite often. Above that, a proportion of all sex offenders have an intellectual disability.

The treatment of these sex offenders with an ID has to focus on protective factors, next to risk factors in order to decrease the risk of recidivism. Due to the chronicity of their disorder, quality of life is an important issue in these patients.

In this paper, we want to address some ethical controversies:

- hormonal treatment in patients with ID who are sex offenders;
- the right to have a 'normal' sexual life in these ID offenders, and the Dutch experience of the Stichting Alternatieve Relatiebemiddeling (SAR, that can be translated as foundation of alternative relationship mediation).

The SAR is an alternative dating service, giving information about the sexuality of physically or mentally disabled people and organizing sexual encounters for them.

Assessment of people with intellectual disability for the court: What does a psychiatrist need to know?

R. Latham

East London NHS Foundation Trust, London, United Kingdom

This presentation will focus on the importance of psychiatrists understanding that they operate at an interface between two very different disciplines; medicine and law. There will be consideration of what and why psychiatrists need to understand the law, the way it operates and the likely implications of their opinions. There will be consideration of an example from England and Wales to illustrate the way in which psychiatry and law might interpret the same information. The aim is that psychiatrists will be better equipped to face the challenges the law presents.

S63

Use of risk assessment tools for people with intellectual disability: The latest evidence

C. Morrissey^{1,2,*}

¹ University of Nottingham, School of Medicine, Nottingham, United Kingdom

² Lincolnshire Partnership NHS Trust, Clinical and Forensic Psychology, Lincoln, United Kingdom

* Correspondence.

A relatively high proportion of people detained in forensic psychiatric hospitals have intellectual disabilities (up to 3000 people in the UK; Royal College of Psychiatrists, 2013), and people with intellectual disability are significantly over-represented among those psychiatric patients with long lengths of hospital stay (CQC, 2013; Vollm, 2015). People with mild to borderline intellectual disabilities are also prevalent in the UK prison system.

Although the relationship between intelligence and offending is complex, lower intelligence is a known actuarial risk factor for offending behaviour. Studies, which have investigated the prediction of re-offending risk in populations with intellectual disability, have nevertheless found lower rates of recorded re-offending compared to those in mainstream forensic populations (e.g. Gray et al., 2010). The relatively high rate of 'offending-like' behaviour, which is not processed through the criminal justice system in people with intellectual disability makes risk prediction a more complex exercise with this group of people. It also makes outcomes measurement more difficult.

This paper will give an overview of the current research evidence and clinical practice in the field of risk assessment, risk management and outcome measurement with offenders with intellectual disability. It will summarise the findings of a recent NIHR funded systematic review by the author, which pertains to this area, and will point to future developments in the field.

Prisoners with intellectual disability: How to adapt interventions and the environment

V. Tort Herrando (Coordinador)

Unitat Polivalent de Psiquiatria Quatre, Camins, Parc Sanitari Sant Joan de Deu, Sant Boi de Llobregat, Barcelona, Spain

There is an increasing interest in the Spanish prison to give the appropriate care when they are in prison. This situation has a special meaning in inmates with learning disabilities, as they are a vulnerable group inside prison. They are vulnerable in different areas as they have a high prevalence dual diagnosis (both with mental illness and drug misuse), they could suffer from abuse from other inmates, difficulties to understand prison regulations, etc. The prevalence of intellectual disability (ID) in the prison setting has been poorly evaluated. In Spain, despite various approximations or estimates regarding people with intellectual disabilities no reliable data is available.

In our presentation, we will give an overview of the care of this group of patients, presenting some data from an epidemiological study in Spain. The rate of learning disabilities was of 3.77% of the study population has an IQ below 70, and 7.3% has borderline IQ rate. We also describe a new setting in one of wards of a prison of Barcelona where has a model of therapeutic community for treating offenders with intellectual disabilities. This resource open two years ago and is run between prison services and an organization "Accepta" (specialized in people with learning disability and penal law problems). This is an effort from the prison services to adapt to the needs of inmates and deliver a better service with a good post-release follow-up.

And finally, we present some data about learning disability in penitentiary psychiatric settings (the prevalence as a main diagnose is around 10%).

Old age depression: Do we need a special approach

S65

Clinical pharmacological management of polypharmacy in old age depression

P. Baumann^{1,*}, W. Greil^{2,3}¹ University Department of Psychiatry (DP-CHUV), Prilly-Lausanne, Switzerland² Psychiatric Department, Universität München, München, Germany³ Psychiatric Hospital, Sanatorium Kilchberg, Kilchberg-Zurich, Switzerland

* Corresponding author.

Polypharmacy is the rule in psychogeriatric patients, as they present frequently comorbidities such as depression, dementia [often including Behavioral and Psychological Symptoms of Dementia (BPSD)] and somatic diseases. Recommended treatments for geriatric depression are antidepressant medications, psychotherapy and psychosocial interventions [1]. Besides antidepressants, other psychotropic drugs are often co-prescribed, but somatic drugs are also needed for the treatment of other concomitant diseases. This situation increases the risk for adverse effects due to pharmacokinetic and pharmacodynamic interactions, especially since the organism of elderly patients displays a lowered homeostatic reserve and a decrease of functions, which allows resisting to xenobiotic influences.

On the other hand, there are also studies which suggest that in hospitalized psychogeriatric patients, the incidence of severe adverse reactions is lower in patients > 60 y than in those < 60 y [2]. This is one of the results of the AMSP-study group, which in German speaking countries has developed a pharmacovigilance program in psychiatric hospitals.

Physical comorbidity and consequences for mortality and treatment

R. Heun^{1,*}, D. Schoepf²¹ Derbyshire Healthcare NHS Foundation Trust, Psychiatry, Derby, United Kingdom² University of Bonn, Psychiatry, Bonn, Germany

* Corresponding author.

Introduction Ageing is related to an increase rate of physical comorbidity. However, the interaction between physical comorbidity and the development of depression in the elderly is not yet clear. Depression may be the cause or consequence of physical morbidity. Both may increase mortality.

Methods A total of 9604 patients with depression and a control sample of 96040 patients who attended a general hospital were followed-up for up to 12 years. Physical comorbidity and mortality was assessed.

Results Twenty-nine physical disorders were more prevalent in subjects with depression, but the effect of individual disorders on

mortality did not differ significantly in the depressed and control sample.

Conclusions Patients with depression suffer more physical health problems than control patients that lead to death. The implications for early treatment will be discussed, a preventative approach may be most relevant.

Distinction of dementia and depression in various stages of the disease processes

W. Maier

University of Bonn, Department of Psychiatry, Bonn, Germany

Old age depression is often difficult to discriminate from dementia (particularly of Alzheimer type) – particularly cross-sectionally. Incident dementia is frequently associated with depressed mood and agitation; depression in the elderly goes together with executive and memory dysfunctions; associated psychotic symptoms and activity-of-daily-life dysfunctions are shared by both conditions as well as major risk factors as vascular and metabolic factors. Frequently both syndromes are “masking” each other; depression may furthermore present as the first clinical sign of Alzheimers disease. Yet, both clinical syndromes/disorders emerging from quite different are pathogenic neurobiological mechanisms with differentiating neuropsychological, – imaging and – chemical features. Clinical tools can be derived and enable accurate differential diagnosis. Thus, the distinction between both syndromes is a first instance for biomarker supported differential diagnoses in psychiatry.

Overcoming the stigma of mental illness: Current proceedings and initiatives

S68

Seven years after ratification of the UNCRPD: Are there any advances for patients with mental health conditions?

Y. Cohen

GAMIAN-Europe, Azor, Israel

The Convention on the Rights of Persons with Disabilities (CRPD) is the first highest international legally-binding standard which aims to promote, protect and ensure the full and equal enjoyment of all human rights and fundamental freedoms by all persons with disabilities, including those with mental health conditions, and to promote respect for their inherent dignity. The CRPD embodies a ‘paradigm shift’, from the charitable and the medical approaches to disability to one, which is firmly rooted in human rights. It provides a clear path towards non-discrimination, full and effective participation and inclusion in society, respect for difference and acceptance of persons with disabilities as part of human diversity and humanity, equality of opportunity and accessibility just to name a few.

States which have signed the CRPD have an obligation to respect, protect and fulfil the internationally agreed upon set of standards

guaranteed to all people included in the Convention. However, even in signatory states, violations often occur behind “closed or open doors” and go unreported and consequently unprevented. The growing number of people with mental health conditions in the world has further contributed to a level of attention paid to quality and human rights conditions in both outpatient and inpatient facilities, which has never been greater. Persons with mental health conditions need both de jure human rights protection and de facto human rights practices.

Seven years after the CRPD came into force the care available in many mental health facilities around Europe is still not only of poor quality but in many instances hinders recovery. The level of knowledge and understanding by staff of the rights of people with mental disabilities is very poor. It is still common for people to be locked away or to be chained to their beds, unable to move. Inhuman and degrading treatment is common, and people in facilities are often stripped of their dignity and treated with contempt. Violations are not restricted to inpatient and residential facilities; many people seeking care from outpatient and community care services are disempowered and also experience extensive restrictions to their basic human rights.

In the wider community, many people with mental disabilities are still denied many basic rights that most people take for granted. For example, they are denied opportunities to live where they choose, marry, have families, attend school and seek employment. There is a commonly held, yet false, assumption that people with mental health conditions lack the capacity to assume responsibility, manage their affairs and make decisions about their lives. These misconceptions contribute to the ongoing marginalization, disenfranchisement and invisibility of this group of people in their communities.

One of the underlying reasons it is difficult to move through the obstacles to fully embrace the CRPD, is that discrimination continues to affect people with mental health conditions on many levels. Changing laws is only a partial solution. We have to change the ways that we relate to each other at every level, and to offer people information and tools to make the transition to a more equitable social reality.

Promoting stigma coping and empowerment: Results from the multi-center clinical trial STEM

W. Gaebel

Department of Psychiatry and Psychotherapy, Medical Faculty, Heinrich-Heine-University, Düsseldorf, Germany

Introduction The stigma of mental illness is still a major challenge for psychiatry. For patients, stigma experiences and self-stigma are associated with reduced quality of life and increased vulnerability to a more chronic illness course. Nevertheless, there is a scarcity of validated therapeutic approaches addressing strategies for coping with stigma.

Objectives and aims A manualized psycho-educational group therapy for stigma coping and empowerment (STEM) should be tested for efficacy in patients with depression and schizophrenia. The study was funded by a research grant of the Federal Ministry of Education and Research.

Methods A cluster-randomized RCT with two arms including 30 mental health care services (psychiatric inpatient services, day-units, and outpatient services, as well as inpatient psychiatric rehabilitation services) was conducted. The intervention consisted of 8 sessions regular psycho-education group therapy and 3 sessions addressing stigma coping and empowerment. Controls received 11 sessions regular psycho-education. Primary outcome

variable was quality of life (WHO-QOL). Assessments were conducted directly before and after the intervention, and at 3, 6 and 12 months follow-ups.

Results A total of 469 patients participated and more than 300 participants (approx. 65%) completed the 12-month follow-up. First results of the analysis will be presented at the conference.

Conclusions Since the statistical analysis is currently in progress, no conclusions concerning the efficacy of the tested therapeutic approach can be done by now. Nevertheless there is a strong need for supporting patients in developing positive stigma coping strategies. STEM is the first therapeutic approach to our knowledge tested for efficacy in a RCT.

Phenomenology of anxiety

S70

Temporality and spatiality of anxious experience

O. Doerr-Zegers

Center for Studies on Phenomenology and Psychiatry, Diego Portales University, Santiago, Chile

Since the first descriptions of anxiety, it has been related with temporality and in particular with the dimension of future. Thus, we already find anxiety defined as a general feeling of threatening (from the future) in the German mystic Jakob Boehme (1575–1634). He also used the image of “the wheel of anxiety”, with which he refers to its probable origin in a conflict between two forces which tend to separate themselves and are not able to do it, as a result from this centrifugal rotation movement of a wheel. This image also has a temporal character. In Kierkegaard, we read that “anxiety is always related with the future... and when we are disturbed by the past we are basically projecting toward the future...” In Heidegger’s masterpiece, “Being and Time”, there is a chapter dedicated to the temporality of *Being-in-the-world*, and in particular to anxiety. Fear and anxiety have their roots, according to Heidegger, in the past, but their relation with the future makes them different: anxiety arises from the future as possibility, while fear arises from the lost present. In this paper, we try to make a contribution to the phenomenology of temporality (and of spatiality) of anxiety in relation with the analysis of a concrete anxiety experience: flight phobia. The analysis allows us to show both the desolation and narrowing of anxiety space, and with respect to temporality, the disappearance of every plan (the future), of every history (the past), and the reduction of the present to a succession of mere punctualities, behind which there arises, threatening, the nothingness itself.

Being on the edge: The psychopathology of the accelerated, agitated and anxious subject

L. Madeira^{1,*}, M.L. Figueira²

¹ Faculdade de Medicina, Universidade de Lisboa, Psychiatry, Lisbon, Portugal

² Universidade de Lisboa, Faculdade de Medicina, Lisbon, Portugal

* Corresponding author.

The accurate identification of accelerated, agitated and anxious states is of paramount relevance for the correct diagnosis and the selection of a suitable psychopharmacological treatment. Choosing antidepressants, antipsychotics and/or mood stabilizers is presently contingent to the identification of specific phenotypic profiles in anxiety disorders, mixed and manic episodes and/or delirium states. Today, the anamnesis and psychopathological examination are hindered by the vagueness of the conceptualization of these experiences in diagnostic textbooks. We propose a selective review of literature of how these have been conceptualised aiming at increasing the segregation of specific phenomenological profiles across these phenomena.

Physical activity for people with psychotic disorders: Realities and prospects

S73

Studies on PA in schizophrenia: What did we learn? What is effective?

G. de Girolamo*, V. Bulgari

Saint John of God Clinical Research Center, Psychiatric Epidemiology and Evaluation Unit, Brescia, Italy

* Corresponding author.

Schizophrenia is frequently associated with abnormal physical activity (PA) per se (e.g., hypokinesia, motor retardation, etc.) or related to antipsychotic medications (e.g., extrapyramidal symptoms including bradykinesia, tremor, etc.). Daily amounts of PA for subjects diagnosed with schizophrenia tend to decrease over the illness course and contribute to metabolic and cognitive disturbances. PA intervention for schizophrenia patients may result in increased well-being, improved cognitive functioning, fewer negative symptoms and increased self-efficacy, leading to improved management of psychosocial life domains. However, PA trials conducted among people suffering from schizophrenia show several methodological limits: small sample sizes, lack of randomized patients’ allocation, heterogeneity of interventions and inappropriate outcome measures.

Firth et al. (2015) have recently conducted a systematic review and meta-analysis of 11 trials on structured PA in schizophrenia ($n = 659$, median age of 33 years). The conclusions of this recent review are the following:

- aerobic exercise (for instance exercise bike) of moderate-to-vigorous intensity done at least 90 minutes per week is effective in improving cardiovascular fitness; studies ($n = 7$) using VO_{2max} as an assessment of fitness have reported clinically significant increases in VO_{2max} , “defined as sufficient to reduce cardiovascular disease risk by 15% and mortality by 20%”;
- several low-dose aerobic interventions did not show any effect;
- there was a “strong effect of exercise on total psychiatric symptoms” (both positive and negative symptoms were reduced);
- total attrition rate was 32%. Group exercise showed a much lower attrition rate than solitary exercise;
- caregivers’ supervision increased compliance as compared to unsupervised intervention;
- in the only study that compared per-protocol and intention-to-treat analysis, a significant improvement in fitness, psychiatric symptoms and overall functioning only occurred in participants who attended > 50% of exercise sessions.

Clinical and neurobiological effects of aerobic endurance training in multi-episode schizophrenia patients

P. Falkai

Department of Psychiatry, Ludwig-Maximilians-University, Munich, Germany

Schizophrenia is a severe brain disorder characterised by positive, negative, affective and cognitive symptoms and can be viewed as a disorder of impaired neural plasticity. Aerobic exercise has a profound impact on the plasticity of the brain of both rodents and humans such as inducing the proliferation and differentiation of neural progenitor cells of the hippocampus in mice and rats. Aerobic exercise enhances LTP and leads to a better performance in hippocampus related memory tasks, eventually by increasing metabolic and synaptic plasticity related proteins in the hippocampus. In healthy humans, regular aerobic exercise increases hippocampal volume and seems to diminish processes of ageing like brain atrophy and cognitive decline.

³ University Medical Center Göttingen, Department of Psychiatry and Psychotherapy, Göttingen, Germany

* Corresponding author.

Patients with schizophrenia might benefit from exercise via multiple ways. It can be assumed that positive effects observed in healthy people counteract different pathological dimensions of

schizophrenia or add to a better compensation. E.g. exercise may serve as a coping strategy, produces changes in brain structure and function and is already known to improve mood and cardiovascular health. First studies have shown beneficial effects of exercise in schizophrenia. These studies feature a multitude of exercise types and diagnostic tests and also lay emphasis on different research questions.

From the diverse information of the studies, heterogenic character conclusions for future therapy and research can be derived. From the point of view of sports science, feasibility and effectiveness of endurance training will be discussed on the basis of current literature and results from our own research. In a controlled trial 22 patients with schizophrenia participated in 12 weeks of endurance training using bicycle ergometers resulting, e. g., in improvements of endurance capacity and functioning. A special focus was laid on analyzing the differences between the adaptations of patients and healthy controls to test the transferability of methods and effects of endurance training. The exercise intervention was feasible and effective for both healthy controls and patients but some interesting differences could be found.

Additionally, ideas and special circumstances regarding the implementation of endurance training in clinical settings or for outpatients will be considered. From the current knowledge it can be concluded, that the implementation of endurance training in multimodal therapy strategies can be recommended to promote recovery.

Adopting and maintaining physical activity behaviour in people with severe mental illness: The importance of autonomous motivation

M. Probst

UPC K.U. Leuven, Belgium

Background Physiotherapy can improve the health of people with serious mental illness (SMI) but many are inactive. Adopting theoretically-based evidence considering the motivational processes linked to the adoption and maintenance of an active lifestyle can assist physiotherapists in facilitating lifestyle changes in people with SMI.

Purpose Within the Self-Determination Theory (SDT) and the Trans-Theoretical Model (TTM) (stages of change) frameworks, we investigated differences in motives for physical activity between different diagnostic SMI groups.

Methods All participants with SMI from 15 different centers completed the Behavioral Regulation in Exercise Questionnaire 2 (BREQ-2), the International Physical Activity Questionnaire (IPAQ) and the Patient-centered Assessment and Counseling for Exercise (PACE) questionnaire.

Results Overall 294 persons with SMI (190♀) (43.6 ± 13.6 years) agreed to participate. People with affective disorders had higher levels of introjected regulations than people with schizophrenia. No significant differences were found for other motivational regulations. Moreover, no significant differences were found according to gender, setting and educational level. Multivariate analyses showed significantly higher levels of amotivation and external regulations and lower levels of identified and intrinsic regulations in the earlier stages of change. Strongest correlations with the IPAQ were found for motivational regulations towards walking.

Conclusions Our results suggest that in all people with SMI the level of identified and intrinsic motivation may play an important role in the adoption and maintenance of health promoting behaviours.

Implications The study provides a platform for future research to investigate the relationships between autonomy support, motivational regulations and physical and mental health variables within physiotherapy interventions for this population.

Problematic sexual behaviours: Diagnostic, categorical, epidemiological, imaging, psychopathological and treatment considerations

S77

Gender-related differences in the associations between sexual impulsivity, psychiatric disorders and trauma

G. Erez^{1,*}, C. Pilver², M.N. Potenza³¹ Yale University, Tel Aviv University, Psychiatry, Tel Aviv, Israel² Yale University, Biostatistics, New Haven, USA³ Yale University, Psychiatry, New Haven, USA

* Corresponding author.

Introduction Sexual impulsivity (SI) has been associated with conditions that have substantial public health costs, such as sexually transmitted infections and unintended pregnancies. However, SI has not been examined systematically with respect to its relationships to psychopathology. The literature regarding associations between SI and history of different types of trauma also scarce.

Aims We aimed to deepen the understanding of the roots of SI, both through the prism of history of trauma and through the prism of psychopathology as an explanation for SI.

Objectives We intended to investigate associations between SI and psychopathology, and between SI and personal history of trauma of different types, including gender-related differences.

Methods We performed a secondary data analysis of Wave-2 of the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC), a national sample of 34,653 adults in the United States. DSM-IV based diagnoses of mood; anxiety, drug and personality disorders were assessed using the Alcohol Use Disorder and Associated Disabilities Interview Schedule DSM-IV Version.

Results For both women and men, SI was positively associated with most Axis-I and Axis-II psychiatric disorders. Significant gender-related differences (GRD) were observed. Among women as compared to men, SI was more strongly associated with social phobia, alcohol abuse/dependence and most personality disorders. As for trauma, SI was positively associated with any trauma for both women and men. Among women as compared to men, SI was more strongly associated with sexual assault and kidnapping.

Classification and clinical issues relating to hypersexuality

M. Potenza*, K. Shane, H. Rani

Yale, Psychiatry, New Haven, USA

* Corresponding author.

Multiple terms have been used to describe excessive and interfering patterns of non-paraphilic sexual behaviors including sex addiction, compulsive sexual behavior (CSB) and hypersexual disorder

(HD). While a field trial was conducted to investigate the reliability and validity of the criteria for HD, the condition was not included in DSM-5, with this decision in part relating to insufficient data on the proposed condition. Currently, CSB is being considered as a diagnostic entity in the category of impulse-control disorders for ICD-11. In this presentation, we will present data relating to HD/CSB. In particular, we will discuss current issues relating to diagnosis and classification, as well as data regarding the assessment and clinical correlates of sexually relevant constructs (e.g., pornography use and craving). Data relating HD/CSB behaviors to sexual risk-taking, sexually transmitted diseases and mental health problems (including suicidality) will be presented. A strategy for addressing HD/CSB in clinical settings will be proposed and discussed.

Pharmacological treatment of sex offenders

F. Thibaut

University Hospital Cochin, University Sorbonne Paris Cité, Inserm U 894, Psychiatry and addictive disorders, Paris, France

Most people recognize that incarceration alone will not solve sexual violence. Indeed, treating the offenders is critical in an approach to preventing sexual violence and reducing victimization. In most cases, a diagnosis of paraphilia is associated with sexual violence. This review is intended to present and summarize the first recently published international guidelines about pharmacological treatment of paraphilias. Pharmacological interventions should be part of a more comprehensive treatment plan including psychotherapy and, in most cases, behavior therapy. Antiandrogens, and mostly GnRH analogues, significantly reduce the intensity and frequency of deviant sexual arousal and behavior. GnRH analogue treatment constitutes the most promising treatment for sex offenders at high risk of sexual violence, such as pedophiles or serial rapists, however informed consent is necessary. SSRIs remain an interesting option in adolescents, in patients with depressive or OCD disorders, or in mild paraphilias such as exhibitionism.

Racism and discrimination in mental health care of immigrants

S80

The impact of racism and discrimination on mental health of refugees and asylum seekers

M. Kastrup (Speciallæge i psykiatri)
Copenhagen, Denmark

With the strong focus on terrorism in recent years, there is an increasing concern that the fundamental rights of refugees and asylum seekers may be violated in the interest to combat acts of terrorism. It may also lead to increasing racism and discrimination towards these populations.

Racism and discrimination encompass the negative stereotypes and prejudicial beliefs that people may hold, as well as inequitable practices that may result hereof.

Knowledge about the mental health consequences of racism and discrimination is of clear clinical relevance for psychiatrists worldwide, as a significant proportion of psychiatric patients will have a background as refugees and asylum seekers. Many of them have experiences of war, strife, persecution and torture that further adds to their mental distress.

The paper will outline the psychiatric symptomatology related to racism as well as ethical dilemmas and educational needs for the psychiatric profession.

Further the role of national psychiatric associations in combating racism and discrimination by e.g. defining best practices and revising medical training curricula will be outlined.

Room for hope: How to deal with growing racism and discrimination?

L. Küey

Istanbul Bilgi University, Psychology Department, Istanbul, Turkey

Discrimination could be defined as the attitudes and behavior based on the group differences. Any group acknowledged and proclaimed as ‘the other’ by prevailing zeitgeist and dominant social powers, and further dehumanized may become the subject of discrimination. Moreover, internalized discrimination perpetuates this process. In a spectrum from dislike and micro-aggression to overt violence towards ‘the other’, it exists almost in all societies in varying degrees and forms; all forms involving some practices of exclusion and rejection. Hence, almost all the same human physical and psychosocial characteristics that constitute the bases for in-group identities and reference systems could also become the foundations of discrimination towards the humans identified as out-groups. Added to this, othering, arising from imagined and generalized differences and used to distinguish groups of people as separate from the norm reinforces and maintains discrimination. Accordingly, discrimination built on race, color, sex, gender, gender identity, nationality and ethnicity, religious beliefs, age, physical and mental disabilities, employment, caste and language have been the focus of a vast variety of anti-discriminatory and inclusive efforts. National acts and international legislative measures and conventions, political and public movements and campaigns, human rights movements, education programs, NGO activities are some examples of such anti-discriminatory and inclusive efforts. All these efforts have significant economic, political and psychosocial components.

Albeit the widespread exercise of discrimination, peoples of the world also have a long history of searching, aiming and practicing more inclusive ways of solving conflicts of interests between in-groups and out-groups. This presentation will mainly focus on the psychosocial aspects of the anti-discriminatory efforts and search a room for hope and its realistic bases for a more non-violent, egalitarian and peaceful human existence.

³ Charité, Universitätsmedizin Berlin, Department of Psychiatry and Psychotherapy, Berlin, Germany

* Corresponding author.

Introduction The development and maintenance of an alcohol addiction is a complex interaction between genetic and environmental factors. Genetic effects seem to contribute substantially to the risk of developing an addiction, but also to its course and patients' responses to different treatments. Recent studies identified associations between polymorphisms in the genes of glutamate and μ -opioid receptors and addiction risk. Those receptors are of special interest, because they are targets of therapeutic agents, such as acamprosate and topiramate.

Objectives and aims Several studies were conducted, in order to further determine the effects of genetic polymorphisms in glutamate and opioid receptor genes on addictive behavior, neural response to alcohol cues and relapse risk.

Methods Genetic effects were investigated in samples of alcohol-dependent patients using functional imaging techniques, neuropsychological tests and follow-up investigation after standard clinical treatment. Data on clinical parameters, neuronal response to alcohol cues, functional neuronal connectivity and relapse risk were collected and analyzed.

Results Results demonstrate effects of genetic polymorphisms in glutamate and opioid receptors on neuronal response to alcohol cues in frontal and mesolimbic brain areas, subjective craving and time to first relapse. Current findings will be discussed in the light of existing evidence on the contribution of genetic effects to treatment outcome and patient stratification.

Conclusions The investigation of genetic risk factors and mechanisms by which they affect addiction related phenotypes seems to be a promising tool to identify molecular treatment targets and predictors for successful treatment strategies.

S83

Role of inhibitory processes in relapse prevention treatment

G. Rudio

Laboratorio de Psicofisiología Clínica, Hospital Universitario 12 de Octubre, Madrid, Spain

Alcohol dependence is a chronic disorder with frequent relapses during recovery. Most studies have pointed out that craving is the main process involved in relapse, but recently other factors have been implicated in it, such as attentional bias and impulsivity. Some authors consider that different stages could be involved in

the relapse process, and each may be governed by different mechanisms: Attentional bias; motivational response to alcohol cues and inhibitory control.

Motivationally salient cues attract and hold selective attention, and this "attentional bias, (AB)" is related to individual differences in appetitive and aversive motivation. In a recent review, attentional bias has been shown to be significantly present in alcohol-dependent and is associated with craving and risk to a relapse in alcohol consumption.

In alcohol-dependent subjects, alcohol-related cues reach a very high motivational valence (Motivational response, MR), which, in effect, increases craving for alcohol and activates behavioral strategies towards alcohol intake. One method used to assess motivational valence of alcohol is the craving self-assessment. In addition, in recent years, the affective modulation of the startle reflex has been used as an objective measure of craving. It has been shown that subjects with a low baseline startle response when viewing alcohol-associated pictures are at major risk of relapse compared to those with increased reactions.

Once alcohol craving has appeared, the subject will either drink or not, depending on his ability to resist his behavior towards alcohol consumption (impulsivity or inhibitory control, IC). Moreover, subjects that exhibit greater impulsivity are those more likely to relapse.

Our group has recently conducted a study on a sample of 172 alcohol-dependent patients seen in outpatient therapeutic program during 12 weeks. All of them were assessed with the following measures: Attentional bias was assessed using the dot task, motivational response was evaluated using the affective modulation of the startle reflex paradigm, inhibitory control was assessed by the stop-signal reaction time task. Alcohol relapse variables were: relapse, days to the first relapse and days of accumulated abstinence.

One of the most relevant results was that processes related to inhibitory control (Stop-signal reaction time and attentional bias) were the most relevant measures to explain variables related to relapse in alcohol consumption during the treatment period.

Our results support the use of assessment strategies, therapeutic and pharmacological inhibitors aimed at improving the ability of serious alcohol-dependent patients.

Disclosure of interest The author has not supplied his declaration of competing interest.

Self-related processes and underlying brain networks: Relevance for major psychiatric disorders

S84

Self-related networks and negative symptoms in psychotic disorders

A. Aleman

Groningen, The Netherlands

Objective Two factors of negative symptoms in schizophrenia have been consistently described based on factor analysis, "expressive deficits" and "social amotivation". We aimed to investigate the putatively differential involvement of self-related networks, as measured with BOLD fMRI during a self-evaluation task, in two dimensions of negative symptoms in schizophrenia (reduced expression and social amotivation).

Method Forty-five patients with a diagnosis of schizophrenia participated in an fMRI study in which they performed a

self-evaluation task. The task comprised a self-reflection, close other-reflection, and a semantic (baseline) condition. We compared correlates of Expressive versus Social amotivation factors (summed items from the PANSS interview) for the contrasts self-baseline and self-other. Significance threshold was set at $P < 0.05$ family-wise error (FEW) corrected.

Results Social amotivation correlated significantly with self-evaluation vs. baseline in right and left ACC, and in the sulcus of frontal lateral lobe between inferior frontal triangularis and middle frontal gyrus. This was also significant, but less pronounced, in the direct comparison of social amotivation vs. expressive deficits scores (for the self-baseline contrast). No activation differences survived critical thresholds for the self-other contrast.

Conclusion Differential neural correlates for the two dimensions of negative symptoms support the validity of this distinction based on factor analyses. Intact functioning of brain circuitry for self-referential processing may be of relevance to actively seek social interaction.

The social self in schizophrenia: A neural network perspective on integrative external and internal information processing

S. Ebisch

University G. d'Annunzio, Department of Neuroscience and Imaging, Chieti, Italy

Social impairment is recognized as a basic aspects of schizophrenia. Although the nature of aberrant self-other relationship in schizophrenia is still poorly understood, it has been suggested that some social impairments could have their roots in self-disturbances typical of schizophrenia. For instance, experiencing otherness could become problematic with anomalous self-recognition. Furthermore, deficits in the processing of self-relatedness of social stimuli disconnect the self from its social environment. On the one hand, this could lead to problems in self-other distinction caused by misattributions of ownership of experience and agency in social interaction. On the other hand, this could result in feelings of isolation and reduced intersubjectivity due to interrupted self-referential processing of social stimuli, likely also mediated by memory and emotion. Brain networks involved in self-referential processing, sense of ownership, and agency also have been implied in social cognition. Whereas cortical midline structures are associated with self-referential processing of external stimuli including social information, sensorimotor and affective networks involved in bodily and interoceptive self-processing are also involved in the ability to share others' experiences. Schizophrenia has been linked with a reduced integrity of these networks underlying various aspects of self and social impairments, though rather separately. Recent neuroimaging findings will be highlighted explaining how self-disturbances can pervade the social domain in schizophrenia. In particular, disruptions of the social self in schizophrenia will be addressed from a neuronal network and connectomics perspective providing a unifying framework.

S86

Psychopathology of the self and the altered cortical midline structures in psychiatric disorders – a marriage?

G. Northoff

University of Ottawa, Institute of Mental Research, Ottawa, Canada

The self is central in our mental life and disturbances of the self-figure most prominently in psychopathological symptoms. The cortical midline structures (CMS) have been associated with self-related processing and its changes in schizophrenia, depression and other psychiatric disorders. However, the exact neuronal mechanisms underlying self-related processing in CMS and its changes in psychiatric disorders remain unclear. Especially the neural overlap between high resting state activity levels and self-related processing in CMS is rather puzzling. I present recent data on the rest-self overlap in healthy subjects showing that resting state activity in CMS can predict self-relatedness. The implications for psychological symptoms as in depression and schizophrenia are pointed out.

Brain networks sub-serving self-referential processing in depression

G. Wagner*, C. Schachtzabel, G. Peikert, K.J. Bär

Jena University Hospital, Psychiatry and Psychotherapy, Jena, Germany

* Corresponding author.

Introduction Persistent pondering over negative self-related thoughts is a central feature of depressive psychopathology.

Objectives In the present study, we sought to investigate the neural correlates of abnormal negative self-referential processing (SRP) in patients with major depressive disorder (MDD) and its impact on subsequent cognitive control-related neuronal activation.

Aims We hypothesized aberrant activation dynamics during the period of negative and neutral SRP in the rostral anterior cingulate cortex (rACC) and in the amygdala in patients with MDD. We assumed abnormal activation in the fronto-cingulate network during Stroop task execution.

Methods Nineteen depressed patients and 20 healthy controls participated in the study. Using an event-related fMRI design, negative, positive and neutral self-referential statements were displayed for 6.5s and followed by incongruent or congruent Stroop conditions.

Results In contrast to controls, patients did not exhibit valence-dependent rACC activation differences during SRP. A novel finding was the significant activation of the amygdala and the reward-processing network during presentation of neutral self-referential stimuli relative to baseline and to affective stimuli in patients. The fMRI analysis of the Stroop task revealed a reduced BOLD activation in the right frontoparietal network of patients in the incongruent condition after negative SRP only.

Conclusions Thus, the inflexible activation in the rACC may correspond to the inability of depressed patients to shift their attention away from negative self-related stimuli. The accompanying negative affect and task-irrelevant emotional processing may compete for neuronal resources with cognitive control processes and lead thereby to deficient cognitive performance associated with decreased frontoparietal activation.

Sex matters – also in psychosis!

S88

Sex differences in emotional reactivity to daily life stress in psychosis

I. Myin-Germeys^{1,*}, G. Merge²¹ Leuven, Belgium² Maastricht University, Department of Psychiatry and Neuropsychology, Maastricht, Netherlands

* Corresponding author.

Background A recent study did not find clear-cut sex differences in psychotic symptoms. Studies investigating altered stress reactivity more consistently report differences between the sexes, although the results are contradicting in suggesting either men or women to be more stress-sensitive. We assessed self-reported experiences in the context of real-life to more fully understand the nature of sex differences in psychosis.

Methods We employed the Experience Sampling Method, a structured diary technique, to investigate in real-life:

- symptoms;
- behavior in context;
- underlying mechanisms in 283 healthy controls, 268 subjects at risk for psychosis and 232 patients with psychotic disorder.

Results Multilevel regression analyses revealed no differences in symptom expression between the sexes. Similarly, men and women did not differ in their level of social interaction and overall activity. However, men at increased risk of psychosis were more often alone and were less involved in goal-directed activities compared to women. Finally, women reported more emotional reactivity to daily life stress than men but women also reported more positive affect when pleasant events had happened.

Discussion The data thus suggest only minor differences between men and women in psychotic symptoms and actual behavior. However, whenever differences were apparent, they consistently pointed towards more severe symptoms and more deficiencies in men compared to women. In contrast, increased environmental reactivity in women (to both negative and positive environments) in addition to more social contacts may constitute a protective factor for the development of more severe psychopathology.

Sex and gender differences in schizophrenic psychoses

A. Riecher-Rössler

University of Basel, Psychiatric Clinics, Basel, Switzerland

Introduction Sex and gender differences in schizophrenic psychoses have often been described but treatment approaches so far have hardly taken them into account.

Objectives To describe the most important sex and gender differences in schizophrenic psychoses with clinical implications.

Methods Review.

Results Schizophrenic disorders show a later age of onset in women and a slightly better course, especially in young women. As to pathogenesis, there is some evidence that the age difference might be at least partly due to the female sex hormone estradiol being a protective factor. Differences in course might also have to do with this biological factor, but at the same time with the psychosocial advantages of a higher age of onset and other psychosocial factors.

These gender differences have important implications for assessment and therapy. Thus, we have to consider gender differences in coping behaviour as well as psychosocial burdens and needs

deriving from differing roles in partnership, family, household and profession, from dependent relationships, potential abuse and violence. Furthermore, there are specific biological risks such as gonadal dysfunction we have to deal with in both sexes differently. Thus, e.g. women with psychosis can also have very special needs regarding fertility, pregnancy and motherhood. Also, around menopause we have to consider special measures such as replacement of physiological 17- β -estradiol.

Conclusions Women, but also men, with schizophrenic psychoses should get a gender-sensitive assessment and treatment.

Menopause and psychosis

J. Usall^{1,*}, E. Huerta-Ramos²¹ Parc Sanitari Sant Joan de Déu, GTRDSM, CIBERSAM, Research Unit, Sant Boi de Llobregat, Spain² Parc Sanitari Sant Joan de Déu, Research Unit, Sant Boi de Llobregat, Spain

* Corresponding author.

There has been little research into the effects of menopause on symptoms, social and cognitive functioning in women with schizophrenia, and the results are controversial. The most replicated finding is that late-onset schizophrenia is more prevalent in women than in men and that this fact appears to be related to the diminution of estrogen levels during menopause.

Estrogens have a known protective effect on CNS. Animal research has shown that estrogen has a modulating effect on the dopaminergic, glutamatergic and serotonergic systems.

There are concerns about long-term use of sexual hormone therapy in postmenopausal women with regard to breast cancer risk, and the use of the selective estrogen receptor modulators (SERMs's) can be a better option.

Raloxifene is a SERM that is used in the preventive treatment of postmenopausal osteoporosis and has no effect in the breast and uterus. A number of studies seem to indicate that raloxifene acts on brain dopamine and serotonin systems in a similar way to conjugated estrogens.

In this presentation, I will show the results of some clinical trials that have studied the efficacy of raloxifene as a coadjuvant treatment of patients with schizophrenia. Our team has done two clinical trials that studied the efficacy of 60 mg of raloxifene for the treatment of negative symptoms in postmenopausal women with schizophrenia. Our results showed that raloxifene improved the negative symptoms better than placebo. We concluded that raloxifene seems to be a promising option to treat some patients with schizophrenia.

Social anxiety disorder – from shyness and blushing to brains and psychotropic drugs

S91

Recent guidelines for evidence-based pharmacological treatment of social anxiety disorder

D. Baldwin

University of Southampton Faculty of Medicine, Clinical and Experimental Sciences, Southampton, United Kingdom

Pharmacological and psychological treatments The findings of meta-analyses and randomized placebo-controlled treatment studies indicate that a range of approaches are efficacious in acute treatment. Pharmacological and psychological treatments, when delivered singly, have broadly similar efficacy in acute treatment. However, acute treatment with cognitive therapy (group or individual) may be associated with a reduced risk of symptomatic relapse at follow-up. Cognitive behaviour therapy is efficacious in adults and children: cognitive therapy appears superior to exposure therapy, but the evidence for the efficacy of social skills training is less strong. It is unlikely that the combination of pharmacological with psychological treatments is associated with greater overall efficacy than with either treatment, when given alone, as only 1 of 4 studies of the relative efficacy of combination treatment found evidence for superior efficacy.

Efficacy and length of acute pharmacological treatment Antidepressant drugs with proven efficacy include most SSRIs, the SNRI venlafaxine, the MAOI phenelzine and the RIMA moclobemide: the potential efficacy of tricyclic antidepressants is unknown. Some benzodiazepines and anticonvulsants and the antipsychotic olanzapine also appear efficacious in acute treatment. A number of small single-dose placebo-controlled crossover studies together suggest that beta-blockers can be beneficial in reducing anxiety symptoms in individuals with 'performance anxiety' (for example, when speaking in public), which overlaps with mild non-generalized social anxiety disorder. Acute treatment studies indicate that the proportion of responding patients increases steadily over time. A post-hoc analysis of the clinical trial database with paroxetine indicates that many non-responders to treatment at 8 weeks become responders with a further 4 weeks of double-blind treatment: however a post-hoc analysis of the clinical trial database for escitalopram indicates that response is unlikely if there is no onset of clinical effect within the first 4 weeks of treatment.

Longer-term treatment and further treatment after non-response The findings of randomized placebo-controlled relapse prevention studies in patients who have responded to previous acute treatment reveal a significant advantage for staying on active medication (clonazepam, escitalopram, paroxetine, pregabalin, sertraline) for up to six months. Fixed-dose randomized controlled trials do not provide consistent evidence of a dose-response relationship with antidepressant drugs: but a fixed-dose study of pregabalin found that only the higher daily dosage was efficacious. A double-blind randomized controlled dosage escalation trial found no advantage for increasing to a higher daily dosage (of duloxetine), when compared to continuing treatment with a lower dosage. Switching between treatments with proven efficacy may be helpful. An uncontrolled study of augmentation of SSRI treatment with buspirone found some evidence of beneficial effects; but a placebo-controlled crossover-study of the augmentation of paroxetine with pindolol found no evidence of efficacy. A small placebo-controlled study of the augmentation of paroxetine with clonazepam found the combination was marginally short of superiority, when compared to paroxetine alone.

Oxytocin in social anxiety: An overview

I. Iancu

Tel Aviv University, Tel Aviv, Israel

Oxytocin is a neuropeptide that is synthesized in the hypothalamus. It acts as a central neurotransmitter, as well as a peripheral hormone. It is called also trust hormone or love hormone. Because of its anxiolytic, pro-social and social cognitive enhancing effects, oxytocin has been suggested as a promising novel treatment for patients with social anxiety disorder. However, controlled research is small and the studies' results are inconclusive. I will present the results of several studies with several recommendations about the role of oxytocin in social anxiety disorder. Whereas oxytocin shows some promising effects in resistant cases, of course the preferred agents are SSRIs, SNRIs and CBT.

The relationship between social anxiety, shyness and blushing

A. Pelissolo*, A. Moukheiber

AP-HP, Hôpitaux Universitaires Henri-Mondor, Department of Psychiatry, UPEC, Créteil, France

* Corresponding author.

The diagnosis of social anxiety disorder (SAD) has seen substantial changes in the last 35 years from its first appearance in the DSM-III in 1980 up to the most recent ones in the DSM-5. Throughout all these changes, this disorder, previously called social phobia, is still considered one homogenous entity with only one specifier ("performance only") introduced in the DSM-5 revision with specific fears or associated personality profiles not being considered relevant clinical markers to define SAD subtypes. However, our therapeutic experience suggested substantial particularities associated with the fear of blushing in patients with SAD. Some patients presenting this profile, historically called "erythrophobia", seem to have a very specific type of social anxiety that does not include shyness and other characteristics of classical SAD. In a study conducted in a sample of 450 new consecutive outpatients seeking treatment for SAD, we compared 142 subjects with fear of blushing without other social fears, 97 subjects with fear of blushing with other associated social fears and 190 SAD subjects without fear of blushing. The group with pure fear of blushing presented a different profile when compared with the two other groups: later age of onset, less comorbidity, lower behavioral and temperamental inhibition, i.e. less shyness, and higher self-esteem. Furthermore, from a therapeutic point of view, some specific strategies such as the Task Concentration Training have shown to be particularly effective in fear of blushing. We will further argue the validity of a possible "fear of blushing" subtype of SAD.

* Corresponding author.

Background People displaying persistent, full-blown psychotic experiences without a need-for-care in the general population are an ideal group to investigate to differentiate those factors that are linked to distress and dysfunction from those that are merely associated with benign anomalous experiences. The UNIQUE study investigated the cognitive and social processes predicted by cognitive models of psychosis to differentiate between benign and pathological outcomes of psychotic experiences (PEs).

Method Two hundred and fifty-nine individuals were recruited (84 clinical participants with PEs; 92 non-clinical participants with PEs; 83 controls without PEs) from urban (South-East London) and rural (North Wales) UK sites. The three groups were compared on clinical and psychological measures, on reasoning tasks, and on their appraisals of experimental tasks inducing anomalous experiences (of thought interference symptoms and auditory hallucinations).

Results The clinical picture demonstrated a distinctive pattern of similarities and differences on PEs between the clinical and non-clinical groups, while their demographic and psychological profiles were markedly different. As predicted, the clinical group showed a 'jump-to-conclusions' reasoning style, and endorsed more threatening appraisals ratings of the experimentally-induced anomalous experiences than the non-clinical group, who did not differ from the controls.

Conclusions The results of this study identified a number of specific factors that may be protective against transition to psychosis in individuals with persistent PEs. They also provide robust experimental evidence for the key role of appraisals in determining outcome, as postulated by cognitive models of psychosis.

Prevention of psychotic disorders in the general population

W. Rössler

University of Zurich, Psychiatric University Hospital, Zurich, Switzerland

Subthreshold psychotic experiences are widely reported within otherwise healthy populations. Their phenomenology is broad and very heterogeneous ranging from meaningful coincidences and

precognitive dreams over haunting to out-of-body experiences and visual as well as auditory hallucinations.

Although creative aspects of these experiences are implied too, a similarity in form and content to positive symptoms in schizophrenia (e.g., delusion, disordered thought, and hallucinations) or schizotypy (e.g. magical thinking, unusual perceptual experiences, ideas of reference or paranoid ideation) seems to be obvious. However, the borderline between normal and pathological experiences and behaviour is unclear.

The so called "continuum approach" assumes that schizophrenia or schizotypy are not discrete or categorical illness entities. It implies a gradient in the severity of the symptoms, ranging from healthy population to full-blown schizophrenia. As such, psychotic signs are no longer restricted to formal diagnoses according to DSM or ICD, but would, instead, complete the spectrum of psychological and biological features that characterize individual variations among human beings.

Can subthreshold psychotic experiences be integrated in this continuum? Do individuals indicating such experiences lack some social cognitive abilities and are particularly vulnerable to false inferences in their social world. How are these experiences related to increased neural activity or an abnormal dopaminergic neurotransmission?

These and similar questions will be discussed in the presentation.

S96

Psychotic experiences as precursors in schizophrenia? Findings from a population-based sample in Germany (DEGS1-MH)

C. Schmidt-Kraepelin

Medical Faculty, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

There are only a few studies that have studied the prevalence of psychotic experiences (PEs) in a representative population-based sample and a broad range of age. The association and predictive role of PEs in the context of psychotic and other mental disorders remains a subject of discussion. The Mental Health Module of the German Health Interview and Examination Survey for Adults is the first wave of a German health monitoring survey describing:

- the distribution and frequency, the severity and the impairments of a wide range of mental disorders;
- risk factors as well as patterns of help-seeking and health care utilization;
- associations between mental and somatic disorders.

A total of 4483 participants participated in the mental health section of the survey. The Composite International Diagnostic Inventory, the Launay-Slade Hallucination Scale and the Peter's Delusion Inventory were used to assess PEs by clinically experienced interviewers. We can confirm and extend previous findings for younger age groups that PEs are very frequent psychopathological expressions in the general population across genders and all age groups. PEs rates were elevated among those with other mental disorders, particularly among possible psychotic disorders, PTSD and affective disorders. This points to the relevant role of PEs as a marker for psychopathology and mental disorders. Future prospective studies will have to focus on specific properties of psychotic experiences such as their appraisal or underlying social influences to determine their significance for the prediction of psychotic and other mental disorders.

Clinic risk associated with comorbidity of (subclinical) psychosis, anxiety and depressive symptoms: A case for stratified medicine in psychiatry

M. van Nierop^{1,*}, I. Myin-Germeys¹, R. van Winkel²¹ KU Leuven, Psychiatry, Leuven, Belgium² Maastricht University, MHeNS, Maastricht, Netherlands

* Corresponding author.

Background Meta-analyses link childhood trauma to depression, mania, anxiety, and psychosis. It is unclear, however, whether these outcomes truly represent distinct disorders following childhood trauma, or that childhood trauma is associated with admixtures of affective, psychotic, anxiety and manic psychopathology throughout life.

Aim To investigate the impact of trauma on psychopathological phenotype, functional outcome, and daily life stress reactivity.

Methods We used data from a representative general population sample (NEMESIS-2; $n=6646$), of whom respectively 1577 and 1120 had a lifetime diagnosis of mood or anxiety disorder, as well as from a sample of patients with a diagnosis of schizophrenia (GROUP; $n=825$). Multinomial logistic regression was used to assess whether childhood trauma was more strongly associated with isolated affective/psychotic/anxiety/manic symptoms than with their admixture. Additionally, we examined these groups in terms of social functioning, clinical severity, and quality of life. In a separate sample ($n=621$), daily life (emotional and cortisol) stress reactivity was assessed, using ambulatory assessment.

Results In all samples, childhood trauma was considerably more strongly associated with an admixture of symptoms of depression, anxiety, psychosis, and mania, rather than with these symptoms in isolation. Individuals exposed to childhood trauma, who also had an admixture of symptoms, had a lower quality of life, more help-seeking behaviour, higher prevalence of substance use disorders, and lower social functioning, compared with individuals not exposed to trauma, without an admixture of symptoms, or neither. Furthermore, trauma-exposed individuals with an admixed psychopathological phenotype show a higher daily emotional stress reactivity.

Conclusion Childhood trauma increases the likelihood of a specific admixture of affective, anxiety and psychotic symptoms cutting across traditional diagnostic boundaries. Stratifying according to childhood trauma exposure thus identifies an admixed phenotype, possibly induced by continuous daily life stress reactivity, that has important clinical relevance. Identification of functionally meaningful aetiological subgroups may aid clinical practice.

Suicidology in the 21st century

S98

Information and communication technologies for the follow-up of patients

E. Baca-Garcia

Fundación Jiménez-Díaz, Madrid, Spain

Clinical assessment in psychiatry is mostly based on brief, regularly scheduled face-to-face appointments. Although crucial, this approach reduces assessment to cross-sectional observations that

often miss critical information about course of disease and risk assessment. Clinicians in-turn make all medical decisions based on this inevitably limited information. We discuss recent technological developments in terms of assessment and information triangulation, analysis of longitudinal data, approaches to enhance medical decision-making and improve communication between patients, caregivers and clinicians.

A neurosciences based – semiology of suicidal behavior

P. Courtet

CHU de Montpellier, Emergency, Psychiatry and acute care, Montpellier, France

The epidemiology, risk factors and biological basis of suicidal behaviors have been the object of an ever-increasing research in the last three decades. During this period, researchers all over the world have identified potential biomarkers of risk and developed several theories about the mechanisms leading to suicidal behavior. However, the lack of common terminology, instruments and cooperation has been a major deterrent. Today, the community has established the bases for this collaboration and evidence coming from neuroscientific studies can already be applied to the field of suicidology. We present here a potential semiology based on current evidence coming from biological, clinical and neuroimaging studies. Besides suicidal ideation and warning signs, the clinical features related to suicide risk and revealed by neuroscientific studies include notably: impulsive-aggression and hopelessness as well as high web consumption, sedentary behaviors and reduced sleep time, an enhanced sensibility to social exclusion and loneliness, a decreased sensitivity to detect social support, interpersonal problems related to decision-making impairments, difficulties to regulate negative emotional states, a propensity to perceive psychic and also physical pain and to receive opiates treatments. Improving the assessment will also open new targets for suicide prevention. In the short-term, some of these targets await us: standard protocols for evaluation of risk, healthcare continuity, implication of the family/caregivers, mitigation of social or psychological pain.

Follow-up and chain of care in the prevention of suicide recurrence

P.A. Sáiz Martínez

Universidad de Oviedo, Área de Psiquiatría, CIBERSAM, Oviedo, Spain

Suicide constitutes one of the most important problems in global public health. However, assessment as well as corresponding verification of suicide risk, either in case histories or clinical reports, is handled poorly in several clinical settings. Aspects as important as the existence of a personal history of suicidal tendencies are frequently omitted, despite this being one of the risk factors that most clearly predict the possibility of a complete suicide in the future. During this presentation, I would like to refer specific interventions in at-risk populations, with special emphasis on individuals who have made previous suicide attempts. Suicidal behaviour is a very complex phenomenon, making a specific treatment for it difficult to produce. Consequently, when the most appropriate therapeutic approach for an at-risk population is raised, the following fact is mentioned: in approximately 90% of suicide cases, there is an underlying psychiatric disorder. This makes psychopharmacological treatment of the base pathology the most adequate. Still

totally in agreement with that affirmation, we want to point out that we often forget there is proven evidence of the preventative utility of non-pharmacological interventions designed to increase clinical follow-up and adherence to post-attempt outpatient treatment. It is important to indicate that these interventions are not aimed at specific disorders or population groups, but rather they are of a more universal character and are thus more easily generalised. During this presentation, some of these approaches will be addressed and discussed.

The effects of neuroleptics on the brain

S101

GROUP 6 year outcome data in relation to antipsychotic medication

W. Cahn*, for GROUP Investigators
UMC Utrecht, Brain center, Utrecht, Netherlands

* Corresponding author.

Objective Genetic risk and outcome of psychoses (GROUP) is a 6 year longitudinal cohort study that focus on gene–environment vulnerability and resilience in patients with psychotic disorders, their unaffected family members and non-related controls. Its main aim is to elucidate etiological and pathogenetic factors that influence the onset and course of psychotic disorders. In this substudy, we will examine medication use over time, its relation with (the change in) metabolic syndrome status and effects on the brain.

Methods A consortium of four university psychiatric centers and their affiliated mental health care institutions, conducted the GROUP study. At baseline, 1120 patients, 1057 siblings, 919 parents and 590 healthy controls were included. After inclusion, participants, except parents, were evaluated again after three and six years of follow-up. Extensive assessment of genetic factors, environmental factors, medication use, metabolic parameters and outcome were performed. Moreover, brain imaging was performed in a subset of participants, using a 1.5 Tesla MRI scanner.

Results At baseline 65% of patients used atypical antipsychotics, 16% used conventional antipsychotics and 19% used clozapine. Siblings and controls used no antipsychotics. Forty-three percent of patients, 21.3% of siblings and 9.1% of controls used antidepressants; 43.9% of patients, 2.1% of siblings and none of the controls used a mood stabilizer. We are currently analyzing the medication data over time in relation to (change in) metabolic syndrome status and the effects on the brain.

Conclusion GROUP is a longitudinal cohort study in patients with psychotic disorders, their healthy siblings and controls without psychosis. This naturalistic substudy examines medication use, its association with (change of) metabolic status and effects on the brain in subjects with (high risk of) psychosis.

Discontinuation vs. continuation treatment with neuroleptics for a better long-term outcome

L. Wunderink^{1,*}, R. Nieboer², F. Nienhuis³, S. Sytema³, D. Wiersma³

¹ Friesland Mental Health Services, University Medical Center Groningen, Research & Education, Psychiatry, Leeuwarden, Netherlands

² Friesland Mental Health Services, Research and Education, Leeuwarden, Netherlands

³ University Medical Center Groningen, Psychiatry, Groningen, Netherlands

* Corresponding author.

Background Long-term functional outcome of dose-reduction/discontinuation strategies in first-episode psychosis (FEP) has not been studied before. The present study compared 7-year outcome of an early antipsychotic dose-reduction/discontinuation (DR) strategy with maintenance treatment (MT). Primary outcome was (symptomatic and functional) recovery; relapse rates, functional and symptomatic remission were secondary outcomes.

Methods FEP patients ($n = 128$) symptomatically remitted for 6 m during their first treatment year who completed an 18 months trial comparing MT and DR were followed-up at 7 years. Symptomatic remission criteria were adopted from Andreasen et al., functional remission criteria were based on a functioning scale. Recovery was defined as meeting both criteria sets. MT or DR strategy, and baseline parameters were entered in a logistic regression analysis with symptom and functional remission and recovery at 7-years follow-up as dependent variables.

Results One hundred and three patients consented to participate. DR-patients showed twice the recovery-rate of MT-patients (40% against 18%), odds ratio 3.5 ($P = .014$). Symptomatic remission-rates were equal (69% and 67%). Better DR recovery-rates were attributable to higher functional remission-rates (46% vs. 20%) in DR. Predictors of recovery were DR, baseline living together and less severe negative symptoms. During the last 2 years of follow-up the mean daily dose in haloperidol equivalents was 2.20 mg in DR vs. 3.60 mg in MT ($P = .031$).

Relapse rates were initially higher in DR but leveled at 3 years; 61.5% relapsed in DR and 68.6% in MT in 7 years.

Conclusion DR of antipsychotics during early stages of remitted FEP significantly improved 7-years outcome in terms of recovery and functional remission compared to maintenance treatment. Though initially relapse rates in GD were higher, these equalled those in MT from 3 years to the end of the study. While the necessity of immediate antipsychotic treatment in FEP and positive symptoms relapse is robustly demonstrated in a great number of studies, this study suggests that we are faced with a dilemma concerning the drawbacks of long-term maintenance antipsychotic treatment on functional capacity. Though antipsychotic discontinuation appears only feasible without relapse in a substantial minority of patients, guided dose-reduction as far as positive symptoms remain subsided and allow it, appears a feasible strategy in view of functional recovery, doing justice to both sides of the dilemma.

The role of emotional instability in adult ADHD, borderline personality disorder, bipolar disorder, autism and intellectual disability: A transdiagnostic construct or disorder specific syndrome?

S103

Emotional instability and adult attention-deficit hyperactivity disorder (ADHD)

P. Asherson

Institute of Psychiatry–Psychology and Neuroscience, King's College London, Social Genetic and Developmental Psychiatry, London, United Kingdom

Background ADHD is defined in DSM-5 by developmentally inappropriate and impairing levels of inattentive and hyperactive-impulsive symptoms. However, emotional dysregulation is considered to be an associated feature of the disorder that supports the diagnosis of ADHD. The common co-occurrence of emotional lability (EL) in ADHD raises the question of whether EL should be viewed as a component of ADHD or reflecting a comorbid condition.

Aims To address the question of whether EL should be viewed as a third dimension of ADHD.

Method We investigated the association of EL with ADHD and impairment scores, in a sample of adults with ADHD that had been carefully selected for absence of comorbid conditions that could give rise to EL using both rating scale and experience sampling methods to measure emotional instability. We reviewed the effects of stimulants and atomoxetine on EL and the covariation of EL with ADHD inattention and hyperactivity-impulsivity. We further considered the phenotypic and genetic association of EL with ADHD using population twin data.

Results From these studies, we found that EL is strongly associated with ADHD even in non-comorbid cases and gives rise to additional impairments after ADHD symptoms are controlled for in the analysis. Stimulants and atomoxetine both improve EL and these improvements are correlated with changes in ADHD symptoms, indicating a shared treatment response. Genetic model fitting suggests a common pathway model, consistent with a single genetic liability for inattention, hyperactivity-impulsivity and EL.

Conclusions Taken together these findings suggest that EL can be viewed as a third dimension of ADHD. Patients presenting with chronic emotional instability should always be screened for ADHD.

² *Central Institute of Mental Health, Psychiatric and Psychosomatics Psychotherapy, Mannheim, Germany*

* *Corresponding author.*

Affective instability is widely regarded as being the core problem in patients with borderline personality disorder (BPD) and the driving force behind the severe clinical manifestations of BPD symptoms. In ICD-10, BPD is even labelled as emotionally unstable personality disorder. In the last years, the advent of electronic diaries, in combination with sophisticated statistical analyses, enabled studying affective instability in everyday life. Surprisingly, most recent studies using state-of-the-art methodology to assess and model affective instability in BPD failed to show any specificity, supporting

the idea of a transdiagnostic construct. In addition, dysfunctional emotion regulation strategies revealed results contradictory to current clinical beliefs. Using multiple data sets and multilevel modelling, we will demonstrate that to understand affective instability it is important:

- to statically model basic subcomponents of affective dynamics simultaneously;
- in combination with dysfunctional regulation strategies;
- cognitive processes in everyday life.

Altogether, current research suggests that the dynamics of affective states and their intentional regulation are even more important to psychological health and maladjustment, than the affective states itself. Current initiatives to fundamentally improve psychopathological research are looking at basic physiological processes spanning across disorders. However, these approaches do fall short in understanding human behaviours as dynamical processes that unfold in the broadest setting imaginable – everyday life. Only the combination of basic physiological processes and methods assessing dynamical affective mechanisms in everyday life will enhance our understanding how dysregulations and dysfunctions of fundamental aspects of behaviour cut across traditional disorders.

S105

Emotional instability and bipolar disorder

S. Frangou

Icahn School of Medicine at Mount Sinai, Psychiatry, New York, USA

Background Affective dysregulation is a core feature of bipolar disorder (BD) and a significant predictor of clinical and functional outcome. Affective dysregulation can arise from abnormalities in multiple processes. This study addresses the knowledge gap regarding the precise nature of the processes that may be dysregulated in BD and their relationship to the clinical expression of the disorder.

Methods Patients with BD ($n=45$) who were either in remission or in a depressive or manic state and healthy individuals ($n=101$) were compared in terms of the intensity, duration and physiological response (measured using inter-beat intervals and skin conductance) to affective and neutral pictures during passive viewing and during experiential suppression.

Results Compared to healthy individuals, patients with BD evidenced increased affective reactivity to neutral pictures and reduced maintenance of subjective affective responses to all pictures. This pattern was present irrespective of clinical state but was more pronounced in symptomatic patients, regardless of polarity. Patients, regardless of symptomatic status, were comparable to healthy individuals in terms of physiological arousal and voluntary control of affective responses.

Conclusion Our study demonstrates that increased affective reactivity to neutral stimuli and decreased maintenance of affective responses are key dimensions of affective dysregulation in BD.

Emotional instability and autism and intellectual disability

J. McCarthy

King's College London, Forensic & Neurodevelopmental Sciences, London, United Kingdom

Aim To explore if emotional instability is a useful construct in adults with autism spectrum disorder (ASD) and intellectual disability (ID).

Method/approach The current diagnostic criteria for ASD and ID will be outlined and related to any relevant literature on emotional instability in those with ASD or ID. Recent cross-sectional studies in a clinic and a prison of adults with ASD and/or ID using standardised screening and diagnostic tools will be described.

Findings Current literature indicates there is little research on emotional instability in adults with ASD and ID. Studies across clinic and forensic settings indicate high levels of comorbidity such as attention-deficit hyperactive disorder (ADHD) and mood disorders in adults with ASD and ID.

Conclusion At present emotional instability as a construct may not have validity for adults with ASD and ID but may do in the context of other comorbid conditions such as ADHD.

Disclosure of interest The author has not supplied his declaration of competing interest.

How increasing the effect of rTMS in the treatment of auditory hallucinations in schizophrenia?

S. Dollfus^{1,*}, C. Nathou², E. Olivier³

¹ CHU de Caen, Department of psychiatry, Caen, France

² CHU Caen, Department of psychiatry, Caen, France

³ CHU de Caen, Department of neurophysiology, Caen, France

* Corresponding author.

Repetitive transcranial magnetic stimulation (rTMS) shows a high inter-subjects variability in the efficacy of treatment of auditory verbal hallucinations (AVH) in schizophrenia. The aim of this presentation is to demonstrate the involvement of several factors in the efficacy of rTMS such as the frequency of stimulation, the placebo effect and the brain morphology underlying the target of stimulation.

Methods A meta-analysis was conducted to determine the effect sizes of placebo effect in 21 controlled studies on rTMS in the treatment of AVH in schizophrenia. MRI was also acquired in patients treated by rTMS to evaluate the scalp to cortex distances (SDCs) and the gray matter densities (GMDs) at the target of stimulation. Finally, we evaluated the efficacy of high (20 Hz) frequency stimulation in a controlled placebo study.

Results Weak or no placebo effect in the control groups led to reveal a superiority of active rTMS over sham rTMS in the treatment of AVH. Clinical efficacy of rTMS was also correlated with the SCD or the GMD at the region of the target stimulation. Finally, we also demonstrated that more responders were observed after 2 weeks in the active group treated by 20 Hz than in the placebo group.

Conclusion We clearly demonstrated that several factors such as high frequency, the placebo effect, anatomical cortical variations can impact on the efficacy of rTMS. These results fundamentally inform the design and the method of further controlled studies, particularly with respect to studies of rTMS in the treatment of AVH.

Phenomenology and neural correlates of formal thought disorder

T. Kircher

Philipps-University, Psychiatry and Psychotherapy, Marburg, Germany

Speech and language disorders, such as concretism and formal thought disorder (FTD) are core symptoms of Schizophrenia, but do occur to a similar extent in other diagnoses such as bipolar disorder and major depression. We will review clinical rating scales of FTD and introduce a new, validated scale, the TALD. Further, structural and functional brain imaging data will be reviewed and own novel findings presented, relating speech and language dysfunctions to neural networks, within schizophrenia and across the “functional psychoses”. The impact of genetic variance and NNDA receptor blockage on brain function will be addressed with a particular focus on speech and language (dys-) function. We demonstrate, from the genetic to the brain structural and functional level, that particular aspects of the neural language system are disrupted in patients with FTD across traditional diagnoses.

Disclosure of interest The author has not supplied his declaration of competing interest.

Language, psychosis and the brain: Novel insights from a dimensional approach

W. Strik

University of Bern, Psychiatry, Bern, Switzerland

The brain mechanisms related to formal thought disorders (FTD) and auditory verbal hallucinations (AVH) appear to be closely linked to structural and functional abnormalities of the language system.

In particular, functional imaging data indicate that several components of the language system are involved in the generation of both, FTD and AVH. Co-activation of the primary auditory cortex (Heschl's gyrus) during verbal thoughts appears to be crucial for the subjective perception of an externally generated voice, and DTI studies indicated that the intrahemispheric fronto-temporal connectivity of the language system is specifically increased in hallucinating patients. On the other hand, FTD are significantly correlated to a gray matter reduction in Wernicke's region along with a hyperactivation of frontal and temporal components of the language system.

AVH are intimately related to a dysfunction of the left hemispheric language system, including the primary auditory cortex and the fronto-temporal fibre tracts connecting Broca's and Wernicke's regions. Co-activation of the primary auditory cortex during verbal thoughts appears to be the basis of the pathological network dynamics during AVH, while FTD are linked to a pathological hyperactivity of central components of the language system. Both phenomena are related to functional imbalances of the language system, and phenomenological differences may depend on the different contributions of the system components.

Towards personalized pharmacotherapy for suicide prevention across the lifespan

S110

Using genomics to predict antidepressant response in suicidal depressed children

Maya Amitai (MD)^{1,2,3}, Alan Apter (MD)^{1,2,*}¹ Department of Psychological Medicine, Schneider Children's Medical Center of Israel, Petach Tikva, Israel² Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel³ The Ruhman Family Laboratory for Research on the Neurobiology of Stress, Department of Neurobiology, Weizmann Institute of Science, Rehovot, Israel

* Corresponding author.

Background Depression and anxiety disorders are among the most common childhood psychiatric disorders. Selective serotonin reuptake inhibitors (SSRIs) are generally considered first-line treatment for both depression and anxiety in this age group. However, it has been reported that 30%–40% of all patients who receive a sufficient dose and duration of treatment fail to respond. Moreover, SSRI use is frequently associated with serious adverse events (SAE), including activation symptoms, manic switch and increased suicidal behavior. These are particularly relevant in pediatric populations because of concerns about the suicide threat of SSRIs, resulting in a black-box warning. Currently there is no way of knowing in advance who of the patients will respond. Identification of biomarkers that would be early predictors of response and of the occurrence of SAE could help to maximize the benefit–risk ratio for the use of SSRIs, and speed up the matching of treatment to patient. The main objective of this project is therefore to identify and validate biomarkers predicting response and SAE in depressed children and adolescents, thus improving treatment, enabling the development of novel diagnostic tests and suggest novel therapeutic targets for future related drug development.

Methods As a preliminary pilot, we already obtained blood samples from 80 depressed and anxious children and adolescents over the last year before, during and after eight weeks of fluoxetine (FLU) therapy. Genetic and epigenetic samples were collected from all participants. The patients were treated with FLU 20–40 mg/day for 8 weeks. Clinical response was measured with several scales including the Children's Depression Rating Scale–Revised (CDRS–R), the Beck Depression Inventory (BDI) and the Screen for Child Anxiety Related Emotional Disorders (SCARED).

Results The participant's age ranged from 6 to 18 (14.12 ± 2.30) years. The overall response rate was 56%. Ten percent responded with SAE. Regarding Pharmacogenetics, The 5-HTTLPR ss genotype was associated with a poorer clinical response with regard to depressive symptoms as well with fewer reports of agitation compared to the ll genotype. Regarding immune measures, we analyzed cytokine levels from 41 children. Plasma concentrations of TNF- α , IL-6 and IL-1 β were measured by enzyme linked immunosorbent assays (ELISA) before and after FLU treatment. Antidepressant treatment significantly reduced TNF- α levels ($P = 0.037$), with no significant changes in the levels of IL-6 and IL-1 β . All three pro-inflammatory cytokines were significantly ($P < 0.05$) higher in SSRI-refractory than SSRI-responsive patients, i.e.: higher levels of TNF- α , IL-6 and IL-1 β might predict non-response to fluoxetine treatment in children.

Future plans Out of the study sample we selected 13 remitters and 13 non-responders and 10 children with SAE (activation symptoms, manic/hypomanic switch, increased suicidality), and analyzed expression profiles in peripheral blood at admission and after 8 weeks of treatment using illumine Truseq technique. Hopefully, we shall find significant differences in miRNA profiles between the different groups which may serve as biomarkers indi-

cating AD treatment response and SAE. The differentially regulated miRNA's can be studied in depth in the future in animal models in order to support the hypothesis that they may be involved in the AD mechanism.

S111

Large-scale suicide prevention by pharmacological treatment of mood disorders

E. Isometsa

University of Helsinki, Department of Psychiatry, Helsinki, Finland

Introduction In psychological autopsy studies, at least half of suicides have suffered from depressive or bipolar disorders at time of death. Improving access to care and provision of evidence-based pharmacotherapies can be important preventive measures.

Objectives To examine suicide risk and pharmacoepidemiology in mood disorders; evidence for efficacy of pharmacotherapies in mood disorders and in preventing suicidal behaviour in them, and limitations to effectiveness of treatment due to problems of adherence.

Aims To evaluate potentials for suicide prevention in mood disorders by improved access to treatment, improved quality of treatment provision, improved adherence, or by specific pharmacotherapies.

Methods Selective review of literature.

Results Risk of suicide death and attempts in mood disorders clusters into major depressive and mixed illness episodes, and time spent in them is a major determinant of risk, but direct evidence for preventive effects of effective pharmacotherapies remains limited. Observational and randomized studies indicate lithium treatment to reduce risk of suicide deaths and attempts. Ecological evidence from Europe shows increasing sales of antidepressants to consistently associate with declining regional suicide rates. Forensic chemical studies still find majority suicides negative for antidepressants. Poor adherence is a central problem in treatment provision. **Conclusions** Positive impact of increase in pharmacotherapy provision in the last few decades on suicide mortality remains uncertain. Lithium is the pharmacological agent with best evidence for preventive utility, but underused. Providing treatments for those at risk, improving quality and continuity of treatment, and integrating them with psychosocial approaches is likely to be beneficial for suicide prevention.

Brain imaging biomarkers in personalizing pharmacotherapy of suicidal depressed patients

J.J. Mann

Columbia University, New York, NY, USA

Background New knowledge has emerged about decision-making, mood regulation, social distortions and learning that is relevant for the diathesis for suicidal behavior. All four domains have identified underlying neural circuits and for decision-making and mood regulation also specific neurotransmitter systems.

Methods We have conducted PET studies of the serotonergic system and CSF studies of the serotonin, norepinephrine and dopamine neurotransmitter systems in patients surviving suicide attempts to determine whether they have neurotransmitter abnormalities that resemble those found in the brain after suicide. We found

alterations in the serotonin transporter and the 5-HT_{1A} receptor that are similar to those seen in suicides and moreover the severity of the abnormality in 5-HT_{1A} binding is correlated with the lethality of suicidal behavior. Other studies examining CSF levels of 5-HIAA are consistent with imaging data and extend the findings to the noradrenergic and dopaminergic systems. Finally, we will present data on use of these biomarkers to predict treatment outcome. Abnormal decision-making and mood regulation in suicidal patients is linked to abnormal brain biology and has direct implications for clinical practice in terms of selecting specific types of medication and how these may be best combined with psychotherapies.

Age and pharmacotherapy of suicidal depressed bipolar patients

M.A. Oquendo^{1,*}, H. Galfalvy²

¹ Columbia University and New York State Psychiatric Institute, New York, NY, USA

² Columbia University, Biostatistics and Psychiatry, New York City, NY, USA

* Corresponding author.

The mortality and morbidity due to suicidal behavior associated with bipolar disorder is the greatest among psychiatric diagnoses. To address this problem, it is essential to find predictors of future risk as well as protective factors. Studies from several international teams have demonstrated that for bipolar disorder, the presence of a depressive episode is the most robust predictor and risk increases as does depression severity. Protective factors such as older age and religious affiliation are also key moderators. The role of pharmacotherapy in suicidal behavior has been studied mostly utilizing data that are either observational and naturalistic, rather than experimental. Only one randomized, double-blind clinical trial has been conducted to date, although another one is underway. The comparison of lithium and valproate in terms of effect on suicidal behavior revealed no differences. Although the trial was not powered to detect small effect sizes, results suggest that the Relative Risk ratio generated from meta-analytic studies (RR~ 5) is too optimistic. The trial also suggested that younger individuals may respond differently to pharmacotherapy, suggesting opportunities to personalize treatment approaches. Robust pharmacotherapy targeting both mood stabilization and depressive symptoms is essential and may assist in the quest against suicidal behavior.

Treating adult ADHD and comorbid substance-related disorders

J.A. Ramos-Quiroga

Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Department of Psychiatry, CIBERSAM, Barcelona, Spain

Attention-deficit/hyperactivity disorder (ADHD) is a complex, and multifactorial and chronic neurodevelopmental disorder. Comorbid psychiatric disorders are highly prevalent in individuals with a diagnosis of ADHD. There is a solid overlap between ADHD and

substance use disorders (SUD). Prevalence of SUD is high among patients with ADHD, so that SUD are approximately double as common among individuals with ADHD than in general population, and individuals with SUD have much higher rates than expected of a comorbid ADHD. Studies shown that treatment during childhood of attention-deficit/hyperactivity disorder with stimulant medication neither protects nor increases the risk of later substance use disorders. Nevertheless, recent studies found that patients with ADHD and SUD can reduce ADHD symptoms and SUD with stimulants and cognitive-behavioral therapy. Treatment of ADHD in patients with SUD requires a comprehensive diagnostic assessment. It is recommendable to stabilize the addiction prior to treating the ADHD. In this talk, the recent literature for the treatment of adults with co-occurring ADHD and SUD will be reviewed.

Value-based health care

S115

Value in mental healthcare: The patient aspect

Y. Cohen (Acting president)

GAMIAN-Europe, Azor, Israel

From the patients' point of view, valued-based mental healthcare is mental healthcare based on a holistic vision of care, according to which patients are actively involved in their treatment to achieve the best possible outcomes. They are invited to collaborate with both mental health care providers such as psychiatrists and primary caregivers to determine what types of treatment are the most effective.

GAMIAN-Europe believes that the best package of care includes the following four elements:

- medication – antipsychotic medication is consensually regarded as first-line treatment for people with mental health problems;
- psychotherapy/counselling – although antipsychotic medications are the mainstay of treatment for mental health problems, pharmacotherapy alone produces only limited improvement in negative symptoms, cognitive function, social functioning and quality of life. Additionally, many patients continue to suffer from persistent positive symptoms and relapses, particularly when they fail to adhere to prescribed medications. These situations emphasize the need for multimodal care, which includes psychosocial therapies as adjuncts to antipsychotic medications in order to alleviate symptoms and to improve social functioning and quality of life;
- psycho-education – the more a patient learns about his/her condition the better placed he/she will be to take control of it. Psycho-education embodies this principle by using a clearly-defined therapeutic programme, in which a trained therapist delivers targeted information designed to reduce both the frequency and the severity of symptoms. Psycho-education increases patients' knowledge and understanding of their illness and treatment options and helps them cope more effectively. Many people find that they benefit not only from the information they receive during psycho-education, but also from the learning process itself. There are several different ways in which psycho-education can be delivered, including one-to-one sessions with a therapist, sessions aimed specifically at carers and family members, group sessions attended by several people coping with mental illness and mixed group sessions attended by people with mental illnesses and family members;

– self-help – self-help groups offer patients a voice and an audience with the time and inclination to listen to patients' concerns and reassure them and ease their anxiety. For example, a self-help group may be able to quell anxiety regarding side effects, to reassure the patient, from first-hand experience, that these side effects are transient, normal and non-threatening and will diminish over time. The real experts on living with a mental disorder are those who are already doing so. Therefore, most support groups are full of people who can share information about how they have managed to cope with their illnesses.

Value-based mental healthcare: The quality aspect

W. Gaebel

Heinrich-Heine-University Düsseldorf, LVR-Klinikum Düsseldorf, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

Introduction The goal of value-based healthcare is to improve the quality of care while also lowering healthcare costs. Values may also include societal or research benefits.

Objectives To outline the emergence and quality-related concepts of value-based healthcare.

Aims To give a comprehensive overview and critical discussion of quality aspects of value-based mental healthcare including aspects of personal, societal and scientific values.

Methods Review of quality aspects of value-based mental healthcare.

Results The quality aspect of value-based healthcare includes the implementation of patient-centered care and may include the assessment of societal values or values for research purposes. Current concepts focus on the reduction of disability-adjusted life years to measure the achievement of values, but may need to be

broadened to include benefits to society as a whole or the progress of knowledge about mental disorders in research. Conceptually, addressing such broader value issues may lead to increased benefits and a better appraisal of the value of mental healthcare.

Conclusions The trend towards value-based mental healthcare aims at creating an efficient care delivery model, that strongly focuses on achieving favorable patient outcomes and may in the future also include creating societal values. It includes the development and implementation of suitable mental health policies and comprehensive quality assessment, plus a broad conceptualization of the value-term and its assessment in value-based mental healthcare.

Value-based mental healthcare: The cost aspect

M. Knapp

London School of Economics and Political Science, London, United Kingdom

Economic hardship can be a factor in the incidence and exacerbation of mental health problems, and economic constraints have always constrained availability of resources. But examining the economic case – whether treatment or longer-term preventive strategies are cost-effective – can actually provide strong support for investing more in them. This presentation will provide illustrations of how economic evidence has helped decision-makers (in government and in funding bodies) to recognise the enormous contributions often generated by prevention, treatment and care.

* Corresponding author.

Introduction Although the onset of bipolar disorder (BD) is usually estimated in early adulthood (Burke et al., 1990; Kessler et al., 1997), it is still not clear which age-specific triggering factors may contribute to the underlying vulnerability.

Objectives/aims The present meta-analysis attempts to clarify the number of untreated years of BD, from first symptoms appearance, to first actions carried out by health services (first diagnosis, treatment and hospitalization).

Methods A literature search of three databases PubMed, Web of Science and Psychology and Behavioral Sciences Collection was performed, looking for peer-reviewed publications in English, French, German and Italian language that reported the AOO of BD; the search string adopted was "bipolar and onset". Standardized mean differences were calculated between (i) mean AOO, operationally defined as onset of first symptoms/episodes, and (ii) mean AOO, operationally defined according to four criteria: first contact with services, date of the diagnosis, first pharmacological treatment, or first hospitalization.

Results The searches yielded 8710 articles; 2424 of these articles met the inclusion criteria. A final set of 19 studies presenting multiple definitions of AOO has been analyzed, revealing an overall effect size of 6.96 of untreated years (Cohen's $d = 0.65$)

Conclusion To our knowledge, this is the first meta-analysis that addresses the definition and the modulation of the AOO in bipolar disorder. Identifying the time-frame of untreated illness is very important for the best planning of timely interventions.

Workshop Age of onset of mental disorders: etiopathogenetic and treatment implications.

Background Age of onset (AOO) of anxiety disorders could serve as a vital statistic in the formulation of mental health policy. Previous reviews have reported on the AOO of anxiety disorders in the general population. However, these review studies did not systematically estimate the AOO of different anxiety disorder subtypes, and did not examine factors that might have influenced reported AOO.

Objective The aims of the present study were (1) to estimate the AOO for all anxiety disorders and for specific subtypes, (2) to examine gender differences in AOO of anxiety disorders, and (3) to examine the influence of study characteristics on reported AOO.

Method Seven electronic databases were searched with keywords representing anxiety disorder subtypes, AOO and study design. The inclusion criteria were studies using a general population sample that provided data on AOO for all anxiety disorders, or specific anxiety disorders, according to DSM-III-R, DSM-IV or ICD-10 criteria. Meta-analysis was used to estimate AOO and gender differences, while meta-regression was used to examine the influence of study characteristics.

Results A total of 1028 titles were examined, which yielded 24 studies meeting the inclusion criteria. Meta-analysis found an average AOO of all anxiety disorders of 21.3 years (95% CI: 17.46 to 25.07). Separation anxiety disorder, specific phobia and social phobia had their mean onset before the age of 15 years, whereas AOO of agoraphobia, obsessive compulsive disorder, post-traumatic stress disorder, panic disorder and generalized anxiety disorder began on average between 21.1 and 34.9 years. Anxiety disorder is more common in women, but meta-analysis revealed no difference in AOO between genders. Prospective study design and higher developmental level of the study country were associated with earlier AOO.

Conclusion Results from this meta-analysis indicate that anxiety disorder subtypes differ in mean AOO, with onsets ranging from early adolescence to young adulthood. These findings suggest that prevention strategies of anxiety disorders should be directed towards the factors associated with the development of subtypes

of anxiety disorder in the age groups with the greatest vulnerability for developing those disorders.

Anticipation of age at onset in anorexia nervosa

A. Favaro*, P. Santonastaso

University of Padova, Neurosciences, Padova, Italy

* Corresponding author.

It is a common clinical observation that early-onset cases of anorexia nervosa (AN) are increasing. In a previous study in a large cohort, we found that age of onset in both AN and bulimia nervosa was significantly decreasing in younger generations. We now present data about cohort effects in a sample of more than 3000 patients with eating disorders.

Methods The sample is composed of 2200 AN subjects and 900 BN subjects without previous AN consecutively referred to our outpatient Unit in the period between 1985 and 2014. Time trends have been analysed according to the year of birth of subjects. All diagnoses were reviewed according to DSM-5 criteria.

Results Age of onset in AN showed a significant decrease according to year of birth. A regression model showed a significant independent effect of socio-economic status, age at menarche and number of siblings in predicting age of onset. A second analysis including a subsample representative of the general population confirmed the effect in AN. In BN, although the age of onset showed a decrease in new generations, the effect is not significant.

Conclusion Age of onset of AN continues to decrease in younger generations. The implications of our findings in terms of long-term outcome remain to be understood. Biological and socio-cultural factors explaining this phenomenon need to be explored by future studies. It is important to acknowledge the clinical implications of this cohort effect.

Familiarity, gender and cannabis use determine age of onset in schizophrenia

R. Murray

Institute of Psychiatry, London, United Kingdom

There is evidence that certain risk factors for schizophrenia (e.g. copy number variations, obstetric complications) are associated with an earlier age of onset of psychosis. One possible explanation is that in such cases, early neurodevelopmental damage is associated with greater perturbation of critical neural systems and that this leads to the early presentation of psychosis. Less is known about the significance of age of onset for treatment response and outcome though patients presenting in childhood are reported to have a worse outcome than those who present later. We have conducted two large first episode psychosis studies in which we have examined those baseline characteristics which predict later treatment resistance, notably the AESOP and GAP studies. In each of these, early age of onset and also male gender were associated with treatment resistance. Interestingly in approximately three quarters of cases, treatment resistance was present at onset of psychosis and only in the remaining quarter did it develop over the course of the illness. One possibility is that there exists a type of schizophrenia which is associated with neurodevelopmental damage, early age of onset and lack of response to dopamine blockade; this is

compatible with our previous finding that patients with treatment resistant schizophrenia do not show the increased synthesis of striatal dopamine which is usually found in actively psychotic individuals.

Child and adolescent mental health services in Europe: The current scenario and the future prospects

W05

The current state of child and adolescent mental health services in Europe: A survey in 28 countries

G. de Girolamo^{1,*}, G. Signorini¹, S.P. Singh², J. Warwick³

¹ Saint John of God Clinical Research Center, Psychiatric Epidemiology and Evaluation Unit, Brescia, Italy

³ Warwick Medical School, University of Warwick, Coventry-UK, Warwick Clinical Trials Unit, Division of Health Sciences, Warwick, United Kingdom

* Corresponding author.

Introduction Transition to adulthood is the period of onset of most serious mental disorders. The current discontinuity of care between Child and Adolescent Mental Health (CAMHS) and Adult Mental Health (AMHS) Services is a major socioeconomic and societal challenge for the EU.

Objectives/aims In the framework of the MILESTONE project this study aims to map current services and transitional policies across Europe, highlighting current gaps and the need for innovation in care provision.

Methods An on-line mapping survey has been conducted across all 28 European countries through the administration of two ad-hoc instruments: the Standardized Assessment Tool for Mental Health Transition (SATMEHT) and the European CAMHS Mapping Questionnaire (ECM-Q). The survey systematically collected data about CAMHS organization and characteristics, with a specific focus on actual national transition policies and practice.

Results Response rate was 100%. Despite up to 49% of CAMHS service users need to continue with specialist AMHS care, written policies for managing the interface between these two services are available only in 4/28 countries and transition support services are reported as missing by half of the respondents. Lack of connection between CAMHS and AMHS is reported as the major (82%) difficulty experienced by young service users.

Conclusion Preliminary results indicate a marked variability in characteristics of services and in data activity among the 28 European countries, with important missing information at national level about CAMHS and their functioning. All these conclusions warrant an improvement in data collection and service planning and delivery.

A systematic review of service transitions in people with ADHD

F. McNicholas^{1,2,*}, M. Tatlow-Golden¹, B. Gavin¹, S. Singh³

¹ University College Dublin, School of Medicine and Medical Science, Dublin, Ireland

² Lucena Clinic- St John of God-Dublin, Child Psychiatry, D6, Ireland

³ University of Warwick, medical School, Warwick, United Kingdom

* Corresponding author.

Background Young people (YP) with attention deficit hyperactivity disorder (ADHD) are recognized to be a group who are particularly vulnerable to falling through the gap regarding transitioning from Child and Adolescent Mental health Services (CAMHS) to Adult Mental Health Services (AMHS). This presentation will combine a systematic review of the literature with some clinical examples of the pathway for a number of YP with ADHD who reach the transition boundary (TB).

Method (1) Databases (e.g., PubMed, PsycINFO, AMED, CINAHL, EMBASE, Web of Knowledge), and grey literature, were searched systematically with database-specific key words, variants and truncations, to cover six subject areas: ADHD; transition or transfer; age; experiences or views; service development; and policies or protocols. Hand searching of key journals, ancestry and forward searches of references, and expert consultation were conducted. Two reviewers critically evaluated studies using a validated appraisal tool for mixed methodologies and findings were synthesized. (2) Following ethical approval, CAMHS clinicians from 9 clinics in Republic of Ireland identified all cases where a YP with ADHD had reached the TB, and identified referral/service outcomes ($n = 20$).

Results The search yielded 27 studies, covering areas of service review and recommendations (7), guidelines (3), medication (5), case note audit (3), professional's views (5), pilot transition clinics (2). A further set of papers covered the perspective of the young person (4) and parent (2). Overall these highlighted the less than optimum experience by both clinicians and service users of the experience with suggestions for future developments. These findings were mirrored in the review of clinical notes and individual interviews of YP identified through their CAMHS. Of the 20 young people identified, only 1 was directly transferred to AMHS. Eight were retained in CAMHS, on average for over a year. A significant number (7) refused onward referral. A perception from CAMHS clinicians, that AMHS did not accept such cases or lacked relevant service/expertise, may have contributed to the low rate of referral.

Conclusion Both the extant literature and the specific study presented highlight the lack of clear cut consensus about the appropriate management of young people with ADHD who reach the transition boundary. Low rates of AMHS transfer may come from CAMHS clinicians' perceptions of AMHS, and preferences of young people and families. Before assuming the very low rate of referral by CAMHS clinicians is poor practice, clinical outcomes need to be identified, young people's reasons for refusing transfer explored and service options identified.

Developing and measuring transition-related decision-making in Europe

P. Santosh

Institute of Psychiatry, Psychology and Neuroscience King's College London, Department of Child and Adolescent Psychiatry, London, United Kingdom

The MILESTONE project developed the Transition Readiness and Appropriateness Measure (TRAM) and the Transition-Related Outcome Measure (TROM) on the HealthTracker™ platform, each prepared in versions for young people, parents/carers and clinicians. Together these instruments aim to support and then evaluate clinician decision-making with respect to transition. The suite of measures were developed on and hosted on the HealthTracker™ Platform. FDA approved protocols were evoked in scale development and validation. A comprehensive list of items potentially significant in transition decision-making was generated from a thorough literature review and discussion with experts. Focus groups were conducted with young people, parents/carers and clinicians centring on the themes of “who should transition” and “identifying successful transition”. In open discussion, further items considered important in transition decision-making were elicited, and the importance of listed items was rated. Analysis of the data allowed items to be removed, kept or amalgamated. Domains considered universally important in transition decision-making emerged; these included diagnosis, impairment, risk, life changes, barriers to a successful transition and transition success markers. A beta version of the scale was tested for comprehension and usability by transition experts, young people and parents/carers. Following pilot testing, qualitative interviews were conducted with some participants to identify further issues. Scales were translated from English into French, Italian, German, Croatian and Dutch and translations uploaded to the HealthTracker™ online platform. Validation of the scales required completion of the TRAM and TROM alongside a series of proxy “gold-standard” measures to assess psychometric validity, test-retest validity and sensitivity to change.

Novel research on transition from child to adult mental health services in Europe: The MILESTONE project

H. Tuomainen*, S.P. Singh, The MILESTONE Consortium

Warwick Medical School, University of Warwick, Coventry, United Kingdom

* Corresponding author.

Introduction Current service configuration of distinct Child and Adolescent Mental Health (CAMHS) and Adult Mental Health Services (AMHS) is considered the weakest link where the care pathway should be most robust. Transition-related discontinuity of care is a major health, socioeconomic and societal challenge for the EU.

Objectives The overall objective of the MILESTONE project is to improve transition from CAMHS to AMHS in diverse healthcare settings in Europe.

Aims To improve the understanding of current transition-related service characteristics, and processes, outcomes and experiences of transition from CAMHS to AMHS using a bespoke suite of measures; to explore the ethical challenges of providing appropriate care to young people as they move to adulthood; to test a model of managed transition in a cluster randomized controlled trial (cRCT) for improving health, social outcomes and transition to adult roles; and to develop training modules for clinicians and policy guidelines.

Methods Data will be collected via systematic literature reviews; bespoke surveys to CAMHS professionals, experts and other stakeholders; focus groups with service providers and users and members of youth and mental health advocacy groups; and a longitudinal cohort study with a nested cRCT in eight EU countries (Belgium, Croatia, France, Germany, Ireland, Italy, Netherlands, UK) involving over 1000 CAMHS service users, their parents/carers, and clinicians, with assessments at baseline, 9, 18 and 27 months.

Results First results are expected in 2016 with further major findings following in 2019.

Conclusions The MILESTONE project will provide unprecedented information on the nature and magnitude of problems at the CAMHS-AMHS interface, and potential solutions to overcome these.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Neurostimulation in alcohol dependence: The effect of repetitive transcranial magnetic stimulation on brain function and craving

J. Jansen^{1,*}, O. van den Heuvel², Y. van der Werf³, S. De Wit², D. Veltman², W. van den Brink¹, A. Goudriaan¹

¹ Academic Medical Centre, Psychiatry, Amsterdam, Netherlands

² VU University Medical Center, Psychiatry, Amsterdam, Netherlands

³ Netherlands Institute for Neuroscience, Amsterdam, Netherlands

* Corresponding author.

Background Alcohol dependence has long been related to impaired processing and handling of negative emotions. This is the first study to compare emotion regulation (ER) at a behavioral and neural level in alcohol dependent patients (ADPs) and healthy controls (HCs). It also examines the effects of high-frequency repetitive transcranial magnetic stimulation (rTMS) on ER abilities and related craving levels in ADPs.

Method Thirty-six ADPs and 32 HCs matched on age, sex, and education, were included in a within-subject fixed-order study with one functional magnetic resonance imaging (fMRI) session and one rTMS plus fMRI session, with high-frequency (10 Hz) rTMS over the right dorsolateral prefrontal cortex (dlPFC). An fMRI emotion regulation task (ERT) was administered during both sessions and craving was measured before and after each ERT.

Results ADPs were impaired in the regulation of negative emotion and showed a higher activation of ER related brain areas compared to HCs. Furthermore, active rTMS improved ER abilities in both ADPs and HCs, but was accompanied by a decrease in anterior cingulate and left dlPFC activity only in ADPs. In addition, the ERT-induced increase in craving levels in ADPs was trend-significantly reduced by active rTMS, with a large effect size.

Conclusions ADPs are impaired in the regulation of negative emotion and show enhanced neural activity in the ER brain circuit. High-frequency rTMS improves ER in ADPs and HCs and normalizes neural activity and tends to reduce craving in ADPs. Future studies are needed to test the long-term effects of (multiple session) rTMS on ER, craving, and drinking.

The impact of appetite regulating peptides on substance use disorders

A. Koopmann*, F. Kiefer

Central Institute of Mental Health, Department of Addictive Behavior and Addiction Medicine, Mannheim, Germany

* Corresponding author.

Background Preclinical and clinical data suggest modulating effects of the appetite regulating peptide ghrelin on food intake.

Recent data suggest that in food intake the “endostatic” energy-homeostatic systems of the lateral hypothalamus (LH) and the motivational, mesolimbic reward system operate in dynamic interplay with each other. Ghrelin receptors have been detected in the ventral tegmentum of the midbrain (VTA), where they modulate the activity of dopaminergic neurons projecting to the NAC. Assuming that Ghrelin modulate mesolimbic reactivity, the question remains: is this only the case in response to food cues? Or is this the case in response to reward-associated cues in general (including those related to nicotine and alcohol)?

Methods Study 1: a consecutive sample of 61 alcohol-dependent male inpatients was included. Blood was drawn at onset of withdrawal 12-24 hours after admission, and following 14 days of controlled abstinence in order to assess plasma concentrations of both active and total ghrelin. In parallel, we assessed alcohol craving applying the Obsessive Compulsive Drinking Scale (OCDS) as well as symptoms of depression (Beck Depression Inventory [BDI]) and anxiety (State Trait Anxiety Inventory [STAI]). The severity of alcohol dependence was assessed with the Alcohol Dependence Scale (ADS). Study 2: 54 non-treatment seeking smokers and 30 healthy controls with normal eating behavior, as measured by the Three Factor Eating Questionnaire (TFEQ) participated in this study. We measured plasma concentrations of both active and total ghrelin, using a blood sample taken two hours after a standardized meal during early nicotine abstinence in the smoking group. Additionally we quantified severity of addiction in the smoking group using the number of cigarettes smoked per day, cotinine plasma concentration and the Fagerström Test for Nicotine Dependence (FTND).

Results Study1: we found a significant positive correlation between the plasma concentration of active ghrelin and alcohol craving in both blood samples. Plasma concentrations of active ghrelin increased significantly during early abstinence. In a linear regression model, the plasma concentration of active ghrelin on day one, the scores of the ADS, and the BDI explained 36% of the variance in OCDS sum score ($P < 0.0001$). By day 14, these same factors accounted for 54% ($P < 0.0001$). We did not detect any association between the plasma concentration of total ghrelin and patients' alcohol cravings. Study 2: plasma concentration of acetylated ghrelin but not total ghrelin was significantly higher in smokers than in non-smokers. Moreover, we found significant negative correlations between acetylated ghrelin and all measures of the severity of nicotine dependence.

Discussion In conclusion, both studies supports the general idea that ghrelin's central effects go beyond the endostatic regulation of energy homeostasis, also involving pathways underlying reward expectation and craving. Physiologic factors modulating the reactivity of mesolimbic pathways represent an important research topic for developing pharmacologic treatments for disorders characterized by altered reward-related behaviors, such as substance use disorders and behavioral addictions.

⁴ University of Hertfordshire, School of Life and Medical Sciences, Department of Pharmacy, Pharmacology and Medical Sciences, Hatfield, United Kingdom

* Corresponding author.

Over the last decade, the “traditional” drug scene has been supplemented – but not replaced – by the emergence of a range of novel psychoactive substances (NPS), which are either newly created or existing drugs, including medications, now being used in novel ways. By the end of 2015, in excess of 700 NPS had been reported by a large number of countries in the world. Most recent data show however that synthetic cathinones; synthetic cannabinoids; and psychedelics/phenethylamines; account for the largest number of NPS. Given the vast range of medical and psychopathological issues associated with the molecules here described, it is crucial for health professionals to be aware of the effects and toxicity of NPS. The “Drugs 2.0.” revolution facilitated the birth and growth of an “Online Drug Culture” which finds its main expression in chats/fora/blogs as well as the diffusion of online drug marketplaces (both in the surface and deep web). The web has progressively modified the drug market from a “street” into a “virtual” one, so by increasing the availability of new drugs/NPS/“legal highs” (“legal alternatives” to the traditional illegal drugs). The rapid pace of change in the NPS online market constitutes a major challenge to the provision of current and reliable scientific knowledge on these substances. The present lecture aims at providing an overview of the NPS phenomenon, also giving an overview of the main clinical and pharmacological issues relating to these most popular NPS categories.

Translational perspectives in addiction psychiatry

A. Schellekens

Radboud University Medical Centre, Donders Centre for Neuroscience, department of Psychiatry, Nijmegen Institute for Scientist Practitioners in Addiction, Nijmegen, Netherlands

Background Heritable factors account for approximately 50–60% of the risk for alcohol dependence. However, which genes confer this risk remains to elucidate. Moreover, genetic association studies are hampered by non-replication. Several strategies can be applied to approach this issue. One option is the application of intermediate phenotypes. Neurobiological measures that are closely related to the addiction phenotype may be more directly related to genetic variation. Intermediate phenotypes related to dopamine function seem particularly suitable, given the strong dopamine hypothesis in addiction. Another strategy is to include environmental factors, such as childhood adverse experience, in genetic association studies. We tested the effect of *COMT* Val158Met and *DRD2* Taq1A genotypes, as modulators of brain dopamine function in the context of self-reported environmental factors, like childhood adverse experience.

Methods Alcohol-dependent patients ($n = 110$) and healthy controls ($n = 99$) were genotyped for the *COMT* Val158Met and *DRD2* Taq1A genotypes. Childhood adversity was measured using self-report questionnaires. Dopamine sensitivity was assessed using an apomorphine challenge with cognitive performance and plasma growth hormone levels as main outcome measures.

Results *COMT* genotype modulated the effect of apomorphine on cognitive performance, but was not directly associated with alcohol dependence. Yet, the interaction between childhood adversity and *COMT* genotype did predict alcohol dependence. *DRD2* genotype modulated the effect of apomorphine on plasma growth hormone levels and was also not directly associated with alcohol dependence. Yet, the interaction between parental rule setting and *DRD2* genotype did predict alcohol use in a separate population-based sample of adolescents.

Conclusion This study provides evidence for a role of *COMT* and *DRD2* genotypes in alcohol dependence using both the GxE and

intermediate phenotype approach. This confirms that both an intermediate phenotype approach and GxE interaction analyses can be useful tools in understanding mechanisms mediating addiction vulnerability. The clinical relevance of dopamine genes and intermediate phenotypes for staging and profiling of alcohol use disorders remains to be investigated.

The magic list of everyday problems in consultation-liaison psychiatry (and hints for solving them)

S. Ferrari*, G. Mattei, G.M. Galeazzi, M. Rigatelli

University of Modena & Reggio Emilia, Department of Diagnostic-Clinical Medicine and Public Health, Modena, Italy

* Corresponding author.

Introduction Consultation-liaison psychiatry (CLP) deals with clinical, research and training activities at the interface between psychiatry and the rest of medicine. The main clinical competencies of CLP include medical-psychiatric comorbidity (co-existing psychiatric and non-psychiatric disorders affecting reciprocally); medically unexplained physical symptoms, “somatization” and functional disorders; and liaison activities, addressed to medical workers and teams.

Objectives/aims To describe and discuss typical clinical scenarios that CL psychiatrists have to work in, and suggest effective, evidence-based solutions.

Methods Long-standing everyday clinical experience of the authors combined to evidence derived from international literature consented to create a list of the most common and complex problems or difficulties typical of the CLP clinical context, and related possible solutions.

Results Most common/complex problems include the following: stigma and prejudice (of patients, relatives, colleagues, and own); excessive technicality of language; short/unpredictable duration of hospital stay of patients, and more in general pressure in clinical

practice due to shortness of time and resources; tendency of colleagues from other disciplines to disregard setting features related to time and space (inadequate rooms, e.g. too busy or noisy); limited time for face-to-face discussion of cases or problems; conflicts with patients/relatives/colleagues, and fear of reciprocal manipulation.

Discussion Moving on the interface between psychiatry and the somatic disciplines, CL specialists need to develop special skills, not only those strictly technical, but also those “soft skills” including relational abilities and flexibility. Understanding the systemic aspects of referrals in the relationship between physician, staff and patients is usually essential in the process of consultation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychotherapeutic interventions in consultation-liaison psychiatry implications for psychiatric trainees

K. Koelkebeck

University of Muenster, School of Medicine, Department of Psychiatry and Psychotherapy, Muenster, Germany

In clinical reality, psychiatric trainees working in consultation and liaison psychiatry (CLP) face a lot of obstacles to gain satisfactory results from their work on somatic wards. Specifically, the deliverance of psychotherapeutic interventions in every-day CLP is a topic of discussion. The talk will present a case of a young anorectic patient that will exemplify the difficulties in delivering psychotherapeutic treatment in every-day clinical work and will outline common difficulties, specifically in relation to interactions with staff of somatic units. The presentation will be wrapped-up by suggestions on how to deal with the most common problems.

Psychopharmacological treatments strategies in consultation-liaison psychiatry: Clinical vignette and pros and cons

G. Mattei^{1,*}, N. Colombini², S. Ferrari¹, G.M. Galeazzi¹

¹ University of Modena and Reggio Emilia, Department of Clinical-Diagnostic Medicine and Public Health, Modena, Italy

² Castelfranco Emilia Community Mental Health Center, Mental Health Department, Modena, Italy

* Corresponding author.

Introduction Multimorbidity and polipharmacotherapy are crucial features influencing the psychiatrist's prescription in the consultation-liaison psychiatry (CLP) setting.

Aims to provide an example of computer-assisted decision-making in psychotropic prescriptions and to provide hints for developing pharmacological treatment strategies in the CLP setting.

Methods Case report. A clinical vignette is presented, followed by a review of available online computer-assisted prescription software.

Results A woman in her seventies was repeatedly referred for psychiatric consultation. Eleven different medications were administered daily, because of multimorbidity. A diagnosis of dystymia was established, with comorbid mixed pain (partly fulfilling the criteria of somatic symptom disorder) and substance use disorder (opioids). After the first assessment, six follow-up visits were needed during hospitalization. Mirtazapine and benzodiazepines were introduced. Beside the pharmacological intervention, conflict mediation was performed in the relationship with the patient, her

relatives, the ward personnel and the GP, to develop a long-term rehabilitation project. Pros and cons of online computer-assisted prescription software were discussed together with the ward personnel, as well.

Conclusions Computer-assisted decision-making in psychotropic prescription is becoming more common and feasible. The use of available software may contribute to safety, effectiveness and cost-effectiveness of clinical decision-making. Risks are also possible: depending for example from regional differences in prescription indications, different guidelines, pharmacogenomics, frequency with which databases are updated, sponsorships, possible conflicts of interest, and real clinical significance of highlighted interactions – all issues the clinician willing to benefit from this modern tools should pay attention to.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Drugs pharmacokinetics interactions with cardiac and renal disease patients in consultation-liaison psychiatry

D. Telles*, A. Barbosa

Hospital de Santa Maria, Consultation-Liaison Department, Lisbon, Portugal

* Corresponding author.

The prevalence of psychiatric disturbances in patients with cardiovascular disease is elevated. For example the prevalence of major depression can reach 15–20% and of anxiety disturbances 5–20%. When we treat psychiatric symptoms in cardiovascular disease we must have in mind four particular effects of psychiatric drugs: (1) disturbances of atrial-ventricular conduction; (2) QTc interval prolongation that can lead to *torsade de pointes* and ventricular fibrillation; (3) hypertension; (4) changes in platelet aggregation. On the other hand, there is a great prevalence of psychiatric disease in patients with renal disease. For example, about 5–25% of the patients with advanced renal disease have major depression.

Renal disease patients can evidence changes in several pharmacokinetic parameters such as: (1) biodisponibility; (2) distribution; (3) metabolism; (4) excretion. Therefore, when we treat these patients we have to keep in mind the effect of psychiatric drugs over the renal functioning, but also the effect of the deficient renal function in the pharmacokinetics of the drugs.

In this presentation we intend to reveal what are the main concerns when we prescribe psychiatric drugs in patients with cardiovascular and renal disease.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How should psychopharmacotherapy be learned by residents in psychiatry – proposals of psychopharmacology curricula

W18

The present situation of psychopharmacology teaching suggests the need for a European curriculum

P. Baumann^{1,*}, G. Laux²

¹ Department of Psychiatry (DP-CHUV), Prilly-Lausanne, Switzerland

² Institute of Psychological Medicine IPM, Department of Psychiatry, Psychotherapy, Ludwig-Maximilians-University, Haag o.B., Germany
* Corresponding author.

Introduction In most European countries postgraduate training for specialization in psychiatry and psychotherapy is acquired over the course of 4–6-year programs. In the European Union, qualification in one country is recognized within other countries of the Union.

Objectives and aims To analyze the present situation of psychopharmacology-pharmacopsychiatry postgraduate teaching in Europe and to present the needs and preliminary instruments for improving the situation by harmonization of the programs.

Methods Analysis of the data available from national psychiatric societies and from the literature; development of a consensus among experts in this field.

Results Despite efforts to standardize post-graduate training, the curricula in different European countries vary greatly. This variability limits comparability between countries and international exchange while carrying consequences in the breadth and quality of education that trainees receive. Literature and curricula mainly published in USA as well as a recently published curriculum and learning catalogue in Germany [1] offer useful tools for the development of a curriculum at a European level.

Conclusions There is clearly a need for standardization of psychopharmacology-pharmacopsychiatry teaching at the European level. This can be achieved by the introduction of a curriculum and learning catalogue developed by European experts and based on tools already available.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Proposal for a model psychopharmacology curriculum for psychiatric residents in Germany

G. Laux

Institute of Evidence-based Medicine in Psychopharmacotherapy, Institute of Psychological Medicine, Haag i.OB, Germany

All German societies of medicine have been ordered by the Federal Association of Physicians (Bundesärztekammer) to propose new revised regulations for the education of residents. The German Association for Psychiatry, Psychotherapy and Psychosomatics (DGPPN) is offering a broad extension of education in psychotherapy while education in pharmacotherapy is still rather small and limited. The working group Biological Psychiatry of the German Association of Psychiatric Hospitals (Bundesdirektorenkonferenz, BDK) suggests a detailed proposal of a psychopharmacology curriculum based on a Delphi method consent of medical directors involved in the education of the majority of German psychiatric residents. Issues include general pharmacology, neurobiological principles, clinical pharmacology of different classes of psychotropics (antidepressants, antipsychotics, mood stabilizers, anxiolytics, hypnotics, stimulants etc.), special aspects (e.g. pregnancy, geriatric patients) as well as ethical, legal and economic aspects. About 160 hours of theoretical education are proposed, clinical teaching should be interactive, with vignettes and supervision covering about 300 hours.

Disclosure of interest The author has not supplied his declaration of competing interest.

Psychopharmacology during residents' training: The role of scientific societies

P.M. Llorca

Hôpital Gabriel Montpied, Psychiatry department, Clermont-Ferrand, France

In France, psychopharmacology is supposed to be one of the bases of the training during the first year of residency. But there is no standardization in the content of the psychopharmacology courses for residents from one region to another. There is also a debate around the way psychopharmacology has to be learned by young professionals, with the development a narrative approach that seems to have a pedagogic relevance, opposed to a more academic approach. In this context, the French Society for Biological Psychiatry and neuropsychopharmacology developed a program of specific psychopharmacology workshops for residents. These workshops combine a fundamental pharmacologic approach, with a more clinical evidence-based one, trying to take into account the discrepancy that residents may experienced between knowledge and every day practice, around specific topics (e.g. polypharmacotherapy). This program highlights different issues in the domain of the psychopharmacology courses for residents around the format (e.g. on-line courses versus face-to-face courses), the topics and the content of the courses (e.g. categorical approach of prescription versus dimensional approach). It underlines the need for a clear definition of what has to be known by residents in this field but also how this initiative can be implemented for a large number of residents using numeric tools and what is the role of scientific societies and their interactions with academic teaching. The funding of such programs has also to be defined and clarified.

The new neuroscience based nomenclature of neuropsychotropic drugs: A chance for a better understanding and teaching of clinical psychopharmacology

H.J. Möller

Psychiatric University Hospital Munich, Munich, Germany

Traditional psychopharmacological terminology is based on historical grounds and under different aspects not systematic and rational. It even tends to confuse patients by prescribing a drug that does not reflect their identified diagnosis, prescribing “antipsychotics” to depression. Four major colleges of neuropsychopharmacology (ECNP, ACNP, Asian CNP, an CINP) proposed a new multi-axial pharmacologically-driven nomenclature. The template has five axes: 1- class (primary pharmacological target and relevant mechanism); 2- family (reflecting the relevant neurotransmitter and mechanism); 3- neurobiological activities; 4- efficacy and major side effects; and 5- approved indications. The results of the surveys suggest that the clinicians found the available indication-based nomenclature system dissatisfactory, non-intuitive, confusing, and doubt-inducing for them and the patients. The proposed five-axis template seeks to upend current usage by placing pharmacology rather than indication as the primary axes. With the proposed nomenclature relating primarily to Axis 1 – the class, and usage of the other axes would largely depend the extent to which the clinician seeks to deepen the scientific and clinical base of his involvement.

A European psychopharmacology curriculum: The young psychiatrist's point of view

M. Spies*, S. Kasper

Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

* Corresponding author.

It goes without saying that psychopharmacologic treatment requires extensive knowledge of topics ranging from pharmacodynamics and efficacy, to pharmacokinetics, side-effects, and toxicity. Knowledge should be supplemented with experience regarding applicability in a clinical setting. It is well accepted that comprehensive psychopharmacologic education is essential to convey necessary knowledge and adequately prepare trainees for independent practice [1]. Currently, a psychopharmacologic curriculum, under the umbrella of the European Psychiatric Association, is in preparation in order to emphasize the importance of psychopharmacologic education in the context of psychiatric training and to foster standardization within the European Union. The aim of this presentation is to discuss psychopharmacologic education and prerequisites for an effective curriculum from the trainee's point of view. We will address challenges facing psychiatric trainees [2] and review existing curricula as well as literature in which they are evaluated. Based on evaluation of the model curriculum by the American Society of Clinical Psychopharmacology, one of the most broadly used psychopharmacologic curricula, it has been emphasized that an effective curriculum should be more than a list of topics. It should also convey pedagogic strategies with a focus on up-to-date technology, and provide a process through which teacher and trainee progress can be assessed [3,4]. Reflection on currently available curricula should aid in the development of an effective and timely EU-wide psychopharmacologic curriculum.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How to overcome the negative image of psychiatry: Facts and fiction

W23

Are psychiatrists an endangered species?

H. Katschnig

IMEHPS.research, CEO, Vienna, Austria

Introduction Recruitment of young doctors into psychiatry is declining in many countries, which might become a threat to the survival of the profession.

Objectives To identify potential reasons for this threat.

Aims To look at psychiatry with concepts used by the sociology of professions.

Methods Professions are characterized – and these concept will be used for analysis here – by (1) ownership of a specialized body of knowledge and skills, which defines the field of competence and the scope of potential clients, including the demarcation from other professions; (2) holding a high status in society; (3) being granted autonomy by society, e.g. in recruiting and excluding members; and (4) being obliged, in return for the above, to guarantee high quality standards in providing services and following ethical rules.

Results Six intertwined areas of concern are identified: three of them, the increasing criticism by users and carers, the intrusion of other professions, and psychiatry's negative image in society, can be traced back to problems with the other three concerning the "ownership of a specialized body of knowledge and skills". With the preparation and advent of DSM-5, discussions about the lack of validity of psychiatric disease entities have gone viral in the time of the internet. The attempts to "carve nature at its joints" have failed, and this is more and more perceived from outside, threatening psychiatry's status in society and potentially turning away to be psychiatrists.

Conclusion Looking at psychiatry as a profession may help to better understand its current situation.

Disclosure of interest The author has not supplied his declaration of competing interest.

The negative image psychiatry from a sociological perspective

A.M. Möller-Leimkühler^{1,*}, H.J. Möller¹, W. Maier², W. Gaebel³, P. Falkai¹

¹ Ludwig-Maximilians-University Munich, Department of Psychiatry and Psychotherapy, Munich, Germany

² University of Bonn, Department of Psychiatry and Psychotherapy, Bonn, Germany

³ Heinrich-Heine-University Düsseldorf, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

* Corresponding author.

The negative image of psychiatry is not only due to unfavourable communication with the media, but is basically a problem of self-conceptualization. It results both from unjustified prejudices of the general public, mass media and health care professionals and of own unfavourable coping with external and internal concerns.

Issues related to negative stereotypes of psychiatry include overestimation of coercion, associative stigma, lack of public knowledge, need of simplification of complex mental issues, problem of the continuum between normality and psychopathology, competition with medical and non-medical disciplines, and psychopharmacological treatment.

Issues related to psychiatry's own contribution to being underestimated include lack of a clear professional identity, lack of biomarkers supporting clinical diagnoses, limited consensus about best treatment options, lack of collaboration with other medical disciplines and low recruitment rates among medical students.

Much can be improved to achieve a positive self-concept, however, psychiatry will remain a profession with an exceptional position among the medical disciplines which should be seen as its specific strength.

W25

The negative image of psychiatry in the medical community

R.J. van der Gaag

University Medical Centre Nijmegen, Utrecht, Netherlands

It is a very unfortunate matter of fact that mental problems and diseases are matter to societal stigmatization. In the slipstream psychiatry has a negative image in the public eye. Fighting stigma should be at the core of all professionals involved in mental health care. Self-reflection should be a primary reaction of any psychiatrist when confronted with a sensitive issue like stigmatization and negative image. It is painful to realize that the negative image of psychiatry is also present to the community to which psychiatrists belong, namely the medical community. This is strange and hurting. Psychiatrists (then closely linked to neurology) have, worldwide strongly contributed to the birth and strengthening of medical associations. Yet psychiatrists have estranged themselves from the medical community, thus, in my view, contributing themselves to stigma on patients with mental conditions and the negative image of psychiatry. So time for action, starting by self-awareness of psychiatrists that they are medical specialist, urging oneself as a psychiatrist to behave as a medical specialist by relating to colleagues in a helpful way and keeping one's own medical knowledge and skills up to standards. Psychiatrists have so much to offer in helping their colleagues in somatic medicine.

Old age psychiatry – towards the future

W26

Training in old age psychiatry: The 30 countries' perspective

M. Orrell

University of Nottingham, Institute of Mental Health, Nottingham, United Kingdom

To improve the care of older people with mental health problems it is necessary to have a highly skilled workforce who is very well-trained in the diagnosis and management of the range of the psychiatric problems affecting older people including the dementias. Key to this is the need to have an adequate number of specialists in geriatric psychiatry and a wider recognition of geriatric psychiatry training across Europe including a broad agreement on training requirements. In 2012 the European Association of Geriatric Psychiatry (Toot et al.) published the results of a Europe wide survey on geriatric psychiatry training to scope current practice and develop recommendations to begin a debate on harmonization. Representatives from 30 out of 38 (79%) representatives responded including many from countries where old age psychiatry was not formally a specialty. Training programs and duration varied between countries. Eleven countries reported that they had geriatric psychiatry training programs and most of these required geriatric psychiatry trainees to complete mandatory training for two years within old age psychiatry. Representatives from ten countries reported having specific Continuing Professional Development (CPD) for old age psychiatrists at consultant level.

The recognition of geriatric psychiatry as a specialist discipline in Europe is on the rise. The training procedures and processes in place vary considerably between and sometimes within countries. There are several options for harmonizing old age psychiatry training across Europe with advantages to each. However, support is

required from national old age psychiatry bodies across Europe and an agreement needs to be reached on a training strategy that encompasses supervision, development, and appraisal of the knowledge and skills sets of old age psychiatrists. This workshop will look at options for harmonization and take first steps towards a consensus.

W27

Harmonization of European training

R. Oude Voshaar

University Medical Center Groningen, Psychiatry, Groningen, Netherlands

Mental health disorders, especially dementia, mood- and anxiety disorders, are among the most prevalent diseases in later life. Due to a greying European society, numbers are expected to increase over the next decades. Consequently, there is a pressing need for well-trained specialists in geriatric psychiatry across Europe in order to meet the mental health needs and to deliver a high standard of care to the aging population. In the past decades, some countries have set up specific training programs for specializing in geriatric psychiatry, whereas others did not. In order to stimulate the development of high-quality services, harmonizing specialty training across Europe will be a first step forward.

The EU stresses the need for standardizing qualifications of medical professionals to enable them to work across the EU. This workshop aims to work towards a consensus on the minimum training level required for geriatric psychiatry. We state that being able to work as an old age psychiatrist requires specific training in geriatric psychiatry and old age over and above general training in psychiatry. Therefore, discussion of opportunities to develop minimal criteria for training and practice across Europe is crucial. Taken the differences between countries into account (many countries do not provide specific training in old age psychiatry), we should finally agree on the minimal level of education and supervision, the minimum level of work experience and finally the minimal level of supervision in peer groups as a starting point.

W28

Old and new reasons for specialization

G. Stoppe

MentAge, MentAge Consulting, Practice, Research, Basel, Switzerland

Mental illness is one of the largest areas of activity in the health service, with mental disorders of the elderly an important part of it. This substantial ageing of the population is a new phenomenon, occurring over the last century. It has given prominence to mental illness in old age. There is a growing interest in making decisions about how many and which services to provide to the older community.

The expertise of old age psychiatry services lies in the care and treatment of people with complex mixtures of psychological, cognitive, functional, behavioral, physical and social problems usually relating to ageing. Current evidence suggests specialist old age services are best equipped to diagnose and treat mental illness in our ageing population. However, the specialists should be integrated optimally into a service system to the benefit of the elderly. It will be crucial to improve access of older patients to the services. The service system and the partners in the system differ to those for younger adult psychiatric patients. Thus, not only knowledge and skills underline the necessity of specialization but also the increasingly complex health service structures of modern societies.

Schizophrenia research: The necessary link between psychopathology and clinical neuroscience

W29

From Griesinger to DSM-V: Do we need the diagnosis of schizophrenia?

A. Erfurth^{1,*}, G. Sachs²

¹ Otto-Wagner-Spital, 6th Psychiatric Department, Vienna, Austria

² Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

* Corresponding author.

The dichotomy between “dementia praecox” and “manic-depressive insanity” by Emil Kraepelin is one of the milestones of nosology in psychiatry [1].

This dichotomy reflects the necessity – particularly in the absence of effective treatment in Kraepelin’s time – to differentiate (and to predict) the functional outcome of individual patients. Since Kraepelin’s original division particularly the influence of Kurt Schneider has led to a full acknowledgment of the dichotomy in both ICD and DSM.

While this division has proven to be clinically useful, alternatives have been proposed covering a large spectrum from the idea of unitary psychosis as in Wilhelm Griesinger and Klaus Conrad to further subdivisions as in Karl Leonhard. Recent research in neuroscience suggests the presence of an overlap between schizophrenia and other psychiatric disorders [2–4].

W30

Role of psychopathology in elucidating the underlying neural mechanisms

F. Oyebo

Birmingham, United Kingdom

Introduction Psychopathology is the systematic study of abnormal subjective experience and behaviour and it aims to give precise description, categorisation and definition of abnormal subjective experiences.

Aim I aim to demonstrate that the most appropriate approach to elucidating the biological origins of psychiatric disorders is firstly to identify elementary abnormal phenomena and then to relate these to their underlying neural mechanisms. I will exemplify this by drawing attention to studies of Delusional Misidentification Syndromes (DSM).

Results I will show that there are impairments in face recognition memory in individuals with DSM without impairments in the recognition of emotion and that there are abnormalities of right hemisphere function and of the autonomic recognition pathways that determine sense of familiarity.

Conclusions Basic psychopathological phenomena are more likely to throw light on the basic neural mechanisms that are important in psychiatric disorders than studying disease level categories.

Cognitive dysfunction is a characteristic feature of patients with schizophrenia. Traditionally, the main distinction between “dementia praecox” and “manic-depressive insanity” was in fact the cognitive outcome during the course of the disease [1].

For the assessment of cognitive dysfunction both large, detailed instruments [2] and brief screening scales for quick and multiple use [3,4] are available.

Recently, the role of social cognition has been thoroughly examined showing differential effects [5].

Treatment of cognitive dysfunction in schizophrenia comprises adherence to a therapy with atypical antipsychotics as well as specific treatment programs for cognitive [6] and social cognitive [7,8] dysfunction.

Shaping the future of healthcare through innovation and technology

W32

New research in outcome management using apps and DSM-5 measures. Preliminary results

V.J.A. Buwalda

Vrije Universiteit/Victas addiction Center, Psychiatry, Amsterdam, Netherlands

The presentation is about the use of outcome measurements in combination of a newly developed app that enables psychiatrists and patients track the progress of their treatment process and adjust it if needed in a shared decision fashion.

In 2013 the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders was introduced. Around the same time there was the start of a paradigm shift in healthcare which increased the focus on patient involvement in individual health care decision-making and on measuring and improving outcomes of care (Sederer

et al., 1997; Sperry, 1997; Hermann, 2005). If outcome measures are psychometrically sound and able to measure clinical change, treatment progress can be made transparent for both patients and clinicians.

In this presentation the presenter will update the audience on a research project where the DSM-5 Field Trials, patient-reported dimensional measures and the World Health Organization Disability Assessment Schedule (WHODAS) (Clarke et al., 2013; Narrow et al., 2013; Mościcki et al., 2013) are secured and placed in a newly developed app.

Addiction component walk along working towards a new app

M. Krausz

Institute of Mental Health at UBC, UBC-Providence Leadership Chair for Addiction Research Professor of Psychiatry, West Vancouver, Canada

Only a very small percentage of adolescents and young adults with mental challenges is able to access specialized care. Access is limited due to a lack of capacity but also internal hurdles and stigma especially among young males. The web creates a new environment for them, which is defining a new culture of communication and interaction. The majority is using smart phones to access the internet and make that their main communication device. Walkalong is a web-based platform, which aims to provide a range of opportunities and tools for youth with especially mood challenges. These tools include screening and assessment, online resources and all kind of orientation and interaction for informed decision making. We are working on that to develop a framework for better online-based mental health care including useful tools beyond crisis based on the principles of empowerment and strength based approaches.

North Carolina Statewide Telepsychiatry Program (NC-STeP): Using telepsychiatry to improve access to evidence-based care

S. Saeed^{1,2,3,4}

¹ Department of Psychiatry and Behavioral Medicine, Brody School of Medicine at the East Carolina University, Greenville, NC, USA

² North Carolina Statewide Telepsychiatry Program (NC-STeP), Greenville, NC, USA

³ ECU Center for Telepsychiatry and e-Behavioral Health, Greenville, NC, USA

⁴ Vidant Medical Center, Greenville, North Carolina, NC, USA

Mental disorders are common [1] and they are associated with high levels of distress, morbidity, disability, and mortality. We know today that psychiatric treatments work and there is extensive evidence and agreement on effective mental health practices for persons with these disorders. Unfortunately, at a time when treatment for psychiatric illness has never been more effective, many people with these disorders do not have access to psychiatric services due to the shortage, and maldistribution of providers, especially psychiatrists. This has resulted in patients going to hospital emergency departments to seek services resulting in long lengths of stay and boarding of psychiatric patients in hospital emergency departments. A growing body of literature now suggests that the use of telepsychiatry to provide mental health care has the poten-

tial to mitigate the workforce shortage that directly affects access to care, especially in remote and underserved areas [2,3].

The North Carolina Statewide Telepsychiatry Program (NC-STeP) was developed in response to NC Session Law 2013-360. The vision of NC-STeP is to assure that if an individual experiencing an acute behavioral health crisis enters an emergency department of a hospital anywhere in the state of North Carolina, s/he receives timely, evidence-based psychiatric treatment through this program. Aside from helping address the problems associated with access to mental health care, NC-STeP is helping North Carolina face a pressing and difficult challenge in the healthcare delivery system today: the integration of science-based treatment practices into routine clinical care. East Carolina University's Center for Telepsychiatry is the home for this statewide program, which is connecting 80-85 hospital emergency departments across the state of North Carolina. The plan for NC-STeP was developed in collaboration with a workgroup of key stakeholders including representatives from Universities in NC, hospitals/healthcare systems, NC Hospital Association, NC Psychiatric Association, LME-MCOs, NC-Department of HHS, and many others. The NC General Assembly has appropriated \$4 million over two years to fund the program. The program is also partially funded by the Duke Endowment.

The program has already connected 56 of the projected 85 hospitals in the first 18 months since its inception and over 12,000 encounters have been successfully completed during this time. A web portal has been designed and implemented that combines scheduling, EMR, HIE functions, and data management systems. This presentation will provide current program data on the length of stay, dispositions, IVC status, and other parameters for all ED patients who received telepsychiatry services. NC-STeP is now positioned well to create collaborative linkages and develop innovative models for the mental health care delivery by connecting psychiatric providers with EDs and Hospitals, Community-based mental health providers, Primary Care Providers, FQHCs and Public Health Clinics, and others. NC-STeP is positioned well to build capacity by taking care of patients in community-based settings and by creating collaborative linkages across continuums of care. By doing so, the program implements evidence-based practice to make recovery possible for patients that it serves.

21st century house call home tele-behavioral medicine

H.A. Schwagar

Alaska Telemedicine Consultants, Inc., Willow, Alaska, USA

Objective This presentation will focus on and demonstrate the effective, secure, cost effective delivery of Tele-Behavioral Medicine services to patients in the privacy or their own home.

Method Today's use of internet technology brings with it "cost effectiveness" for Tele-behavioral medicine applications. Today, with a relatively current laptop computer, a web-cam or iPad, broadband connectivity (256 kB or faster), and a downloadable,

free, secure video conference application, makes this technology available literally and virtually everywhere, anywhere, in the world at any time.

Results Medical History clearly supports the value of the “house call” as a means of getting to “see the entire picture”. Chronically ill patients are frequently visited by home health nurses and or “in home” medical monitoring programs. Psychiatrically ill patients may now receive their medication management and behavioral intervention and assessment right in the privacy of their own home. Psychiatrists and psychologists merely schedule “in home” appointments with their patients in the same manner as they would if the patient were being seen in their office.

Conclusion Chronically ill patients favored treatment rendered in “their private space” as well as providers tended to learn much more about their patients when the provider is the “guest” in the patients home versus the patient as the “customer” in the providers office. The convenience and cost savings for both provider and patient is significant. Availability of spouses, parents etc. was a valuable addition to the Tele-Home-Behavioral Medicine model.

* Corresponding author.

Introduction The inter-relationships of neurocognition, social cognition, residual psychopathology and real-life functioning are poorly understood. A large multicenter study was carried out by the Italian Network for Research on Psychoses to model relationships between neurocognitive deficits, psychopathology and real-life functioning, taking into account the role of functional capacity and social cognition.

Methods A structural equation model was used to investigate direct and indirect effects of neurocognition and psychopathology on real-life functioning. Social cognition and functional capacity were modeled as mediators.

Results In 921 patients with schizophrenia, neurocognition had both direct and indirect effects, through functional capacity and social cognition, on real-life functioning. Neurocognition predicted to a large extent social cognition on which depression and disorganization had a modest effect. Social cognition showed a significant direct impact on real-life functioning.

Conclusion Our results support a strong link between neurocognition and functional outcome, independent of psychopathology. Social cognition accounted for unique incremental variance in real-life functioning.

Social cognition, functional capacity and symptoms in the longitudinal prediction of outcome in subjects with first-episode schizophrenia

M. Nordentoft^{*}, R. Wills, D. Gotfredsen

University of Copenhagen, Mental Health Center Copenhagen, Copenhagen, Denmark

* Corresponding author.

Background Several national guidelines recommend continuous use of antipsychotic medication after a psychotic episode in order to minimize the risk of relapse. However some studies have identified a subgroup of patients who can obtain remission of psychotic symptoms while not being on antipsychotic medication for a long period of time. This study investigated the long-term outcome and characteristics of patients in remission of psychotic symptoms with no use of antipsychotic medication at the 10-year follow-up.

Methods The study was a cohort study including 496 patients diagnosed with schizophrenia spectrum disorders (ICD 10: F20 and F22–29). Patients were included in the Danish OPUS Trial and followed up 10 years after inclusion, where patient data was collected on socio-demographic factors, psychopathology, level of functioning and medication.

Findings Among the patients, 30% had remission of psychotic symptoms at the time of the 10-year follow up with no current use of antipsychotic medication. This favorable outcome was associated with female gender, high GAF-F score, participation in the labor market and absence of substance abuse.

Interpretation Results from several RCTs advise against discontinuation of antipsychotic medication, but our results from the 10-year follow-up indicate that a subgroup do obtain long-term remission while not being on antipsychotic medication. Hence, guidelines on antipsychotic medication do not pay sufficient attention to patients who discontinue antipsychotic medication and are still able to obtain remission of psychotic symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

W38

The impact of the different dimensions of social cognition on functional outcome in schizophrenia

P. Rocca

Department of Neuroscience, University of Turin, Turin, Italy

Social cognition (SC) refers broadly to the domains of cognitive functions that are employed in socially relevant situations. These include three primary domains (i.e., emotion perception, Theory of Mind-TOM-, and attributional style), as well as more complex and developing concepts such as social metacognition.

Patients with schizophrenia demonstrate significant deficits across multiple dimensions of SC and throughout all phases of the illness. The correlation between SC and real-life functioning ranged from small to large, mainly depending on the examined aspect of SC, with largest effects observed for TOM. Indeed, it has been suggested that TOM difficulties may lead to social misperceptions that influence how an individual reacts to others, which in turn may lead to maladaptive social patterns and/or social withdrawal, which both may influence real-life vocational outcome more than neurocognition (NC) abilities. Moreover, SC appears to act as a mediator between nonsocial basic NC and community functioning.

The goals of this study are to analyze the pattern of SC variables in schizophrenia using cluster analysis, to examine the relationship of real-life functioning with cluster membership, and to identify cut-offs that best discriminate among clusters in a large sample of patients with schizophrenia recruited to the Italian Network for Research on Psychoses (NIRP). A full assessment of different aspects of SC was carried out, including emotional intelligence, recognition and theory of mind (TOM).

The effects of integrated treatment with atypical antipsychotics and social cognition training on functional outcome

G. Sachs^{1,*}, B. Winklbaur¹, A. Erfurth²

¹ Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

² Otto-Wagner-Spital, 6th Psychiatric Department, Vienna, Austria

* Corresponding author.

Social cognition is impaired in patients with schizophrenia [1]. This impairment is one of the core features of the illness and has a clear impact on functional outcome.

While conventional antipsychotics might have a worsening effect on social cognition, e.g. on amygdala attenuation in fMRI studies on facial recognition [2], atypical antipsychotics might not show this effect [3].

Social cognitive training [4] – such as the training of affect recognition [5] – is a promising approach in the treatment of schizophrenia.

Holistic strategies including both treatment with atypical antipsychotics and social cognitive training can improve functional outcome in patients with schizophrenia [6].

Disclosure of interest The author has not supplied his declaration of competing interest.

Suicide risk evaluation: From research to clinical practice

w40

Future direction of suicidal risk assessment

H. Blasco-Fontecilla

CIBERSAM, Autonoma University, Navacerrada, Spain

Objective to explore future directions on the assessment of the risk of suicidal behavior (SB).

Methods narrative review of current and future methods to improving the assessment of the risk of suicidal behavior (SB).

Results Predicting future SB is a long-standing goal. Currently, the identification of individuals at risk of SB is based on clinician's subjective reports. Unfortunately, most individuals at risk of SB often

do not disclose their suicidal thoughts. In the near future, predicting the risk of SB will be enhanced by: (1) introducing objective, reliable measures – i.e. biomarkers – of suicide risk; (2) selecting the most discriminant variables, and developing more accurate measures – i.e. questionnaires – and models for suicide prediction; (3) incorporating new sources of information – i.e. facebook, online monitoring; (4) applying novel methodological instruments such as data mining, or computer adaptive testing; and, (5) most importantly, combining predictors from different domains (clinical, neurobiological and cognitive).

Conclusions Given the multi-determined nature of SB, a combination of clinical, neuropsychological, biological, and neuroimaging factors, among other might help overcome current limitations in the prediction of SB. Furthermore, given the complexity of prediction of future SB, currently our efforts should be focused on the prevention of SB.

New technologies for detecting suicidal risk of psychiatric patients

J. Lopez-Castroman

CHRU de Nimes, Psychiatry, Nimes, France

Suicide is a major health issue with considerable human and economic costs. There have been many attempts to develop techniques capable of predicting future suicidal behavior, but known risk factors are insufficiently specific. However, during the last decades, technical developments have made possible the use of new technologies to assess potential clinical markers for psychiatric patients. In many cases the technologies are affordable, wearable and interconnected, multiplying the wealth of data resulting from their use. Quite logically, psychiatrists from all over the world are investing in recently developed devices for their research projects and have consequently started to collaborate with engineering and pattern recognition groups in the study of potential clinical markers. These groups provide the expertise and computational methods required to process this wealth of data, and can improve the classification accuracy to predict a certain condition using data mining techniques. In the field of suicidal behavior, new devices that capture promising predictors such as electrodermal response activity, some facial expressions or speech properties have been developed and are being tested. In view of these facts, during the workshop we will review some of the new methodologies that can be used for the assessment of suicidal risk and how can multidisciplinary and complementary approaches be implemented.

Electrodermal hyporeactivity evaluation for detecting suicidal propensity in depressed patients

L.H. Thorell

Linköping University, Linköping, Sweden

Introduction Since 1987 several publications have focused on electrodermal reactivity in groups with different suicidal behaviors, but with varying results. However, using an untraditional statistical approach with clinical application in focus revealed between themselves confirming results of a strong relationship between electrodermal hyporeactivity and suicide.

Objectives The objectives were to investigate how this research tool can be implemented for detecting suicide risk in depressed patients.

Aims The aims were to find a base for the objective test of electrodermal reactivity to be used as support in suicidal risk assessments in depressed patients.

Methods More than ten published studies on electrodermal hyporeactivity and suicide were reviewed subsequent to the application of an untraditional statistical approach. Gender, age, subdiagnoses and depressive depth were considered. All subjects were tested in a habituation experiment of the electrodermal response to a moderately strong tone stimulus.

Results The percentage of electrodermally hyporeactive depressed patients who later committed suicide was 86–97%. The percentage of electrodermally reactive patients that did not commit suicide was 96–98%. Hyporeactivity seems to be stable in at least 1–2 years in remission.

Conclusions It was considered favorable to test for hyporeactivity as early as possible, i.e. already in the primary care. That enables right treatment of right patients very early. The number of referrals to psychiatric specialists could be expected to decrease. Possible causes of hyporeactivity begin to be revealed, giving ideas of several treatment approaches.

The assessment of negative symptoms: Achievements and perspectives

W43

Self-assessment instruments: Development and validation

S. Dollfus

CHU de Caen, Department of psychiatry, Caen, France

Introduction Negative symptoms are found in many patients with schizophrenia, but their assessment remains delicate. Standardized assessments are therefore needed to facilitate their identification. Many tools have been developed but most of them are assessments based on observer rating. Nevertheless, patient subjective evaluation can provide an additional outcome measure and allow patients to be more engaged in their treatment. Therefore, the aim of this study is to present past and recent tools assessing the subjective experience of negative symptoms; we will particularly focus on a novel tool, the Self-evaluation of Negative Symptoms (SNS).

Methods Forty-nine patients with schizophrenia and schizoaffective disorders (DSMIV) were evaluated in order to demonstrate three components of the scale's validity: face and content validities and reliability.

Results Cronbach's coefficient showed good internal consistency. Factor analysis extracted 2 factors (apathy and emotional). SNS was significantly correlated with the Scale of Assessment of Negative Symptoms and the Clinician Global Impression on severity of negative symptoms supporting good convergent validity. SNS scores were not correlated with level of insight, Parkinsonism, or with BPRS positive sub-scores in favor of good discriminant validity. Intra-subject reliability of SNS revealed excellent intraclass correlation coefficients.

Conclusion This study shows good psychometric properties of SNS as well as quite satisfactory acceptance by patients. It also demonstrates the ability of patients with schizophrenia to accurately report their own experience. Self-assessments of negative

symptoms should be used more in clinical practice since they might allow patients with schizophrenia to develop appropriate coping strategies.

W44

Evolution of negative symptom assessment instruments

M.P. García-Portilla Gonzalez

University of Oviedo, Psychiatry, Oviedo, Spain

In this talk we will review the psychometric evolution of available instruments for assessing the negative syndrome of schizophrenia, describing their strengths and weaknesses.

Current instruments were classified into two categories according to their content validity and assessment approach as first- or second-generation instruments. The BPRS, SANS, the SENS and the PANSS belong to the first generation while the BNSS, the CAINS and the MAP-SR belong to the second generation. The NSA can be considered a transitional instrument between the two. First-generation instruments have more content validity problems than second-generation instruments do, as they do not accurately reflect the currently accepted negative syndrome (they do not include all negative symptoms and signs or they include symptoms from other dimensions). They also have more problems relative to the use of behavioral referents instead of internal experiences of deficits when assessing symptoms, which may lead to measuring functioning instead of negative symptoms.

Further research needs to be done in this area in order to ensure the evaluation of primary negative symptoms and internal experiences involved in negative symptoms rather than external behaviors.

Disclosure of interest The author has not supplied his declaration of competing interest.

W45

Assessment of negative symptoms beyond schizophrenia

S. Kaiser

Psychiatric Hospital, University of Zurich, Department of Psychiatry, Psychotherapy and Psychosomatics, Zurich, Switzerland

Introduction Negative symptoms have long been recognized as a hallmark of schizophrenia. Newer evidence suggests that negative symptoms can be observed in persons with other disorders or even in non-clinical populations. However, most negative symptom scales are designed to identify clinically relevant symptoms, which might lead to underappreciation of subclinical symptom expression.

Objectives The aim of the present study was to establish distributional properties of well-established negative symptom scales in comparison with the newly developed Zurich Negative Symptom Scale, which employs a fully dimensional and continuous approach.

Methods We included participants with established schizophrenia ($n = 65$), first-episode psychosis ($n = 25$), schizotypal personality traits ($n = 29$) and remitted bipolar disorder ($n = 20$). Assessment of negative symptoms was conducted with the Zurich Negative Symptom Scale and compared to established rating scales.

Results In this broad sample, measurement of negative symptoms with established negative symptom scales lead to a highly skewed distribution. In other words, established negative symptom scales were able to identify negative symptoms in some participants in the non-schizophrenia spectrum, but a differentiation of negative symptom severity in the subclinical range was not possible. In contrast, the distribution of negative symptoms measured with the Zurich Negative Symptom scale approached normality.

Conclusions Negative symptoms can be observed outside the schizophrenia diagnosis. However, in order to fully explore the continuity of negative symptoms, measurement instruments need to be designed to cover the full range of symptomatology starting at a subclinical level. We propose the newly developed Zurich Negative Symptom Scale as a useful tool in this respect.

The second-generation assessment scales: Brief negative symptom scale and clinical assessment interview for negative symptoms

A. Mucci*, S. Galderisi

University of Naples SUN, Department of Psychiatry, Naples, Italy

* Corresponding author.

The construct of negative symptoms has undergone significant changes since the introduction of first generation assessment scales, such as the Scale for the Assessment of Negative Symptoms or the Positive and Negative Syndrome Scale. Blunted affect, Avolition, Anhedonia and Avolition are largely recognized as valid domains of the negative symptoms construct.

Among the new assessment instruments, both the Brief Negative Symptom Scale (BNSS) and the Clinical Assessment Interview for Negative Symptoms (CAINS) are considered adequate in their coverage of the negative symptoms domains. They include the assessment of both behavior and internal experience for Anhedonia, Asociality and Avolition to avoid overlap with functional outcome measures, as well as consummatory and anticipatory components of anhedonia with an emphasis on the internal experience of pleasure.

Strengths and limitations of these new assessment instruments will be reviewed in the light of some existing challenges, such as the distinction between primary and secondary negative symptoms and development of innovative treatments.

The impact of societal forces on the mental health of LGBT populations across cultures

W47

LGBT adolescents in America: Depression, discrimination and suicide

A. Ahuja

Los Angeles LGBT Center, Los Angeles, USA

Introduction The mental health of Adolescents in America is a major concern for the field of psychiatry. In particular, Lesbian, Gay, Bisexual and Transgender (LGBT) adolescents are at higher risk of adverse mental health outcomes. This is largely attributed to "minority stress" and from outright bullying and discrimination. In this presentation, this link between bullying and depression will be explored.

Objectives By the end of this presentation, the audience will be able to better understand the link between anti-LGBT bullying and mental illness and identify the ways to help their patients.

Methods This presentation is informed by a literature search from PubMed In addition, it is informed by a symposium previously done at the American Psychiatric Association (APA) annual meeting in 2014.

Results There is clear evidence in the literature that bullying of LGBT adolescents is pervasive. In addition, LGBT people are more likely to be depressed than their heterosexual counterparts. This combination has led to 4-5 times higher rates of attempted suicide by LGBT adolescents. Having Gay-Straight Alliances in schools, supportive teachers and school administrators, and broader anti-discrimination legislation has a protective effect on this.

Conclusion LGBT adolescents are exposed to more stress by being a minority in society and by being explicitly bullied and discriminated against. This can lead to depression in some of these adolescents, and can also lead to suicide in the most vulnerable among them. There are proven ways to reduce these risks, and psychiatrists have a role to play in advocating for these reforms.

W48

Cultural variations in LGBT issues

D. Bhugra

World Psychiatric Association, London, United Kingdom

Culturally determined gender roles influence relationships between different-sex partners, and cultural values affect attitudes towards sexual variation. LGBT patients face stigma, discrimination and prejudice and have specific issues related to a number of factors, in addition to the nature of sexuality. These factors affect help-seeking and also cause delays in pathways to care. In specific instances, gay, lesbian and transgender individuals show higher than expected levels of psychopathology. The clinician's attitudes affect therapeutic adherence and therapeutic alliance. LGBT patients may also have specific issues related to "coming out" and this may influence their relationships directly and indirectly. Furthermore, they may experience a reluctance to share their sexual orientation. Matching of therapists may offer one way forward but this is not always possible, and may not work due to a number of reasons.

Disclosure of interest The author has not supplied his declaration of competing interest.

HIV pre-exposure prophylaxis (PrEP) and treatment as prevention (TasP): What mental health providers should know

T. Hall

University of California-Los Angeles, Center for Behavior and Addiction Medicine, Los Angeles, USA

Pharmacologic methods of treating and preventing HIV have advanced tremendously in recent years. Understandings of HIV risk and recommendations for risk-reduction strategies have also changed substantially. A majority of new cases of HIV in many developed countries are now acquired through sex with long-term partners who are unaware of their HIV-positive status, rather than from casual or anonymous sexual encounters. Persons with bipolar disorder and substance use disorders are at particularly high risk. Mental health providers who work with LGBT persons and other populations at higher risk for HIV need to understand strategies their patients are using for HIV risk reduction, and to refer appropriate patients for consideration for pre-exposure prophylaxis (PrEP). PrEP is the daily use of an antiretroviral (ARV) medication for

prevention of HIV infection in higher-risk individuals. The United States approved tenofovir + emtricitabine for PrEP in 2012; this is under review in several European countries, Canada, and Australia, and is already prescribed off-label in many. Additionally, studies have shown that treatment with ARV medications to an “undetectable viral load” greatly reduces the risk of further transmission by persons already infected with HIV, called “treatment as prevention” (TasP). As of September 2015, WHO recommends early ARV treatment for all persons with HIV, and consideration of PrEP for men who have sex with men. This paper reviews findings from the PrEP studies (especially iPrEx, iPrEx Ole, IPERGAY, and PROUD) and TasP, and looks at their impact on LGBT and HIV+ communities, with relevance for mental health providers.

The association of bullying with suicide ideation and attempt among adolescents with different dimensions of sexual orientation

R. Montoro^{1,*}, K. Igartua¹, B.D. Thombs²

¹ McGill University Health Centre, Psychiatry, Montreal, Canada

² Jewish General Hospital, Psychiatry, Montreal, Canada

* Corresponding author.

Introduction Sexual minority youth are at increased risk for bullying and suicide, but they are heterogeneous in their sexual orientation dimensions (attraction, behavior and identity).

Objective To compare the association of bullying and suicide parameters between (1) heterosexually identified students without same-sex attractions or behaviors (2) heterosexually identified students with same-sex attractions or behaviors and (3) non-heterosexually identified students.

Methods The Quebec Youth Risk Behavior Survey was a self-report questionnaire given to 1852 students 14–18 years old.

Results The heterosexually identified students without same-sex attraction or behavior, and no bullying, was our reference group. When these students had bullying, the likelihood of suicidal ideation was double, but their likelihood of suicide attempts was the same. For non-heterosexually identified students, those with no bullying were twice as likely, and those with bullying were four times as likely to have suicidal ideation. When these students had no bullying, they were not more likely to have suicide attempts, but they were almost three times as likely when they had bullying. Heterosexually identified students with same-sex attraction or behavior were never more likely on any of the suicide measures.

Conclusion This study was the first to show that adolescents with a non-heterosexual identity will have a disproportionately greater likelihood in their suicide parameters when subject to bullying, than heterosexually identified students with or without same-sex attraction or behavior, suggesting that these latter two dimensions were non-contributory to suicide risk. The significance of identity as a predictor of suicidal ideation and behavior will be discussed.

“Dual disorder with drugs”: Comparison of two French databases

A. Batisse^{1,*}, N. Taright², C. Chevallier¹, M. Marillier¹,
S. Djeddar¹

¹ Groupe hospitalier Lariboisière/Fernand-Widal/Saint-Louis,
CEIP-Addictovigilance, Paris, France

² AP-HP, Département d'information médicale, Paris, France

* Corresponding author.

Context Dual diagnosis (substance used disorders (SUD) and mental illness) represents 3% of general population. Among United States population, 42.3% of SUD patients have psychiatric troubles (without tobacco). Moreover, SUD can concern all psychoactive substances (PAS) or illicit PAS only named “dual disorder with drugs” (DDD).

Methods A quantitative analysis of DDD data from January 2013 to July 2014 of two epidemiological tools has been performed: PMSI database (Programme Médicalisé des Systeme d'Information) hospital discharge data is made up of data providing medical information for all patients discharged in Paris public hospital system (AP-HP) and NOT'S is a vigilance database of spontaneous NOTifications of drug abuse and dependence. We propose a descriptive analysis of DDD in Paris metropolitan area.

Results With PMSI, 9.2% of SUD inpatients ($n=617$) have DDD, with mean age of 46 years (62% of men). In comparison, NOT'S reports 36% of SUD with DDD ($n=302$) with mean age of 39.5 years (68% of men). Suicide attempt is also listed and reach 23% of cases.

Conclusion These two databases (Table 1) show the difficulty of DDD diagnosis with the discordance in results. DDD miss in PMSI database since addictovigilance database shows a first prevalence of DDD. Despite the high rates of DDD, the problem is often under diagnosed by clinicians practising. It is also important to promote the collaboration among health care workers (addictologist and psychiatrist) because these patients require intensive mental and substance abuse care.

Table 1

	PMSI	NOTS
Psychosis / schizophrenia	68%	13%
Depression / anxiety	21%	54%
eating disorders	6%	2%
bipolar disorder	5%	6%
ADHD	0%	1%

Autònoma de Barcelona, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Novel psychoactive substances (NPS) use is progressively increasing year on year. A new group of phenethylamines sold as legal stimulants and hallucinogens is being reported increasingly since 2012. Within this group, 25I-NBOMe is an outstanding substance with powerful effects and high affinity with the serotonin 2a (5HT2a) receptor. Several toxicity cases have been reported so far.

Objectives To describe the presence of 25I-NBOMe and its characteristics in samples delivered to Energy Control from 2009 to 2015 in Spain.

Methods Among the samples, 21,198 analyzed from august 2009 to august 2015 and only those samples containing 25I-NBOMe were studied ($n=56$). Samples were analyzed by Energy Control, a Spanish harm-reduction NGO that offers users the possibility of analyzing the substances they intend to consume. Analysis was done by Gas Chromatography–Mass Spectrometry.

Results From 56 samples were 25I-NBOMe was found, 24 were bought as LSD (42.8%), 12 as 25I-NBOMe (21.4%), 4 as 25C-NBOMe (7.1%), 4 as 25I-NBOH (7.1%) and 12 as other substances (21.4%), gummy bears included. All samples were received from 2012 on, having the highest peak on 2013 (19 samples).

Conclusions 25I-NBOMe consumption represents an emerging issue with potential harmful effects, especially when the substance used is not the expected. Further pharmacokinetic, pharmacodynamic, clinical and epidemiological researches should be conducted to deepen knowledge about 25I-NBOMe and the management of its possible toxic effects. Physicians should be aware of NPS, their increasing use and the clinical differences between them.

* Corresponding author.

Introduction The use of psychoactive substances is quite widespread among general population. Data on the prevalence of drug use among pregnant women are not available for most European countries.

Aims To assess the prevalence of substance use during pregnancy and associated risk factors with regard to sociodemographic and obstetric variables, coping strategies, and personality traits.

Methods Design: a population-based, prospective, multicentre study. Setting: seven teaching hospitals in Spain. Participants: 1804 women were recruited on day 2–3 postpartum. Measurements: All participants completed a semi-structured interview, including sociodemographic, reproductive and obstetric variables, personal and family psychiatric disorders and self-reported drug use during pregnancy. The STAI, EPQ-R, COPE-28 and the DUKE-UNC questionnaires were administered to assess personality traits, coping skills and social support.

Results Fifty percent reported substance use during pregnancy. Of the 909 who did so, 52.5% used caffeine only, 14.7% tobacco only, 0.8% alcohol only, 24% caffeine and tobacco, 3.6% caffeine and alcohol, and 2.5% caffeine, tobacco and alcohol, and 1.9% others. Lower education (OR=1.32, 95% CI=1.00–1.73), sick leave (OR=1.74, 95% CI=1.15–2.63) and personal psychiatry history (OR=1.36, 95% CI=1.04–1.78) were independent factors associated with substance use during pregnancy. Primiparity was a protective factor (OR=−0.71, 95% CI=0.59–0.87), and psychoticism (OR=1.02,

95% CI=1.00–1.03), extraversion (OR=1.01, 95% CI=1.00–1.02) personality traits and the use of substances to cope with emotions (OR=2.49, 95% CI=1.38–4.49) were identified as risk factors.

Conclusions In our non-clinical sample, one out of every two women reported substance use during pregnancy. Substance use during pregnancy was associated with sociodemographic characteristics, history of psychiatric disorder, health problems and specific pattern of personality traits and coping strategies.

Maternal smoking during pregnancy and offspring's psychiatric morbidity in early adulthood. Findings from the Finnish Family Competence Birth Cohort Study

S. Niemelä^{1,*}, S. Mikola², A. Sourander³, P. Rautava², M. Sillanpää²

¹ University of Oulu, Department of Clinical Neurosciences, Oulu, Finland

² University of Turku, Department of Public Health, Turku, Finland

³ University of Turku, Department of Child Psychiatry, Turku, Finland

* Corresponding author.

Introduction Prenatal smoking exposure is one of the most common insults during the fetal period prevalence varying from 5 to 19% in the European countries [1].

Objectives Prenatal smoking exposure increases the risk of psychiatric morbidity in the offspring, externalizing disorders in particular. However, less is known whether maternal smoking during pregnancy increases the risk for anxiety disorders [1].

Aims To study the associations between maternal smoking during pregnancy and offspring psychiatric morbidity in early adulthood in a Finnish birth cohort study.

Methods A prospective data collection from 10th gestational week (GW10) to early adulthood ($n=475$, 37% from the original sample). Information on self-reported smoking during pregnancy was collected using questionnaires at GW10 and GW28. Offspring psychiatric diagnoses and clinically relevant symptoms were assessed using Development and Well-being Assessment (DAWBA)-interviews at age 18 to 20 years. Information on parental alcohol use, depressive mood, anxiety, and education level, as well as offspring's gender, education level, and birth weight were used as covariates.

Results Maternal smoking during pregnancy associated independently with PTSD (OR=6.9, 95% CI 1.3–35.6, $P=0.021$), and conduct disorder (OR=2.7, 95% CI 1.02–6.9, $P=0.046$) in a multivariate analysis after adjusting for other psychiatric diagnoses, offspring and parental variables (OR=1.9, 95% CI 0.5–6.9, $P=0.359$).

Conclusions In addition to conduct problems, prenatal nicotine exposure may increase the offspring's risk for posttraumatic stress disorder (PTSD). This relationship may be explained, in part, by effects on nicotinic acetylcholine receptors and uteroplacental mechanisms [1].

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Regeneration processes are the new target in looking for biological markers of psychiatric disorders.

Aims In this study, we considered the role of stem cells and factors responsible for their trafficking in panic disorder (PD).

Methods A group of 30 patients with panic disorder was examined and compared with a group of 30 healthy volunteers. In peripheral blood we have analysed: the number of hematopoietic stem cells – HSC (Lin–/CD45+/CD34+) and HSC (Lin–/CD45+/AC133+), the number of very small embryonic – like stem cells – VSEL (Lin–/CD45–/CD34+) and VSEL (Lin–/CD45–/CD133+) and concentration of stromal derived factor-1 (SDF-1), sphingosine-1-phosphate (S1P), and some proteins of the complement cascade.

Results Peripheral blood concentration of HSCs (Lin–/CD45+/AC133+) was significantly lower in PD group compared to control group, before and after antidepressant treatment. Peripheral blood concentration of VSEL (Lin–/CD45–/CD133+) was significantly lower in PD group before treatment compared to concentration after treatment. In PD group concentrations of factors involved in stem cell trafficking were statistically significantly lower in PD group (before and after treatment) compared to control group.

Conclusion Examination of regeneration system seems to be useful in PD diagnostics.

Multimorbidity in affective disorders: Impact on length of stay

F. Cealicu Toma^{*}, J. Moammi
University of Ottawa, Psychiatry, Gatineau, Canada

* Corresponding author.

Background Multimorbidity (MM) refers to the coexistence of two or more chronic diseases in the same individual; it encompasses medical comorbidity (MC) and psychiatric comorbidity (PC).

Hypothesis: MM is prevalent amongst in-patients suffering from affective disorders (AD) and also impacted on length of stay.

Aims To determine the prevalence of MM and its impact on duration of hospitalization in AD admissions.

Method This cross-sectional study was conducted using secondary data taken from discharge records of 1056 adults admitted for AD to a Quebec-based facility, between 2006 and 2014. Distribution of AD cases: 47% depression, 53% bipolar disorders.

Results The prevalence rate of MM: 85%. PC was present in 70% of sample whereas MC was present in 62%. The median number of comorbid illnesses was 2.7 for each study subject. The rate of MM was not related to age or gender. Metabolic syndrome (54%), cardiovascular diseases and chronic pain syndrome (17%) were the most prevalent MC in both depressed and bipolar populations. Personality disorder (65%) was highest in the depression population, whereas substance misuse (55%) was the most prevalent PC in the bipolar subjects. A longer length of stay was correlated with MM. However, a logistic regression analysis indicated that duration of hospitalization was only correlated with MC.

Conclusions The observation that MM is the norm, even in this relatively young population with AD. The results confirmed that MC prolongs hospital stay. These findings advocate strongly for integrated management of psychiatric and physical health problems in clinical practice.

⁴ Children's Hospital of San Antonio - Texas, Department of Pediatrics, San Antonio, USA

* Corresponding author.

Objectives Bipolar I (B-I) is an important cause of morbidity and mortality in hospitalized patients. While B-I has been extensively studied in the past, the contemporary data for impact of B-I on cost of hospitalization are largely lacking.

Methods We queried the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (HCUP-NIS) dataset between 1998–2011 using the ICD-9 codes. Severity of comorbid conditions was defined by Deyo modification of Charlson comorbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, Chi² test, *t*-test and Cochran-Armitage test were used to test significance.

Results A total of 1,80,681 were analyzed; 56.29% were female and 43.71% were male ($P < 0.0001$); 70.63% were white, 17.14% black and 12.23% of other race ($P < 0.0001$). Rate of hospitalization increased from 7469.65/million to 9375.27/million from 1998–2011. Overall mortality was 0.12% and mean cost of hospitalization was 19,821.50\$. The in-hospital mortality increased from 0.13% to 0.16% ($P < 0.0001$) and mean cost of hospitalization increased from 12,091.31\$ to 29,292.97\$. Total yearly spending on B-I related admissions increased from \$0.72 million/year to \$2.16 billion/year.

Conclusions While mortality has slightly increased from 1998 to 2011, the cost has significantly increased from \$0.72 million/year to \$2.16 billion/year, which leads to an estimated \$1.46 billion/year additional burden to US health care system. In the era of cost conscious care, preventing B-I related Hospitalization could save

billions of dollars every year. Focused efforts are needed to establish preventive measures for B-I related hospitalization.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Black Dog Institute, Research Unit, Sydney, Australia

⁶ Aarhus University Hospital, Risskov, Aarhus, Denmark

* Corresponding author.

Introduction Bipolar disorder varies with season: admissions for depression peak in winter and mania peak in summer. Sunlight presumably increases the risk of mania through suppression of melatonin. If so, we expect admissions for mania to vary in accordance with climate variations.

Objectives To investigate how climate and climate changes affects admissions for mania.

Aims To identify which climate variables – sunshine, ultraviolet radiation, rain and snow cover – affect admissions for mania.

To examine whether year-to-year weather variation as well as long-term climate changes reflects the variation in number of admissions for mania.

Methods This register-based nationwide cohort study covers all patients admitted for mania (ICD-10 code F31 or F30.0–F30.2) between 1995 and 2012 in Denmark. Climate data, obtained from the Danish Meteorological Institute, were merged with admission data and correlated using an Unobserved Component Model regression model.

Preliminary results In total, 8893 patients were admitted 24,313 times between 1995 and 2012: 6573 first-admissions and 17,740 readmissions. Linear regression shows significant association between admissions per day and hours of sunshine ($P < 0.01$) and ultraviolet radiation (UV) dose ($P < 0.01$). Average days with snow cover and rain were not significantly correlated with admissions. Analyses on year-to-year variation and long-term change are not yet available.

Preliminary conclusions Admissions for mania are correlated with sunshine and UV, but not rain and snow cover. If more patients are admitted during very sunny summers compared with less sunny summers this implies a relation with light itself and not just season.

Delays to diagnosis and treatment in patients presenting to mental health services with bipolar disorder

R. Patel^{1,*}, H. Shetty², R. Jackson³, M. Broadbent², R. Stewart³, J. Boydell¹, P. McGuire¹, M. Taylor¹

¹ Institute of Psychiatry, Psychology and Neuroscience, Department of Psychosis Studies, London, United Kingdom

² South London and Maudsley NHS Foundation Trust, Biomedical Research Centre Nucleus, London, United Kingdom

³ Institute of Psychiatry, Psychology and Neuroscience, Department of Psychological Medicine, London, United Kingdom

* Corresponding author.

Introduction There are often substantial delays before diagnosis and initiation of treatment in people bipolar disorder. Increased delays are a source of considerable morbidity among affected individuals.

Aims To investigate the factors associated with delays to diagnosis and treatment in people with bipolar disorder.

Methods Retrospective cohort study using electronic health record data from the South London and Maudsley NHS Foundation Trust (SLaM) from 1364 adults diagnosed with bipolar disorder. The following predictor variables were analysed in a multivariable Cox regression analysis on diagnostic delay and treatment delay from first presentation to SLaM: age, gender, ethnicity, compulsory admission to hospital under the UK Mental Health Act, marital status and other diagnoses prior to bipolar disorder.

Results The median diagnostic delay was 62 days (interquartile range: 17–243) and median treatment delay was 31 days (4–122). Compulsory hospital admission was associated with a significant reduction in both diagnostic delay (hazard ratio 2.58, 95% CI 2.18–3.06) and treatment delay (4.40, 3.63–5.62). Prior diagnoses of other psychiatric disorders were associated with increased diagnostic delay, particularly alcohol (0.48, 0.33–0.41) and substance misuse disorders (0.44, 0.31–0.61). Prior diagnosis of schizophrenia and psychotic depression were associated with reduced treatment delay.

Conclusions Some individuals experience a significant delay in diagnosis and treatment of bipolar disorder, particularly those with alcohol/substance misuse disorders. These findings highlight a need to better identify the symptoms of bipolar disorder and offer appropriate treatment sooner in order to facilitate improved clinical outcomes. This may include the development of specialist early intervention services.

³ University of Bari "A. Moro", Department of Basic Medical Sciences, Neurosciences and Sense Organs, Bari, Italy

* Corresponding author.

Introduction Bipolar disorders (BD) are chronic and recurrent psychopathological conditions characterized by therapeutic failures (TFs), regardless of the initial choice of psychiatric medication with a high prevalence of adverse drug reactions (ADRs). Cytochrome P450(CYP)2D6 genetics has been recently suggested to have a role in the response to treatment and extra-pyramidal symptoms (EPS) across several psychiatric conditions.

Objectives To evaluate interindividual differences in CYP2D6 enzyme activities, TFs and ADRs rates in BDs patients.

Aims To tailor psychiatric medication choice and dose based on pharmacogenetic test.

Methods We analyzed 16 clinical relevant polymorphisms CYP2D6 genotype in Psychiatric Unit of Foggia using the Infini-tiM Analyzer; the Simpson Angus Scale (SAS) was used to measure drug-induced EPS and Brief Psychiatric Rating Scale-24 (BPRS-24) response to treatment.

Results Ten drug-resistant patients were consecutively enrolled, and six of these experience major ADR during therapy with worsening of symptoms before screening for CYP polymorphism: BM (*2A/*5 genotype, BPRS-24 T₀: 63, T₁₄: 51), SR (*2A/*4, BPRS-24 T₀: 66, T₁₄: 59), LT (*4/*17 BPRS-24 T₀: 72, T₁₄: 64), DC (*2A/*4A BPRS-24 T₀: 69, T₁₄: 54), AL (*2A/*2A, BPRS-24 T₀: 72, T₁₄: 64), PA (*2A/*2A BPRS-24 T₀: 52, T₁₄: 46).

Conclusions According to the specific CYP2D6 polymorphism, we personalized patients' treatment considering that poor and extensive metabolizers have different rates of ADR and responses to treatment. CYP2D6 genotype's knowledge is useful for the reduction of therapeutic attempt during patient clinical history, thus reducing admission time and costs, and to guide clinicians toward a better patient management.

⁷ Icahn School of Medicine at Mount Sinai, Department of Psychiatry, New York, USA

* Corresponding author.

Introduction Guanfacine extended release (GXR) is a non-stimulant treatment for attention-deficit/hyperactivity disorder (ADHD).

Objective To separate efficacy and sedative treatment-emergent adverse events (TEAEs) associated with GXR in four randomized, controlled trials in children (6–12 years) and adolescents (13–17 years) with ADHD.

Methods SPD503-301 ($n = 345$) and SPD503-304 ($n = 324$) were 8 and 9 week studies of fixed-dose GXR (≤ 4 mg/day). SPD503-312 ($n = 314$; adolescents only) and SPD503-316 ($n = 338$) were 10–13 week studies of dose-optimized GXR (1–7 mg/day).

Results In fixed-dose studies, pooled incidences of sedative TEAEs with GXR were highest at week 1 (GXR, 13.9–18.7%; placebo, 8.7%) and decreased to placebo levels at week 8 (0–1.4%; placebo, 0%). In contrast, proportions of responders ($\geq 30\%$ reduction from baseline in ADHD Rating Scale IV [ADHD-RS-IV] total score) increased from week 1 (GXR, 29.6–34.8%; placebo, 25.0%) through endpoint (GXR, 66.7–72.2%; placebo, 42.6%). Incidences of sedative

TEAEs, but not proportions of responders, increased with GXR dosing. GXR was associated with a statistically significant reduction in ADHD-RS-IV total score from baseline to endpoint in patients without sedative TEAEs in both fixed-dose and dose-optimized studies (GXR versus placebo, effect size = 0.49 and 0.67, respectively; $P < 0.001$). GXR was associated with statistically significant improvements compared with placebo in both ADHD-RS-IV Hyperactivity/Impulsivity and Inattentiveness subscale scores ($P < 0.001$).

Conclusion These data from pooled GXR clinical trials indicate that incident sedative TEAEs do not contribute to increased treatment response over time, and that sedation and symptomatic improvement are distinct effects of GXR.

* Corresponding author.

Objective To evaluate the effect of comorbid psychiatric disorders (PD) on the association between childhood ADHD and suicidality and the effect of gender on the association between PDs and suicidality among adults with childhood ADHD.

Method Subjects were recruited from a birth cohort of all children born 1976–1982 remaining in Rochester, MN after five years of age. Participating subjects with research-identified childhood ADHD ($n = 232$; mean age 27.0 years; 72% men) and non-ADHD controls ($n = 335$; mean age 28.6 years; 63% men) were administered a structured psychiatric interview (MINI International Neuropsychiatric Interview) to assess suicidality and psychiatric comorbidities.

Results Compared to controls, ADHD cases were significantly more likely to meet criteria for suicidality [odds ratio (OR) = 2.7, 95% CI 1.7–4.5]. Although this association was not moderated by the presence of PDs ($P = 0.63$ for interaction effect), the association between ADHD and suicidality was partially mediated by the presence of PDs [OR decreased from 2.7 to 2.1 (95% CI 1.2–3.5)]. Among adults with childhood ADHD, there was no significant moderating effect of gender on the association between suicidality and PD ($P = 0.26$ for interaction effect). However, the odds of suicidality was 6.1 (95% CI, 2.3–15.9) times higher among males with both externalizing and internalizing PDs compared to males with no disorders; among females the corresponding odds ratio was 3.4 (95% CI, 0.7–16.6).

Conclusion Childhood ADHD is significantly associated with adult suicidal risk. Among those with ADHD, associations between suicidality and comorbid psychiatric disorders are more apparent in men among those with comorbid externalizing and internalizing disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A novel protocol to assess dual task cost as a potential measure of cognitive reserve

A. Oliveira-Maia^{1,*}, I. Coelho¹, J.B. Barahona-Corrêa¹, V. Paixão², M. Camacho¹, R.M. Costa²

¹ Champalimaud Clinical Centre, Champalimaud Centre for the Unknown, Neuropsychiatry Unit, Lisbon, Portugal

* Corresponding author.

Introduction Methods for measuring cognitive reserve (CR) are limited and controversial. Dual task cost (DTC) paradigms, assessing links between gait and cognition, are increasingly regarded as robust measures of CR.

Objectives Here, we aimed to validate a simplified methodology for a DTC paradigm in healthy volunteers for application in clinical settings as a measurement of CR.

Methods We tested if subtracting by 7's (cognitive task) while walking (motor task) induced a DTC in a sample of 39 healthy young adults. For the cognitive task, we recorded the number of correct and incorrect subtractions, as well as the latency between subtractions. Gait parameters were recorded on a tri-axial accelerometer fixed to the left ankle. Both tasks were performed separately (single task) and simultaneously (double task) to assess the DTC. A battery for neuropsychological assessment and questionnaires to assess quality of life and affective symptoms were also applied, to measure possible correlations with the DTC.

Results Subtracting 7's while walking caused significant changes in gait parameters and in cognitive task performance. A significant decrease in the autocorrelation of the accelerometer signal during the dual task was also found (DTC = 37.92 ± 7.56%; $P < 0.0001$). This measure has not been previously used and may be a more sensitive measure of the dual task induced disturbance of the gait periodic signal pattern. Correlations between DTC and quality of life, affective or cognitive measures were not significant.

Conclusion Our study provides an effective, portable and non-intrusive DTC experimental protocol that can be easily applied in clinical settings.

Cortisol, life events and cognition in non-demented subjects: A population-based study

S. Ouanes*, E. Castelao, A. Von Gunten, M. Preisig, J. Popp CHUV, Department of Psychiatry, Lausanne, Switzerland

* Corresponding author.

Background Older people are particularly exposed to stressful events, known to activate the hypothalamus-pituitary-adrenal axis. Many studies highlighted the possible deleterious effects of elevated cortisol on cognition, assuming a likely role of stressful events. Yet, very few studies actually examined these assumed links between life events, cortisol and cognition.

Objective To examine associations between salivary cortisol, cognition and life events in a population of non-demented old individuals.

Methods A cross-sectional analysis was conducted using data from Colaas/PsyColaas, a longitudinal population-based study involving 6733 Lausanne residents. Salivary cortisol samples (upon

waking, 30 minutes after waking, at 11 am and at 8 pm) were obtained from 799 non-demented participants aged at least 60.

Life events, activities of daily life along with depressive symptoms were assessed using a standardized questionnaire. A comprehensive neuropsychological test battery was used to determine the Clinical Dementia Rating (CDR).

For multiple comparisons, P values were adjusted (P') according to Holm-Bonferroni's method.

Results Cortisol at 11 am and cortisol area under the curve (AUC) were positively correlated with CDR sum of boxes (CDRSOB) scores ($P' = 0.035$; $Rho = 0.097$ and $P' = 0.024$; $Rho = 0.110$, respectively). The association between cortisol AUC and CDRSOB remained significant after controlling for age, sex, body mass index, education, smoking and depression ($P = 0.001$; $\beta = 0.001$; R^2 change = 0.016). The number and the total impact of life events were associated neither with cortisol nor with CDRSOB.

Conclusions Elevated cortisol was associated with poorer cognitive functioning yet independently of life events. This suggests that the increased cortisol associated with poorer cognition might be not a mere reflection of stressful events but rather explained by other factors, yet to be elucidated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

The relation of social cognitive disorders and schizophrenic symptoms are well-established. Yet, assessment methods have not reached a consensus. In addition, causal paths between neurocognition, social cognition, symptoms and functional expression are not clearly understood. During the past few years, some authoritative accounts proposed specialized batteries of tests and emphasized theory of mind, emotion recognition, and interpretation bias constructs:

– NIMH's "Social cognition psychometric evaluation" battery (Pinkham AE, Penn DL, Green MF, Harvey PD. *Schizophrenia Bulletin*, 2015);

– "Social cognition and functioning in schizophrenia" (Green MF, Lee J, Ochsner KN. *Schizophrenia Bulletin*, 2013).

Interestingly, these accounts stemming either from expert consensus and psychometric considerations or from neuroscience knowledge recognized some difficulties in providing a fully usable set of instruments. The project described here (EVACO protocol, funded by the Programme Hospitalier de Recherche Clinique national) follows an alternative approach and aims at providing a psychometrically validated battery. Based on a cognitive neuropsychology view on schizophrenic functional disability, several tests were gathered and are assessed in a 12-months multi-center follow-up of 160 individuals with schizophrenia. The FondaMental foundation network of Expert Centers is involved in recruiting patients from eight centers (Clermont-Ferrand, Colombes, Créteil, Grenoble, Marseille, Montpellier, Strasbourg, Versailles). To-date, the first evaluation of the population has been achieved. Experience reports and inclusions follow-up demonstrate the good acceptability of this battery both on the patients and the evaluator's side. We emphasize the usefulness of this project to meet the clinicians' needs of validated social cognition tools, by describing different scenarios of use.

* Corresponding author.

Introduction Premorbid adjustment (PA) is one of the main prognostic indicators of schizophrenia. Both social and cognitive deficits observed during the premorbid period hold a predictive value for the onset of schizophrenia.

Objectives To investigate how cognitive functions are related to aspects of PA.

Aims To examine the relationship of each PA domain (academic and social) at each of the three developmental stages (childhood, early adolescence and late adolescence), as well as their course with the cognitive functions in schizophrenia patients.

Methods PA, intellectual quotient (IQ), verbal learning, memory, processing speed, executive functions and verbal fluency were assessed using PAS, WAIS, RAVLT, TMT, WCST and COWAT measures respectively in a sample of 85 clinically stabilized male schizophrenia inpatients.

Results Negative correlations emerged between academic PA during adolescence and both verbal IQ and processing speed, while

positive correlations were found with working memory. Negative correlations emerged between deterioration in academic PA during adolescence and both processing speed and immediate auditory verbal recall, while correlations with verbal learning were positive. There was no relationship between cognitive functions and either social PA or its deterioration.

Conclusion Our findings revealed significant associations between both academic PA and its course with cognitive functions in schizophrenia patients. In summary, deficits in several fields of cognitive functions seem to follow a different path long before and after the onset of the disease, but further investigation is necessary.

² Policlinico Hospital, Endoscopy Unit, Modena, Italy

* Corresponding author.

Introduction Pro-inflammatory states of the large bowel have a multifactorial aetiology, including metabolism, atherogenesis, and psychological determinants. Inflammation plays a role in depressive and anxiety disorders, is tightly associated with early pro-atherogenetic alterations and metabolic dysregulation, and is also a key factor for the development of colorectal cancer.

Aim To investigate the association between pro-atherogenetic factors, metabolic status, psychological assessment and presence of colorectal adenomas.

Methods Case-control study, approved by the local Ethic Committee. Patients aged 40 or more and undergoing colonoscopy for positive faecal blood test and/or abdominal symptoms, with a negative history for neoplasia or inflammatory bowel diseases, were enrolled. For each patient the following data were collected: waist and hip circumferences, BMI, arterial pressure, fasten serum glycemia, current medications. Beside colonoscopy, carotid intima-media thickness (IMT) was assessed by means of echographic evaluation. Psychometric assessment included HADS, TCI, IMSA, SF-36. Statistics performed with SigmaPlot v.12 Platform.

Results Preliminary results are available for 18 patients (male/female 8/10) Mean age 62.6 ± 8.4. Ten patients had at least one adenoma, 8 patients had no lesions. The following differences were noticeable: HADS-depression (mean ± SD) adenoma vs. no-adenoma: 4.9 ± 3.2 vs. 1.7 ± 1.8 ($P < .01$); IMT median value adenoma vs. no-adenoma: 793 vs. 638 micrometers ($P = .04$); Body weight (mean ± SD) adenoma vs. no-adenoma: 66.4 ± 8.7 kg vs. 80.9 ± 15.3 kg ($P = .03$); waist circumference (mean ± SD) adenoma vs. no-adenoma: 105.2 ± 13.4 cm vs. 89.5 ± 4.7 cm ($P < .01$).

Conclusions Preliminary data from PNEI-MO Research Group support the relation between systemic inflammation, psychological status and development of precancerous colorectal cancer lesions. Depression seems associated with the presence of colorectal adenomas.

Epigenetic signature of glucocorticoid receptor is associated with the familial component of depression: A twin-based study

H. Palma-Gudiel, A. Cordova-Palomera, L. Marquès Feixa, F. Cirera Miquel, L. Fañanás*

University of Barcelona, Animal Biology, Barcelona, Spain

* Corresponding author.

Introduction Despite the fact that depression has an estimated heritability around 40%, there is no definitive candidate gene contributing to its etiology. The lack of an identified genetic component for high-heritability disorders, like depression, gave rise to the concept of missing heritability. The epigenetics' field has pushed forward new hypotheses to fill this gap since transgenerational inheritance of epigenetic patterns has been described both in animal models and, more recently, in humans. Depression is usually associated with an abnormal stress response and an altered hypothalamic-pituitary-adrenal axis, regulated by the glucocorticoid receptor (coded by *NR3C1* gene). Therefore, *NR3C1* has been widely investigated as a functional candidate gene involved in anxious-depressive spectrum disorders (ADSD) although a more comprehensive study of its methylation is further required (Palma-Gudiel et al., 2015).

Aims To analyze *NR3C1* promoter's methylation and to study its association with anxious-depressive spectrum disorders.

Methods The sample consisted of 48 pairs of monozygotic twins, from the UB twin register, grouped as concordant, discordant and healthy pairs depending on whether both, one or none of the co-twins of each pair were affected by a lifetime ADSD, according to DSM-IV criteria (SCID). DNA methylation was assessed by bisulfite conversion and subsequent pyrosequencing.

Results Hypermethylation at specific CpG sites, not previously reported, was detected in concordant twin pairs as compared with discordant and healthy groups ($P=0.03$).

Conclusions The epigenetic pattern newly described in *NR3C1* gene may be contributing to the familial component of depression and thus could be putatively explained by transgenerational inheritance of epigenetic phenomena.

Pilot Project: Sound pillow treatment to improve sleep quality for patients with depression or bipolar diagnosis with sleeping problems

H.N. Lund*, I.N. Pedersen

Aalborg Psychiatric Hospital, Klinik Syd, Aalborg, Denmark

* Corresponding author.

A well-known symptom for patients with depression and bipolar diagnosis is poor quality of sleep. This has a major impact on the quality of life for the individual. Most recently, an article in the *Cochrane Review*, Music for insomnia in adults, concludes that music may be effective for improving sleep quality in adults with insomnia symptoms [1].

A Research Project at Aalborg University Hospital, Psychiatry, in Denmark has been initiated involving psychiatrists and nurses from an outpatient unit and researchers and music therapists from the Music Therapy Research Clinic at the hospital in an innovative collaboration. A pilot project is started, where patients with depression are given a sound pillow with special designed playlists, offering selected calm music for the patients to use at home for a period of 30 days. The listening periods are registered by the patients. Questionnaires are filled out before and after the listening period. A short semi-structured interview is taking place four times throughout the listening period and as a follow-up, when patients come in for control.

The aim is to investigate, whether music listening is helpful to improve sleep quality and quality of life, and to investigate if music listening can limit or replace medication. Discussion of first results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Clinic for Psychiatry, Clinical Centre of Serbia, Clinic for Psychiatry, Clinical Centre of Serbia, Belgrade, Serbia

* Corresponding author.

Introduction Treatment with pegylated interferon alpha (PEG-IFN- α) is associated with depression more frequently in chronic hepatitis C (CHC) patients than with other inflammatory diseases.

Objectives To prospectively assess sex differences in the prevalence of depression in CHC patients during the PEG-IFN- α , as well as in the CHC group with no therapy.

Methods Sample consisted of 103 subjects with CHC on the PEG-IFN- α and 103 subjects with CHC without interferon therapy. The diagnosis of depressive disorder was established by using Structured Clinical Interview and Criteria of International Classification Disorder. The severity of depression was assessed by using Hamilton Depression Rating Scale (HAMD ≥ 8) prior to PEG-IFN- α (baseline) and at the follow-up visits (4th, 12th, 24th, 48th, 72nd week).

Results During the course of PEG-IFN- α , 49.5% of subjects showed depressive symptomatology (HAMD ≥ 8). Except at baseline and in the 72nd week, on the all other follow-up visits the prevalence of depression was significantly higher in female subjects (*all $P_s < 0.05$). The strongest difference was observed in the 12th week: of all the subjects with HAMD ≥ 8 , 68.8% were female and

32.7% were male ($P < 0.001$). The multivariate logistic regression model showed that female sex is a very strong predictor for the development of depression during the interferon treatment [Exp (B) = 6.729]. There were no significant sex differences in the prevalence of depression in the control group.

Conclusions Our study (the longest study in this area) indicate that the prevalence of depression is significantly higher in female subjects with CHC during antiviral treatment.

Depression as an interdisciplinary problem

A. Vasileva^{1,*}, N. Neznanov (Director)²

¹ Bekhterev Psychoneurological Institute, Medical Faculty of St. Petersburg University, neurosis and psychotherapy, Saint-Petersburg, Russia

² Bekhterev Psychoneurological Institute, Medical Faculty of St. Petersburg University, Saint-Petersburg, Russia

* Corresponding author.

Traditionally depression was defined as a mental illness. Acknowledgment of biopsychosocial model in modern medicine brought about a number of interdisciplinary studies. In the meantime, a number of correlations in the onset, cause and prognosis between depression and other somatic as well as mental illnesses were discovered. The research results showed that from one hand, depression could be an independent factor of the possible development of heart infarct, on the other hand it can influence the recovery process in cardiological patients. The conducted studies established some common pathways in depression and vascular diseases development. Psychoneuroimmunological research gives the data about the influence of anxiety and depression on the interleukine profile that could be a matter of further investigation of the possible links between depression and cancer diseases. The other dimension is the addiction impact on depression onset. The interrelationship between epilepsy as organic brain disease and depression is also worth of attentional. Hypercortisolemia and low-grade inflammation plays an important role both in depression and dementia. There is also a strong correlation between personality traits and depression itself and as response to unfavorable circumstances and somatic illness as well. We propose to apply to depression the principles of pathological stable circuits with the self-sustained reverberation engram chains mechanisms. All these data calls for consideration of depression as an interdisciplinary phenomena.

³ AOU Cagliari, Unità Operativa di Diabetologia, Monserrato, Italy

* Corresponding author.

Adherence to self-management and medication regimens is required to achieve blood glucose control in diabetic patients. Therefore, diabulimia, the deliberate insulin restriction/omission to lose weight, and other disordered eating behaviors (DEBs) or eating disorders (EDs), place these patients at risk of complications.

We aimed to establish the frequency of diabulimia, DEBs and EDs among patients with type 1 and 2 diabetes (T1DM and T2DM) and their association with other clinical features.

A total of 211 insulin-treated diabetic patients (13–55 years old) answered the Diabetes Eating Problem Survey-Revised (DEPS-R), a diabetes-specific screening tool for DEBs, and the Eating Disorders Inventory-3 (EDI-3). SCID-I modified according to DSM-5 criteria was used to diagnose EDs.

At the DEPS-R, 20.8% of the sample scored above the cutoff, more frequently females ($P = 0.005$), patients with T1DM ($P = 0.045$), with a diagnosis of ED ($P < 0.001$), positive to the EDI-3 ($P \leq 0.001$), with physical comorbidities ($P = 0.003$), with HbA1c $> 7\%$ ($P = 0.020$). Combining data from the interview with the results at the DEPS-R, 60.2% of the sample presented diabulimia. Dividing the sample by gender, we found that diabulimic females more frequently used diet pills ($P = 0.006$), had significantly higher HbA1c ($P = 0.019$) and STAI-Y1 scores ($P = 0.004$). Other DEBs comprised dietary restraint (51.8% of the sample), binge eating (42.2%), vomiting (6.2%), diet pills (7.1%) or laxatives (1.9%) or diuretics use (4.3%). Overall, 21.8% of the sample, mostly females ($P < 0.001$) met criteria for at least one DSM-5 diagnosis of ED.

Diabetic patients, especially women, should be carefully monitored for the presence of diabulimia, BEDs and EDs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gender and age differences in eating and drinking risk behaviors in Italian high school students

V. Deiana^{*}, L. Sanna, P. Milia, F. Pinna, L. Puddu, F. Fatteri, S. Lostia di Santa Sofia, A. Ghiani, A. Lai, F. Medda, M.G. Atzeni, D. Manca, C. Arzedi, B. Carpiniello

University of Cagliari, Clinica Psichiatrica, Cagliari, Italy

* Corresponding author.

Drunkorexia, limiting food intake before alcohol consumption, increases teenagers and young adults' risk for negative alcohol-related health consequences.

The purpose of the present study is to explore gender and age differences regarding weight management behaviors and alcohol consumption among 3004 students aged 13 to 24 years.

The following questionnaires were administered: Eating Disorder Inventory-3 (EDI-3), Alcohol Use Disorders Identification Test (AUDIT) and Compensatory Eating and Behaviors in Response to Alcohol Consumption Scale (CEBRACS).

EDI-3 showed that 11.3% of the sample met the threshold on the "Drive for Thinness" (DT) scale, 28.9% on the "Bulimia" (B) scale, 17.2% on the "Body Dissatisfaction" (BD) scale. Females presented a higher risk at DT, B and BD scales ($P < 0.001$), and the risk of bulimia was higher in those aged ≤ 16 years ($P = 0.028$). AUDIT revealed a greater clinical risk of alcohol-related problems in males ($P < 0.001$) and in those aged > 16 years ($P < 0.001$). Drunkorexia was found in 44% of the sample, without significant difference in relation to gender and age.

Girls and younger students have more weight concerns, while boys and older students are at greater risk of alcohol use disorders. Therefore, no specific group should be considered risk-free with respect to drunkorexia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The prevalence and correlates of haematological abnormalities in adult inpatients with anorexia nervosa

C. Hopkins^{1,*}, A. Bruno², P. Jenkins², A. Ayton²

¹ Berkshire Healthcare NHS Foundation Trust, Prospect Park Hospital, Reading, United Kingdom

² Oxford Healthcare NHS Foundation Trust, Cotswold House, Oxford, United Kingdom

* Corresponding author.

Introduction There is only limited literature concerning haematological abnormalities in anorexia nervosa (AN), with little past investigation into these abnormalities in adult AN patients admitted to inpatient eating disorder (ED) units.

Objectives This study sought to determine the prevalence and severity of haematological abnormalities in admitted AN patients, and to examine correlates of these abnormalities.

Methods All adult patients with a clinical diagnosis of AN admitted to the Cotswold House specialist ED inpatient unit between November 2013 and December 2014 were included in the study. Demographic, anthropometric and haematological parameters were systematically recorded for the duration of each admission. The proportions of patients affected by haematological abnormalities (anaemia, leucocytopenia, neutropenia, thrombocytopenia and pancytopenia) were selected as primary outcomes, and binary logistic regression was performed using SPSS 22.0.

Results A total of 37 AN patients (91.9% female; mean age: 29.7 years) were included in this study, with a mean admission BMI of 13.7 kg/m² (SD: 1.8) and a mean admission duration of 128 days; 54.1% of patients were anaemic, 64.9% of patients experienced leucocytopenia, 56.8% of patients developed neutropenia, 16.2% of patients suffered thrombocytopenia, and 8.1% of patients were pancytopenic. Logistic regression identified low admission BMI ($P=0.009$) and low serum albumin level ($P=0.017$) as significant correlates of anaemia, and isolated increased age ($P=0.034$) as a significant associate of leucocytopenia.

Conclusions Haematological abnormalities occur frequently in AN inpatients. Given the frequency at which abnormalities occurred in this cohort, further large-scale and prospective studies examining haematological abnormalities in inpatient AN populations are warranted.

¹⁰ Melbourne, Australia

* Corresponding author.

Introduction Multi-attribute utility instruments (MAUIs) are generic health-related quality of life (HRQoL) measures that enable valuation of health states relative to death (0.0) and full health (1.0). The usefulness of MAUIs in people with psychosis has been questioned, with the EQ-5D considered “insensitive”, the 15D “problematic” and the SF-6D “unsuitable”.

Objectives Confirm the Assessment of Quality of Life (AQoL)-4D MAUI is useful and meaningful in people with psychosis.

Aims Assess utility values across demographic, general and disease-specific health categorisations for a large nationally-representative sample with psychosis ($n=1825$).

Methods Participants underwent a comprehensive 32 module interview encompassing psychopathology to service use. Utility values were calculated by applying a standard algorithm to responses to each of 12 items of the AQoL-4D.

Results Utility values were assessed for 1793 participants (98.2%). No ceiling effect was observed and only 6.6% of participants scored in the top decile of HRQoL [0.9–10.0]. In contrast, 10.8% scored in the lowest decile [–0.04–0.10], a floor effect observed in 0.4%. The mean utility value was 0.49 (95% CI: 0.48–0.51), significantly lower than the Australian population norm of 0.81 (95% CI: 0.81–0.82). Greatest impacts on HRQoL were for diminishing global independent functioning as measured by the MSIF (ES_{MSIF} : 0.68–2.24), self-rated current mental health (ES_{MH} : 0.15–1.65) and physical health status (ES_{PH} : 0.11–1.21). Strong effects also observed for course of disorder (ES_{CoD} : 0.08–1.13), current suicidal ideation (ES_{CSI} : 0.76–1.08), and labor force participation (ES_{LFP} : 0.11–0.97).

Conclusions The AQoL-4D had good lower end sensitivity in a large sample of people with a psychotic illness, and demonstrated responsiveness across subjective, objective and symptom measures.

Loneliness is adversely associated with lifestyle and physical and mental health

A. Richard^{1,*}, S. Rohrmann¹, C.L. Vandeleur², M. Schmid¹, M. Eichholzer¹

¹ Epidemiology-Biostatistics and Prevention Institute EBPI, University of Zurich, Chronic Disease Epidemiology, Zurich, Switzerland

² Centre for Research in Psychiatric Epidemiology and Psychopathology, University Hospital of Lausanne, Department of Psychiatry, Prilly, Switzerland

* Corresponding author.

Introduction Loneliness is a common emotional distress experience and there is increasing evidence of associations with unhealthy lifestyle and adverse health-related factors. Little is known about age and sex as potential effect modifiers, and about the prevalence of loneliness.

Objective/aims To assess the associations of loneliness with behavioral, physical and mental health factors, taking sex and age into account and to examine the prevalence of loneliness in individuals aged 15+ years.

Methods Data from 20,007 participants of the cross-sectional population-based Swiss Health Survey 2012 were analyzed. The association of loneliness with lifestyle and health-related factors were assessed with logistic regression analyses. Wald tests were used to test for age and sex differences.

Results Loneliness was reported by 64.1% of individuals, and was associated with smoking (OR 1.13, 95% CI 1.05–1.23), physical inactivity (1.20, 1.10–1.31), non-adherence to the 5-a-day recommendation for fruit and vegetable consumption (1.21, 1.07–1.37), and more visits to a physician within the last year (1.29, 1.17–1.42). Loneliness was also associated with high cholesterol levels (1.31, 1.18–1.45), diabetes (1.40, 1.16–1.67), self-reported chronic diseases (1.41, 1.30–1.54), impaired self-perceived health (1.94, 1.74–2.16), moderate and high psychological distress (3.74, 3.37–4.16), and depression (2.78, 2.22–3.48). Age modulated the associations in BMI, smoking, visiting a physician within the past year, and self-perceived health. Sex did generally not modulate the associations.

Conclusion Loneliness is associated with unhealthy lifestyle, and poorer physical and mental health. Associations were modulated by age, but not sex. Further longitudinal studies are needed to elucidate the causal relationships of these associations.

Potential blood gene expression markers for postpartum psychosis

M. Fuste

King's College London, psychosis Studies, London, United Kingdom

Background Postpartum psychosis (PP) is the most severe psychiatric disorder associated with childbirth. Previous evidence has shown gene expression alterations in immune profile in women with PP when compared with healthy postpartum women. However, no study has ever evaluated women at risk who do not develop the disorder.

We conducted an exploratory analysis of a gene expression profile that could distinguish women with PP episode (PPE) from women at risk who do not develop PP (NPPE) after delivery.

Methods The sample was characterised by 24 women at risk of PP of which $n = 12$ with PPE and $n = 12$ with NPPE and 21 healthy women in the same postpartum period. Following Microarray analysis, we assessed gene expression signature across the 3 groups using ANOVA. We then studied Pathway analysis of genes differently expressed in PPE and NPPE exploring canonical pathways and upstream regulators using Ingenuity Pathway Analysis software.

Results Following an exploratory gene expression analysis we identified 719 genes that are differently expressed across PPE and NPPE. The PPE presented upregulation of several genes involved in the inflammatory pathway and increased gene expression levels of *GRIA4*, *AKT3*, *SP4* and *NRG1* genes, which have been previously

described in psychotic disorders. Moreover, 5 differently expressed canonical pathways were identified including ones relevant to development, mitochondrial formation and immune system.

Conclusion These preliminary results reveal the presence of an immuno-neuro-endocrine dysregulation in postpartum psychosis, with an upregulation of the immune system specific to those women at risk who actually develop postpartum psychosis episodes.

Background Gene × environment (G × E) interactions in eating pathology have been increasingly investigated, however studies have been limited by sample size due to the difficulty of obtaining genetic data.

Objective To synthesize existing G × E research in the eating disorders (ED) field and provide a clear picture of the current state of knowledge with analyses of larger samples.

Method Complete data from seven studies investigating community ($n = 1750$, 64.5% female) and clinical ($n = 426$, 100% female) populations, identified via systematic review, were included. Data were combined to perform five analyses: 5-HTTLPR × Traumatic Life Events (0–17 events) to predict ED status ($n = 909$), 5-HTTLPR × Sexual and Physical Abuse ($n = 1097$) to predict bulimic symptoms, 5-HTTLPR × Depression to predict bulimic symptoms ($n = 1256$), and 5-HTTLPR × Impulsivity to predict disordered eating ($n = 1149$).

Results The low function (s) allele of 5-HTTLPR interacted with number of traumatic life events ($P < .01$) and sexual and physical abuse ($P < .05$) to predict increased likelihood of an ED in females but not males (Fig. 1). No other G × E interactions were significant,

possibly due to the medium to low compatibility between datasets (Fig. 1).

Conclusion Early promising results suggest that increased knowledge of G × E interactions could be achieved if studies increased uniformity of measuring ED and environmental variables, allowing for continued collaboration to overcome the restrictions of obtaining genetic samples.

Fig. 1 The interaction between 5-HTTLPR (s-allele present versus s-allele absent) and number of traumatic life events to predict likelihood of an eating disorder in females.

A quality improvement intervention in geriatric psychiatry care: Results of a pre-post design study

E. Albuquerque*, S. Fernandes, J. Cerejeira
Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Innovative approaches are needed to respond to the increasing number of elderly subjects with complex psychiatric conditions who require flexible and rapid responses, avoiding unnecessary hospital admissions. A new organizational model was implemented in our psychogeriatric service in September 2011 consisting of:

- a comprehensive multidisciplinary geriatric assessment;
- a helpline for caregivers for management of acute behavioral problems;
- programmed visits to nursing homes.

Aims To evaluate whether the implementation of this program was associated with a reduction in hospital admissions and emergency department visits.

Methods This is a pre-post test design study, involving 1197 patients who attended the Old Age Psychiatric (OAP) Unit three years before and three years after the implementation of the organizational intervention (1.09.2008 to 1.10.2014). An index of patient × year was calculated considering the period during which the patient was followed in OAP Unit. Data was obtained from the medical files of all eligible patients regarding demographic variables, number and type of hospital admissions and emergency department visits.

Results During the 3 years before the intervention 671.2 patients × years were included (mean age of 75.8 years) while after the intervention this reached 2010.1 patients × years (mean age of 77.8 years). The intervention was associated with a decrease of 44% in psychiatry emergency visits, 48% in general emergency visits, 44% in psychiatric ward admissions and 51% in geriatric ward admissions.

Conclusions The implementation of this new model was associated with significant reduction of hospital-based service utilization. Future research should determine if this was coupled with increased health outcomes.

* Corresponding author.

Introduction Cognitive frailty has recently been defined as the co-occurrence of physical frailty and cognitive impairment. Late-life depression is associated with both physical frailty and cognitive impairment, especially processing speed and executive functioning.

Aim and objectives In this study, we investigated the association between physical frailty and cognitive functioning in depressed older persons.

Methods In a total of 378 patients (>60 years) with depression according to DSM-IV criteria and a MMSE score of 24 points or higher, the physical frailty phenotype as well as its individual criteria (weight loss, weakness, exhaustion, slowness, low activity) was studied. Cognitive functioning was examined in 4 domains: verbal memory, working memory, interference control, and processing speed.

Results Of the 378 depressed patients (range 60–90 years; 66.1% women), 61 were classified as robust (no frailty criteria present), 214 as prefrail (1 or 2 frailty criteria present), and 103 as frail (>3 criteria). Linear regression analyses, adjusted for confounders, showed that the severity of physical frailty was associated with poorer verbal memory, slower processing speed, and decreased working memory, but not with changes in interference control.

Conclusion In late-life depression, physical frailty is associated with poorer cognitive functioning, although not consistently for executive functioning. Future studies should examine whether cognitive impairment in the presence of physical frailty belongs to cognitive frailty and is indeed an important concept to identify

a specific subgroup of depressed older patients, who need multimodal treatment strategies integrating physical, cognitive, and psychological functioning.

Association between physical frailty and inflammation in late-life depression

M. Arts^{1,*}, R. Collard², H. Comijs³, P. Naudé⁴, R. Risselada⁵, P. Naarding⁶, R. Oude Voshaar¹

¹ UMCG, Old Age Psychiatry, Groningen, Netherlands

⁶ GGNet, Old Age Psychiatry, Apeldoorn, Netherlands

* Corresponding author.

Introduction Although the criteria for physical frailty and depression partly overlap, both represent unique, but reciprocally related constructs. The association between inflammation and frailty has been reported consistently, in contrast to the association between inflammation and late-life depression (LLD).

Aim and objectives To determine whether physical frailty is associated with low-grade inflammation in LLD.

Methods The physical frailty phenotype, defined as three out of five criteria (weight loss, weakness, exhaustion, slowness, low physical activity level), and three inflammatory markers [C-reactive protein (CRP), interleukin-6 (IL-6), and neutrophil gelatinase-associated lipocalin (NGAL)] were assessed in a sample of individuals aged 60 and older with depression according to Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, criteria ($n = 366$).

Results The physical frailty phenotype was not associated with inflammatory markers in linear regression models adjusted for sociodemographic characteristics, lifestyle characteristics, and somatic morbidity. Of the individual criteria, handgrip strength was associated with CRP and IL-6, and gait speed was associated with NGAL. Principal component analysis identified two dimensions within the physical frailty phenotype: performance-based physical frailty (encompassing gait speed, handgrip strength, and low physical activity) and vitality-based physical frailty (encompassing weight loss and exhaustion). Only performance-based physical frailty was associated with higher levels of inflammatory markers.

Conclusion The physical frailty phenotype is not a unidimensional construct in individuals with depression. Only performance-based physical frailty is associated with low-grade inflammation in LLD, which might point to a specific depressive subtype.

Antidepressants and mortality risk in a dementia cohort – data from SveDem, the Swedish Dementia Registry

D. Enache^{1,*}, S.M. Fereshtehnejad², P. Cermakova², S. Garcia-Ptacek², I. Kåreholt², K. Johnell², D. Religa², V. Jelic², B. Winblad², C. Ballard³, D. Aarsland², J. Fastbom², M. Eriksdotter²

* Corresponding author.

Background The association between mortality risk and use of antidepressants in people with dementia is unknown.

Objective To describe the use of antidepressants in people with different dementia diagnoses and to explore mortality risk associated with use of antidepressants 3 years before a dementia diagnosis.

Methods Study population included 20,050 memory clinic patients from Swedish Dementia Registry diagnosed with incident dementia. Data on antidepressants dispensed at the time of dementia diagnosis and during three-year period before dementia diagnosis was obtained from the Swedish Prescribed Drug Register. Cox regression models were used.

Results During a median follow-up of 2 years from dementia diagnosis, 25.8% of dementia patients died. A quarter (25.0%) of patients were on antidepressants at the time of dementia diagnosis while 21.6% used antidepressants at some point during a three-year period before a dementia diagnosis. Use of antidepressant treatment for 3 consecutive years before a dementia diagnosis was associated with a lower mortality risk for all dementia disorders (HR: 0.82, 95% CI: 0.72–0.94) and in Alzheimer's disease (HR: 0.61, 95% CI: 0.45–0.83). There were no significant associations between use of antidepressant treatment and mortality risk in other dementia diagnoses.

Conclusion Antidepressant treatment is common among patients with dementia. Use of antidepressants during prodromal stages may reduce mortality in dementia and specifically in Alzheimer's disease.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differential mortality rates in late-life depression and subthreshold depression: 10-year follow-up in the community

C. Ho^{1,*}, T.P. Ng²

¹ Singapore, Singapore

² National University of Singapore, Department of Psychological Medicine, Singapore

* Corresponding author.

Background Although the association between depression and excess mortality is well-established, effects of subthreshold depression on mortality are unclear. We compared excess mortality between threshold and subthreshold depression, and investigated risks factors and disease-specific mortality rates according to the depression threshold levels.

Methods Cross-sectional and longitudinal analyses of data from 1070 participants aged 55 and above of the Singapore Longitudinal Aging Study (SLAS). Baseline depression levels (Geriatric Mental State Examination, GMS), chronic medical comorbidity, instrumental activities of daily living (IADL) were related to baseline and 10-year follow-up of differential mortality rates according to depression threshold level.

Results The prevalence of late-life subthreshold and threshold depression was 9.9% and 5.1%, respectively; 26.3% of respondents died by the 10-year follow-up, with a mortality rate of 28.2 per 1000 person-years. The risk of mortality increased with age, male gender, lower physical activity, multiple medical comorbidities and IADL-disability, but when stratified according to depression status,

none of the variables was statistically significant for the subthreshold depression group. Depression, regardless of threshold levels, increased mortality risk by at least 1.6 folds, with small difference between the two. Cardiovascular mortality risk was significantly increased by 2.17 fold ($P=0.024$) in threshold but not subthreshold depression.

Conclusion Both subthreshold and threshold depression increase the risk of excess mortality, though it is slightly higher when reaches threshold levels. Subthreshold depression should be regarded as part of the depressive illness spectrum and more emphasis on recognition and timely treatment of this disorder should be considered in clinical practice.

Premorbid personality characteristics and CSF markers of Alzheimer's pathology

D. Kukreja^{1,*}, D. Tautvydaitė¹, J.P. Antoinetti², H. Henry³, A. von Gunten¹, J. Popp¹

¹ University Hospital of Lausanne, Psychiatry Old age Psychiatry SUPAA-Cery, Lausanne, Switzerland

² University of Lausanne, Statistics, Lausanne, Switzerland

³ University Hospital of Lausanne, Psychiatry, Lausanne, Switzerland

* Corresponding author.

Background Beginning as early as in young adulthood, personality characteristics may contribute to cognitive reserve by their influence on lifestyle and health-related behavior. A "resilient" personality profile may be associated with less cognitive and functional impairment in persons with cerebral Alzheimer's disease (AD) pathology.

Aim The aim of this study was to investigate whether premorbid personality characteristics modulate the relationships between cognitive performance and AD pathology as measured using CSF biomarkers at preclinical and early clinical disease stages.

Subjects and methods Sixty-eight patients with mild cognitive impairment or mild dementia and forty-two older subjects with normal cognition have been included. Premorbid personality characteristics were assessed by the NEO Personality Inventory Revised (as reported by a close relative) along with cognitive performance, functional status and CSF concentrations of A β 1-42, tau, and ptau181.

Multivariate regression analysis, including age, gender, education years, and APOE4 genotype was used to evaluate associations between disease severity and premorbid personality scores, and the CSF markers of AD pathology.

Results Overall, there were significant associations between Clinical dementia rating-Sum of boxes (CDRSOB) and the interactions of each personality trait with the ptau181/A β 1-42 ratio. In subjects with cognitive impairment, there were significant associations between CDRSOB and the interactions of ptau181/A β 1-42 ratio with Neuroticism, Extraversion, Openness and Conscientiousness. Significant results were also found using the interaction between different personality traits and the tau/A β 1-42 to predict the CDRSOB.

Discussion The findings suggest that premorbid personality characteristics modify the relationship between cerebral pathology and cognitive performance at very early clinical stages of AD.

Introduction Depression is a common disorder in late-life. Structured clinical interviews may be less efficient compared to self-administered questionnaires, but provide more accurate findings in terms of diagnosis. No population-based studies with both these depression assessment instruments have been ever performed.

Objectives To estimate the GDS-30 accuracy for depression assessment against the gold standard [Semi-structured Clinical Diagnostic Interview for DSM-IV-TR Axis I Disorders (SCID)] in subjects 65+ years in a random sampling of the general population.

Methods The sample was collected in a population-based study (GreatAGE) conducted among elderly residents in Castellana, Southeast Italy. It includes 597 participants (57.62% males, mean age 73 years). Depression was assessed through the GDS-30 and the SCID, both double-blinded administered respectively by a trained neuropsychologist and psychiatrist. The GDS-30 screening performances were analyzed using ROC curves.

Results According to the gold standard SCID, the rate of depressive disorder was 10.22% (15.81% of women; 6.1% of men) while with GDS-30 instrument 12.06% of the residents met the depression cutoff. Only 36.1% of GDS cases were true positive. At the optimal cutoff score (> 5), GDS had 62% sensitivity and 81% specificity. Using a more conservative cutoff (> 9), the GDS-30 specificity reached 91% while sensitivity dropped to 43%.

Conclusions These preliminary results from the first population-based study that compares GDS-30 and SCID showed that the GDS-30 identified adequate levels of screening accuracy (AUC 0.76) compatible with scores established in community settings.

* Corresponding author.

Introduction Specific changes in personality profiles may represent early symptoms of Alzheimer's disease (AD). Knowledge about relationship between personality changes and biomarkers of cerebral pathology can contribute to early diagnosis of AD.

Objectives To investigate to what extent the personality changes predict the cerebral AD pathology.

Aims To describe the relationship between the personality changes and pathological cerebro-spinal fluid (CSF) biomarkers.

Method One hundred and ten subjects, of whom 57 patients with mild cognitive impairment (MCI), 9 subjects with mild dementia, and 44 healthy controls had an extensive medical and neuropsychological examination as well as lumbar puncture to evaluate concentrations of CSF biomarkers of AD pathology [amyloid- β_{1-42} ($A\beta_{1-42}$), phosphorylated tau (ptau-181), and total-tau (tau)]. The proxies of the participants completed the Revised NEO Personality Inventory (NEO-PI-R) to assess subjects' personality at the time being and 5 years retrospectively.

Results In a hierarchical multivariate regression analysis, including age, gender, education, Mini Mental State Examination (MMSE), and APOE ϵ 4 status, lower $A\beta_{1-42}$ concentrations in CSF were associated with increasing neuroticism, and decreasing extraversion and conscientiousness. Decreasing extraversion, openness to experience and conscientiousness were associated with higher tau/ $A\beta_{1-42}$ ratio, and higher ptau-181/ $A\beta_{1-42}$ ratio was related to decreasing extraversion. Personality changes in the domain of agreeableness did not yield any significant effect as a predictor on any of CSF biomarkers.

Conclusions Our findings suggest that early and specific changes in personality traits are associated with cerebral AD pathology, in particular with amyloid pathology, and may serve as clinical signs to consider when evaluating MCI and mild dementia.

Diuretic medication use reduces incident dementia risk: A meta-analysis of prospective studies

P. Tully^{1,*}, O. Hanon², S. Cosh³, C. Tzourio⁴

¹ University of Adelaide, Medicine, Adelaide, Australia

² Inserm, Université Paris Descartes, Service de Gériatrie, Paris, France

³ University of Adelaide, Psychology, Adelaide, Australia

⁴ University of Bordeaux, Neuroepidemiology, Bordeaux, France

* Corresponding author.

Introduction Numerous observational studies suggest that blood pressure management with antihypertensive drugs may be effective in reducing dementia risk.

Objective To quantify dementia risk in relation to diuretic medication use.

Methods Electronic databases were searched until June 2015. Eligibility criteria: population, adults without dementia at baseline from primary care, community cohort, residential/institutionalized or randomized controlled trial (RCT); exposure, diuretic medication; comparison, no diuretic medication, other or no antihypertensive medication, placebo-control; outcome, incident dementia in accordance with standardized criteria. Adjusted hazard ratios (HR) with 95% confidence intervals (CI) were pooled in fixed-effects models with RevMan 5.3. The overall quality and strength of evidence was rated with GRADE criteria.

Results Fifteen articles were eligible comprising a pooled sample of 52,599 persons and 3444 incident dementia cases (median age 76.1 years, 40% male) with a median follow-up of 6.1 years. Diuretic use was associated with 17% reduction in dementia risk

(HR 0.83; 95% CI 0.75 to 0.90) and a 21% reduction in Alzheimer's disease risk (HR 0.79; 95% CI 0.68 to 0.93). GRADE was rated as moderate. Risk estimates were consistent comparing monotherapy versus combination therapy, study design and follow-up. Meta-regression did not suggest that age, gender, systolic blood pressure, attrition, mortality rate, education, cognitive function, stroke, Apolipoprotein E allele, heart failure or diabetes altered the primary results.

Conclusions Diuretic medication was associated with a consistent reduction in dementia and Alzheimer's disease risk and the absence of heterogeneity points to the generalizability of these findings.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Benzodiazepines are the most utilized anxiolytic and hypnotic drugs. The high consumption of benzodiazepines has been a concern due to reported side effects of long-term use and dependence. Portugal has the highest benzodiazepine utilization in Europe.

Objectives To analyze the change in general practitioners' (GPs) benzodiazepine prescription pattern after an intervention period.

Methods An educational session was delivered to a group of intervened GPs. The benzodiazepine prescription pattern of intervened group was compared to the pattern of a non-intervened matched group from the same region, and of another non-intervened matched group from a different region. The research time frame was 12 months before and after intervention. The analysis of the prescription trends used the defined daily dose (DDD) and defined daily dose per 1000 patients per day (DHD) methodology. The statistical methods consisted of segmented regression analysis.

Results There was a decrease in benzodiazepine prescription pattern of intervened GPs after intervention ($P=0.005$). There was also a decrease in benzodiazepine prescription pattern for the non-intervened group from the same region ($P=0.037$) and for the non-intervened group from a different region ($P=0.010$). Concerning an analysis by gender, female gender prescribed a higher amount of benzodiazepines. The intervened female gender prescribers presented the highest decrease in prescription trend after intervention ($P=0.008$).

Conclusions Intervention was effective in reducing benzodiazepine prescription after intervention. It demonstrates that a single intervention has a positive impact on improving prescription trends. The replication of this intervention might be an opportunity for changing the worrying benzodiazepine utilization in Portugal.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Parkinsonian motor signs are the most frequent of the genuine motor abnormalities present in drug-naïve patients with schizophrenia, and are also present in patients with a first-episode of psychosis (FEP).

Objective To study whether there are differences in basal ganglia volumes depending on the presence of Parkinsonism in FEP.

Methods Forty-six patients with a FEP were included in the study. Twenty-three controls were included to normalise patients' brain volume data. Parkinsonism was assessed with the UKU scale. Brain volumes were obtained with MRI (1.5 Tesla Siemens Avanto). Reconstruction and volumetric segmentation was made with the Freesurfer© software (<http://surfer.nmr.mgh.harvard.edu/>). Patients were divided into two groups, considering the presence/absence of Parkinsonism (UKU total score cutoff point=4). Patients have been treated with antipsychotics a mean of less than 2 months. There were not significant differences in the total exposure to antipsychotics between both groups. ANCOVAs were performed including gender as covariate.

Results Patients with Parkinsonism showed a trend towards significance to exhibit reduced volumes in the left caudate and right putamen (Fig. 1).

Conclusions FEP patients who exhibit Parkinsonian signs tend to show reduced left caudate and right putamen volumes in the early phases of psychotic illness, after correcting by gender.

The role of neurometabolites in emotional processing

D. Denzel^{1,*}, L.R. Demenescu², L. Colic², F. von Düring³, H. Nießen³, M. Walter²

¹ Magdeburg, Germany

² Clinical Affective Neuroimaging Laboratory CANLAB, Leibniz Institute for Neurobiology, Magdeburg, Germany

³ Clinical Affective Neuroimaging Laboratory CANLAB, Otto-von-Guericke University Magdeburg, Magdeburg, Germany

* Corresponding author.

Objective To investigate how brain metabolites, especially glutamate and glutamate to glutamine ratio of pgACC modulate the neural response within these areas and how this affects their function during emotion facial expression matching task.

Methods Seventy healthy volunteers underwent magnetic resonance spectroscopy (MRS) and task functional magnetic resonance imaging (fMRI) in 7 Tesla scanner. PgACC MRS data were obtained using STEAM sequence and analyzed using LCModel.

Angry, fearful, and happy facial expressions were presented in an affect-matching block where one of the two facial expressions presented matched the target facial expression. The control condition was form matching. Data were preprocessed and analyzed in SPM 8.

Results Glutamate to Creatine ratio measured in pgACC positively correlated with BOLD response in the right DLPFC during negative emotional perception (FWE=0.05) Glutamate to glutamine ratio indicating on-off mechanisms in pgACC positively correlated with BOLD responses in FFA extending to cerebellum cluster (FWE < 0.05).

Conclusion This study indicate that pgACC, baseline metabolism predicts neural response to emotional processing. We conclude that individuals with higher glutamate ratios, an excitatory neurotransmitter, in pgACC during rest might have a better coping mechanism to potential danger indicated by perception of angry or afraid faces. The higher glutamate to glutamine ratio in pgACC indicates a higher turnover of excitatory metabolite glutamate. This mechanism is associated with higher emotional response in fusiform area and cerebellum suggesting higher visual attention towards negative emotions.

* Corresponding author.

Introduction Emerging evidences indicate that the alteration of interhemispheric functional coordination may be involved in the pathogenesis of major depressive disorder (MDD). In present study, we aim to explore the potential marker by using the voxel-mirrored homotopic connectivity (VMHC) approach, which may be contributing to predict the clinical prognosis in MDD.

Methods Eighty-two MDD patients and 50 normal control (NC) subjects participated in this study. We divided the MDD group into unremitted and remitted group according to the reduction rate of Hamilton Rating Scale for Depression (HAMD) within 2 weeks.

Results The study detected significantly decreased VMHC in bilateral precuneus (pCu), inferior temporal gyrus (ITG) and increased VMHC in middle frontal gyrus (MFG) and caudate nucleus when compared remitted depression (RD) group to unremitted depression (URD) group. Meanwhile, when compared with NC group, the URD group presented reduced VMHC in bilateral cerebellum anterior lobe, thalamus and postcentral gyrus. Furthermore, the VMHC in media frontal gyrus, postcentral gyrus and precentral gyrus were significantly decreased in RD group. Correlation analysis suggested that reduced VMHC in bilateral pCu was negatively correlated with the baseline HAMD score of URD ($r = -0.325$, $P = 0.041$). Receiver operating characteristic (ROC) curve indicated that three regional VMHC changes could identify depressed patient with poorer treatment response: ITG [area under curve (AUC) = 0.699, $P = 0.002$, 95% CI = 0.586–0.812], MFG (AUC = 0.692, $P = 0.003$, 95% CI = 0.580–0.805), pCu (AUC = 0.714, $P = 0.001$, 95% CI = 0.603–0.825).

Conclusion The current study combined with previous evidence indicates that the subdued intrinsic interhemispheric functional connectivity might represents a novel neural trait involved in the pathophysiology of MDD.

Introduction ³¹P MRS is a unique way of in vivo energy metabolism research. This method allowed revealing schizophrenia-induced disturbances of energy exchange in resting state [1]. We use ³¹P MRS in presence of visual stimulation that allows neuronal energy-consuming processes studying.

Objective Revealing of stimulation effects on high-energy phosphates (PCr, ATP) in early-stage schizophrenia.

Aim Discovery of energy processes contribution in schizophrenia pathogenesis.

Methods Twelve right-handed 18–26 years old male patients with early-staged schizophrenia (F20, ICD-10) and 20 age-matched healthy right-handed controls. Spectra were acquired on Philips Achieva 3.0 T using Rapid Biomed 31P/1H birdcage coil and 2D ISIS pulse sequence. fMRI was used for accurate 2D slice positioning, spectroscopy voxels containing primary visual cortex (V1) were averaged (see Fig. 1). Two ³¹P spectra of V1 were obtained: firstly in resting state and then during 6 minutes of continuous stimulation by 6 Hz flashing checkerboard. Spectra were processed in jMRUI.

Results Excitation reduced PCr in the norm and had no effect on schizophrenia (see Fig. 2). No excitation-induced ATP changes in both groups were revealed.

Conclusion Alteration in PCr behavior in this study witnesses for deviations in energy-consuming processes in schizophrenia. A new scheme of neuronal response to stimulation in schizophrenia is offered.

Fig. 1 fMRI-guided voxel positioning in visual cortex.

Fig. 2 PCr of visual cortex in the norm (1) and in schizophrenia (2) during continuous stimulation relative to PCr in resting state. * $P < 0.05$ by Mann-Whitney U-criteria.

Introduction The aim of the FP7-European funded project TRIM-AGE is to create a trimodal, cost-effective imaging tool consisting of PET/MR/EEG to enable effective early diagnosis of schizophrenia.

Objective In the scope of this project we are interested in the multimodal assessment of response inhibition. The loudness dependence of auditory evoked potential (LDAEP) is a suitable biomarker of inhibitory action in signal processing. Variations in response inhibition can have great impact on different aspects of life. Individuals with reduced capability of inhibitory control have a tendency to impulsive behavior. Studies showed that they have stronger LDAEP values. Patients with schizophrenia may exhibit alterations in the responsiveness to sensory stimuli. Thus, a reduced LDAEP was found in these patients. However, these deviations differed in clinical features of the disorder. Therefore, we would like to further elucidate the relationship between multimodal neuroimaging methods and dimensions of symptoms, observable behavior, personality traits and general psychopathological dysfunction.

Methods A sample of 20 healthy controls and 20 patients with manifest schizophrenia will be examined with the LDAEP paradigm in a trimodal approach with customary imaging tools. PET measurements with the radiotracer [¹¹C]-flumazenil will be used to assess the binding potentials of GABA-A receptors. MRS will provide data about GABA concentrations. Simultaneously recorded EEG-fMRI data will permit new insight in the relationship between LDAEP and impulsivity.

Discussion The project will use alternative approaches to psychiatric classification. Response inhibition in sensory processing will be investigated from different angles (biochemical, neurophysiological, and neuroanatomical) and combined with psychological characteristic values.

A diffusion tensor imaging study of white matter microstructure concerning suicidal ideation in major depressive disorder

H. Zhang^{1,*}, Z. Jia²

¹ West China Hospital, Sichuan University, Radiology, Chengdu, China

² West China Hospital, Sichuan University, Nuclear medicine, Chengdu, China

* Corresponding author.

Introduction Suicide is a serious public health problem. Microstructural abnormalities of white matter (WM) in major depressive disorder (MDD) patients had been studied with diffusion tensor image (DTI) before. However, little is known regarding suicidal ideation (SI).

Objectives To use diffusion tensor imaging to characterize abnormalities of white matter integrity in major depressive disorder patients with and without SI.

Methods Sixteen depressive patients with SI, 16 depressive patients without SI and 32 age- and gender-matched healthy controls received MRI scans on a 3T magnet. Whole brain voxel-based analysis was used to compare fractional anisotropy (FA) across the three groups with threshold at $P < 0.005$ (uncorrected) at voxel level and 50 for cluster size with SPM8. Pearson analyze was conducted to examine the association between clinical measurements and regional FA value.

Results The three groups had significant differences of FA in the left centrum semiovale (peak $Z = 4.64$ at $-30, -38, 34$), right centrum semiovale (peak $Z = 3.54$ at $32, -34, 32$) and right splenium of

corpus callosum (peak $Z = 4.64$ at $4, -34, 12$; Fig. 1). We also found a negative correlation between mean regional FA values in the white matter under the left centrum semiovale and the intensity of suicidal ideation scores ($r = -0.563, P = 0.023$).

Conclusion Suicidal ideation is associated with microstructure abnormalities of the white matter in centrum semiovale and corpus callosum.

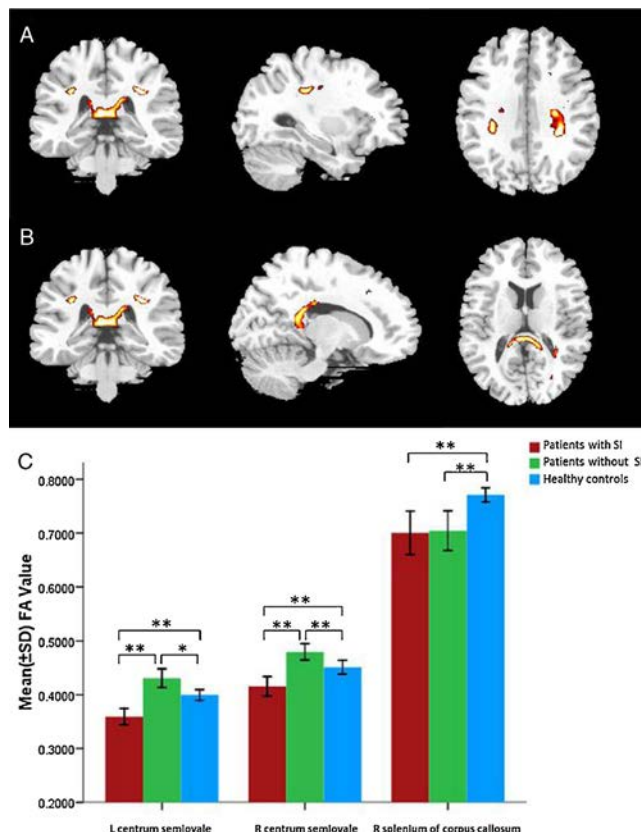

Fig. 1 Brain regions differed significantly among groups. A. Bilateral centrum semiovale. B. Right splenium of corpus callosum. C. Patients tested.

Obsessive-compulsive disorder

FC48

Actions speak louder than words: Enhanced action tendencies in obsessive-compulsive disorder: An ERP study

A. Dayan Riva^{1,*}, A. Berger², G. Anholt²

¹ Beer Sheva, Israel

² Ben Gurion University of the Negev, Psychology, Beer Sheva, Israel

* Corresponding author.

Obsessive-compulsive disorder (OCD) is characterized by repeated thoughts and behaviors. Several studies have detected deficient response inhibition ability in individuals with OCD, leading researchers to suggest this deficit as an endophenotype of OCD.

However, other researchers maintain that the effect size of this deficit is modest and that it lacks clinical significance. The current investigation examines a potential alternative explanation for difficulties in response inhibition, namely enhanced action tendencies in response to stimuli. Therefore, early processes of motor response preparation preceding action performance (or inhibition) were studied with the event-related potential (ERP) component of readiness potential (RP). RP measures brain reactions related to motor activity in response to external stimuli. ERPs were recorded while 15 participants with OCD and 16 healthy controls performed a variation of a go/no-go task and a stop-signal task using schematic faces (angry and neutral). The OCD group presented with a greater RP slope gradient and amplitude over bilateral parietal areas corresponding to the motor cortex. The amplitude effect was further enhanced under negative valence, compared with the neutral condition. Differences in RP between the OCD and control groups remained significant when controlling for levels of trait anxiety. Results support the hypothesis that a stronger readiness for action might characterize OCD, especially in the presence of threatening stimuli. This finding, specific to OCD and not to anxiety symptoms, may underlie habitual tendencies in OCD. This study suggests that early-stages of motor preparation might be important to the etiology and maintenance of OCD.

Introduction The existing literature on chronic pain points to the effects anxiety sensitivity, pain hypervigilance, and pain catastrophizing on pain-related fear; however, the nature of the relationships remains unclear. The three dispositional factors may affect one another in the prediction of pain adjustment outcomes. The addition of one disposition may increase the association between another disposition and outcomes, a consequence known as suppressor effects in statistical terms.

Objective This study examined the possible statistical suppressor effects of anxiety sensitivity, pain hypervigilance and pain catastrophizing in predicting pain-related fear and adjustment outcomes (disability and depression).

Methods Chinese patients with chronic musculoskeletal pain (n=401) completed a battery of assessments on pain intensity, depression, anxiety sensitivity, pain vigilance, pain catastrophizing, and pain-related fear. Multiple regression analyses assessed

the mediating/moderating role of pain hypervigilance. Structural equation modeling (SEM) was used to evaluate suppression effects. **Results** Our results evidenced pain hypervigilance mediated the effects of anxiety sensitivity (Model 1: Sobel z=4.86) and pain catastrophizing (Model 3: Sobel z=5.08) on pain-related fear. Net suppression effect of pain catastrophizing on anxiety sensitivity was found in SEM where both anxiety sensitivity and pain catastrophizing were included in the same full model to predict disability (Model 9: CFI=0.95) and depression (Model 10: CFI=0.93) (all P<0.001) (see Tables 1 and 2, Figs. 1 and 2).

Conclusions Our findings evidenced that pain hypervigilance mediated the relationship of two dispositional factors, pain catastrophic cognition and anxiety sensitivity, with pain-related fear. The net suppression effects of pain catastrophizing suggest that anxiety sensitivity enhanced the effect of pain catastrophic cognition on pain hypervigilance.

Table 1 Multivariate regression analyses of the relationships between pain hypervigilance, anxiety sensitivity, pain-related fear.

Model	β	SE	95% CI	P value
Model 1: Anxiety sensitivity → Pain hypervigilance → Pain-related fear				
Anxiety sensitivity (Predictor) → Pain hypervigilance (Mediator)	0.25	0.04	0.17, 0.34	<0.001
Pain hypervigilance (Mediator) → Pain-related fear (Outcome)	0.19	0.02	0.15, 0.23	<0.001
Anxiety sensitivity (Predictor) → Pain-related fear (Outcome)	0.15	0.02	0.12, 0.18	<0.001
Anxiety sensitivity (Predictor) → Pain-related fear (Outcome) Pain hypervigilance (Mediator) [†]	0.11	0.02	0.08, 0.14	<0.001
Sobel test				
	Z = 4.86 P < 0.001			
Model 2: (Anxiety sensitivity × Pain hypervigilance) → Pain-related fear				
Anxiety sensitivity (Predictor)	0.12	0.02	0.09, 0.15	<0.001
Pain hypervigilance (Moderator)	0.15	0.02	0.11, 0.18	<0.001
Anxiety sensitivity (Predictor) × Pain hypervigilance (Moderator)	-0.00	0.00	-0.00, 0.00	0.186
Model 3: Pain catastrophizing → Pain hypervigilance → Pain-related fear				
Pain catastrophizing (Predictor) → Pain hypervigilance (Mediator)	0.47	0.05	0.38, 0.57	<0.001
Pain hypervigilance (Mediator) → Pain-related fear (Outcome)	0.18	0.02	0.15, 0.22	<0.001
Pain catastrophizing (Predictor) → Pain-related fear (Outcome)	0.21	0.02	0.17, 0.24	<0.001
Pain catastrophizing (Predictor) → Pain-related fear (Outcome) Pain hypervigilance (Mediator) [†]	0.15	0.02	0.11, 0.19	<0.001
Sobel test				
	Z = 5.08 P < 0.001			
Model 4: (Pain catastrophizing × Pain hypervigilance) → Pain-related fear				
Pain catastrophizing (Predictor)	0.15	0.02	0.11, 0.19	<0.001
Pain hypervigilance (Moderator)	0.11	0.02	0.07, 0.15	<0.001
Pain catastrophizing (Predictor) × Pain hypervigilance (Moderator)	0.00	0.00	0.01, 0.00	0.068

Note: β: Unstandardized beta coefficient; SE: standard error; CI: confidence interval; NS: non-significant P value at 0.05 level. All regression equations were controlled for age, sex, number of pain site, and pain duration. The total scores of the measurement scale of anxiety sensitivity, pain hypervigilance and pain-related fear were used in all regression models.
[†]Four separate regression models were generated to test the mediation pathway of pain hypervigilance on the link between anxiety sensitivity and pain-related fear (Model 1) and the link between pain catastrophizing and pain-related fear (Model 3).
[‡]Pain hypervigilance, as mediator, was controlled in the regression equation.
[§]Using pain-related fear as dependent variable, one regression model was generated to test the moderation pathway of pain hypervigilance on the link between anxiety sensitivity and pain-related fear (Model 2) and the link between pain catastrophizing and pain-related fear (Model 4).

Table 2 Results of SEM testing the relationships between anxiety sensitivity, pain catastrophizing, and pain hypervigilance for two pain adjustment outcomes.

Model	S-B ²	df	CFI	NNFI	RMSEA	90% CI	SRMR
Simple model: Anxiety sensitivity → Pain hypervigilance → Pain-related fear → Adjustment outcome							
Model 5: Disability	49.97	18	0.96	0.94	0.07	0.05, 0.10	0.05
Model 6: Depression	58.17	18	0.96	0.93	0.08	0.06, 0.10	0.06
Simple model: Pain catastrophizing → Pain hypervigilance → Pain-related fear → Adjustment outcome							
Model 7: Disability	79.22	18	0.94	0.91	0.10	0.08, 0.12	0.05
Model 8: Depression	112.51	18	0.91	0.96	0.12	0.10, 0.15	0.06
Full model							
Model 9: Disability	122.24	40	0.95	0.93	0.08	0.06, 0.09	0.05
Model 10: Depression	154.49	40	0.93	0.91	0.09	0.08, 0.11	0.06

Note: The full models include both anxiety sensitivity and pain catastrophizing, and specify that pain hypervigilance mediates the link of both anxiety sensitivity and catastrophizing with pain-related fear, which in turn predicts adjustment outcomes. Disability was indexed by the Chronic Pain Grade Disability score. Depression was indexed by the Depression subscale of the Hospital Anxiety and Depression Scale. S-B² = Satorra & Bentler scaled chi-square statistics; df = degrees of freedom; CFI = comparative fit index; NNFI = non-normed fit index; RMSEA = root mean square error of approximation; CI = confidence interval; SRMR = standardized root mean square residual.

Model 5: $S - B\chi^2(18) = 49.97, CFI = 0.96, RMSEA = 0.07, SRMR = 0.05.$

Model 6: $S - B\chi^2(18) = 58.17, CFI = 0.96, RMSEA = 0.08, SRMR = 0.06.$

Model 7: $S - B\chi^2(18) = 79.22, CFI = 0.94, RMSEA = 0.10, SRMR = 0.05.$

Model 8: $S - B\chi^2(18) = 112.51, CFI = 0.91, RMSEA = 0.12, SRMR = 0.06.$

Fig. 1 Simple models testing the mediating role of pain hypervigilance in the link between anxiety sensitivity and pain-related fear (Models 7 and 8) predicting disability and depression. Anxiety Sensitivity was indexed by the Anxiety Sensitivity Index (ASI). PC: ASI Physiological Concerns subscale; CC: ASI Physiological Concerns subscale; SC: ASI Social Concerns subscale. Pain catastrophizing was indexed by the Pain Catastrophizing scale (PCS). RUM: PCS Rumination subscale; MAGN: PCS Magnification subscale; HELP: PCS Helplessness subscale. Background Cluster B personality disorder (PD) is a highly prevalent mental health condition in general population (1 to 6% depending on the subtype and study). Patients affected are known to be heavier users of both mental and medical healthcare than other clinical conditions such as depression. Few studies have highlighted their elevated mortality rate compared to general population.

Methods The estimates were produced using data from the integrated monitoring system for chronic disease of Quebec. It provides annual and life prevalence, mortality rate, years of and healthcare utilization profile Quebec inhabitants.

Results A total of 7,995,963 people were included in the study. The life prevalence of cluster B PD is 2.6%. The mean years of lost life is 13 for men and 9 for women when they are compared to general population. The 3 most important causes of death are: suicide (20.4%), cardiovascular diseases (19.1%) and cancers (18.6%). The standardized mortality ratio (SMR) for each medical condition is superior in cluster B personality disorders than general population. The most important SMR is for suicide (male: 10.2 and female: 21). In the year 2011–2012, 78% had consulted a general practitioner, 62% a psychiatrist, 41% were admitted in an emergency department and 21% were hospitalized.

Introduction Both attachment style and personality traits are closely related to individual's interpersonal patterns. Association between these constructs has been widely studied, but variability in results makes it difficult to reach definite conclusions. Similarly, dopaminergic pathways are considered to underlie some personality traits and to be related to attachment styles, but evidence, hitherto, remain inconclusive.

Aims To assess the correlation between personality and attachment dimensions and to study whether a common association to the catechol-O-methyltransferase (COMT) Val158Met polymorphism exists.

Methods One hundred and three Caucasian controls (mean age 39.6±6.4; 65% women) were recruited in the province of Biscay, Spain. DAPP-BQ and ECR-Spanish scales were administered to assess personality and attachment dimensions respectively. DNA was obtained from saliva and the COMT Val158Met polymorphism was determined. Pearson's correlation coefficient and ANOVA were calculated using R statistical software.

Results High positive correlation is observed between inhibition personality dimension and attachment avoidance ($r=0.75$). Besides, both inhibition and avoidance dimensions' scores are significantly higher in the COMT ValMet genotype than in the

other genotypes. MetMet: 63.1±13.6; ValMet: 71.0±13.9; ValVal: 63.0±16.7 (ANOVA $F=3.75$, $P=0.027$) for inhibition and MetMet: 3.44±0.17; ValMet: 3.82±0.2; ValVal: 3.33±0.23 (ANOVA $F=3.83$, $P=0.025$) for avoidance.

Conclusions Attachment patterns are rooted in early interactions with parental figures, and according to our results they could be linked to self-perceived personality traits in adulthood. Our study also suggests that genetics may predispose individuals to certain interaction styles. Our findings, linking ValMet individuals to avoidant attachment, are similar to Luijk's (2011) results, and would support a genetic-environmental model of both attachment and personality.

* Corresponding author.

Introduction A history of traumatic events is prevalent in people with schizophrenia spectrum disorders and mood disorders. However, little is known about their etiological relationship.

Objectives To explore whether patients with acute or post-traumatic stress disorder are at higher risk of developing a schizophrenia spectrum disorder or mood disorder.

Methods In this prospective cohort study using registers covering the entire Danish population, we used the Danish Psychiatric Central Research Register to identify patients with ICD-10 diagnoses of acute traumatic stress disorder and/or posttraumatic stress disorder. From inpatient and outpatient mental hospitals, we identified 4371 diagnoses with more than 18 million years of follow-up. Main outcomes and measures were relative risks (RR) with 95% confidence intervals (95% CI) of schizophrenia, schizophrenia spectrum disorder, bipolar disorder and mood disorder.

Results The incidence of traumatic stress disorder (TSD) has increased steadily from 0.6% in 1996 to 6% in 2012, showed a higher incidence in women and an age distribution with a peak-incidence in early adulthood. We found that diagnoses of TSD increase the risk of schizophrenia (RR 5.85, 95% CI 3.59–8.91), schizophrenia spectrum disorder (RR 3.82, 95% CI 2.38–5.75), bipolar disorder (RR 5.83, 95% CI 3.11–9.83) and mood disorder (RR 4.10, 95% CI 3.15–5.22). Risks were high in the first year after diagnosis of TSD and declined going forward in time.

Conclusions Our findings indicate that acute and posttraumatic stress disorder are etiological risk factors for schizophrenia spectrum disorders and mood disorders. If replicated, this may underline treatment of traumatized patients in prevention of severe mental disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Some inconsistent evidence indicates experiences of trauma and the presence of symptoms of PTSD are associated with increased risk of cardiovascular diseases. This relation has rarely been explored with community samples including participants with PTSD symptoms or who fulfill criteria for PTSD disorders. **Objectives** We identify those with a high number of PTSD symptoms and those fulfilling criteria for PTSD are more likely to have CVD than those without a PTSD syndrome or diagnosis. We examine rates of mental health access for those with PTSD and CVD.

Methods We use Collaborative Psychiatric Epidemiology Surveys (CPES) to examine differences in trauma/PTSD prevalence and the association of prior trauma exposure and PTSD diagnoses with CVD ($n = 13,286$). CIDI was used to make psychiatric diagnoses and medical data was acquired regarding onset and severity of CVD.

Results Individuals with prior exposure to trauma and PTSD diagnoses had twice the likelihood of developing a cardiovascular disease as those without trauma exposure [OR = 1.77, 95% CI (1.0, 2.94)]. Having a PTSD diagnosis is a significant predictor of having a CVD for individuals who experienced a traumatic event.

The probability of developing a CVD was higher when patients had prior diagnosis of substance abuse [OR = 1.36, 95% CI (1.11, 1.65)] or mental health disorders [OR = 1.43, 95% CI (1.10, 1.87) for depression; OR = 1.33, 95% CI (1.04, 1.69) for anxiety]. Men were almost twice as likely as women to be diagnosed with a CVD [OR = 1.67, 95% CI (1.37, 2.00)].

Conclusions Exposure to trauma and the presence of PTSD symptoms are significantly associated with CVD.

Prevalence of the metabolic syndrome in patients at risk of psychosis

J. Cordes^{1,*}, A. Bechdolf², S. Moebus³

¹ Medical Faculty, Düsseldorf, Germany

² Klinik für Psychiatrie-Psychotherapie und Psychosomatik, Vivantes Klinikum am Urban, Akademisches Lehrkrankenhaus, Berlin, Germany

³ Zentrum Urbane Epidemiologie Cue, Universitätsklinikum Essen, Universität Duisburg-Essen, Essen, Germany

* Corresponding author.

The metabolic syndrome (MetS) is one of the most frequent reasons for the higher mortality in patients with schizophrenia. It is difficult to separate between effects of medication or the disorder itself on the development of MetS. In the present study, patients at clinical high risk for first-episode psychosis (CHR) were examined and the prevalence of the MetS was assessed. One hundred and sixty-three

unmedicated antipsychotic naïve CHR patients aged between 18 and 42 years and suffering from unmanifested prodromal symptoms were compared to 35,869 patients of the “German Metabolic and Cardiovascular Risk Study” (GEMCAS). We observed a slightly higher prevalence of single MetS criteria in CHR group compared to the GEMCAS sample, in particular: high blood pressure (35.0 vs. 28.0%), waist circumference (17.6 vs. 15.1%), and high fasting blood glucose (9.4 vs. 4.0%). We assume the higher risk for MetS in schizophrenia patients or CHR patients to derive from genetic factors.

* Corresponding author.

Introduction In vitro studies have demonstrated possible neuroprotective effects of the following pro-inflammatory cytokines: IL-6, IL-1 β and TNF- α against glutamatergic excitotoxicity in brain through different pathways.

Objectives In the current study, we aim to correlate level of the above pro-inflammatory cytokines in serum with glutamate levels in head of caudate nucleus measured using Proton Magnetic Resonance Spectroscopy (¹H-MRS) in patients with obsessive-compulsive disorder (OCD), a neuropsychiatric illness with possible multifactorial aetiology including immunological and excitotoxic factors.

Method Thirty psychotropic-naïve patients with OCD and an equal number of gender and age-matched normal controls were recruited in the study. A detailed psychiatric assessment was carried out including sociodemographic and clinical variables. A 3T MR imaging and spectroscopy session was carried out in head of caudate nucleus. Further, absolute quantification of glutamate level was obtained using LC model. Simultaneously, 5 mL of blood sample was collected and assayed for the above pro-inflammatory cytokines (Siemens, ImmuliteTM). The level of glutamate was correlated with the cytokine levels in patients with OCD.

Results The level of Glx was significantly higher in patients with OCD as compared to controls ($P < 0.05$). The Glx level negatively correlated with two of the three pro-inflammatory cytokines: IL-6 and TNF- α ($r = -0.807$; $r = -0.838$; $P < 0.05$) while no significant correlation was demonstrated with IL-1 β .

Conclusions The findings provide preliminary evidence regarding possible neuroprotective effects of pro-inflammatory cytokines

against glutaminergic excitotoxicity in patients with OCD. Further studies including patients with other psychiatric illnesses as controls are required for confirmation of the above findings.

Impact of DRD2 polymorphisms on prolactin level in risperidone-treated Thai children and adolescent with autism spectrum disorders

C. Sukasem*, Y. Hongkaew

Faculty of Medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

* Corresponding author.

Introduction A large number of studies have reported that the prolactin concentration was significantly increased in the Taq1A A1 allele carriers because several reports revealed that individuals with the DRD2 Taq1A A1 allele have a reduced density of brain D2 receptors.

Objective The main aim of this study was to identify the impact of pharmacogenetic markers associated with prolactin concentration in risperidone-treated children and adolescents with autism spectrum disorders.

Methods One hundred and forty-seven children and adolescents with autism, aged 3 to 19, received risperidone. The clinical data of patients were recorded from medical records. Prolactin levels were measured by chemiluminescence immunoassay. Three CYP2D6 single nucleotide polymorphisms (SNPs), CYP2D6*4 (1846G>A), *10 (100C>T), and *41 (2988G>A), one gene deletion (*5), and DRD2 Taq1A (rs1800497) polymorphism were genotyped by TaqMan real-time PCR.

Results The three common allelic frequencies were CYP2D6*10 (55.10%), *1 (32.65%) and *5 (6.12%), respectively. Patients were grouped according to their CYP2D6 genotypes. The DRD2 genotype frequencies were Taq1A A2A2 (38.77%), A1A2 (41.50%), and A1A1 (19.73%), respectively. There were statistically significant differences in prolactin level of patients among the three groups ($P=0.033$). The median prolactin level in patients with DRD2 Taq1A A2A2 (17.80 ng/mL) was significantly higher than A1A2 (17.10 ng/mL) and A1A1 (12.70 ng/mL).

Conclusion DRD2 Taq1A A2A2 polymorphisms may be a critical role in an influence prolactin elevation during risperidone treatment in ASD.

Detection of CYP2D6 polymorphism using Luminex xTAG technology in autism spectrum disorder: CYP2D6 activity score and its association with risperidone levels

C. Sukasem*, S. Santon

Faculty of Medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

* Corresponding author.

Introduction The determination of the accurate CYP2D6 genotyping is essential in the clinical setting and individualization of drug therapy.

Objectives In this study, was to apply the Luminex xTAG technology to detect significant CYP2D6 polymorphisms and copy number variation, including assessment the relationship of CYP2D6 polymorphisms and risperidone plasma concentration in autism spectrum disorder children (ASD) treated with risperidone.

Methods All 84 ASD patients included in this study had been receiving risperidone at least for 1 month. The CYP2D6 genotypes were determined by luminex assay. Plasma concentrations of risperidone and 9-hydroxyrisperidone were measured using LC/MS/MS.

Results Among the 84 patients, the most common genotype was CYP2D6*1/*10 (26.19%). The most common allele was CYP2D6*10 (51.79%) and the second most allele was CYP2D6*1 (27.98%). There were 46 (55.42%) classified as EM, 33 (39.76%) as IM, and 4 (4.82%) as UM. The plasma concentration of risperidone and risperidone/9-hydroxyrisperidone ratio in the patients were significant differences among the CYP2D6 predicted phenotype group ($P=0.001$ and $P<0.0001$, respectively). Moreover, the plasma concentration of risperidone and risperidone/9-hydroxyrisperidone ratio in the patients with CYP2D6 activity score 0.5 were significantly higher than those with the CYP2D6 activity score 2.0 ($P=0.004$ and $P=0.002$, respectively).

Discussions The present study suggests that it would be ideal to identify the CYP2D6 genotype of patients before prescribing and administering risperidone. Furthermore, the use of CYP2D6 gene scoring system to determine an individual's metabolic capacity may become an essential tool for a more rational and safer drug administration.

Angiotensin II type 1 receptor blockade diminishes negative effect of chronic stress on memory via upregulation of brain-derived neurotrophic factor

D. Wincewicz^{1,*}, A. Juchniewicz²

¹ Medical University of Bialystok, Department of Clinical Pharmacology, Bialystok, Poland

² Medical University of Bialystok, Department of Clinical Molecular Biology, Bialystok, Poland

* Corresponding author.

Introduction A critical need exists for progress in the characterization of targets for pro-cognitive drug discovery. We previously demonstrated that Telmisartan (TLM), an angiotensin type 1 receptor (AT1) blocker and partial agonist of peroxisome proliferator-activated receptor gamma (PPAR γ), alleviates cognitive decline in chronically stressed rats. Understanding of mechanistic background of this phenomenon is hampered by both dual binding sites of TLM and limited data on the molecular consequences of central AT1 blockade and PPAR γ activation.

Objectives To discriminate molecular effects of AT1 blockade and PPAR γ activation in stress induced memory impairment.

Aims In this study, we investigated mechanism of neuroprotection provided by TLM in chronic psychological stress.

Methods We analyzed BDNF gene expression in the hippocampus (HIP) and medial prefrontal cortex (mPFC) in chronically restrained stressed Wistar rats (2.5 h, 21 days), repeatedly treated with TLM (1 mg/kg), GW9662 (0.5 mg/kg) – a selective PPAR γ receptor antagonist, or both in combination. TATA box binding protein (Tbp) was an internal control for expression studies.

Results Alterations of mRNA expression of BDNF are shown on Figs. 1 and 2.

Conclusions AT1 receptor blockade restores cognitive functions in chronically stressed subjects, which is associated with changes in primarily cortical gene expression.

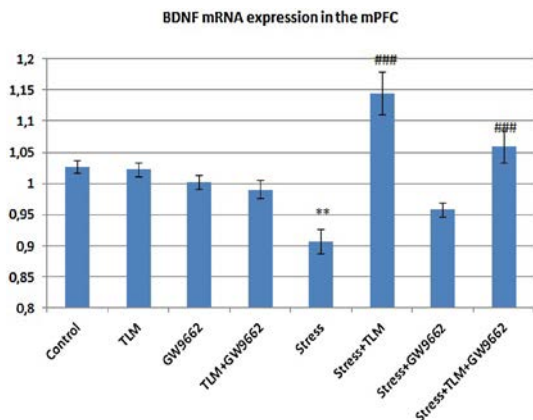

Fig. 1 Effect of chronic stress (2.5 h, 21 days), chronic TLM (1 mg/kg, 21 days), chronic GW9662 (0.5 mg/kg, 21 days) or all in combination on mRNA BDNF expression in the mPFC (BDNF/Tbp ratio). Bars represent mean \pm SEM; $n=5$; ** $P<0.01$; Control vs. Stress; ### $P<0.001$ Stress vs. Stress + TLM and Stress vs. Stress + TLM + GW9662.

Fig. 2 Effect of chronic stress (2.5 h, 21 days), chronic TLM (1 mg/kg, 21 days), chronic GW9662 (0.5 mg/kg, 21 days) or all in combination on mRNA BDNF expression in the HIP (EDNF/Tbp ratio). Bars represent means \pm SEM; $n=5$; * $P<0.05$; Stress vs. Stress + TLM and Stress vs. Stress + TLIVH-GW9662.

Neuropsychiatric consequences of deep brain stimulation surgeries in the patients affected by chronic movement disorders: A brief report

S. Mahdavi^{1,*}, S.K. Malakouti², B. Naji², M. Asadi¹, S. Kahani³

¹ Iran University of Medical Sciences, psychiatry, Tehran, Iran

² School of Behavioral Sciences and Mental Health, Iran University of Medical Sciences, psychiatry, Tehran, Iran

³ Rasoul Akram Hospital, Iran University of Medical Sciences, psychiatry, Tehran, Iran

* Corresponding author.

The main surgical procedure for PD and other chronic movement disorders is deep brain stimulation. DBS has been reported to have specific consequences such as decline in verbal fluency and episodes of depression.

We designed an interventional study in 12 patients affected by Parkinson, dystonia and tic who underwent DBS surgery. Patient assessed before surgery, one month and one year after surgery.

The results proved a significant improvement in SF36. The Hamilton's anxiety scale showed an overall but insignificant improvement. The mean of scores of the BDI had a great drop one month after surgery but a raise at the 12th month (insignificant pattern).

Pearson's correlation test showed a significant negative correlation between age and the SF36 scores. The BDI's scores were assessed in relation with age. Although there was no actual relation between them before surgery, we detected a positive correlation between them after one year.

Conclusion The pattern of changes can be related with the differences between perioperative expectations and real long-term outcomes. Correlations between changes seen in BDI and SF36 scores with age can be considered as a confirmatory evidence for this idea.

All cases showed an insignificant gradual decline in digit span test, which may be independent of the surgical procedure. Although the COWA test could not prove a significant deterioration in verbal fluency but a slight decline after one year was obvious, in addition to one patient who turned aphasic during this period.

The outcomes showed that the benefits of DBS outweigh the slight risk of developing depression.

Transcranial direct current stimulation in treatment – resistance unipolar major depressive disorder

M. Asadi*, S. Mahdavi

Tehran University of medical science, psychiatry, Tehran, Iran

* Corresponding author.

Objective MDD is a common, chronic and recurrent illness .it is essential to reach full remission in acute treatment. tDCS is a non-invasive brain stimulation that uses direct electrical currents to stimulate specific parts of the brain.

Aim Is to assess the effectiveness of tDCS in patients with treatment resistance MDD.

Method Eighty outpatients of a psychiatric clinic were selected. Subjects meet (DSM-IV) diagnostic criteria for MDD. All patients had failed to respond to at least two standard antidepressant

medication, in the current episode. Patients with bipolar depressive disorder, MDD with psychotic and atypical features, other psychiatric disorders, severe medical condition, acute suicidality and pregnancy were excluded. All patients received stable drug regimens for at least two weeks before enrollment and drug dosages remained unchanged throughout the study. They revised 8 stimulation sessions, using a 2 mA current, for 20 minutes, in 8 consecutive days. The anodal electrode was placed over the left DLPFC. Cathode electrode over the right supraorbital region. Mood was evaluated with 21-item Hamilton Rating Depression Scale and the Beck Depression Inventory.

We designed a pretest–posttest study and evaluate depression at baseline (pre-intervention), immediately after 8 sessions (post-intervention) and two months after treatment onset (follow-up).

Results There is a significant difference between Pre- vs. post-intervention ($F_{BDI} = 246.58$, $P < 0.001$; $F_{HRSD} = 214.56$, $P < 0.001$) and pre vs. Follow-up intervention ($F_{BDI} = 323.10$, $P < 0.001$; $F_{HRSD} = 150.96$, $P < 0.001$).

Conclusion It can be said that tDCS had effective and enduring variation ($P_{\text{post vs. follow-up}} > 0.05$) in improving the clinical symptoms of MDD.

Cryostimulation of whole body as a possible supportive biological approach in mild cognitive impairments

J. Rymaszewska*, D. Szczesniak, U. Katarzyna, T. Elzbieta, S. Bartlomiej

Wroclaw Medical University, Division of Consultation Psychiatry and Neuroscience, Wroclaw, Poland

* Corresponding author.

Background Limitations of available treatment methods of dementia imply constant need to search for new, supplementary therapy strategies. There is a consensus that vascular lesions, oxidative stress, inflammatory processes and abnormal neurotransmission are associated with dementia. Due to the anti-inflammatory (modification of pro-inflammatory cytokines concentration), antioxidative effect of cryogenic temperatures as well as the hormonal and lipid changes, they may play an important role in preventing or inhibiting pathophysiological processes.

Aim To assess the influence of whole-body cryostimulation on cognitive functions of patients with MCI.

Methods RCT design is used to examine the influence of whole-body cryotherapy (WBC) on people with mild cognitive impairments (MCI) with the evaluation of psychometric, somatic and laboratory parameters. Participants undergo 10 sessions each day of 2–3 min of WBC in experimental group (–110 till –160 °C) and placebo (–20 °C). The CDR, MoCA, TYM, DemTect and SLUMS scales are used among others at baseline and follow-up. Preliminary data of 7 volunteers ($n = 7$, 49–79 years old) were presented. Results on Fig. 1.

Discussion Among obtained psychometric results show that all, except of one, patients significantly improved their scores after WBC. That is a very promising feedback for future evaluation of WBC effectiveness in prevention of dementia in patients with MCI.

Clinical symptomatology and facial emotion recognition in schizophrenia: Which relationship?

A. Arous*, J. Mrizak, R. Trabelsi, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Department Psychiatry F, Tunis, Tunisia

* Corresponding author.

Introduction Patients with schizophrenia show impairments in social cognitive abilities, such as recognizing facial emotions. However, the relationships between specific deficits of emotion recognition and with clusters of psychotic remain unclear.

Objectives To explore whether facial emotion recognition was associated with severity of symptoms and to which presentation of psychotic symptoms.

Methods Facial emotion recognition (FER) were evaluated in 58 patients with stable schizophrenia with a newly validated FER task constructed from photographs of the face of a famous Tunisian actress representing the Ekman's six basic emotions (happiness, anger, disgust, sadness, fear, and surprise). Symptomatology evaluation comprised the Positive and Negative Syndrome Scale (PANSS), the Calgary Depression Scale for Schizophrenia (CDSS) and the Clinical Global Impressions Scale Improvement and severity (CGI).

Results Patients who failed to identify anger had significantly higher scores in hyperactivity item ($P < 0.0001$). The patients who had a difficulty to identify sadness had more grandiosity ($P \leq 0.002$). The impairment in happiness recognition was correlated with hallucination ($P = 0.007$) and delusion ($P = 0.024$) items. Incapacity to identify fear was associated with lack of judgment and insight ($P = 0.004$).

Conclusions Deficits in recognition of specific facial emotions may reflect severity of psychiatric symptoms. They may be related to specific clusters of psychotic symptoms, which need to be confirmed in further studies.

⁵ Universidad de Valencia, Department of Psychiatry, Valencia, Spain

* Corresponding author.

There is a growing interest in inflammation and immune dysfunction in severe psychiatric disorders such as schizophrenia and bipolar disorder. This dysfunction seems to consist in abnormal blood levels of cytokines and acute-phase proteins, with increased levels of C-reactive protein (CRP), fibrinogen, homocysteine and erythrocyte sedimentation rate (ESR). Higher levels can be found in acute episodes and in patients with a higher cardiovascular risk. Acute-phase protein serum parameters were determined in a sample of 100 outpatients with schizophrenia ($n=50$) or bipolar disorder ($n=50$) so as to assess differences in pro-inflammatory state. Metabolic state was assessed through BMI, waist circumference, glucose, cholesterol and triglyceride levels.

The whole sample showed higher levels of fibrinogen (mean 4 ± 0.9 g/L), triglycerids (mean 2.9 ± 8.5 mmol/L), cholesterol-LDL (mean 3 ± 0.9 mmol/L), and homocysteine (mean 16.2 ± 7.3 μ mol/L) than our laboratory reference values from healthy individuals.

After correcting for gender and pharmacological treatment, patients with schizophrenia showed higher levels of ESR, fibrinogen, glucose and CRP, while homocysteine was not statistically different between patients with schizophrenia or bipolar disorder (see Table 1).

These results may suggest a different biomarker profile in bipolar and schizophrenic outpatients, with a more severe pro-inflammatory state in schizophrenia. Serum homocysteine levels could be a state marker in both disorders.

Table 1

	ESR (mm)	Fibrinogen (g/L)	Glucose (mmol/L)	CRP (mg/L)	Homocysteine (mmol/L)
Schizophrenia	6 \pm 5.7	4.1 \pm 0.85	5.7 \pm 2.0	5.4 \pm 4.2	17.1 \pm 8.6
Bipolar disorder	3.1 \pm 2.2*	3.6 \pm 0.76*	4.4 \pm 0.95*	2.2 \pm 2.0*	15.9 \pm 5.7 (NS)

NS: not significant. * $P < 0.05$.

⁵ Université Paris-Est, Inserm U955 eq15, GHU Mondor, DHU Pe-psy, Psychiatry, Créteil, France

* Corresponding author.

The main objective of this study was to determine the prevalence of akathisia in a community-dwelling sample of patients with schizophrenia, and to determine the effects of treatments and the clinical variables associated with akathisia. Three hundred and seventy-two patients with schizophrenia or schizoaffective disorder were systematically included in the network of FondaMental Expert Center for Schizophrenia and assessed with validated scales. Akathisia was measured with the Barnes Akathisia Scale (BAS). Ongoing psychotropic treatment was recorded. The global prevalence of akathisia (as defined by a score of 2 or more on the global akathisia subscale of the BAS) in our sample was 18.5%. Patients who received antipsychotic polytherapy were at higher risk of akathisia and this result remained significant (adjusted odd ratio=2.04, $P=.025$) after controlling the influence of age, gender, level of education, level of psychotic symptoms, substance use comorbidities, current administration of antidepressant, anticholinergic drugs, benzodiazepines, and daily-administered antipsychotic dose. Our results indicate that antipsychotic polytherapy should be at best avoided and suggest that monotherapy should be recommended in cases of akathisia. Long-term administration of benzodiazepines or anticholinergic drugs does not seem to be advisable in cases of akathisia, given the potential side effects of these medications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antipsychotic-induced tardive dyskinesia: The role of glutamatergic system

A. Boiko^{1,*}, S. Ivanova¹, A. Semke²

¹ Mental Health Research Institute SB RAMSci, Laboratory of Molecular Genetics and Biochemistry, Tomsk, Russia

² Mental Health Research Institute SB RAMSci, Department of Clinical Psychiatry, Tomsk, Russia

* Corresponding author.

Tardive dyskinesia (TD) occurs in 20–25% of patients with long-term antipsychotic therapy. Abnormalities in glutamatergic transmission are considered one of the key components of the pathogenesis of drug-induced side effects. Glutamate acts as excitotoxin under certain conditions and in excessive concentrations. Aim is to study the concentration of glutamate and analysis of single nucleotide polymorphisms (SNP) in genes coding the glutamate transporter and NMDA-receptors in schizophrenic patients with TD and without it.

The study group included 156 patients with schizophrenia receiving long-term antipsychotic treatment. Patients were divided into two groups: 63 patients with TD and 93 patients without it. Glutamate was determined in serum by spectrophotometric method. Determination of allelic variants of gene SLC1A2 (rs4354668) and GRIN2A (rs2650427, rs1969060) was performed by polymerase chain reaction in real-time.

We found a significant ($P < 0.05$) increase of the concentration of glutamate in patients with TD. Significant ($P < 0.05$) reduction in frequency of genotype GG of GRIN2A (rs1969060) and TT of SLC1A2 (rs4354668) were found in patients with TD in comparison to group without TD. In the study of glutamate concentration depending on the genotype GRIN2A (rs1969060) and genotype SLC1A2 (rs4354668) we observed a statistically significant change: elevated levels of glutamic acid identified with the heterozygous genotype in patients.

It is possible to suggest that reduction in frequency of these genotypes increases the risk of movement disorders due to the protective effect of these genotypes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive function in female patients with schizophrenia and metabolic syndrome

A.C. Botis^{1,*}, I. Miclutia¹, N. Vlasin²

¹ University of Medicine and Pharmacy Cluj-Napoca, Psychiatry and pediatric psychiatry, Cluj-Napoca, Romania

² Emergency County Hospital Cluj-Napoca, Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction The metabolic syndrome (MetS) and cognitive impairments, both related with poor outcomes in schizophrenia, are common in patients with this disorder. MetS has been associated with cognitive impairments in schizophrenia, but there is no general consensus regarding the description of various domains of neurocognition in patients with schizophrenia related to MetS.

Objectives The goal of this study was to assess cognitive functions in female patients with schizophrenia complicated by metabolic syndrome compared to those with schizophrenia without metabolic syndrome.

Methods Fifty-four female patients diagnosed with schizophrenia were divided into two groups: MetS group (MetS+) and non-MetS group (MetS-). Cognitive functioning were investigated using the Brief Assessment of Cognition in Schizophrenia (BACS).

Results Twenty-seven (52%) patients with schizophrenia met criteria for the MetS diagnosis. Mean age of patients was 40.80. Patients from MetS+ group performed significantly worse on verbal memory ($P = 0.005$), executive functions ($P = 0.028$) and motor speed ($P = 0.035$) as compared to MetS- group. Patients with schizophrenia who were hypertensive showed cognitive impairments in 2 domains of cognition: attention and speed of information processing ($P = 0.004$) and verbal fluency ($P = 0.001$). Patients with hypertriglyceridemia performed significantly worse on verbal memory ($P = 0.005$). Motor speed was associated with waist circumference ($P = 0.02$).

Conclusions At a mean age of 40 years old, female patients with schizophrenia and metabolic syndrome show difficulties in more domains of cognitive function compared to female patients with schizophrenia without metabolic syndrome. Our findings suggest a link between cognition and metabolic syndrome in female patients with schizophrenia.

Comparing cognitive functions in medication adherent and non-adherent patients with schizophrenia

A. El-Missiry

Ain Shams University, Neurology & Psychiatry, Cairo, Egypt

Background Medication non-adherence presents a considerable problem in patients with schizophrenia. Cognitive and executive functions can affect adherence. The association between medication non-adherence and cognitive impairment in schizophrenia is under investigated with limited and conflicting research data.

Purpose of the study To prospectively assess the rate of drug adherence among a sample of patients with schizophrenia and to compare the cognitive and executive functions between adherent and non-adherent patients.

Subjects and methods One hundred and nine patients with schizophrenia diagnosed according to the DSM-IV classification were initially assessed by the Wechsler Adult Intelligence Scale (WAIS), Wechsler Memory Scale-Revised (WMS-R) and Wisconsin Card Sorting Test (WCST) and six months later by the Brief Adherence Rating Scale (BARS).

Results Among the patients, 68.8% were non-adherent to their antipsychotic medication. Adherent patients (31.2%) had significantly higher mean scores for the total, verbal and performance IQ. Moreover, they had significantly higher mean scores in most of WMS subtests (orientation, information, verbal paired association, digit span, visual memory span), and higher mean scores for; total correct, conceptual level response, percentage and categories completed on the WCST subscales ($P < 0.0001$). Whereas the non-adherent group had higher mean scores in; trials administered, total errors, perseverative responses, and perseverative errors ($P < 0.0001$). In a step regression analysis, digit span, conceptualization, total and percentage of errors were putative predictors of non-adherence to antipsychotic medications.

Conclusion Cognitive deficits, especially verbal memory and executive functions were the strongest patients' related factors associated with non-adherence to medication. Psychiatrists should consider possible cognitive factors influencing adherence to enable offering proper interventions.

Disclosure of interest The author has not supplied his declaration of competing interest.

Peripheral sub-inflammation is associated with antidepressant consumption in schizophrenia. Results from the multi-center FACE-SZ dataset

G. Fond^{1,*}, O. Godin¹, P.M. Llorca², M. Leboyer¹

¹ Schizophrenia Expert Center Fondation Fondamental, Créteil, France

² Schizophrenia Expert Center Fondation Fondamental, Clermont-Ferrand, France

* Corresponding author.

Objectives The relation between C-reactive protein (CRP), depression and antidepressant consumption has been well explored in major depressive disorders but not in schizophrenia, which has a high rate of depression comorbidity. The objectives of this study were:

- to determine the prevalence of abnormal CRP levels, depression and antidepressant consumption in a multi-center community-dwelling sample of subjects with schizophrenia;
- to determine the association between abnormal CRP levels, depression and antidepressant consumption in schizophrenia.

Method Two hundred and nineteen stable patients with schizophrenia (mean age = 31.6 years, 75.3% male gender) were systematically included in the multicentre network of FondaMental Expert Center for schizophrenia (FACE-SZ) and assessed with Calgary Depression Scale for depression. High sensitivity CRP (hs-CRP) was measured with an assay using nephelometry (Dade Behring). Abnormal CRP level was defined by levels > 3 mg/L. Current medication was recorded.

Results Overall, 63 subjects (28.8%) were found to have abnormal CRP levels, 43 (20.1%) received a diagnosis of comorbid current depression, and 51 (31.9%) had ongoing antidepressant treatment. In univariate analysis, abnormal CRP levels were found to be significantly associated with metabolic syndrome ($P=0.0011$) and with antidepressant consumption ($P=0.01$), while depression, psychotic symptomatology, age of onset, illness duration, sociodemographic characteristics, current tobacco or cannabis status were not (all $P>0.05$).

In a multivariate model, abnormal CRP was highly associated with antidepressant consumption independently of other confounding variables (adjusted odd ratio = 2.9, 95% confidence interval 1.2–6.8). **Conclusion** Abnormal CRP levels in schizophrenia were found to be associated with antidepressant consumption, but not with depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Birth by cesarean section and schizophrenia. Results from the multi-center FACE-SZ dataset

G. Fond^{1,*}, L. Boyer², P.M. Llorca³, M. Leboyer¹

¹ Schizophrenia Expert Center Fondation Fondamental, Créteil, France

² Pôle de psychiatrie universitaire, Pôle de psychiatrie universitaire, Marseille, France

³ Schizophrenia Expert Center Fondation Fondamental, Clermont-Ferrand, France

* Corresponding author.

Objectives Children born by cesarean section (“c-birth”) are known to have different microbiota and a natural history of different disorders including allergy, asthma and overweight compared to vaginally born (“v-birth”) children. C-birth is not known to increase the risk of schizophrenia (SZ), but to be associated with an earlier age at onset. To further explore possible links between c-birth and SZ, we compared clinical and biological characteristics of c-born SZ patients compared to v-born ones.

Method Four hundred and fifty-four stable community-dwelling SZ patients (mean age = 32.4 years, 75.8% male gender) were systematically included in the multicentre network of FondaMental Expert Center for schizophrenia (FACE-SZ).

Results Overall, 49 patients (10.8%) were c-born. These patients had a mean age at schizophrenia onset of 21.9 ± 6.7 years, a mean duration of illness of 10.5 ± 8.7 years and a mean PANSS total score of 70.9 ± 18.7 . None of these variables was significantly associated with c-birth. Multivariate analysis showed that c-birth remained associated with lower peripheral inflammation (aOR = 0.07; 95% CI 0.009–0.555, $P=0.012$) and lower premorbid ability (aOR = 0.945; 95% CI 0.898–0.994, $P=0.03$) independently of age, age at illness onset, sex, education level, psychotic and mood symptomatology, antipsychotic treatment, tobacco consumption, birth weight and mothers suffering from schizophrenia or bipolar disorder.

Conclusion Altogether, literature data as well as our results suggest that c-birth is associated with lower weight gain and lower inflammation in schizophrenia, which could be explained by microbiota differences. Further studies should take into account c-birth when exploring the role of microbiota in SZ patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objectives The aim of this study is to explore connectivity of the left dorsolateral prefrontal cortex (LDLPC) by functional magnetic resonance imaging during resting state, in subjects affected by schizophrenia and unaffected relatives.

Methods We recruited a group of 29 patients diagnosed with schizophrenia, who were treated with atypical antipsychotics, who are and were clinically stable in the last 6 months and had an illness duration range from 5 up to 15 years. We also recruited a group of 23 unaffected relatives, without history of other mental, neurological or somatic disease and a group of 37 healthy volunteers. No subject in any of the three groups met criteria for substance use disorders.

All three groups were clinically evaluated, and a functional magnetic resonance during Resting State was performed.

Functional images were reoriented to the first scan, normalized to the MNI EPI template and smoothed with an 8 mm Gaussian kernel, with SPM. The CONN-FMRI Toolbox v1.2 was used to create individual subject seed-to-voxel connectivity maps, to the corresponding seeds of the default mode network.

Results Fig. 1.

Conclusions Our results show a significant increase in connectivity between LDLPC and anterior prefrontal cortex, dorsolateral prefrontal cortex and somatosensory association areas, especially between patients and controls. It is noteworthy to mention that we found a significant decrease in connectivity between LDLPC and supramarginal gyrus, superior temporal gyrus and somatosensory association areas between unaffected relatives and controls.

An interventional, multi-center, randomized, double-blind, placebo-controlled, active reference, flexible dose study of brexpiprazole in adults with acute schizophrenia

S.R. Marder¹, M. Hakala^{2,*}, M. Gislum³, A. Skuban⁴, E. Weiller⁵, C. Weiss⁶

Introduction Brexpiprazole is a serotonin-dopamine activity modulator that is a partial agonist at 5-HT_{1A} and dopamine D₂ receptors at similar potency, and an antagonist at 5-HT_{2A} and noradrenaline alpha_{1B/2C} receptors.

Objectives Evaluating the efficacy, safety, and tolerability of flexible doses of brexpiprazole compared with placebo in patients with acute schizophrenia.

Aim Primary endpoint was change from baseline to week 6 in PANSS total score and key secondary endpoint was change from baseline to week 6 in CGI-S score.

Methods Phase 3, multi-center, randomized, double-blind, placebo-controlled, active reference, trial (NCT01810380). Hospitalized patients were randomized to brexpiprazole (2 to 4 mg/day), placebo, or quetiapine extended release (400 to 800 mg/day) for

6 weeks. Quetiapine was included as an active reference. Changes from baseline were analyzed using an MMRM approach.

Results Mean change in PANSS total score was -20.0 and -15.9 in the brexpiprazole ($n = 150$) and placebo ($n = 159$) groups, respectively ($P = 0.056$). Sensitivity analyses suggested treatment effect (e.g., ANCOVA, LOCF: $P = 0.025$; ANCOVA, OC: $P = 0.026$). Mean change in PANSS total score (-24.0) with quetiapine ($n = 150$) was significantly greater than that with placebo ($P < 0.001$), demonstrating sensitivity of the assay. Brexpiprazole separated from placebo on the mean change in CGI-S score (-1.2 vs. -0.9, $P = 0.014$). The proportion of patients reporting TEAEs were similar between the brexpiprazole and placebo treatment groups (54% versus 54.7%).

Conclusion Treatment with brexpiprazole showed a clinically meaningful improvement in patients with acute schizophrenia. While the difference between brexpiprazole and placebo only approached statistical significance, sensitivity analyses and secondary endpoints supported a treatment effect of brexpiprazole.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Are self-stigma and coping strategies interrelated in outpatients with schizophrenia spectrum disorders using the psychiatric medication?

Cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹, R. Hruby³, K. Latalova¹, M. Slepecky⁴, M. Marackova¹, D. Kamaradova¹, T. Gubova²

* Corresponding author.

Introduction Self-stigma is the maladaptive psychosocial phenomenon that can affect the patient's self-image, may lead to dysphoria, social isolation, reduced adherence and quality of life. Maladaptive coping strategies may adversely disturb the overall functioning of psychiatric patients.

Objectives Thinking about coping strategies and self-stigma in practice may play a significant role in understanding patients with schizophrenia spectrum disorders, especially for mental health professionals. Focus on coping strategies could be a useful concept in supportive and educational therapy to help patients in using more adaptive coping strategies and decrease their self-stigma.

Aims The aim of this study was to determine the relation between coping strategies and the self-stigma among outpatients with schizophrenia and related disorders.

Methods Stress Coping Style Questionnaire (SVF-78), Internalized Stigma of Mental Illness (ISMI) and severity of the disorder (measured by Clinical Global Impression objective and subjective form) were assessed.

Results One hundred and four patients suffering from schizophrenia ($n = 67$), schizoaffective disorder ($n = 30$), polymorphic psychotic disorder ($n = 3$), schizotypal disorder ($n = 2$) and delusional disorder ($n = 2$) were included in the study. The results showed that there was a high positive correlation between negative coping and self-stigma, and the negative correlation between positive strategies and the overall score of self-stigma. Stepwise regression analysis showed that negative coping (especially resignation), subjective severity SubjCGI and positive coping

strategies (especially positive self-instruction) explains 52.8% of the overall score variance of self-stigma (Tables 1–3).

Conclusions This study revealed that there is a connection between self-stigma and coping strategies in patients suffering from schizophrenia spectrum disorders.

Introduction The effects of long-term antipsychotic medication use on structural brain changes in psychoses are still unknown. Severity and duration of illness are key confounders when evaluating antipsychotic effects on brain morphology.

Objectives Understanding the role of antipsychotic medication on brain morphology in psychoses.

Aims To analyze whether cumulative lifetime or current antipsychotic medication dose relates to brain morphology in schizophrenia and other psychoses at age of 43 years.

Methods Forty-four schizophrenia cases and 35 with other psychoses from the Northern Finland Birth Cohort 1966 were scanned on a 1.5T GE Signa scanner and brain structures were extracted using volBrain automated volumetry system (<http://volbrain.upv.es>). Data of antipsychotic medication were collected from medical records and interviews. We used linear regression model to analyze the effect of antipsychotic medication on brain volumes and used intracranial volume and onset age as covariates. We also performed additional analyses adding psychotic symptoms (PANSS Total score) as a covariate.

Results Higher lifetime and current dose associated to left lateral ventricle increase ($b=0.33$, $P=0.033$; $b=0.307$, $P=0.042$, respectively) and right and left accumbens decrease ($b=-0.405$, $P=0.013$, $b=-0.404$, $P=0.010$; $b=-0.302$, $P=0.027$, $b=-0.282$, $P=0.036$, respectively) in schizophrenia but not in other psychoses. When PANSS was added to the model, the findings remained regarding right and left accumbens, but not regarding left lateral ventricle.

Conclusions It seems that antipsychotic medication affects the brain in schizophrenia, but not in the heterogeneous group of other psychoses. In schizophrenia, brain changes associated to antipsychotic medication cannot be explained by illness duration or symptom severity.

Objectives To observe the association between adverse effects of long-term use of antipsychotic drugs in female schizophrenic patients and dopamine D2 receptor (DRD2), cytochrome P450 (CYP) 2D6, estrogen receptor- α gene (ESR1).

Method The subjects were 89 female schizophrenic patients (age range from 18 to 40) who had been taking the same medication for more than 3 months. The adverse effects with regard to hyperprolactinemia were studied through the blood collection at one point of the subjects. Furthermore, the effect of DRD2, CYP2D6, ESR1 on serum prolactin level and amenorrhea was analyzed.

Results There was a lower concentration of E2 in patients with amenorrhea. In addition, an inverse correlation was found between prolactin level and E2 level. Hyperprolactinemia (HPRL) was commonly found in patients who had been using risperidone, amisulpride and paliperidone; in contrast, HPRL was found less in those who had been taking aripiprazole, olanzapine, ziprasidone, clozapine and quetiapine. Moreover, female schizophrenic patients who had DRD2 Taq1 A1 allele had twice the chance of developing amenorrhea than those who did not have A1 allele. Female schizophrenic patients who had Taq1 A1 allele also had 48% higher concentration level of prolactin than those who did not have A1 allele. There was no association found between prolactin and CYP2D6 or ESR1.

Conclusion Female schizophrenic patients who had DRD2 Taq1 A1 allele showed high prolactin level and high-frequency of HPRL. Therefore, reducing the use of prolactin-elevating antipsychotics for female schizophrenic patients with DRD2 Taq1 A1 allele would

be one method minimizing the adverse effects of drug-induced hyperprolactinemia.

Introduction Rats are social animals that produce high-frequency whistles said to reflect their underlying affective state. Injecting rats with a glutamate agonist (domoic acid) at a sensitive period of brain development, models aspects of schizophrenia. This is known as the neonatal DOM model.

Aims We investigated whether DOM rats display altered social behaviour – as seen in patients with schizophrenia – using their high-frequency whistles as a proxy for the emotional valence of social situations.

Methods We used 19 male Sprague Dawley rats, injected with either a low-dose of domoic acid or saline at postnatal days 8 to 14. The social behaviour of the rats was investigated at four levels:

- anticipation of social interaction;
- dyadic encounter;
- three-chamber test;
- tickling.

Tests were carried out at postnatal days 34 to 40 and 50 to 56. Rat whistles were recorded on all days of testing.

Results In progress.

Conclusions The interest in rat whistles as a supplement to traditional behavioural tests has increased. New software allows for detailed qualitative analysis of the whistle subtypes and thus new complexity to their interpretation. This study can help unravel information encoded in the whistles and shed light on the social behaviour of the DOM rat thus investigating its applicability as a model of schizophrenia.

* Corresponding author.

Objectives Intellectual functioning in schizophrenia has been associated with genetic vulnerability and obstetric complications.

Aims The aim of this study was to assess:

– the incidence of complications during pregnancy, labor and delivery;

– the association of OCs with general intellectual ability in two groups: patients with schizophrenia and their healthy siblings.

Methods Forty-two patients with schizophrenia according to DSM-IV and 43 their healthy siblings were included in the study and examined using MINI and WAIS-R. Their mothers were interviewed to gather data on OCs. The ‘midwife protocol’ of Parnas et al. was used to quantify the presence and entity of OCs.

Results Asphyxia, mother’s serious illness during pregnancy, premature delivery with weight <2500 g, labor time >48 h, infarcts in the placenta and eclampsia were statistically more frequent in schizophrenic group. OCs were more common in individuals with a family history. The two investigated groups were different in the following WAIS-R subtests: comprehension ($P=0.018$), block design ($P=0.0001$), digit symbol ($P=0.001$), as well as in performance IQ and total IQ. In the patient group, correlations between OCs indexes and WAIS-R results include all intelligence quotients (verbal, performance, total IQ) and 5 WAIS-R subtests, while in the sibling group: verbal and total IQ and 2 subtests. The correlation between Vocabulary subtest and OCs was the strongest in both groups.

Conclusion OCs may interact with genetic vulnerability to increase the risk of schizophrenia and have been associated with cognitive deficits in the patient group.

* Corresponding author.

Introduction A number of authors have hypothesized that psychotic patients who consume cannabis constitute a differentiated subgroup of patients that have better cognitive and social skills, necessary to engage in illegal drug consumption, than non-using patients.

Objectives Given that the prevalence, and patterns, of cannabis use are culturally driven, we wanted to study first-episode psychosis (FEP) cannabis-using and non-using patients coming from different European countries as part of the EUGEI-STUDY.

Aims We tested the hypothesis of better premorbid social adjustment in cannabis-using FEP patients, by comparing them to FEP non cannabis users and to their respective healthy controls.

Methods A total of 1745 people (746 cases; 999 controls) completed the assessment for premorbid adjustment [Premorbid Adjustment Scale (PAS)] and cannabis use (CEQ-Revised). We first extracted the Premorbid Social Adjustment Factor (PSA) from PAS and then performed linear mixed models with PSA as dependent variable and cannabis lifetime (Yes/No) and subject status

(Cases/Controls) as independent variables. We then considered ‘Country’ as random intercept.

Results Across all countries, PSA scores were better in patients who had smoked cannabis in their lifetime than patients who had not ($P=0.009$). The difference in PSA score between cannabis users and non-users was significantly greater in cases than controls ($P=0.038$). The relationship between PSA, cannabis lifetime (Yes/No) and subject status among nations (random intercept) is shown on Fig. 1.

Conclusions Cannabis-using psychotic patients show better premorbid social adjustment than non-using patients, across 5 European countries.

Fig. 1 PSA scores by subject status (cases/controls) and cannabis use (yes/no) across different countries.

Disrupted thalamo-orbitofrontal but not fronto-temporal white matter connectivity in people with schizotypal personality disorder

T.Y. Lee*, S.N. Kim, J.S. Kwon

Seoul National University College of Medicine, Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction Despite patients with schizophrenia showed the deficits in the fronto-temporal and thalamo-frontal connectivity, the white matter connectivity in patients with schizotypal personality disorder had not been systematically investigated.

Methods This study involved 40 neuroleptic-naïve patients with schizotypal personality disorder (SPD), 60 patients with schizophrenia (SCZ), and 100 healthy controls (HC), and scanned on the 3T MRI scanner. Probabilistic tractography was performed using the FATCAT software in AFNI. The target brain regions (bilateral lateral frontal, medial frontal, orbitofrontal, temporal and thalamus) were extracted from the automated segmentation and cortical parcellation. Cross-sectional comparisons in mean fractional anisotropy (FA) performed on the thalamo-lateral frontal, thalamo-medial frontal, thalamo-orbitofrontal, lateral frontal-temporal and

orbitofrontal-temporal pathway. We also analyzed the relationship between the white matter pathway and the Positive and Negative Syndrome Scale and GAF.

Results The diffusion tensor imaging showed that SCZ and SPD had decreased FA in the left thalamo-orbitofrontal pathway. However, SPD showed no alteration in the fronto-temporal pathway, despite SCZ showed decreased FA in the left temporo-orbitofrontal pathway. In SCZ, there were significant correlations between FA value in the left temporo-orbitofrontal pathway and negative symptoms score in PANSS and GAF score. However, SPD showed the trend level relationship between the GAF score and FA value in the left temporo-orbitofrontal pathway.

Conclusion These results suggest that the deficits in thalamo-frontal connectivity may be a trait marker of schizophrenia spectrum disorder, and the deficits in fronto-temporal connectivity may play a key role towards the vulnerability of psychosis.

Trends of hospitalization for schizoaffective disorder (SD) in USA: A nationwide analysis

Z. Mansuri^{1,*}, S. Shambhu¹, P. Yadav², M. Rathod¹, U. Mansuri³

¹ Drexel University, School of Public Health, Philadelphia, USA

² Thomas Jefferson University, Kimmel Cancer Center, Philadelphia, USA

³ Icahn School of Medicine at Mount Sinai, School of Public Health, New York, USA

* Corresponding author.

Objectives Schizoaffective disorder (SD) is an important cause of morbidity and mortality in hospitalized patients. While SD has been extensively studied in the past, the contemporary data for impact of SD on cost of hospitalization are largely lacking.

Methods We queried the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (HCUP-NIS) dataset between 1998–2011 using the ICD-9 codes. Severity of comorbid conditions was defined by Deyo modification of Charlson comorbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, Chi² test, *t*-test and Cochran-Armitage test were used to test significance.

Results A total of 4,66,800 patients were analyzed; 50.90% were female and 49.10% male ($P < 0.0001$); 61.15% were white, 25.97% black and 12.88% of other race ($P < 0.0001$). Rate of hospitalization increased from 13,035.05/million to 26,703.21/million from 1998–2011. Overall mortality was 0.50% and mean cost of hospitalization was 20,995.19\$. The in-hospital mortality increased from 0.46% to 0.50% ($P < 0.0001$) and mean cost of hospitalization increased from 11,504.94\$ to 31,460.67\$. Total spending on SD related admissions increased from \$1.2 billion/year to \$6.6 billion/year.

Conclusions While mortality has slightly increased from 1998 to 2011, the cost has significantly increased from \$1.2 billion/year to \$6.6 billion/year which leads to an estimated \$5.4 billion/year additional burden to US health care system. In the era of cost conscious care, preventing SD related hospitalization could save billions of dollars every year. Focused efforts are needed to establish preventive measures for SD related hospitalization.

Severity of comorbid conditions was defined by Deyo modification of Charlson comorbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, Chi² test, *t*-test and Cochran-Armitage test were used to test significance.

Results A total of 443,659 patients were analyzed; 38.78% were female and 61.22% were male ($P < 0.0001$); 48.19% were white, 35.30% black and 16.51% of other race ($P < 0.0001$). Rate of hospitalization increased from 56,768.47/million to 79,444,666/million from 1998–2011. Overall mortality was 0.70% and mean cost of hospitalization was 23,568.47\$. The in-hospital mortality decreased from 0.75% to 0.73% ($P < 0.0001$) and mean cost of hospitalization increased from 12,775.64\$ to 36,768.58\$. Total spending on schizophrenia related admissions have increased from \$1.75 billion/year to \$6.23 billion/year.

Conclusions While mortality has slightly decreased from 1998 to 2011, the cost has significantly increased from \$1.75 billion/year to \$6.23 billion/year which leads to an estimated \$4.48 billion/year additional burden to US health care system. In the era of cost conscious care, preventing schizophrenia related hospitalization could save billions of dollars every year. Focused efforts are needed to establish preventive measures for schizophrenia related hospitalization.

Electrophysiological mechanisms underlying ERP amplitude reduction in patients with schizophrenia: A time-frequency analysis

D.D. Marasco^{1,*}, A. Vignapiano², G. Di Lorenzo³, A. Mucci², M. Altamura¹, A. Petito¹, M. Caroprese¹, C. Niolu³, A. Bellomo¹, S. Galderisi²

² Department of Psychiatry, University of Naples SUN, Naples, Italy

³ Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy

* Corresponding author.

Background It is hypothesized that the event-related potentials are generated by different electrophysiological mechanisms, i.e., event-related power increase and enhanced degree of phase-locking over trial. The study aimed to characterize the relative

contribution of these mechanisms to the ERP in patients with schizophrenia (SCZ).

Materials and methods One hundred and fifteen chronic stabilized SCZ and 62 healthy controls (HC) recruited to the study of the Italian Network for Research on Psychoses were included. Scalp potentials were recorded during a standard auditory oddball task. Stimulus-locked segments were extracted for all standard trials and correctly hit target trials. Trials contaminated by other artifacts were rejected. For each subject and stimulus type the event-related spectral perturbation (ERSP) and the inter-trial-coherence (ITC) were computed to assess event-related power increase and inter-trial phase-locking. The two groups were compared using Student's *t*-test followed by Bonferroni correction for multiple comparisons.

Results SCZ presented a reduced amplitude of both N100 and P3b. For both standard and target stimuli, at Cz and Pz, ERSP was reduced in SCZ in the delta-theta band (from 0 up to 400 ms). The ITC index, at the same channels, was reduced in SCZ in the delta band for standard stimuli (from 0 to 300 ms), and in both delta and theta bands for target stimuli (from 300 to 400 ms).

Conclusions Our results indicate that alterations of both mechanisms are involved in N100 and P3b amplitude reduction observed in SCZ. Inter-trial phase-locking abnormalities for N100 were limited to the delta band, while for P3b involved delta and theta frequencies.

Methylenetetrahydrofolate reductase (MTHFR) gene polymorphisms and antipsychotic-induced metabolic disturbances in first-episode schizophrenia patients

B. Misiak^{1,*}, Ł. Łączmański², K. Słoka², E. Szmida³, R. Ślęzak³, P. Piotrowski¹, A. Kiejna¹, D. Frydecka¹

³ Wrocław Medical University, Department of Genetics, Wrocław, Poland

* Corresponding author.

Introduction There is a scarcity of prospective studies addressing the influence of the *methylenetetrahydrofolate reductase* (*MTHFR*) gene polymorphisms on antipsychotic-induced metabolic changes in first-episode schizophrenia (FES) patients.

Objectives We aimed at investigating metabolic side effects of second-generation antipsychotics (SGAs) with respect to the *MTHFR* gene polymorphisms in FES patients.

Methods Polymorphisms in the *MTHFR* gene (C677T and A1298C) were investigated with respect to changes in body mass index (BMI) and waist circumference (WC) together with serum levels of glucose, lipids, homocysteine, vitamin B12 and folate after 12 weeks of treatment with SGAs in 135 FES patients.

Results The 677TT genotype was associated with significantly higher BMI, WC and serum levels of triglycerides, as well as significantly lower folate levels at baseline. Additionally, the 677T allele was associated with significantly lower folate levels at baseline. The 677CC homozygotes had significantly higher increase in BMI and serum levels of triglycerides. The 677TT genotype predicted significantly higher increase in homocysteine levels and significantly higher decrease in folate levels. These associations were also significant in the allelic analysis. Only the patients with the 677T allele had significantly lower folate levels and significantly higher homocysteine levels at the follow-up. The 677T allele was also related to

significantly lower increase in WC. The 1298CC homozygotes had significantly higher weight gain in the course of treatment with SGAs.

Conclusions The *MTHFR* gene polymorphisms might predict antipsychotic-induced weight gain in FES patients. In addition, the *MTHFR* C677T polymorphism might be also predictive with respect to other metabolic adversities of SGAs.

Clinical symptomatology and theory of mind in schizophrenia: Which relationship?

J. Mrizak*, R. Trabelsi, A. Arous, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction Theory of mind (ToM) has repeatedly been shown to be compromised in many patients with schizophrenia (SCZ). It now seems to be quite well-established that patients with profound negative or disorganized symptoms perform poorly on ToM tasks. By contrast, findings in patients with predominant positive symptoms are much more ambiguous.

Objectives To investigate the relationship between ToM deficits and different symptoms dimensions in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the intention-inferencing task (IIT), in which the ability to infer a character's intentions from 28 short comic strip stories is assessed. Symptomatology evaluation comprised the Positive and Negative Syndrome Scale (PANSS), the Calgary Depression Scale for Schizophrenia (CDSS) and the Clinical Global Impressions Scale Improvement and severity (CGI).

Results The number of correct answers in the IIT negatively correlated with both the positive ($P=0.015$) and negative ($P<0.0001$) scales of the PANSS. ToM deficits were correlated with the conceptual disorganization, hallucinations and the suspiciousness/persecution items.

The patients who had more false answers in the IIT also had significantly higher scores at the positive ($P=0.005$), negative ($P<0.0001$) and general ($P<0.0001$) scales of the PANSS. Worse IIT performance correlated with a higher severity index in the CGI. No correlations were found between IIT scores and CDSS scores.

Conclusions Our results confirm the relationship between ToM deficits and negative symptoms and suggest that ToM may also be correlated to specific positive symptoms.

Effectiveness of long-acting injectables and clozapine in a real-world setting during the early-stages of psychotic illness

E.G. Ostinelli*, E. Guanella, S. Cavallotti, C. Casetta, A. D'Agostino

San Paolo Hospital, Department of Health Sciences, Milan, Italy

* Corresponding author.

Introduction Intervention in the early-stages of psychosis may be able to shape the clinical course; critical period (CP) is best represented by the first 5 years from first admission (FA).

Objectives To investigate the effectiveness of pharmacological intervention within and beyond the CP.

Aims (1) To compare hospitalization rates of patients stabilized on treatment with LAIs and CLZ. (2) To determine whether treatment with LAIs and CLZ within CP can influence hospitalization rates.

Methods Data were retrospectively collected from patients diagnosed with non-affective psychoses with FA between 2000 and 2014; 200 patients were then divided into three groups, according to stabilized treatment regimen during the final year of observation: treatment as usual (TAU), CLZ, LAIs. hospitalization duration (HSPD) and frequency (HSP) were calculated for each group.

Results Despite a major severity before assignment to either CLZ or LAIs treatment, HSPD and HSP in both groups shifted below those observed for the TAU arm. Patients who began treatment with LAIs within the CP showed a highly significant decrease of both HSPD and HSP (respectively 17.4 ± 18 vs. 2.6 ± 8.2 ; $Z = -2.856$; $P < 0.005$ and 1.1 ± 0.8 vs. 0.2 ± 0.5 ; $Z = -3.115$; $P < 0.005$). No significant changes in hospitalization rates were observed for subjects who began treatment with LAIs after the CP.

Conclusions Our study confirms that treatment with either CLZ or LAIs significantly impacts the course of psychotic disorders. The data seem to suggest that LAIs and CLZ should be considered more effective than conventional oral antipsychotics in the early-stages of psychotic illness. The difference among treatments tends to wane beyond the CP, especially for LAIs.

* Corresponding author.

Introduction Lurasidone has demonstrated low propensity for metabolic disturbance in adult patients with schizophrenia in short-term studies.

Objectives To evaluate metabolic syndrome occurrence during long-term lurasidone treatment in patients with schizophrenia.

Aims To compare metabolic syndrome rates with lurasidone versus other antipsychotic agents.

Methods Metabolic syndrome rates (as defined by the US National Cholesterol Education Program-Adult Treatment Panel III) were evaluated in adult patients with schizophrenia treated with lurasidone in 2 long-term, active-controlled studies (quetiapine XR or risperidone). In the quetiapine XR-controlled study, patients completing a 6-week, double-blind, placebo-controlled, fixed-dose trial of lurasidone (74 mg/d or 148 mg/d) or quetiapine XR (600 mg/d) continued on double-blind, flexibly dosed lurasidone (37–148 mg/d) or quetiapine XR (200–800 mg/d) for up to 12 months. In the risperidone-controlled study, patients received double-blind, flexibly dosed lurasidone (37–111 mg/d) or risperidone (2–6 mg/d) for up to 12 months.

Results Among patients without metabolic syndrome at baseline in the quetiapine XR-controlled study, 2.4% (2/84) of lurasidone-treated patients and 7.4% (2/27) of quetiapine XR-treated patients developed metabolic syndrome at month 12 ($P = NS$). Of patients without metabolic syndrome at baseline in the risperidone-controlled study, 10.3% (12/117) and 23.2% (16/69) of lurasidone- and risperidone-treated patients, respectively, developed metabolic syndrome at month 12 ($P = 0.02$).

Conclusions Long-term treatment with lurasidone was associated with lower rates of metabolic syndrome in patients with schizophrenia compared to treatment with quetiapine XR or risperidone.

Neurochemical and behavioral sensitization to d-amphetamine in healthy subjects measured with [¹¹C]-(+)-PHNO-PET

A. Popovic^{1,*}, M. Bauer², L. Bartova¹, U. Sauerzopf¹, N. Praschak-Rieder¹, C. Rami-Mark³, L. Nics³, C. Philippe³, M. Mitterhauser³, W. Wadsak³, S. Kasper¹, M. Willeit¹

¹ Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

² Medical University of Vienna, Department of Clinical Pharmacology, Vienna, Austria

³ Medical University of Vienna, Department of Nuclear Medicine, Vienna, Austria

* Corresponding author.

Introduction It has been shown that patients with schizophrenia are super-sensitive towards dopamine-releasing agents such as amphetamine. Here, we studied the effects of amphetamine sensitization on amphetamine-induced dopamine release in healthy subjects.

Objectives To measure d-amphetamine-induced dopamine release as measured with the D_{2,3} agonist radioligand [¹¹C]-(+)-PHNO-PET via change in non-displacable binding potential (BP_{ND}) and behavioral measures of d-amphetamine effects with drug effects questionnaire (DEQ) and subjective states questionnaire (SSQ).

Aims To study d-amphetamine-induced sensitization in healthy subjects on a behavioral and neurochemical level with [¹¹C]-(+)-PHNO-PET in order to gain more knowledge on sensitization-induced changes in the dopaminergic system.

Methods Twelve stimulant-naïve healthy male subjects underwent three 90-min [¹¹C]-(+)-PHNO-PET-scans and four oral administrations of d-amphetamine. After a naïve baseline scan, subjects underwent a PET scan with previous ingestion of 0.4 mg/kg bodyweight of d-amphetamine 90–120 minutes before scanning. Subsequently, subjects were sensitized to d-amphetamine with the same dose on two separate days. Thereafter, they underwent another PET scan with previous d-amphetamine ingestion. DEQ and SSQ were administered before, 60 min, 90–120 min, and 210 min after amphetamine ingestion.

Results We found significant sensitization effects on a behavioral level and on a neurochemical level after four administrations of amphetamine. Items of the SSQ, which showed significant sensitization effects were “outgoing”, “energetic”, “lively”, “alert” and “focused”.

Conclusions We were able to induce significant behavioral and neurochemical sensitization in healthy humans, which were measured with [¹¹C]-(+)-PHNO-PET for the first time. This sensitization model will be useful for studying the neurobiology of schizophrenia.

Introduction Clozapine is the only drug approved for resistant schizophrenia, but remains underused because of its side effects. Sedation is common, but its management is unclear.

Objectives To analyze factors associated with clozapine-induced sedation and the efficacy of common treatment strategies.

Aims To determine clozapine-induced sedation factors and possible therapeutic strategies.

Methods Using two years' electronic records of a community cohort of resistant schizophrenia spectrum disorder cases on clozapine, we performed three analyses: a cross-sectional analysis of which factors were associated with number of hours slept (objective proxy of sedation), and two prospective analyses: which factors were associated with changes in hours slept, and the efficacy of the main pharmacological strategies for improving sedation.

Results One hundred and thirty-three patients were included; 64.7% slept at least 9 hours/daily. Among monotherapy patients ($n = 30$), only norclozapine levels ($r = .367$, $P = .033$) correlated with sleeping hours. Multiple regression analyses confirmed the findings ($r = .865$, $P < .00001$). Using the cohort prospectively assessed ($n = 107$), 42 patients decreased the number of hours slept between two consecutive appointments. Decreasing clozapine (40%) or augmenting with aripiprazole (36%) were the most common factors. In the efficacy analysis, these two strategies were recommended to 22 (20.6%) and 23 (21.5%) subjects, respectively. The majority (81.8% and 73.9%) did not report differences in the hours slept.

Conclusions Sedation is common and involves pharmacological and non-pharmacological factors. The only correlation was a weak correlation between norclozapine plasma levels and total sleeping hours. Reducing clozapine and aripiprazole augmentation were the most successful strategies to ameliorate sedation, although both strategies were effective only in a limited number of subjects.

³ Icahn School of Medicine at Mt. Sinai, School of Public Health, New York, USA

* Corresponding author.

Objectives Schizophreniform disorder (SD) is an important cause of morbidity and mortality in hospitalized patients. While SD has been extensively studied in the past, the contemporary data for impact of SD on cost of hospitalization are largely lacking.

Methods We queried the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (HCUP-NIS) dataset between 1998–2011 using the ICD-9 codes. Severity of comorbid

conditions was defined by Deyo modification of Charlson comorbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, Chi² test, t-test and Cochran-Armitage test were used to test significance.

Results A total of 8645 patients were analyzed; 36.21% were female and 63.79% were male ($P < 0.0001$); 49.04% were white, 39.06% black and 19.9% of other race ($P < 0.0001$). Rate of hospitalization decreased from 599.22/million to 394.47/million from 1998–2011. Overall mortality was 0.23% and mean cost of hospitalization was 17930.23. The in-hospital mortality reduced from 0.21% to 0.15% ($P < 0.0001$) and mean cost of hospitalization increased from 9662.88\$ to 27,749.68\$ from 1998–2011. Total spending on SD related admissions have increased from \$47.59 million/year to \$853.83 million/year.

Conclusions While mortality has slightly decreased from 1998 to 2011, the cost has significantly increased from \$47.59 million/year to \$853.83 million/year, which leads to an estimated \$806.24 million/year additional burden to US health care system from 1998 to 2011. In the era of cost conscious care, preventing SD related hospitalization could save billions of dollars every year. Focused efforts are needed to establish preventive measures for SD related hospitalization.

Assessment of cognitive impairment with the cognitive assessment interview (CAI) was useful for identifying poor psychosocial functioning outcome in patients with psychosis

A. Sánchez-Torres^{1,2,3,*}, M.R. Elosúa², R. Lorente-Omeñaca^{1,3}, L. Moreno-Izco^{1,3}, V. Peralta^{1,3}, J. Ventura⁴, M.J. Cuesta^{1,3}

⁴ UCLA, Department of Psychiatry, Semel Institute for Neuroscience and Human Behavior, Los Angeles, USA

* Corresponding author.

Introduction Cognitive impairments clearly impact the daily functioning of patients with psychosis.

Objectives To assess cross-sectionally whether there are differences in the cognitive domains assessed with the CAI, for considering the real-world functioning of a sample of patients with psychosis.

Methods The sample consisted of 76 patients with a DSM-IV psychotic disorder. Patients were assessed with the cognitive assessment interview (CAI), which is an interview-based measure of cognitive functioning that is intermediate between cognitive functioning and daily functioning, and three subscales of the specific levels of functioning (SLOF), an informant-rated measure of functioning. The CAI was used to assess the patient and an informant, and these scores were integrated into a rater composite score. We divided the sample by a median-split procedure for each of the three functional domains, and then applied ANOVAs to compare the two groups (impaired/not impaired) in the six cognitive domains of the CAI: working memory, attention, verbal memory, problem solving, processing speed, and social cognition.

Results We found significant differences between the impaired vs. non-impaired groups in most of the cognitive domains assessed with the CAI (Fig. 1).

Conclusions Interview-based assessment of cognition with the CAI allows for the prediction of everyday functioning in patients with psychosis. Impairment in almost all CAI cognitive domains, except for social cognition, was associated with poorer psychosocial functioning.

Cerebral hemodynamics in schizophrenia during the Trail Making Test: A functional transcranial Doppler sonography study

D. Schuepbach¹, S. Egger^{2,*}, S.C. Herpertz³

¹ Zentrum für Psychiatrie Weinsberg, Clinic of General Psychiatry and Psychotherapy, Sector West, Weinsberg, Germany

² Psychiatric University Hospital Zurich, Department of Psychiatry, Psychotherapy and Psychosomatics, Zurich, Switzerland

³ University of Heidelberg, Department of General Psychiatry, Heidelberg, Germany

* Corresponding author.

Introduction Schizophrenia is a severe mental disorder, with complex symptoms involving psychosis, negative symptoms and cognitive impairment. The Trail Making Test (TMT) has been widely used to assess attention and executive function. Functional transcranial Doppler sonography (fTCD) of basal cerebral arteries allows monitoring of aberrant cerebral hemodynamics during cognitive tasks in this patient group.

Objectives We assessed cerebral hemodynamics in the middle cerebral arteries (MCA) using fTCD while patients with schizophrenia and healthy subjects performed the TMT and a control task.

Methods Fifteen patients with chronic schizophrenia and 15 healthy controls performed the TMT-A and -B during fTCD measurements of the MCA. Dependent measures were performance, mean cerebral blood flow velocity (MFV) and the lateralization.

Results Patients demonstrated an overall decreased speed of solution ($P=0.002$), and there was no significant effect of age. They showed a significantly increased flow pattern for the TMT-B ($P=0.005$). There were no lateralization differences between diagnostic groups.

Conclusions There was a performance deficit in patients with schizophrenia for both TMT-A and -B that fits well with results of existing literature. The aberrant hemodynamic response supports the idea that cognitive performance elicits an aberrant cerebral hemodynamic correlate. It adds to the notion that fTCD is a valuable tool to correlate psychological paradigms with brain perfusion in patients with schizophrenia.

Does family history of schizophrenia affect the severity of disease?

M. Sisek-Šprem*, M. Herceg, V. Jukić

University Psychiatric Hospital Vrapče, Integral Ward, Zagreb, Croatia

* Corresponding author.

Introduction Previous studies have demonstrated that family history is associated with earlier age at onset, severity of positive and negative symptoms, and the duration of untreated illness. Hereditary factors may contribute a vulnerability for antisocial and/or violent behaviour per se, and for other stable characteristics such as aggressive behaviour.

Aim To analyze the impact of family history of schizophrenia and aggressive behavior among members of family on severity of disease and aggressive behavior of patients.

Method The study population consisted of 120 male schizophrenic patients classified into non-aggressive ($n=60$) and aggressive ($n=60$) groups, based on indication for admission in hospital (aggression/anything else but aggression). For severity of disease, we assessed psychopathology using the Positive and Negative Syndrome Scale (PANSS), the number of hospitalizations and the total equivalent dose of therapy (collected from medical record). The presence of a family history and aggression in family was assessed using a semi-structured interview of patients and, when available, family members.

Results Twenty-seven (22.5%) participants were determined to have at least one family member with schizophrenia or another psychotic disorder, with no difference between aggressive (10%) and non-aggressive (12.5%) group. There was no significant interaction between family history and severity of disease (PANSS, number of hospitalizations, total equivalent dose of therapy). Aggressive behaviour in first-degree family member had no influence on aggressive behaviour of patients with schizophrenia.

Conclusion Family history of schizophrenia does not affect the severity of disease nor aggressive behaviour.

Keywords Family history; Schizophrenia; Severity of disease; Aggressive behavior

Soluble Fas ligand (sFasL) as a predictor of reduction of general psychopathology in schizophrenia after antipsychotic treatment

K. Szymona^{1,*}, H. Karakula-Juchnowicz², B. Zdzisinska³, M. Flis⁴, K. Kaławaj³, W. Rosa⁵, M. Kandefer-Szerszeń³

¹ Medical University of Lublin, Mental Health Outpatient Clinic, Lublin, Poland

³ Maria Curie-Skłodowska University in Lublin, Department of Virology and Immunology, Lublin, Poland

⁴ Medical University of Lublin, Department of Clinical Neuropsychiatry, Lublin, Poland

⁵ Lublin University of Technology, Department of Applied Mathematics, Lublin, Poland

* Corresponding author.

Introduction Dysregulation of the apoptotic process is associated with the etiopathogenesis of schizophrenia, which is observed at the brain and peripheral blood levels. A significant negative correlation between the duration of the disease and serum sFasL concentration was demonstrated by other authors. It was shown that an increased rate of apoptosis is more pronounced in neuroleptic-free patients with the first-episode of schizophrenia than in patients with chronic disease.

Aim Search for a predictor of good response to antipsychotic treatment based on the analysis of the sFasL plasma level and its relationship with clinical symptoms.

Methods Fifty-three patients with chronic schizophrenia and 46 healthy individuals were enrolled in the study. The concentration of sFasL was measured by ELISA. Clinical assessments (PANSS, SANS, SAPS) and blood analyses were conducted three times: during the active phase of disease (at admission), after 4 weeks of pharmacotherapy, and after reaching remission.

Results In the schizophrenia group, non-altered levels of sFasL ($P=0.1$; U Mann-Whitney test), compared to the control, were detected at admission. The initial level of sFasL correlated negatively ($r=-0.33$; $P=0.04$; Spearman's rank) with blood leukocyte count. Despite clinical improvement, no significant changes in the level of sFasL were observed. However, the sFasL level correlated negatively with the PANSS general psychopathology reduction after 4 weeks of pharmacotherapy ($r=-0.7$; $P=0.04$) and after remission ($r=-0.39$; $P=0.026$).

Conclusions The results indicate a possible role of sFasL in apoptosis of blood leukocytes and suggest that the reduction of sFasL level can predict level of PANSS general psychopathology after antipsychotic treatment in schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Basic symptoms as subjective cognitive deficit in schizophrenia: Cognitive, clinical and functional associations

M.L. Vargas^{1,*}, S. López-Lorenzo², I. Legascue², A. Nagore², P. Serrano², N. Jimeno-Bulnes³

¹ Complejo Asistencial de Segovia, Grupo de Investigación en Neurociencia Clínica de Segovia GINCS, Psychiatry, Segovia, Spain

² Grupo de Investigación en Neurociencia Clínica de Segovia GINCS, Psychiatry, Segovia, Spain

³ Universidad de Valladolid, Grupo de Investigación en Neurociencia Clínica de Segovia GINCS, Psychiatry, Segovia, Spain

* Corresponding author.

Introduction Basic symptoms are subjective complaints that present at the early states in psychotic disorders and persist in the long-term. They can be studied using hetero applied clinical instruments or self-administered questionnaires. Basic symptoms can be useful as screening tools in at risk populations.

Aims To determine if basic symptoms (subjective cognitive deficits) are associated with the objectively measured cognitive deficit after controlling for functioning and symptomatology.

Methods One observational, transversal, psychopathological and neuropsychological study was performed on a schizophrenia outpatients sample ($n=78$). Correlations were measured by using Spearman's Rho coefficient. Basic symptoms were registered by using the Frankfurt Complaints Questionnaire (FCQ-3); cognitive status was assessed by Repeatable Battery for the Assessment of Neuropsychological Status (RBANS); clinical status was assessed by PANSS and Clinical Global Impression (CGI); functional status was measured with Global Assessment of Functioning (GAF).

Results All the dimensions were related to subjective complaints: cognitive functioning ($r=-.38$; $P<.001$); positive symptoms

($r=.54$; $P<.001$); negative symptoms ($r=.26$; $P<.02$); general symptoms ($r=.41$; $P<.001$); CGI ($r=.57$; $P<.001$); GAF ($r=-.45$; $P<.001$). The association between subjective and objective cognitive deficit remains significant after controlling for the clinical and functional variables, except when controlling for CGI.

Conclusions The evaluation of basic symptoms with FCQ-3 is related with an objective cognitive deficit and could be useful as a screening tool.

Introduction In a recent 26-week placebo-controlled, crossover trial ($n=52$) we found significant positive effects on verbal and visual memory, and negative symptoms in clozapine-treated patients with refractory schizophrenia.

Objectives In this 1-year extension study, we report the long-term effects and tolerability of memantine add-on therapy to clozapine.

Aims To evaluate the persistence of improvements in cognitive functioning and symptoms of memantine add-on therapy to clozapine in schizophrenia.

Methods Completers of the first trial who experienced a beneficial effect of memantine after 12 weeks continued memantine for one year. Primary endpoints were change from baseline to 26 weeks treatment and 26 weeks to 52 weeks treatment on memory and executive function using the Cambridge Neuropsychological Test Automated Battery (CANTAB), Positive and Negative Syndrome Scale (PANSS), and Clinical Global Impression Severity Scale (CGI-S). Secondary endpoints were change on the Health of the Nation Outcome Scales (HoNOS) and Liverpool University Neuroleptic Side Effect Rating Scale (LUNTERS).

Results Of 32 completers who experienced a beneficial effect of memantine 23 patients continued memantine for one year. Memory improvement was sustained, verbal recognition memory improved even further between $t=26$ weeks and $t=52$ weeks. Continued treatment with memantine add-on to clozapine was associated with significantly improved PANSS positive, negative and overall score, CGI-S and HoNOS scores.

Conclusions In the extension phase the positive effect of memantine add-on therapy on verbal memory sustained and positive, negative and overall symptoms of schizophrenia, clinical global status and psychosocial functioning significantly improved. Memantine was well tolerated without serious adverse effects.

Decreased interhemispheric resting state functional connection in schizophrenic patients with auditory hallucinations

H. Wang^{1,*}, G. Wang²

¹ Renmin Hospital of Wuhan University, Wuhan, China

² Renmin Hospital of Wuhan University, Department of Psychiatry, Wuhan, China

* Corresponding author.

Introduction Auditory hallucination (AH) has been always concerned as a main core symptom of schizophrenia. However, the mechanisms of AH are still unclear.

Objectives The aim of this study is to further explore the complicated neuroimaging mechanism of AHs from a new insight by using voxel-mirrored homotopic connectivity (VMHC).

Methods Forty-two patients with AH (APG), 26 without AHs (NPG) and 82 normal controls (NC) participated in resting state fMRI scan. Correlation analyses were used to assess the relationships between VMHC and Hoffman scores. Additionally, ROI analysis was used to further know about the functional connectivity between the brain areas with changed interhemispheric FC and the whole brain.

Results APG showed reduced VMHC in the parahippocampus, fusiform gyrus, rolandic operculum, insula, heschl's gyrus and superior temporal gyrus (STG). Hoffman score of APG group had negative correlation with VMHC in these regions. Besides, ROI analysis supported decreased interhemispheric FC in schizophrenia with AH and verified functional connectivity abnormalities in schizophrenia.

Conclusions These findings suggest impairment of interhemispheric coordination and whole brain FC in schizophrenia with AH, which may be implicated to the neuroimaging mechanism of auditory hallucination. Furthermore, this research highly support dysconnectivity hypothesis that schizophrenia related to abnormalities in neuronal connectivity.

Efficacy and safety of brexpiprazole in schizophrenia: Meta-analysis of three double-blind, randomized, placebo-controlled phase 3 studies

C. Weiss^{1,*}, P. Zhang², M.J. Hakala³, A. Skuban⁴, E. Weiller⁵

¹ Otsuka Pharmaceutical Development & Commercialization Inc., Global Medical Affairs, Princeton, USA

² Otsuka Pharmaceutical Development & Commercialization Inc., Biostatistics, Princeton, USA

³ H. Lundbeck A/S, ICR Psychiatry, DK, Valby, Denmark

⁴ Otsuka Pharmaceutical Development & Commercialization Inc., Global Clinical Development, Princeton, USA

⁵ H. Lundbeck A/S, Medical Affairs, Valby, Denmark

* Corresponding author.

Introduction Brexpiprazole is a serotonin-dopamine activity modulator that is a partial agonist at 5-HT_{1A} and dopamine D₂ receptors at similar potency, and an antagonist at 5-HT_{2A} and nor-adrenaline alpha1B/2C receptors.

Objectives To evaluate the efficacy, safety, and tolerability of brexpiprazole in patients with acute schizophrenia in a meta-analysis of three phase 3 studies with brexpiprazole.

Aim The primary endpoint was change from baseline to week 6 in PANSS total score.

Methods Data from the 3 clinical studies in patients with acute schizophrenia were combined and analyzed using individ-

ual patient data meta-analysis. In two similarly designed studies (NCT01396421; NCT01393613), patients with acute schizophrenia were randomized to fixed-doses of brexpiprazole 2 mg/day, 4 mg/day or placebo (a low-dose treatment group was included in each study [0.25 mg and 1.0 mg]; not included in the meta-analysis). In the third study (NCT01810380), patients were randomized to flexible dosing of brexpiprazole (2 to 4 mg/day), placebo, or an active reference (quetiapine extended release). Changes from baseline for brexpiprazole vs. placebo were analyzed using an MMRM approach.

Results Brexpiprazole 2–4 mg ($n=868$) was superior to placebo ($n=517$) in change from baseline in PANSS total score (-20.1 vs. -14.3 ; estimated treatment difference to placebo: -5.8 [95% CI: -8.0 ; -3.6]; $P<0.001$). The proportions of patients reporting TEAEs were similar between the brexpiprazole and placebo treatment groups (57.9% vs. 57.5%). No unexpected safety concerns were observed.

Conclusion This meta-analysis supports evidence from three individual trials that brexpiprazole is efficacious and safe in treating patients with acute schizophrenia.

Sleep disturbances and substance use disorders: An international study of primary care and mental health specialty care patients

L. Fortuna^{1,*}, N. Noyola², B. Cook³, A. Amaris²

¹ Boston Medical Center, Psychiatry, Child and Adolescent Psychiatry, Boston, USA

² Massachusetts General Hospital, Disparities Research Unit, Boston, USA

³ Cambridge Health Alliance and Harvard Medical School, Health Equity Research Lab, Cambridge, USA

* Corresponding author.

Introduction There is no comprehensive evidence on the influence of sleep disturbances (SD) on substance use disorders (SUD) or treatment use patterns of individuals with comorbid disturbances. **Objective/aim** To better understand comorbidities and treatment use patterns of individuals with SD and SUD.

Methods We combine 2010–2012 electronic health record (EHR) data from healthcare system in Boston ($n=131,966$ person-years) and Madrid, Spain ($n=43,309$ person-years). Patients with sleep disturbances (SD) were identified in the EHR through ICD-9 codes and medical records and substance use disorders (SUD) identified by documented treatment for drug or alcohol abuse or dependence. Rates of SUD are compared between individuals with and without SD. Among those with both, adequacy of mental health treatment (defined as eight or more outpatient visits or four or more outpatient visits with a psychotropic prescription) and ER use is compared.

Results Among the individuals, 21.1% with SD also report SUD, compared to only 10.6% of individuals without SD ($P<.01$). Those with comorbidities were more likely than their specialty care counterparts without comorbidities to be seen in the ER (57.1% vs. 36.6%, respectively, $P<.05$). Limiting the sample to only those with both SD and SUD in specialty mental health care ($n=268$ in Boston and $n=28$ in Madrid), 49.2% of Boston patients received adequate care

compared to 38.5% of Madrid patients, and 57.8% of Boston patients had any ER use in the last year vs. 50% of Madrid patients.

Conclusions SD is correlated with SUD and comorbid patients are more likely to use emergency services.

* Corresponding author.

Introduction Major affective disorders ranging from subthreshold affective temperaments to severe affective diseases and anxiety, are frequently associated with sleep–wake dysregulation. Interestingly, recent studies suggested an active role of Sensory Processing Disorders (SPD) in the emergence of sleep disturbances. **Objectives** The objective of this study was to investigate the relationship between SPD and sleep quality in subjects with major affective disorders and specific affective temperaments.

Aims This study aimed to examine the sensory profile (expressed in hypersensitivity or hyposensitivity) of patients with major affective disorders and its relative contribution to the prediction of sleep quality while also considering affective temperaments and depression, known as factors that may impact sleep quality.

Methods We recruited 176 participants (mean age = 47.3) of which 56.8% have unipolar depression and 43.2% bipolar disorder. Reduced sleep quality was evaluated using the Pittsburgh Sleep Quality Index (PSQI) whereas affective temperaments were assessed using the Temperament Evaluation of Memphis, Pisa, Paris and San Diego (TEMPS).

Results Sensory hypersensitivity, assessed using Adolescent/Adult Sensory Profile (AASP), significantly distinguished between poor and good sleepers. Sleep quality was mainly predicted by the Beck Depression Inventory-II total score and anxious temperament. Yet, sensory hypersensitivity contributed to this prediction mainly in regard to sleep efficiency and related daytime dysfunctions.

Conclusions The careful assessment of the unique sensory profile and its behavioral/functional influence on patients' quality of life may help clinicians and health providers in developing targeted treatment interventions.

* Corresponding author.

Introduction Circadian rhythms and quality of sleep have been associated with temperament characteristics in healthy populations. Since temperaments are personality traits concerning the behavioral, motivational and emotional responses, adaptive capacity for sleep and circadian rhythm may also be related with temperament traits.

Aims To identify the determinants of sleep quality (SQ) and biological rhythm (BR) in bipolar disorder, schizophrenia and depression among temperament measures.

Methods Patients with bipolar disorder (BD, $n=49$), major depression (MD, $n=35$), schizophrenia (SZ, $n=30$) and a healthy control group (HC, $n=36$) were enrolled. Pittsburgh Sleep Quality Index (PSQI), Biological Rhythms Interview of Assessment in Neuropsychiatry (BRIAN) and the Temperament and Character Inventory (TCI) were the measures. One-way ANOVA, Spearman Correlation Test and Linear Regression analyses were the other comparisons.

Results Determinants of sleep quality were self-directedness in MD [$F(1,26)=6.10$, $P=0.020$] and BD [$F(1,31)=10.88$, $P=0.002$] groups. Self-transcendence ($P=0.004$), self-directedness ($P=0.038$) and persistence ($P=0.05$) were the determinants of sleep quality in schizophrenia group [$F(3,21)=9.71$, $P<0.001$]. Harm-avoidance was the determinant of sleep quality in the HC group [$F(1,28)=7.97$, $P<0.001$]. Determinants of biological rhythms were harm-avoidance in the BD group [$F(1,32)=9.65$, $P=0.004$] and self-directedness in the SZ group [$F(1,23)=11.09$, $P=0.003$] and harm-avoidance ($P<0.001$) and self-transcendence ($P=0.039$) in the HC group [$F(2,27)=15.81$, $P<0.001$].

Conclusions Self-Directedness was associated with circadian rhythm and sleep quality in MD, BD and SZ groups. Extreme temperament features may contribute to emotional and behavioral dysfunction, which may lead to abnormal sleep patterns in psychiatric disorders.

The effects of the last global economic crisis on the suicide rate in Europe

M.M. Dumitru^{1,*}, B.S. Constantin²

¹ Romanian Academy, "Francisc Rainer" Institute of Anthropology, Iasi, Romania

² Romanian Academy, "Francisc Rainer" Institute of Anthropology, Bucharest, Romania

* Corresponding author.

Introduction Since 1897, Émile Durkheim noted that suicides occur more often during the economic changes that disrupt the social structure of society.

Objective and aims The objective of this study is to analyze the consequences of last global economic crisis on mortality by suicide in the EU countries in period 2007–2012.

Material and method We extracted data on mortality from the WHO database and unemployment trends from the EUROSTAT database. We had used this data to calculate the effect of unemployment on suicide rate, in pre-2004 and post-2004 EU countries.

Results If the number of suicides from 2007 was maintained in 2008–2012 period, EU 27 countries would have registered with 16,572 fewer suicides. The increase of suicides is based on the increasing number of suicides in men. The small increase in the suicide rate was recorded in Austria, France, Hungary and Slovenia. Luxembourg was the only country where the number of suicides was lower compared to 2007. In 2008, we can notice a slight decrease in the unemployment rate compared to 2007 and an increase in suicide by 3% in both groups of countries, followed by increasing suicide only in the post-2004 EU, where reach 10% in 2010, followed by a slight decrease in the coming years, while the unemployment rate gradually increases to 46% compared with 2007.

Conclusions In European Union countries, suicides have increased both before and during the crisis, in periods in which unemployment rose. States that joined the EU after 2004 are more vulnerable in times of crisis.

⁵ Karolinska Institute, Department of Psychiatry, Solna, Sweden

⁶ University of Molise, Department of Psychiatry, Molise, Italy

⁷ Fundacion Jimenez Diaz, Department of Psychiatry, Madrid, Spain

* Corresponding author.

Introduction An expanding body of research suggests that childhood trauma and adverse experiences can lead to a variety of negative health outcomes, including substance abuse, depressive disorders, and attempted suicide among adolescents and adults. Alcoholism, depressed affect, and illicit drug use, which are strongly associated with such experiences, appear to partially mediate this relationship as observed in population studies.

Objectives We have tested the association between early trauma and suicide attempts in a sample of suicide attempters from the Eureka International Project and a matched healthy control sample.

Methods We have studied the prevalence of childhood stressful events compared with healthy controls in a multicentre sample of 791 suicide attempters (SA) and 630 healthy controls (C), we have measured childhood parental neglect, physical abuse, sexual abuse, and emotional abuse, using the Childhood Trauma Questionnaire (CTQ). Chi² tests were performed using SPSS v15.0.

Results A significant increase in prevalence of childhood trauma was found in the suicide attempters sample for all types of trauma: childhood physical abuse: 25.3% (SA) vs. 11.1% (C) (Chi² test: 120,108 $P=0.000$); childhood sexual abuse: 18.2% (SA) vs. 2.4% (C) (Chi² test: 88,212 $P=0.000$); parental neglect 25.3% (SA) vs. 1.1% (C)

(Chi² test: 164,910 $P=0.000$); childhood emotional abuse: 34.9% (SA) vs. 5.6% (C) (Chi² test: 176,546 $P=0.000$).

Suicide attempters were increasingly overrepresented compared with controls if experiencing more than 1 trauma: represented 77% of the sample who suffered 1 type of childhood trauma vs. more than 90% of the sample with 2 or more types of trauma.

Conclusions A powerful graded relationship exists between adverse childhood experiences and risk of attempted suicide.

Profile of users of a new E-Mental Health ecological momentary assessment web-based program: MEMind

C. Bonal*, M.L. Barrigon, J.J. Carballo,

E. Baca-Garcia, MEMind studygroup

IIS-Fundación Jiménez Díaz, Psychiatry, Madrid, Spain

* Corresponding author.

Background e-Mental Health is an emergent area within e-Health. In the evaluation area, ecological momentary assessment (EMA) has been used to investigate separately on different psychiatric disorders while a comprehensive tool to cover the entire spectrum of mental health has not yet been developed. In this study, we aimed to present the MEMind wellness tracker and to characterize the group of patients who use it.

Methods We developed an EMA web application: MEMind, accessed through the web page <http://www.memind.net>. Since 20th May 2014 on, adult outpatients ($n=13,883$) attended in all psychiatric services within the Psychiatry Department of Fundación Jimenez Diaz in Madrid were proposed to use MEMind and then registered. Data collected from first year of implementation of the tool were transferred to an SPSS sheet and then analysed. A comparison between patients using and not using MEMind were performed.

Results MEMind users ($n=2842$) were significantly younger than MEMind non-users ($n=11,041$) (42.2 ± 13.5 vs. 48.5 ± 16.3 ; $P=0.000$) and mostly women (65% vs. 61.4%; $P=0.001$). Also, patients with neurotic disorders were the main users of MEMind (see Table 1). Furthermore, patients with thoughts about death and suicide were more likely to use MEMind (Table 2).

Conclusions Women, young people and patients with neurotic disorder were the main users of MEMind. Furthermore, people with suicidal thoughts were willing to use MEMind. Novel interventions for suicide prevention could be developed with the use of EMA web-based tools. Further studies are warranted.

Table 1

* Corresponding author.

Introduction Internet-delivered treatments for depression have proved successful, with supported programs offering the potential for improved adherence and outcomes. Internet interventions are particularly interesting in the context of increasing access to interventions, and delivering interventions population-wide.

Objective Investigate the potential feasibility and effectiveness of an online intervention for depression in the community.

Aims Establish the effectiveness of a supported online delivered cognitive behavioural intervention for symptoms of depression in adults in the community.

Methods The study was a randomized controlled trial of an 8-module internet-delivered cognitive behavioral therapy (iCBT) program for adults with depressive symptoms ($n = 96$) compared to a waiting-list control group ($n = 92$). Participants received weekly support from a trained supporter. The primary outcome was depressive symptoms as measured by the Beck Depression Inventory (BDI-II). The program was made available nationwide from an established and recognized charity for depression.

Results For the treatment group, post-treatment effect sizes reported were large for the primary outcome measure ($d = 0.91$). The between-group effects were moderate to large and statistically significant for the primary outcomes ($d = 0.50$) favoring the treatment group. Gains were maintained at 6-month follow-up.

Conclusion The study has demonstrated the efficacy of the online delivered space from depression treatment. Participants demonstrated reliable and statistically significant changes in symptoms from pre- to post-intervention. The study supports a model for delivering online depression interventions population-wide using trained supporters.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Preventing weight gain and increased waist circumference during the first two years after antipsychotic initiation in youth with first-episode psychosis

P. Ward^{1,*}, J. Curtis², S. Rosenbaum¹, A. Watkins², S. Teasdale², O. Lederman², M. Kalucy², K. Samaras³

¹ University of NSW, Psychiatry, Sydney, Australia

² Southeastern Sydney Local Health District, Mental Health, Bondi Junction, Australia

³ Garvan Institute of Medical Research, Diabetes and Obesity Program, Darlinghurst, Australia

* Corresponding author.

Background We recently demonstrated that weight gain could be prevented in young people experiencing a first-episode of psychosis commencing treatment with antipsychotics. A 12-week, intensive lifestyle and life skills intervention – the Keeping the Body in Mind program, – was delivered by dedicated nursing, dietetic and exercise physiology clinicians, for new referrals with <one month of antipsychotic exposure. (Curtis et al., Early intervention in psychiatry, in press). At the conclusion of the

intervention the 16 young people participating in the program experienced a mean weight gain of 1.8 kilograms, and a mean increase in waist circumference of 0.1 centimeters. The participants were followed up for two years after initial referral.

Methods During the two-year follow-up, participants had continuing access to an in house gym and weekly cooking groups, but without the same intensity of follow-up. Two year follow-up data were obtained from 11 participants from the original cohort.

Results Mean weight gain at two-year follow-up was 0.90 (SD 8.7) kilograms, and this difference was not statistically significant [$t(10)=0.3$, NS]. Waist circumference decreased by 0.7 (SD 7.7) centimeters, which was not statistically significant [$t(10)=0.3$, NS]. Nine of the participants (82%) did not experience clinically significant weight gain two years after initiation of antipsychotic medication.

Conclusion This two-year follow-up data demonstrated that it is feasible to prevent weight gain in youth with first-episode psychosis over the first two years of treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differences between countries in adult acute psychiatric hospitalization: Clinical features and drug prescription in Spain and the United States of America

L. Gonzalez-Blanco*, S. Bestene-Medina, E. Torio-Ojea, I. Abad-Acebedo, J. Rodriguez-Revuelta, G. Paniagua-Calzon
Servicio de Salud del Principado de Asturias, Psiquiatría, Oviedo, Spain

* Corresponding author.

Introduction Diverse prescription patterns and differences in length of psychiatry inpatient stay among European and American countries have been reported [1,2].

Objectives To describe and compare clinical features and drug prescriptions in two Acute Psychiatric Units from Spain and USA.

Methods Cross-sectional and comparative study. Sample: 73 inpatients from Reno (USA-Inpatients) and 65 from Oviedo (Spain-Inpatients) admitted to public Adult Acute Psychiatric Unit over a two-month period. Sociodemographic/clinical data and drug prescription were collected.

Results Sociodemographic/clinical comparison (Table 1) and drug prescription differences (Table 2) are shown.

No significant differences in antipsychotics' prescription except for the most frequently used [risperidone in Spain (36%)/ziprasidone in US (19.6%), $\chi^2 = 39.7^{**}$].

Conclusions (A) Psychiatric inpatients in US are younger, have longer hospitalization, show more comorbid substance use disorder and differ from Spanish inpatients in frequency of diagnostic categories (schizophrenic disorders represent a larger proportion). (B) Inpatients in Spain usually receive polytherapy, and are more frequently treated with antidepressants and anxiolytics, especially benzodiazepines. In contrast, USA-Inpatients take lithium more often [1,2].

Table 1

	Spain-Inpatients (mean±SD;%)	USA-Inpatients (mean±SD;%)	Statistics
Gender(%male)	49.2%	52.1%

Adherence to rehabilitation treatment in HIV-positive and HIV-negative opioid-addicted patients with psychiatric comorbidity

Z. Bereza
 Sain-Peterburg, Russia

Introduction Early diagnostics and treatment of comorbid disorders in drug addicts is an integral part of the rehabilitation process and a critical factor in the success of rehabilitation measures as a whole.

Subjects One hundred and thirty-three patient of inpatient rehabilitation department. The inclusion criteria in the study were: age above 18 years, withdrawal status, diagnosis (F 11.20 ICD-10). They were divided into two groups: HIV positive ($n = 38$) and HIV negative ($n = 95$).

Aims To estimate the prevalence of HIV infection and comorbid mental disorders in substance abuse patients and the impact of comorbidities disorders on the compliance.

Methods Clinico-anamnestic method, clinical-psychopathological method (criteria ICD-10 and clinical diagnostic scales: PANSS, HADS, MMPI). All participants also had serological blood test for antibodies to HIV.

Results According to our data, the incidence of comorbid mental disorders among HIV negative patients is 65%. The research also showed a correlation ($P < 0.05$) between HIV infection and mental disorders. So, mental disorders were diagnosed in 82% of HIV infected patients. Patients who stopped their treatment early ($n = 42$) significantly ($P < 0.05$) more often had specific personality disorders (17%). Most of them suffered from dissocial personality disorder (9%) and borderline personality disorder (18%).

Conclusions This analysis showed that HIV is not significant factor ($P > 0.05$) of early rehabilitation treatment interruption. But comorbid personality disorders in both groups are a significant factor ($P < 0.05$) of the treatment interruption, while the endogenous, neurotic or affective mental disorders are not.

Aggression as risk factor of delinquent behaviour (gender aspect)

N. Bokhan^{1,*}, A. Abolonin², I. Nazarova²

¹ Mental Health Research Institute, Administration, Tomsk, Russia

² Mental Health Research Institute, Addictive States Department, Tomsk, Russia

* Corresponding author.

In many studies it is noted that common traits of aggressive adolescents are frustration, dissatisfaction with social environment; emotional coarseness, hostility against people around. Substance abuse leads to restructuring the motifs and gender roles. Heightened aggression of offenders as compared with common people is noted.

Objective To study characteristics of aggression of male and female offenders with substance dependence.

Materials and methods One hundred and fifty-five male and 110 female adolescents abusing psychoactive substances and serving their sentence were examined. "Hand-test" and Buss-Durkee questionnaire were used in this study.

Results During comparison of number of offences committed by male and female adolescents, it was revealed that male adolescents commit significantly more crimes against life and female adolescents more crimes against property. Conducted analysis showed high level of aggressive and hostile reactions in this sample, indices of female adolescents (13.7 ± 2.95 and 27.6 ± 5.5) are significantly higher ($P < 0.05$), than in male adolescents (8.6 ± 2.8 and 23.6 ± 5.3). Significant correlations between level of aggression in female adolescents and beginning of substance use were revealed ($r = 0.46$, $P < 0.05$). In male adolescents, long-term substance use correlated with increase in level of physical aggression and tendency to manipulative behaviour ($r = 0.37$, $P < 0.05$). In male adolescents, high potential of adjustability, use of communication for self-assertion and achievement of goals, low level of attachment were revealed. Female adolescents are more aggressive in contacts, build relationships according to type of control-submission.

Discussion Conducted study allowed revealing gender traits of juvenile offenders influencing the structure of aggressive behaviour, allowing the broadening the understanding of mechanisms of aggressive behaviour.

Predictors for readmission within one year after discharge from an alcohol rehabilitation program

M. Müller*, G. Weniger, S. Prinz, S. Vetter, S. Egger
University Hospital for Psychiatry Zurich, ZIP-Rheinau, Zurich,
Switzerland

* Corresponding author.

Introduction Alcohol use disorders have been associated with an increased risk of frequent readmissions. This study aimed to examine factors that contribute to the risk for readmission within one year after discharge from an alcohol rehabilitation program.

Methods Rehospitalization status was assessed for all patients with an alcohol use disorder as primary diagnosis ($n = 468$) admitted to our inpatient unit between July 1, 2012, and June 30, 2014. All patients were followed up for one year after their first hospitalization (index hospitalization) within this period. Time to readmission within one year after discharge was measured using the Kaplan–Meier method. Risk factors for readmission were examined using Cox proportional hazard regression models. Three set of variables were selected to be included in the analyses:

- demographic features at time of admission of index hospitalization;
- comorbid conditions at time of admission of index hospitalization;
- treatment-related variables in relation to the index hospitalization including observer-rated outcome measures.

Results Readmissions within one year after discharge from an alcohol rehabilitation program as well as the corresponding time to readmission were linked to higher numbers of previous hospitalizations and the presence of comorbid opioid use disorders.

Conclusion Higher numbers of past treatments for AUD are indicators for a chronic course of the disorder, which, in turn, increase the risk of further relapses. Our findings further confirmed previous findings suggesting high rates of comorbidity among alcohol and opioid use disorders, and their link with poorer clinical outcomes.

Keywords Alcohol use disorder; Alcohol rehabilitation program; Readmission; Survival analysis

* Corresponding author.

Introduction Mephedrone is a synthetic cathinone derivative included in the class of “New-Novel Psychoactive Substances”. Synthetic cathinones are marketed as “bath salts” or “plant food” and gained notable popularity for similar effects to 4-methylenedioxymethamphetamine (MDMA, ecstasy), or amphetamines. Mephedrone is commonly consumed simultaneously with alcohol.

Objectives and aims The aim of the present study was to evaluate the interactions between mephedrone and ethanol in humans.

Methods Twelve healthy male, recreational users of psychostimulants participated as outpatients in four experimental sessions. They received a single oral dose of mephedrone (200 mg) and alcohol (0.8 g/kg), mephedrone placebo and alcohol (0.8 g/kg), mephedrone (200 mg) and placebo alcohol, and both placebos. Design was double-blind, double-dummy, randomized, cross-over and controlled with placebo. Study variables included: vital signs (blood pressure, heart rate, temperature, and pupil diameter), subjective effects (visual analogue scales-VAS, ARCI-49 item short form, and VESSPA questionnaire).

Results The combination produced an increase in the cardiovascular effects of mephedrone and induced more intense feeling of euphoria and well-being in comparison to mephedrone and alcohol. Mephedrone reduced the drunkenness and sedation produced by alcohol.

Conclusions These results are similar to those obtained with the combination of other psychostimulants as amphetamines and MDMA. Abuse liability of the combination is greater than induced by mephedrone.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ Hospital Universitari Germans Trias i Pujol, IGTP, Universitat Autònoma de Barcelona, Pharmacology, Barcelona, Spain

* Corresponding author.

Introduction Since 2004, herbal mixtures for smoking use have been sold under the generic brand “Spice”. Many of them contain synthetic cannabinoids (agonists of the cannabinoid receptors). JWH-018 was one of the first spice drugs. There is no scientific evidence of their effects on humans, except cases of intoxications and users opinions.

Objective The present study describes the presence of the synthetic cannabinoids JWH's and their characteristics in the samples delivered for analysis to the harm reduction NGO Energy Control from 2010 to 2014 in Spain.

Methods From 15,814 samples analyzed from 2010 to 2014, those containing synthetic cannabinoids JWH's were studied ($n = 47$). Analysis was done by gas chromatography–mass spectrometry.

Results From these 47 samples containing JWH, 55% were delivered as “legal highs” ($n = 21$) and 44% as JWH. Most common presentations were powder 47% and herbals 32%. Samples containing JWH 45% ($n = 21$) were mixed with more than one kind of JWH or were adulterated and other active principles were found 28% ($n = 13$) JWH-018, 11% ($n = 5$) JWH-210, 8% ($n = 4$) JWH-081 and

the 6% WH-250 ($n=3$). Origin of the sample was Catalunya 23% ($n=11$), other provinces of Spain 46% ($n=22$); other EU countries 23% ($n=11$) and internet-unknown country 8% ($n=8$). From the ($n=47$) samples, were delivered ($n=16$) in 2012, ($n=12$) in 2013, ($n=11$) in 2011, ($n=3$) in 2010 and ($n=3$) in 2014.

Conclusion JWH'S represent a low percentage of new psychoactive substances analyzed. Its presence in the market seems decreasing.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Tobacco is a source of mineral elements that can affect human health in various ways, such as lithium, which is used as a psychiatric medication. Lithium salts are used as mood-stabilizing drugs and indicated in the treatment of manic-depressive psychosis.

Objective Studying the lithium content in tobacco over the smokers' plasma content and evaluate the potential role of lithium in tobacco addiction.

Methods A total of 18 different tobacco products (cigarettes, smokeless and water pipe tobacco) and 125 plasma samples (45 from smokers, 10 from ex-smokers and 70 from non-smokers) were collected to determinate the lithium content. Tobacco samples were digested with nitric acid and lithium concentration was measured by inductively coupled plasma-optical emission. The collected plasma samples were diluted 1/10 with a nitric acid solution and the lithium level was measured by inductively coupled plasma-mass spectrometry.

Results The average concentration of lithium in the cigarettes ($16.59 \pm 0.59 \mu\text{g/g}$) was higher compared to those in the smokeless tobacco ($8.39 \pm 4.44 \mu\text{g/g}$) and in the water pipe tobacco ($6.13 \pm 6.32 \mu\text{g/g}$) but with no significant difference ($P=0.182$). For plasma lithium levels, there was no significant difference ($P=0.186$) between smokers and non-smokers (6.20 ± 6.24 vs. $4.98 \pm 6.20 \mu\text{g/g}$). However, a significant negative correlation was noted between plasma and the lithium content in tobacco products ($r=-0.435$; $P=0.04$). The lithium plasma level was significantly and negatively correlated with the dependence score ($r=-0.316$; $P=0.031$).

Conclusion The correlation between plasmatic lithium and dependence score in smokers suggests that lithium would be involved in tobacco addiction probably through its regulating action of mood.

Sleep quality and sexual function in patients under methadone maintenance treatment

A. Kheradmand^{1,*}, N. Nakhaee², A.R. Sabahy², Z. Amini Rnjbar³, Z. Zeynali³

¹ Shahid Beheshti University of Medical Sciences, Taleghani Hospital Research Development Committee, Tehran, Iran

² Kerman University of Medical University, Kerman neuroscience research center, Kerman, Iran

³ Kerman University of Medical University, Institute of Futur Studies in Health, Kerman, Iran

* Corresponding author.

Background Methadone maintenance has remained the main modality of treatment for opioid dependent subjects. Side effects of methadone treatment may be potential obstacles to its continuation. Sleep quality and sexual function are two culture-based concerns, directly related to patients' compliance with methadone maintenance treatment (MMT) program. This research was conducted to examine the frequency of sleep disparity and sexual dysfunction in patients under MMT referring to MMT clinics of Kerman, Iran.

Methods In this cross-sectional study, 198 adult subjects under MMT for more than 6 months were enrolled. Measurement tool consisted of Pittsburgh Sleep Quality Index (PSQI), Arizona Sexual Experience Scale (ASEX), the 12-item General Health Questionnaire (GHQ-12), and a demographic questionnaire. The questionnaires were self-completed, except where individuals were illiterate.

Results Mean \pm SD age of the subjects was 41.2 ± 7.9 years and 93.4% of them were male. More than half of them used heroin. Prevalence of poor sleeping and sexual dysfunction in patients under MMT were 67.7% and 18.2%, respectively. There was no association between sleep quality and sexual dysfunction and demographics or methadone dose. However, a significant correlation was observed between mental health and sleep quality ($r=0.16$, $P=0.033$), and sexual function ($r=0.18$, $P=0.011$).

Conclusions Sleep quality showed a poorer profile than sexual function. Therefore, more emphasis should be laid on treatment of sleep disparity during follow up of MMT patients comparing to their sexual function. Patients should be reassured that probable sexual dysfunctions should not be regarded as a consequence of MMT.

Optimization of therapy clinic-immunological disorders with heroin addiction

N. Khodjaeva*, S. Sultanov

Tashkent medical academy, Psychiatry and Narcology, Tashkent, Uzbekistan

* Corresponding author.

The immune defect can be found in all forms of addiction (Frank, 2004). These data determine the use of funds in immunotropic heroin addiction.

Objective To study the effectiveness of antidepressant sevram (citalopram) and its combination with galavit (immunomodulator) on a background of standard pharmacotherapy in heroin addiction. To evaluate the immune status of the following methods:

- evaluation of lymphocytes (CD4), (CD8) with monoclonal antibodies in cytotoxicity assay;
- determination of serum immunoglobulin classes A, M, G performed by turbidimetric analysis;

– the concentration of the CIK (circulating immunokompleks) was determined by precipitation with polyethylene glycol.

Patients of the 1st group was administered into the sevpram 10 mg/day in combination with galavit (25 mg daily); group 2 – only the standard therapy (ST).

The results of research As a result of the treatment in the first group showed an increase of 34.8% the number of immunoglobulin A, which however does not reach the level of healthy people and reducing the number of circulating complexes by 13.8%, which also indicates the normalization of this index. The first group – a significant improvement of immunological parameters increase of 3 indicators (CD4, CD8, CD4/CD8) and a decrease in the CIK. Analysis of changes in indicators Hamilton Rating Scale for Depression, also notes a reduction in the symptoms scores.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Exercise addiction: Identification and prevalence in physically active adolescents and young eating disordered patients

M. Lichtenstein^{1,*}, R.K. Støving²

¹ Department of Psychology, University of Southern Denmark, Odense, Denmark

² Department of Clinical Research, Odense University Hospital, Odense C, Denmark

* Corresponding author.

Introduction Exercise addiction is characterized by increasing exercise amounts, withdrawal symptoms and lack of control. Eating disorders and exercise addiction often appear together, but only eating disorders are recognized as diagnoses. However, exercise addiction can exist independently from eating disorders and can be as harmful as any other addictive behavior.

Objectives The Exercise Addiction Inventory (EAI) is useful to identify exercise addiction symptoms in adults and prevalence rates of 3–10% have been found. But a scale for adolescents does not yet exist even though behavioral addictions seem to be more prevalent among young people.

Aims To develop an instrument for identification of exercise addiction in adolescents and to estimate the prevalence and negative consequences.

Methods We developed a Youth version of the EAI and screened 383 adolescents in sport settings and 69 patients from an eating disorder department (age range 11–20 years).

Results The psychometric properties of the scale were good (Cronbachs alpha 0.71). The prevalence of exercise addiction was 5.5% in adolescents in sport settings and 21.2% in eating disorder patients. We found a positive linear relationship between EAI-score and “high weekly exercise amounts” ($r=0.4, P=0.00$), “the tendency to exercise in spite of injury” ($r=0.4, P=0.00$), “feelings of guilt when not exercising” ($r=0.5, P=0.00$), “reduced sport performance related to overtraining” ($r=0.2, P=0.00$), and “food dominating life” ($r=0.2, P=0.00$).

Conclusions On basis of this study, we recommend the EAI-Y for identification of exercise addiction in adolescents. Early identification is important since it can prevent excessive and obsessive exercise, injuries, reduced sport performance and eating disorder pathology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Novel psychoactive substances (NPS) use is progressively increasing year on year. The new analogues of phencyclidine are frequently sold as legal dissociative anesthetic drug with hallucinogenic and sedative effects, a legal alternative to ketamine, acting as a high affinity and selective ligand of NMDA receptor antagonists.

Objectives To describe the presence of 3- and 4-MeO-PCP in samples delivered to Energy Control from 2009 to 2015 in Spain.

Methods A total of 21,198 samples were analyzed from august 2009 to august 2015. Only those samples containing 4-MeO-PCP or 3-MeO-PCP were studied. They were analyzed by Energy Control, a Spanish harm reduction NGO that offers the possibility of analyzing the substances that users report. Analysis was done by gas chromatography–mass spectrometry.

Results All the samples resulted to be the acquired drug of the consumer. Three samples were adulterated with substances as tramadol, cocaine, acetone among others.

Conclusions Three and 4-MeO-PCP consumption is not found to be an emerging issue according to the results of our samples. Even the potential harmful effects of these dissociative drugs, our indirect indicator seems to show that consumption has not increased. A more precise monitoring would make a better approach to the real consumption and the impact of these substances in our society.

Disclosure of interest The authors declare that they have no competing interest.

Acknowledgement Supported in part by grants of ISCIII-FEDER (FIS PI11/0196), and The European Commission (Drug Prevention and Information Program 2014–16, (JUST/2013/DPIP/AG/4823, EU-MADNESS project). L. Galindo is a Rio Hortega fellowship (ISCIII; CM14/00111).

⁵ Hospital Universitari Germans Triás i Pujol, IGTP, Universitat Autònoma de Barcelona, Pharmacology, Barcelona, Spain

* Corresponding author.

Introduction In recent years, the increasing use tendency of NPS has motivated both awareness and concern about their identification and potential harmfulness. Synthetic cathinones represent a significant proportion of the NPS available and methylone is one of the most frequently found in Europe.

Objectives The aim of the present study is to determine methylone presence and characteristics from the samples analyzed by Energy Control between the years 2009 and 2015 in Spain.

Methods From all 21,198 samples analyzed from august 2009 to august 2015, only those in which methylone was found are studied ($n = 140$). The samples have been analyzed by Energy Control, a Spanish harm-reduction NGO that offers to users the possibility of analyzing the substances they intend to consume. The analysis is done by gas chromatography–mass spectrometry.

Results From the 140 samples containing methylone, 87 were handled as methylone, 20 as MDMA, 8 as other synthetic cathinones and 25 as other substances. The peak of consume was registered in 2011 with 41 samples then the number decreased until 10 samples in 2015.

Conclusions Results suggest that methylone is most frequently handled as methylone or as MDMA and that its consumption could be decreasing. Further pharmacokinetic, pharmacodynamic, clinical and epidemiological studies should be conducted to enhance the knowledge not only about methylone consumption, but also about synthetic cathinones in general in order to assess their potential risk and study the complications and its management.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Leptin and ghrelin levels in alcohol dependent patients and their relationship with withdrawal and craving

S. Mehta^{1,*}, A. Baruah², S. Khattri¹, S. Das², P. Avinash²

¹ SMI, Psychiatry, Dehradun, India

² LGB Regional Institute of Mental Health, Psychiatry, Tezpur, India

* Corresponding author.

Introduction Association between leptin and ghrelin plasma levels and alcohol craving have been found in few studies.

Objectives To search this correlation in a different population while comparing levels of these hormones with healthy individuals and also to study this correlation with respect to hyper-excitability state of alcohol withdrawal.

Aim To assess leptin and ghrelin levels after 3 weeks of abstinence in alcohol-dependent patients.

Methods Twenty-five indoor patients fulfilling the alcohol dependence criteria were assessed for withdrawal symptoms and craving for alcohol. Leptin and ghrelin levels were measured on 1st day, at the end of 1st week, at the end of 3rd week of stopping alcohol. Withdrawal was assessed using CIWA-A at day 1 and day 7, craving was assessed using PENN's scale of craving at the end of week 1 and week 3. Control group consisted of 15 first-degree relatives.

Results It was found that leptin [$t(38) = 2.95, P = 0.005$] and ghrelin [$t(38) = 2.56, P = 0.015$] were significantly higher in

alcohol-dependent patients. Levels of hormones had no significant correlation with alcohol withdrawal scores but had positive correlation with craving scores after abstinence.

Conclusions Study shows that leptin and ghrelin, known for balancing the energy homeostasis of body, also seem to play role in pathways of drug dependence and craving. This relation is independent of stress hormone axis as leptin and ghrelin levels are not correlated with withdrawal scores, which is an indicator of stress hormone axis activation during alcohol withdrawal.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction New psychoactive substances (NPS) are substances that have recently appeared on the market and are not under international control. NPS use is experiencing an unprecedented increase. DiPT, 4-HO-DiPT and 4-AcO-DiPT are new psychoactive tryptamines and their effects may differ from those of other psychoactive tryptamines.

Objective To explore the presence of DiPT, 4-HO-DiPT and 4-AcO-DiPT from samples delivered to and analyzed by Spanish harm reduction service Energy Control.

Materials and methods All samples analyzed from 2009 to 2014 delivered as DiPT, 4-HO-DiPT and 4-AcO-DiPT or containing these substances. Analysis was performed by gas chromatography–mass spectrometry.

Results From 17,432 samples, 4-HO-DiPT was found in 16, delivered as 4-HO-DiPT (6); 4-AcO-DiPT (7); DiPT (1); 4-AcO-DMT (1) and cocaine (1). 4-AcO-DiPT was found in 16, delivered as 4-AcO-DiPT (12); 5-MeO-DMT (1); 5-MeO-DiPT (1); 4-AcO-DMT (1) and cocaine (1). Only 4 samples contained DiPT, all presented as DiPT. Nine samples contained both 4-AcO-DiPT and 4-HO-DiPT. During the years of study, 4-HO-DiPT deliverance was increasing (4 samples in 2014) while deliverance of 4-AcO-DiPT and DiPT was decreasing (1 sample in 2014).

Conclusions Increasing 4-HO-DiPT presence could translate a progressive replacement of 4-AcO-DiPT and DiPT recreational use. Clinical relevance comes from its growing use and the absence of scientific evidence on humans, therefore relying on users subjective experience to predict the effects.

Disclosure of interest The authors declare that they have no competing interest.

Introduction Although psychoactive substance use disorders (PSUD) belong to the domain of mental health, their management varies greatly among European countries. Furthermore, both the role of psychiatrists and trainees in the treatment of PSUD is not the same for each European country.

Aims Among the context of the European Federation of Psychiatric Trainees (EFPT), the PSUD Working Group has developed a survey to carry out in year 2016, at the aim of gathering information about the training in PSUD in Europe, both from Child and Adolescent, and General Adult Psychiatric (CAP and GAP) trainees. **Objectives** The survey will investigate, at European level, the organisation of the PSUD training, trainees satisfaction, attitudes towards people who use psychoactive substances, management of pharmacologic and involvement in common clinical situations.

Methods A 70-items questionnaire regarding the aforementioned objectives has been developed, and will be shared through an online data-collecting system among European CAP and GAP trainees, with 40 trainees per country filling the survey in at least 30 countries (sample expected population of 1200). One national coordinator per country will facilitate the delivering of the survey. **Results** Twenty-five national coordinators were enrolled so far. It is still needed to reach coordinators from other 5 European countries to fulfil the above criteria and start the study.

Conclusions This survey will be the first to explore European psychiatric trainees attitudes and practices about PSUD. Findings from this independent survey may serve in understanding the needs of trainees in the field of substance misuse psychiatry.

Research assessments more important than duration of treatment? A systematic review and meta-analysis of the duration of psychosocial treatments for alcohol use disorders

L. Schmidt*, A.S. Nielsen, A.B. Bojesen, K. Andersen
Institute of Clinical Research- University of Southern Denmark,
Psychiatry, Odense, Denmark
* Corresponding author.

Background and aims The recommendations of duration of treatment for alcohol use disorders (AUD) in clinical guidelines are based on consensus decisions. There is a risk that patients will receive too little or too much therapy. We hypothesize that there is an association between duration and effect up until a point where the effects of treatment diminish.

Methods A systematic review and meta-analysis of randomized controlled trials of psychosocial interventions in the alcohol outpatient treatment centers. Population: adults (> 17 years) suffering from AUD treated with at least two sessions of therapy.

Statistics Multiple linear regression analysis with outcome measured in percentage of days abstinent (PDA), percentage of heavy days drinking (PHD), drinks per drinking day (DDD) and/or proportion of participants abstinent (ABS) as a function of duration of treatment.

Results Forty-four studies with 8485 participants were included. Mean duration: 18 (8–82) weeks and 15 (2–36) sessions. Mean follow-up time: 43 (8–104) weeks with a mean of 5 (2–18) research assessments. Only ABS was significantly associated with duration of treatment; ABS increased with 1.6%-point ($P < 0.01$) with each additional week in treatment. Surprisingly the analysis showed that each research assessment increased PDA with 11%-point ($P < 0.001$), decreased PHD with 4%-point ($P < 0.05$) and decreased DDD with 8%-point ($P < 0.001$).

Conclusion Duration of treatment was associated positively with proportion of participants abstinent but not percentage of days abstinent drinks per drinking day or percentage of heavy drinking days. The three latter outcomes were affected positively by number of research assessments.

Background Longitudinal studies on how temperament is related to alcohol use in general population are scarce.

Objectives Finding relations with temperament and problematic alcohol use using prospective birth cohort data.

Aims To investigate trends in self-reported alcohol consumption in adulthood.

Methods In the Northern Finland Birth Cohort 1966 ($n = 5247$), alcohol use was studied with questionnaires at ages 31 and 46. Participants were classified into abstainers, bingers, heavy drinkers, steady drinkers, increasers or reducers based on the change in consumption (g/day). Cloninger's TCI-scores were calculated for each group. Multinomial regression analysis was conducted with TCI-scores as factors influencing the change in alcohol consumption.

Results High novelty seeking was associated with increased consumption, binge and heavy drinking among both sexes at both time points ($P < 0.01$). Lower persistence was associated with increased consumption at both time points among men and among women at age 46. Baseline novelty seeking predicted both increasing (OR 1.1; 95% CI: 1.0–1.1) and reducing (1.1; 1.0–1.1) for men and for women also increasing (1.1; 1.0–1.1) and reducing (1.1; 1.0–1.1), but when adjusted with baseline alcohol use novelty seeking only predicted increasing for men (1.0; 1.0–1.1).

Conclusions High novelty seeking and low persistence are associated with problematic alcohol use among middle-aged Northern Finns. Gender differences in predictors existed: novelty seeking predicted increase only for men in the adjusted model. Temperament scores do not seem to affect strongly changes in alcohol use.

Depressive symptoms and bone mineral density in menopause and postmenopausal women: A still increasing and neglected problem

A. Bener

Istanbul University, Biostatistics & Public Health, Istanbul, Turkey

Objective The objective of current study was to investigate whether association exist between depression and low BMD during menopause and post-menopausal period.

Methods A cross-sectional descriptive study and 1650 women aged 45–65 years were included during 1182 women agreed to participate (71.6%). Data on body mass index (BMI), clinical biochemistry variables including serum 25-hydroxyvitamin D were collected. The Beck Depression Inventory (BDI) was administered for depression purposes.

Results A total of 1182 women agreed to participate and responded to the study. The mean age and SD of the menopausal age were 48.71 ± 2.96 with depressed and 50.20 ± 3.22 without depressed ($P < 0.001$). Also, the mean and SD of postmenopausal age were 58.55 ± 3.27 depressed and 57.78 ± 3.20 without depressed ($P < 0.001$). There were statistically significance differences between menopausal stages with regards to number of parity, and place of living. There were statistically significance differences between menopausal stages with regards to BMI, systolic and diastolic blood pressure, vitamin D deficiency, calcium deficiency and sheesha smoking habits. Overall, osteopenia and osteoporosis and bone loss were significantly lower in post-menopausal women than in menopausal women ($P < 0.001$). Similarly, T-score and z-score were lower with depressed menopause and postmenopausal women ($P < 0.001$).

Conclusion The multivariate logistic regression analyses revealed that the depression, the mean serum vitamin D deficiency, calcium level deficiency, less physical activity, co-morbidity, number of parity, systolic and diastolic blood pressure and sheesha smoking habits were considered as the main risk factors associated with bone mineral loss after adjusting for age, BMI and other variables.

Depression, anxiety and stress [DASS21] symptoms in menopausal Arab women: Shedding more light on a complex relationship

A. Bener

Istanbul University, Biostatistics & Public Health, Istanbul, Turkey

Objective To determine correlation between depression, anxiety and stress in menopausal and post-menopausal women and shedding more light on a complex relationship.

Methods A cross-sectional descriptive study was used and 1468 women aged 45–65 years were included and 1101 women agreed to participate (75.0%). Depression, anxiety and stress were measured using the Depression Anxiety Stress Scales (DASS-21). Data on body mass index (BMI), clinical and other parameters was used.

Results A total of 1101 women agreed to participate after informed consent was obtained. The mean age and SD of the menopausal age was 49.55 ± 3.12 , the mean and SD of postmenopausal age was 58.08 ± 3.26 ($P < 0.001$). There were statistically significant differences between menopausal stages with regards to age, ethnicity, educational status, occupation status, and place of living. Also, there were statistically significant differences between menopausal stages with regards to BMI, systolic and diastolic blood pressure, vitamin D deficiency, and diseases. Depression and anxiety were more common among post-menopause women. Also, there were no differences between the groups regarding the frequency of certain levels of stress among menopause and post-menopause. Multivariate regression analyses revealed that age in years, diastolic BP, consanguinity, regular exercise were predictor for depression. Meanwhile, diastolic BP, occupation and physical activity considered the main risk factors for anxiety. Furthermore, age in years, occupation and sheesha smoking habits were considered as the main risk factors associated with stress.

Conclusion A large number of factors were associated with experiencing menopausal and psychosocial problems which had negative effects on the quality of life among Arabian women.

Neurocognitive deficit in first-episode, drug-naïve obsessive-compulsive disorder

S.N. Kim^{1,*}, T.Y. Lee², Y.B. Yoon¹, J.S. Kwon¹

¹ *Seoul National University Hospital, Psychiatry, Seoul, Republic of Korea*

² *Seoul National University, Neuropsychiatry, Seoul, Republic of Korea*
* *Corresponding author.*

Objective Obsessive compulsive disorder (OCD) is one of the most common psychiatric chronic disorders (prevalence 2–3%) and has been associated with various neurocognitive impairment, including visual memory function. Although the relapse rate of OCD is highly considerable, little is known regarding the relationship between neurocognitive dysfunction and the chronicity of the illness, mainly because there are confounding factors as the medication effect. Therefore, we compared the difference of neurocognitive functions of the first-episode, medication-naïve OCD patients to chronic, medication-naïve OCD patients.

Method We defined the first-episode (FEOCD) if the illness duration was less than 3-year by DSM-IV criteria. Twenty-one FEOCD and 28 chronic OCD patients performed Korean version of the Wechsler Adult Intelligence Scale (K-WAIS), the Trail Making Test (TMT). All the participants were medication-naïve.

Results There was no differences in the severity of illness (YBOCS), depressive symptoms (Hamilton depression rating scale), general anxiety symptoms (Hamilton anxiety rating scale). FEOCD group showed significant impairment on the block design subtest of the K-WAIS ($P=0.04$, $t=1.294$).

Conclusions These results suggest that visual spatial cognitive dysfunction in patients with OCD may deteriorate as the untreated duration of illness get longer.

Behavioral inhibition/behavioral activation systems are relevant with the interpersonal problem?

H. Na

Seoul St. Mary's hospital, psychiatry, Seoul, Republic of Korea

Introduction and objectives It is well known that interpersonal dysfunction has influence on the onset, treatment response, and prognosis of depression. Exploring factors influencing interpersonal problems is important and anxiety-related characteristics could be considered as one of the significant points. Based on this background, we aimed to investigate the influence of anxiety-related characteristics such as state anxiety, trait anxiety and anxiety sensitivity on interpersonal problems in patients with depressive disorders.

Aim and methods A total of 152 outpatients diagnosed with depressive disorders completed questionnaire measuring socio-demographic, clinical symptom severity, such as depression and anxiety, and interpersonal problems. Beck Depression Inventory (BDI) was used to measure depression severity and State and Trait Anxiety Inventory (STAI) and Anxiety Sensitivity Index (ASI-R) were used to evaluate various anxiety related symptoms. Interpersonal relationship problems were measured by the short form of the Korean version of the Inventory of Interpersonal Problems Circumplex Scales (KIIP-SC).

Result General interpersonal problem was affected by trait anxiety and anxiety sensitivity. General and any other specific interpersonal problems were not significantly different according to state anxiety. Patients with higher trait anxiety and anxiety sensitivity score tend to more distant, socially inhibited and non-assertive interpersonal pattern. More domineering and intrusive interpersonal pattern was observed in patient with high anxiety sensitivity.

Conclusion The present study provides preliminary evidence that predisposing characteristics, such as trait anxiety and anxiety sensitivity, might influence interpersonal dysfunction, especially socially inhibiting behaviors.

Keywords Interpersonal relationship; Trait anxiety; Anxiety sensitivity; Depression

Dynamics of biochemical changes in anxious-depressed patients under treatment with antidepressants with different mechanisms of action on serotonin reuptake

M. Uzbekov*, N. Maximova

Moscow Research Institute of Psychiatry, Brain Pathology, Moscow, Russia

* Corresponding author.

Objectives Pharmacodynamics of serotonergic antidepressants differently influencing on serotonin reuptake receptors is poorly investigated.

Aim To compare biochemical profiles at patients with anxious depression under treatment with tianeptine–serotonin reuptake enhancer and sertraline–selective serotonin reuptake inhibitor.

Methods Platelet monoamine oxidase (MAO) and serum amine oxidase (AO) activities, level of middle mass endotoxigenic molecules (MMEM) and serum albumin functional properties – effective albumin concentration (EAC) and reserve of albumin binding (RAB) were investigated at 43 patients with anxious depression (F 32.1 and F 33.1). Clinical severity of illness was assessed using Hamilton Depression (21 items) and Hamilton Anxiety Scales. All patients were divided in two groups: group I (21 person) received tianeptine (37, 5 mg/day), group II – sertraline (50 mg/day).

Results It was established that patients with anxious depression were characterized by significant increase in MAO activity (by 95%) and the level of MMEM (by 86%) and significant decrease in AO activity (by 28%) and EAC and RAB parameters by 43 and 38%, respectively, in comparison with healthy volunteers. Under tianeptine and sertraline treatment, there were revealed contrary directed changes of all investigated parameters.

Conclusion Results of study show that both tianeptine and sertraline are equally effective in treatment of anxious depression. Present biochemical investigation, however, suggest that underlying biochemical changes are more complete following tianeptine treatment.

Thyroid profile and its relationship with response to treatment with lithium in bipolar mood disorder patients

P. Avinash^{1,*}, K. Pathak²

¹ Deva Institute of Health Care and Research, Psychiatry, Varanasi, India

² LGBRIMH-Tezpur, Psychiatry, Tezpur, India

* Corresponding author.

Introduction There is substantial evidence that even minor perturbation of thyroid function plays a significant role in clinical course and treatment outcome in bipolar mood disorder.

Aims and objectives To understand the relationship between thyroid profile and bipolar disorder subtypes and to study the relationship between pre-treatment thyroid profile and response to treatment with lithium along with other predictors of response to treatment with lithium in cases of bipolar mood disorder.

Methods This study was conducted in the indoor facilities of LGBRIMH, Tezpur in the year of 2012, after clearance from scientific and review committee and Ethics committee of the institute. Forty-five consecutive indoor patients diagnosed with bipolar mood disorder using DSM-IV TR criteria were selected. On day 1, blood was collected for thyroid profile and BPRS 24 item scale version 4.0 was applied. They were all started on lithium monotherapy, and only lorazepam was used on SOS basis. On day 30, the BPRS was applied again to check the response to treatment. Appropriate statistical analysis was done using SPSS version 16.

Results The response to treatment was good with the mean % fall of the BPRS score being 40%, with the maximum fall in the subscale

of grandiosity and minimum for depression. Age, illness duration, substance use, family history 2nd or later episodes were negatively correlated with treatment response. Pretreatment T4 level was positively correlated while pre-treatment TSH level was negatively correlated with the treatment response.

Conclusion Pre-treatment T4 and TSH level were predictors of treatment response with lithium.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁷ Wonkwang University School of Medicine, Psychiatry, Iksan, Republic of Korea

⁸ College of Medicine, Jeju National University, Psychiatry, Jeju, Republic of Korea

* Corresponding author.

Objectives The aim of this study was to determining the cut-off for recurrent depressive episode to predict diagnostic conversion from unipolar depression to bipolar disorder by means of retrospective reviews of medical records.

Methods The medical records of 250 patients with a diagnosis of major depressive disorder for at least 5 years were retrospectively reviewed for this study. We reviewed DSM-IV diagnosis and detailed clinical information at the index admission with assessments made every year after discharge to determining the cut-off for recurrent depressive episode to predict diagnostic conversion from unipolar depression to bipolar disorder.

Results Receiver operating characteristic curve analysis indicated cut-off scores for recurrent depressive episode of more than three times (area under curve=0.647, sensitivity=0.435, specificity=0.819, positive predictive value=0.351, negative predictive value=0.865).

Conclusions These findings suggest that it could predict the best diagnostic conversion from unipolar depression to bipolar disorder when depressive episodes are recurrent more than three times. Based on these findings, it will be able to promote the accuracy of diagnosis and the efficiency of treatment.

* Corresponding author.

Patients with bipolar disorder (BD) show a typical neuropsychological profile, characterized by an alteration of attentive, amnesic and executive ability. The aim of the study is evaluate the effectiveness of cognitive training in integrated treatment (CTiIT) for bipolar disorder.

Methods A total of 30 BD euthymic patients were enrolled. All participants completed a comprehensive neuropsychological and psychosocial (SF-36 and PSQ) assessment. Patients were random assigned to CTiIT group or control group. CTiIT is designed to be a short therapy (20 individual sessions of about 1 hour for three days at week) for the neurocognition, and for psychosocial aspects. Cognitive training consisted of computerized tasks selected from CogPACK. Attention, memory and executive tasks available within the CogPACK program were selected for use in this study, based on the cognitive domains typically affected in BD patients. Training with this program is hierarchically organized. All individuals in the present study had the potential to complete all of the tasks, regardless of degree of impairment. Statistical analyses were conducted using Statistical Package for the Social Sciences Version 20.0 (SPSS 20.0) for windows (SPSS Inc., Chicago, Ill).

Results Results showed that CTiIT for BD is effective in improving verbal learning and memory, executive functions and attention. Moreover CTiIT increases social wellness measured by SF-36 and reduces stress perception's (PSQ).

Conclusions Cognitive training in integrated treatment – CTiIT is an important tool for achievement of personal recovery and becomes necessary to use it, in the daily treatment of BD.

First rank symptoms in mania: An indistinct diagnostic strand

A. Channa^{1,*}, S. Aleem², H. Mohsin¹

¹ Liaquat National Hospital, Psychiatry, Karachi, Pakistan

² Agha Khan University, Psychiatry, Karachi, Pakistan

* Corresponding author.

First rank symptoms (FRS) are considered to be pathognomic for schizophrenia. However, FRS is not distinctive feature of schizophrenia. It has also been noticed in affective disorder, albeit not inclusive in diagnostic criteria. Its existence in the first episode of bipolar disorder may be predictor of poor short-term outcome and decompensating course of illness.

Objective To determine the frequency of first rank symptoms in manic patients.

Method The cross sectional study was done at psychiatric services of Aga Khan University Hospital, Karachi, Pakistan. One hundred and twenty manic patients were recruited from November 2014 to May 2015. FRS was assessed by administration of validated Urdu version of Present State Examination (PSE) tool.

Result The mean age of the patients was 37.62 ± 12.51. The mean number of previous manic episode was 2.17 ± 2.23. In total, 11.2% males and 30.6% females had FRS. This association of first rank

symptoms with gender in patients of mania was found to be significant with a *P* value of 0.008. All-inclusive, 19.2% exhibited FRS in their course of illness, 43.5% had thought broadcasting, made feeling, impulses, action and somatic passivity, 39.1% had thought insertion, 30.4% had auditory perceptual distortion, and 17.4% had thought withdrawal. However, none displayed delusional perception.

Conclusion The study confirms the presence of FRS in mania in both male and female, irrespective of the duration of current manic illness or previous number of manic episodes. A substantial difference was established between both the genders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional reactivity, functioning and chronic inflammation in remitted bipolar patients: Clinical relevance of a dimensional approach

A. Ayub Dargél^{1,2,*}, V. Hirakata³, C. Henry⁴

¹ Institut Pasteur and Molecular Psychiatry Laboratory, Perception and Memory Laboratory, Paris, France

² Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

³ Hospital de Clínicas de Porto Alegre, GPPG-Statistics, Porto Alegre, Brazil

⁴ Institut Pasteur, Université Paris XII, Inserm U955, Paris, France

* Corresponding author.

Aims To examine emotional reactivity (ER) as a dimension that may contribute to the better characterization of subsyndromal mood symptoms in bipolar disorder (BD) patients during remission, and to explore the association between ER, psychosocial functioning and levels of C-reactive protein (CRP, a biomarker of low-grade inflammation) including as to whether CRP is a biosignature of ER in BD.

Method Six hundred and thirteen adult BD outpatients. Assessments: psychosocial functioning by Functional Assessment Short Test (FAST), mood by Multidimensional Assessment of Thymic States (MATHyS). The MATHyS ER sub-score (0–40) characterized 3 patients:

- <16: emotional hyporeactivity (HypoER);
- 16–24: normal emotional reactivity (NormalER);
- >24: emotional hyperreactivity (HyperER).

CRP was measured by using standard enzyme immunoassay. Statistical analyses were performed using SPSS v21.

Results HypoER (*n* = 144; *m* = 12.4 ± 3.4), NormalER (*n* = 198; *m* = 19.9 ± 2.6); HyperER (*n* = 271; *m* = 28.9 ± 3.7). BD patients with HypoER or HyperER had significantly greater levels of residual mood symptoms than patients with NormalER (*P* < .0001). Patients with HypoER (FAST *m* = 21 ± 14.1) or HyperER (FAST *m* = 20 ± 11.2) presented lower functioning (*P* < .0001). CRP levels were significantly increased in BD patients with HypoER (*m* = 2.8 ± 2.0; *P* < .0001) and mostly with HyperER (*m* = 4.3 ± 2.8; *P* < .0001) compared with NormalER patients (*m* = 1.4 ± 1.4).

Conclusions ER appear to impact psychosocial functioning as well as to be a pertinent dimension to discriminate subsyndromal mood states in remitted BD patients. CRP could be a biological validator of emotional reactivity in BD. Association between ER-CRP may be useful proxy to examine the relationship between specific symptom profiles and chronic inflammation, a potential biological state associated with BD. These novel findings could be clinically relevant, if tested and confirmed by future studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Impact of sleep disturbance in functioning and quality of life in euthymic patients with bipolar disorder

L. de la Fuente-Tomás^{1,*}, M. García-Portilla¹, G. Safont², B. Arranz³, M. Sánchez⁴, P. Sierra⁵

¹ Universidad de Oviedo, Área de Psiquiatría, CIBERSAM, Oviedo, Spain

² Hospital Universitario Mutua de Terrasa, Psiquiatría, Barcelona, Spain

³ Fundación San Juan de Dios, Universidad de Barcelona, Psiquiatría-Cibersam, Barcelona, Spain

⁴ Hospital Mutua de Terrasa, Psiquiatría, Barcelona, Spain

⁵ Hospital La Fe, Psiquiatría, Valencia, Spain

* Corresponding author.

Introduction Sleep impairment has been described as a core mechanism of bipolar disorder (BD) frequently associated low global function and quality of life (QoL) [1].

Aim To investigate the impact of sleep disturbance in daily functioning and QoL in a sample of euthymic BD patients with presence and absence of sleep complaints, assessed with a valid sleep quality questionnaire [2].

Methods Naturalistic, multicenter, cross-sectional study. Sample: 119 euthymic outpatients with BD [34.5% males; mean age (SD) = 46.28 (12.22)]; (1) without sleep complaints (60.5%); (2) with sleep complaints (31.9%) and insomnia diagnosis (7.6%). Instruments: Cuestionario de Oviedo de Calidad de Sueño (COS), FAST, SF-36, HDRS, CGI and SCIP.

Results No significant differences were found between groups in age, sex, global severity illness, and cognitive impairment (*P* > 0.05). Likewise, there was not statistical difference neither in daily functioning (*P* > 0.05) nor in QoL (*P* > 0.05), with the exception of emotional role (*t* = 2.26; *P* < 0.05), sleep complaints group showing higher interference.

Conclusions Despite 39.5% euthymic patients with BD experienced sleep complaints, this study showed that sleep disturbance not affected patients' daily functioning and QoL. Both groups report similar outcomes.

Haloperidol, risperidone and quetiapine in the treatment of acute severe manic episode in bipolar disorder: The experience at the mood disorder unit in Milan

D. Delmonte^{1,*}, C. De Santis², S. Brioschi², B. Barbini¹, C. Colombo²

¹ San Raffaele-Turro Hospital, Clinical Neurosciences, Milan, Italy

² University Vita-Salute San Raffaele, Clinical Neurosciences, Milan, Italy

* Corresponding author.

Introduction Patients affected by severe manic episode, often with delusional symptoms, are commonly treated with a

combination of mood stabilizers, antipsychotics and other sedatives. The choice of a specific drug, dose and term is still debated.

Objectives A naturalistic study on a sample of 84 inpatients affected by acute severe mania treated with a combination therapy.

Aims To compare efficacy and tolerability of haloperidol/risperidone/quetiapine in association with lithium and/or valproate.

Methods Eighty-four bipolar inpatients affected by a manic episode according to DSM-5 criteria. Drugs administered according to our best practice. Clinical course weekly monitored with Young Mania Rating Scale (YMRS) for 4 weeks. Extrapiramidal side effects (EPSE) monitored with Saint Hans Rating Scale (SHRS).

Results Twenty-five men (29.76%) and 59 women (70.24%); mean age 43.37 ± 13.58 years. Mean YMRS score T0 40.27 ± 9.04 . Forty-one patients (48.81%) treated with haloperidol (3.4 mg/die); 16 (19.05%) with risperidone (4.3 mg/die); 27 (32.14%) with quetiapine (438 mg/die). The 3 groups showed no difference regarding clinical characteristics and YMRS basal scores. Chi² analysis confirmed a higher response rate (50% of reduction of YMRS final score compared to T0) with haloperidol ($\chi^2 = 14.88$; $P = 0.00$). The repeated-measures model analysis showed a significant decrease ($P < 0.05$) in YMRS scores in haloperidol vs. risperidone vs. quetiapine patients for all time points from second week. No statistical difference for EPSE was found.

Conclusions We suggest that haloperidol could be advisable in the treatment of severe mania, with rapid efficacy, even with low doses. Occurrence of EPSE was not considerable during the acute treatment. Studies with a larger sample size, randomization, fixed doses, double blind design are needed.

Late-onset bipolar disorder: What else?

C.P. Ferreira*, S. Alves, C. Oliveira, M.J. Avelino
 Centro Hospitalar Psiquiátrico de Lisboa, SETA, Lisbon, Portugal
 * Corresponding author.

Introduction Geriatric-onset of a first-episode mania is a rare psychiatric condition, which may be caused by a heterogeneous group of non-psychiatric conditions. To confirm late-onset bipolar disorder (LOBD) diagnosis, secondary-mania causes should be ruled out.

Objectives To provide a comprehensive review reporting prevalence, features, differential diagnosis, comorbidity and treatment of LOBD.

Methods The literature was systematically reviewed by online searching using PubMed®. The authors selected review papers with the words "Late-onset mania" and/or "Late-onset bipolar" in the title and/or abstract published in the last 10 years.

Results and discussion With population ageing, LOBD is becoming a more prevalent disorder. Clinical presentation may be atypical and confounding, making the diagnosis not always obvious. Several non-psychiatric conditions must be considered in an elderly patient presenting with new-onset mania, namely stroke, dementia, hyperthyroidism or infection causing delirium. Only then LOBD diagnosis may be done, making that an exclusion diagnosis. Comorbidities, such as hypertension or renal insufficiency are often present in the elderly and must be taken into account when choosing a mood stabilizer.

Conclusions LOBD remains a complex and relatively understudied disorder with important diagnostic and therapeutic implications. This diagnosis must be kept in mind for every elderly patient presenting with new-onset mania. Further investigations could contribute to a better understanding of LOBD etiopathogenesis and to set out better treatment guidelines.

Telemedicine and bipolar disorder

A. García-Alocén^{1,*}, C. Bermudez-Ampudia²,
 M. Martínez-Cengotitabengoa³, I. González-Ortega³,
 S. Ruiz de Azua³, I. Zorrilla³, P. Lopez³, A. González-Pinto³
¹ HUA-Santiago, Psiquiatria, Vitoria, Gasteiz, Spain
² HUA-Araba, Psiquiatria, Vitoria, Spain
³ HUA, Psiquiatria, Vitoria, Spain

Show the efficacy of an innovate telemedicine psyeducational invention based on a psychoeducational intervention treatment with a group of bipolar patients.

Objectives To assess the efficacy of an innovate telemedicine psyeducational treatment (TPT) based on a psychoeducational intervention (21 sessions) with an additional support through telemedicine which has 12 videos versus treatment as usual (TAU) based on psychiatry reviews. Specifically, the objective was to evaluate patients' efficacy of psyeducational treatment with telemedicine (TPT) in the fuctionality, depressive symptoms and manic symptoms.

Methods Thirty-eight patients with bipolar disorder were included in the study and randomly distributed in the two groups. The telemedicine treatment is performed through a www.puedoser.es web platform provided by Astra Zeneca. In the web platform is available forums, emails and digital-course with the sessions worked as a reminder. In order to assess the effectiveness of treatments, FAST scale was administered at baseline and 6 months after the intervention. To obtain the results we used comparative data analysis.

Results In patients, we found a low daily functionality. The main issues were: interpersonal cognitive area ($t = -2.611$; $P = 0.014$) and interpersonal-area ($t = -2.617$; $P = 0.014$). We found, at baseline, that TPT group had worse overall results in daily functionality ($t = -2.876$; $P = 0.008$). After intervention, there is an improvement in the daily functionality of the TPT group. This improvement occurred in cognitive area ($z = -3.24$; $P < 0.001$), leisure area ($z = -1.85$; $P = 0.065$) and interpersonal area ($z = -1.72$; $P = 0.086$).

Conclusions The psychoeducational program combined with telemedicine shows to be more effective than TAU in the improvement of general patient functioning in bipolar disorder patients.

The prevalence of bipolar mood disorders in the medically ill patients hospitalized in general hospitals

A. Ghanbari Jolfaei*, S. Ataei
 Mental Health Research Center, Iran University of Medical Sciences,
 Psychiatry, Tehran, Iran
 * Corresponding author.

Introduction Bipolar mood disorders are the eighth cause of disability in the world. Several studies have shown the prevalence of bipolar disorders in patients with medical diseases is higher than healthy controls.

Aims This study aimed to investigate the prevalence of bipolar disorders in the medically ill patients hospitalized in general hospitals.

Methods In this cross-sectional study, 706 patients (342 men, 49%) admitted to different wards of three general hospitals randomly enrolled to the study. Demographic questionnaire, MDQ

(Mood Disorder Questionnaire) and BSDS (Bipolar spectrum Diagnostic Scale) were used. The criteria for inclusion were informed consent and cooperation for the study, lack of cognitive and mental disorders and being literate.

Results In 84 (12.1%) and 145 (20.8%) patients, respectively BSDS and MDQ questionnaire results were positive. In 75% of patients, the results of both tests were negative, while in 9.7% of hospitalized patients, the results of both tests were positive. The frequency of bipolar mood disorders was not significantly different between male and female, but the frequency of bipolar disorders was significantly higher in singles, smokers, alcohol abusers, younger age and lower education level. The highest rate of bipolar disorders was reported in the orthopaedic ward.

Conclusion The prevalence of bipolar mood disorders in hospitalized medically ill patients is significant, due to the impact of the disorder on the lifestyle, compliance and the prognosis, identification and treatment of bipolar mood disorders is important in these patients.

* Corresponding author.

Background The SIMPLe project was designed with the aim of developing a smartphone application (i.e. app) to monitor and psychoeducate subjects with bipolar disorder through highly personalized messages from both passive and active data. The project was based on a face-to-face group program, which has an increasing scientific evidence of its efficacy and cost-effectiveness reducing bipolar disorder relapses.

Aims An initial feasibility study was conducted to evaluate the usability and satisfaction of an Android version of the SIMPLe app 1.0.

Methods The SIMPLe feasibility study was conducted from March 2015 to June 2015. The participation in the study was offered to a consecutive sample of adult patients diagnosed of bipolar disorder I, II or NOS (not otherwise specified) attending the outpatient mental health clinic of the Hospital Clinic of Barcelona, Spain.

Results The participation in the study was offered to 72 stable bipolar patients. Forty-three subjects were enrolled in the study. Since the day the patients were enrolled in the study, the rate of completed tests was 0.74 per day and 1.13 per week. Nine emergency alerts were received through the application and notified to the reference patients' psychiatrists. Ninety-five percent of the initial participants remained actively using the app and no relapses were identified during the 3 months of the study.

Conclusion These preliminary results suggest a high feasibility of the SIMPLe app based on the rates of tasks completed and retention.

Neurocognitive impairments in euthymic patients with bipolar disorder type II

R.S. İlhan^{1,*}, V. Senturk-Cankorur²

¹ Dr. Nafiz Korez Sincan State Hospital, Ministry of Health, Psychiatry, Ankara, Turkey

² Ankara University Medical School, Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction Most of the studies have indicated that there have been neurocognitive impairments especially in the domains of executive functions, attention, verbal and working memory among euthymic patients with bipolar disorder type I (BD-I). However, there has been limited research investigating neurocognitive functioning in euthymic patients with BD- II.

Objectives/aims Aim of this study was to investigate neurocognitive functions in euthymic BD-II patients. Our hypothesis was that euthymic BD-II patients would have neurocognitive impairments in the domains of executive functions, attention, verbal and working memory.

Methods Euthymic BD-II patients ($n=37$) and healthy controls (HC) ($n=35$) were compared in terms of their neurocognitive functioning in the domains of executive functions assessed by the number of perseverative errors, non-perseverative errors and category completed on the Wisconsin Cart Sorting Test (WCST); working memory assessed by Auditory Consonant Trigrams (ACT); immediate verbal memory assessed by the Logical Memory subscale of the Wechsler Memory Scale I (WMS I) and attention assessed by Stroop Colour-Word Interference Test (SCWIT). Euthymic state was confirmed by the low scores both on Hamilton Depression Rating Scale, Young Mania Rating Scale.

Results Significant differences were found between two groups in terms of WCST non-perseverative errors ($Z=3.8$, $P<0.01$) and category completed subtests ($Z=3.8$, $P<0.01$), ACT ($t=2.97$, $P<0.01$) WMSI ($Z=2.4$, $P=0.01$), SCWIT ($t=3.52$, $P<0.01$) performances.

Conclusions Our study indicated that euthymic BD-II patients had poorer performance on the domains of executive functions, attention, working memory and verbal memory than the HC group. But future studies with large samples are needed to support our results.

Introduction Smoking is a serious health problem for people with mental illness and especially for bipolar disorder patients (Rüther et al., 2014). It is necessary to explore the possibilities of brief intervention in the context of community care that may act on the level of motivation for change.

Objectives Assess the effectiveness of the 3 A's intervention (Ask, Advise and Assess) in a sample of euthymic bipolar patients after 12 months.

Methods Two hundred and twenty patients diagnosed with bipolar disorder (according DSM-5 criteria) that were in the euthymic phase (defined as less than 7 points in YMRS and 10 points in HDRS) and attended the community care centers of three provinces of Andalusia (Spain). Patients who consumed in the last month qualified for the level of motivation for change (measured by URICA scale); before and after conducting a brief intervention of no more than 30 minutes in total, divided in three contacts during a month, two face to face and one phone contact. We evaluated the results in the smokers at baseline after 12 months of the intervention.

Results After 12 months of follow-up, a 7.1% was abstinent, a 35.7% tried to abandon the consume at least once during the follow-up an average 8 days (2–30). A 14.3% discontinued the study.

Conclusions This is the first paper that evaluate the 3 A's intervention in bipolar disorder with 12 months of follow-up. The results of abstinence after were similar to those obtained in patients with schizophrenia using the same intervention (5%) (Dixon et al., 2009).

Subthreshold symptoms in bipolar disorder: Impact on quality of life

R. Khemakhem*, W. Homri, D. Karoui, H. Belhadj, L. Mouelhi, N. Bram, I. Ben Romdhane, R. Labbene
Razi Hospital, Psychiatry C, Mannouba, Tunisia

* Corresponding author.

Introduction Several studies have analyzed the influence of bipolar disorder (BD) related to many kinds of functioning. Even if it is obvious that patients in relapse have poor quality of live (QoL), what's about it in interictal phases with subthreshold symptoms?

Aims To study the potential relationship between QoL and subthreshold symptoms in bipolar I patients in remission.

Objective To evaluate the above relationship, we hypothesized that subsyndromic BD phases can be related to worse subjectively QoL.

Methods This was a cross-sectional study. Forty-four BD patients were enrolled. The subthreshold symptoms were evaluated by Hamilton Depression Rating Scale (HDRS) and Young Mania Rating Scale (YMRS). Patients with HDRS lower than 7 and YMSR lower than 6 were the successful applicants. Then, we run the Tunisian version of SF-36 to measure the QoL.

Results Twenty-seven men and seventeen women with an average age of 39.3 years were selected. Age of beginning of BD was 31.5 years and patients were in relapse since 1.56 years. The HDRS's average score was 2.73. Twenty patients (45.5%) have an HDRS upper than 4. The YMRS's average score was 2.25 and twenty-nine BD's patients have a score between 1 and 6. The overall average score at SF-36 scale were 64.2 and 25% of BD patient with subthreshold symptoms had a poor QoL.

Conclusions Subsyndromic interictal phases affect the QoL of BD patients and it's necessary to introduce therapy adapted according to troubles in order to improve patient's quality of life and functioning.

⁴ CIBERSAM- University Hospital of Alava, University of the Basque Country EHU-UPV, Psychiatry-Neurosciences, Vitoria, Spain

* Corresponding author.

Introduction It is important to make an early and effective intervention from the first bipolar episode. The presence of depressive symptoms in the course of a manic episode could influence negatively the evolution and the prognosis of the patient. Inflammation and oxidative stress are also related with functionality.

Objectives To explore the relationship between depressive symptoms during a first episode of mania, inflammatory parameters and patient functionality during the follow-up.

Method We included in the study 92 are patients with a first manic episode and 92 matched healthy controls. We compared 13 inflammatory/oxidative stress parameters measured at baseline (TFN α , IL6, PGE2, MCP1, TBARS, NO2, SOD, CAT, GSHTOT, GSSG, GSHfree, GPx, TAS) between both groups. Between patients, 46 presented pure mania (PM) (no depressive symptoms) and 46 mixed mania (MM) (with depressive symptoms). We explored the influence of inflammatory factors in functionality, exploring differences between PM and MM. To measure patients' general functioning one year after illness onset, we used the Functional Assessment Short Test (FAST).

Results We found significant differences in TFN α , MCP1 and TBARS (higher in patients) and in SOD, GSHTot, GSSG, GSHfree, GPx and TAS levels (lower in patients). Only In MM group, there was a significant influence of SOD and GSHfree in FAST scores suggesting that a higher antioxidant levels at baseline the patient functionality improves one year after.

Conclusions Some parameters of oxidative stress at baseline are related with patient's functionality one year after the first episode of mania, but only when mania debuts with depressive symptoms simultaneously.

Aspects of sexuality in bipolar women

L. Damian^{1,*}, I. Miclutia²

¹ Psychiatric hospital Ergoterapie, Cluj Municipal Hospital, Cluj-Napoca, Romania

² University of Medicine & Pharmacy Cluj-Napoca, Neuroscience-discipline of Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction In spite of more studies dedicated to the topic of sexual disorders among schizophrenic patients or to the sexual effects of antipsychotics and antidepressants, few studies entangle broadly the issue of sexual attitudes and behaviors of bipolar patients, due partly to the heterogeneity of the disorder and the variety of episodes, and treatments.

Objectives To establish if special sexual patterns are specific to depressive or manic episodes and if the sexual disorders are related to the severity of the mood episodes.

Aims To compare depressive, manic, and matched controls regarding their sexuality.

Methods The current study is an observational cross sectional study, carried out on 173 women, among them 112 bipolar, diagnosed according to ICD-10 criteria (81 depressive, and 31 manic), and 61 controls. All subjects fulfilled the Sexual Disorders Interview (SDI), Female Sexual Function Index (FSFI) and to bipolar patients BDI, YMRS have been administered.

Results Female bipolar patients were significant less sexual active than controls, depressive women being less interested in sexuality than manic patients; there were not significant differences between the two patients' samples regarding the frequency of sexual intercourse, degree of psychopathology. Sexual problems on FSFI were detected in 75% of bipolar patients, both bipolar groups emphasizing difficulties in arousal, lubrication and sexual satisfaction.

Conclusions The issue of sexual problems in bipolar female patients is delicate to investigate and often neglected, being difficult to ascertain to the mood disorder itself or to different treatments the patients have been exposed to, or to stigma.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A peripheral composite proteomic and gene expression biomarker related to diagnosis and affective state in rapid cycling bipolar disorder

K. Munkholm*, M. Vinberg, L.V. Kessing

Psychiatric Center Copenhagen, Rigshospitalet, Copenhagen, Denmark

* Corresponding author.

Introduction Management of bipolar disorder is limited by absence of laboratory test. While alterations related to multiple biological pathways have been found in bipolar disorder, findings have not translated into clinically applicable biomarkers. We previously found promise for a combined gene expression biomarker. The combination of gene expression and proteomic biomarkers could have potential as a meaningful clinical test.

Objectives To identify a composite biomarker based on multiple potential peripheral biomarkers related to neuroplasticity, inflammation and oxidative stress, both on a proteomic and gene expression level.

Aims To test the ability of a composite biomarker to discriminate between bipolar disorder patients and healthy control subjects and between affective states in bipolar disorder patients.

Methods mRNA expression of a set of 19 candidate genes and protein levels of immune markers and neurotrophic factors were measured in peripheral blood mononuclear cells and combined with urinary levels of oxidized nucleosides of 37 rapid cycling bipolar disorder patients in different affective states (depression, mania and euthymia) during a 6–12-month period and in 40 age- and gender-matched healthy control subjects. A composite measure was constructed in the first half of the sample and independently validated in the second half of the sample. The composite measure was evaluated using ROC curves and by calculating sensitivity and specificity.

Results Statistical analysis is ongoing. Results will be presented at the congress.

Conclusions A peripheral composite biomarker based on multiple biological pathways on both proteomic and gene expression levels may have potential as a clinically applicable biomarker.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Ketamine effect of the neural response of emotinal processing

H. Nießen

Leibniz Institute for Neurobiology, Clinical Affective Neuroimaging Laboratory, Magdeburg, Germany

Introduction The NMDA antagonist ketamine has shown a good antidepressant effect in drug resistant patients with MDD. The exact mechanism of these antidepressant effects are unknown but some studies indicate that ketamine changes neuronal emotion processing. Amygdala is an important brain structure for the emotion processing in people with affective disorders. Previous studies showed functional and morphological changes, for example elevated neuronal activation in the amygdala in depressive patient. Previous studies also indicated that ketamine seems to inhibit this elevated amygdala function.

Methods Sixty-three healthy subjects (28 female, group mean age 25.65 ± 4.32 years) took part in a double-blinded fMRI study. Half of the participants received ketamine infusion with 0,5 mg/kg BW, and half received placebo (saline infusion). To investigate the temporal development of the drug impact, the experiment was repeated at three time points: baseline, one hour and 24 hours after the infusion. We used a block design with positive and negative facial expressions and forms (task adapted from Hariri [7]). Pre-processing and statistical data analysis were performed in SPM8.

Results We found a continuous suppression of the amygdala during negative face recognition in the ketamine group, with a maximum 24 hours after infusion.

Conclusion Ketamine seems to inhibit amygdala function during negative face perception.

Assessment of executive functions in bipolar depression

R. Paunescu*, I. Miclutia

Iuliu Hatieganu University of Medicine and Pharmacy, Neurosciences, Cluj-Napoca, Romania

* Corresponding author.

Introduction Cognitive functions in bipolar disorder have been assessed during acute mood episodes but also during remission. While other cognitive functions, such as verbal and working memory, attention, verbal fluency and psychomotor speed seem to recover after the acute episode, executive functions impairment remains also during remission; this aspect led to the assumption that executive functions may be a trait marker for bipolar disorder. **Objective** The purpose of this study was to assess the executive functions, such as cognitive flexibility, set shifting, problem solving and abstract thinking in bipolar depression compared to healthy subjects.

Method Forty patients diagnosed with Bipolar Disorder and Major Depressive Episode according to DSM IV-TR were included into the study. Executive functions were investigated using Wisconsin Card Sorting Test (WCST). Results obtained by patients were compared with those of 30 healthy who underwent the same cognitive evaluation.

Results Depressed bipolar patients scored significantly worse on the majority of WCST measures. Thus, for total trials, total errors, perseverative errors and perseverative responses (raw scores and percents) and failure to maintain set scores, the differences between the two groups were significant at the 1% threshold ($P=0.000$). The patients and controls displayed similar behavior for total correct ($P=0.215$) and conceptual levels scores ($P=0.421$).

Conclusions Patients with bipolar disorder show during a depressive episode difficulties in most cognitive tasks involving executive functions. Results obtained by patients at failure to maintain set score suggest frontal dysfunctions for this category of patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of antidepressants in maintenance phase of patients with bipolar disorder in an outpatient setting

A. Peh*, W.K. Tay

Changi General Hospital, Dept of Psychological Medicine, Singapore, Singapore

* Corresponding author.

Introduction Guidelines for the maintenance treatment of bipolar disorder discourage the use of antidepressants chiefly on grounds of unproven efficacy and risk if mania for bipolar I. However, for patients stabilised on an antidepressant, naturalistic data support its continued use.

Aim The aim is to describe use of antidepressants in patients with bipolar disorder in remission seen at an outpatient clinic in Singapore.

Methods The case notes of patients with bipolar disorder in remission, seen by psychiatrist in an outpatient psychiatric clinic in a general hospital unit from December 2014 to March 2015 were studied. Data describing the age, sex, type of bipolar disorder and psychotropic medications prescribed, was obtained.

Results Forty-two patients were included, of which 13 (31%) were male and 29 (69%) were female. The age ranged from 23 to 82, with mean age of 47 years. Of these 17 (40%) had bipolar I and 25 (60%) had bipolar II. Antidepressant use for maintenance treatment was present in 19 out of 42 (45%) of these patients; of these 7 out of 17 (41%) were bipolar I and 12 out of 25 (48%) were bipolar II. Eighteen out of the 19 (95%) patients who were prescribed antidepressants were on combination treatment with mood stabilizers. Antidepressant type included SSRI (37%), NDRI (37%), SNRI (10.5%), TCA (10.5%), NASSA (5%).

Conclusion Almost half of patients with bipolar disorder managed in an individual practice were on antidepressants together with mood stabilisers. They remained in remission with combination treatment, which did not seem to jeopardise their condition.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Bipolar mood disorder BMD can be classified into 4–5 broad molecular categories based on parametric oscillation theory and signs and symptoms

K. Pirkalani^{1,*}, Z. Talaeead²

¹ Mehr Medical Group, Internal Medicine, Tehran, Iran

² Mehr Medical Group, Gynecology, Tehran, Iran

* Corresponding author.

Introduction BMD is regarded as spectrum and needs finer classification.

Objectives Wide clinical and molecular data on BMD are available but no correlation.

Aims To correlate malfunction of circadian oscillators with different clinicopathologic presentations of BMD spectrum.

Methods Based on 73 patients, we have differentiated 5 disease activity patterns. A divergent model of one master (CLOCK/BMAL1 heterodimer) + 4 slave circadian oscillators (neuronal PAS domain protein 2, Rora, Rev-erb, and CSNK1E) and downstream effector genes (*PER1*, *PER2*, *PER3*, *CRY1*, *CRY2*, *Teneurin 4*, *NCAN (Neurocan)*, *GSK3-b*, *casein kinase I epsilon*) were designed to highlight heterogeneity in regard to genetics and presentation.

Results Five patterns of activity curves with the appropriate molecular explanations can be drawn:

- one attack, rare exacerbations, near normal inter-interval mental functioning; pathogenesis lies in master mutation. Lifetime events are the cause of deregulation;

- frequent attacks with inter-interval derangements due to major mutation of the master oscillator and ambiguity between master and slave. No time for circadian re-establishment, wide range of downstream genes activity, and a full-blown clinical picture;

- one major attack and no apparent remission, wide range of signs. Hyperactive mutant of slave and suppression of the master;

- rapid cycling due to master mutation and complete change of the innate frequency;

- a diagnostic dilemma of mild continuous signs and symptoms with no prominent attacks and overlap with borderline or schizotypal PD due to mutation in some downstream genes (i.e. *GSK3-b* or *Per*, *CRY*, *NCAN*).

Conclusions Finding molecular correlation with disease subtypes and activities is possible.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Multiple oscillators assure soft margin of diurnal function and are the result of alternate splicing and later genetic rearrangement: Possible role in bipolar disorder

K. Pirkalani^{1,*}, Z. Talaeead²

¹ Mehr Medical Group, Internal Medicine, Tehran, Iran

² Mehr Medical Group, Gynecology, Tehran, Iran

* Corresponding author.

Introduction Appearance of multiple effector proteins on a single receptor seems mysterious. These new effectors appear during alternate splicing, gene duplication and genomic re-arrangement during evolution. In chronobiology, this might have vital protective importance for migration to places with extreme climates.

Objectives Residing on a simple light/darkness system of circadian cycle is in contrast with human cultural development.

Aims Developing a model of molecular interaction to explain the BMD spectrum.

Methods We classify circadian oscillators into one master (CLOCK/BMAL1) and 4 slave oscillators. The master has suppressing action on 4 parallel slave oscillators. In case of disruption of this tract, one of them reigns. Input from the retinal ganglion cells has minor effect (noise) for the parametric oscillation of the master but not slave oscillator. Mutations in the master that disrupts these feedbacks, or increases sensitivity to ganglion cells input or cause hyperactivity of the slave oscillators are explanations for BMD development. Downstream to this, a divergent set of genes (*PER1*, *2*, *3*, *NCAN*, *GSK3-b* and *CRY1*), 2 with different functions are activated. Derangement of any of the downstream genes causes incomplete symptoms and signs.

Results This model with elegant curves can successfully incorporate many laboratory and clinical findings and explains in a comprehensive way how genetic and environmental factors interact to build up disease picture and spectrum of BMD. In addition, some innovative (less intensive and with less side effects) treatment strategies can be suggested.

Conclusions More research in this field is warranted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ *King's College, Psychiatry, London, United Kingdom*

* *Corresponding author.*

Introduction DSM-5 criteria for the mixed features specifier exclude symptoms, such as psychomotor agitation, irritability and mood lability.

Objectives The goal of the BRIDGE-MIX study was to provide an estimate of the frequency of mixed states (MXS) in depressed patients according to different definitions and to compare their clinical validity.

Aims The aim of this sub-analysis is to examine the importance of distinct hypomanic symptoms in mixed depression, including those excluded from DSM-5.

Methods A total of 2811 subjects were enrolled in this multicentric cross-sectional study. Psychiatric symptoms, socio-demographic and clinical variables representing risk factors for bipolar disorder (BD) were collected. Multiple comparisons analysis was performed using a Bonferroni-corrected threshold and stepwise-backward logistic regression.

Results Two hundred and twelve patients fulfilled DSM-5 criteria for MXS. The most common symptoms in this subset and in the total sample are shown in Table 1 (Tables are not available for this abstract). Logistic regression demonstrated specific associations of psychomotor agitation (Wald 5.092, $P=0.024$), impulsivity (Wald 28.47, $P<0.0001$), racing thoughts (Wald 12.657, $P<0.0001$) and logorrhoea/pressured speech (Wald 230.720, $P<0.0001$) with DSM-5 diagnosis of MXS (Table 2).

Conclusions The DSM-5 definition of MXS excludes “overlapping” mood criteria, such as psychomotor agitation, irritability and mood lability, among the most frequent features of mixed depression in our sample and in literature. The results of this study highlight the impact of the excluded symptoms on MXS diagnosis. Although these symptoms may be non-specific, their exclusion from DSM-5 may not be justified, in the absence of evidence that the remaining criteria are sufficiently sensitive to identify MXS.

* *Corresponding author.*

Introduction Misidentification phenomena and Capgras Syndrome (CS) occur in different psychiatric (psychotic or major affective illnesses) and neurological (traumatic brain injury, epilepsy, neurosyphilis, etc.) disorders [1,2]. The aim of this report is to redefine dissociative spectrum dimensions inside CS and misidentification syndromes in patients with Bipolar Disorder (BD). **Method** Five inpatients were assessed with the SCID-P, SCID-DER, DSS, HRSD, YMRS, a neurological and general medicine review, a first-level brain imaging examination (CT and/or MRI). We conducted a systematic literature review (PubMed, Embase, PsychInfo) using the key terms “Capgras Syndrome” and “Misidentification”. **Results** All patients were diagnosed with type-I BD and had concomitant CS that presented with misidentification phenomena in the context of psychotic mixed state. They reported high scores for autopsychic and affective depersonalization symptoms as well as high SCI-DER (mean = 24.4) and DSS (mean = 13) total scores.

Discussion and conclusion To our knowledge in literature, there are not studies that evaluated dissociative spectrum symptoms in CS in BD. This condition of identity and self fragmentation could be the key to shedding light on the interconnection between affective and non-affective psychotic disorders from schizophrenia to BD, and may underscore the possible validity of the concept of the unitary psychosis proposed by Griesinger [3–5]. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Although early interventions in individuals with bipolar disorder may reduce the associated personal and economic burden, the neurobiologic markers of enhanced risk are unknown. **Objectives** The objective of this paper is to analyze the existence of neurobiological abnormalities in individuals with genetic risk for developing bipolar disorder (HR)

Material and methods A literature search was performed in the available scientific literature on the subject study object, by searching MEDLINE.

Results There were 37 studies included in this systematic review. The overall sample for the systematic review included 1258 controls and 996 HR individuals. No significant differences were detected between HR individuals and controls in the selected ROIs (regions of interest): striatum, amygdala, hippocampus, pituitary and frontal lobe. The HR group showed increased grey matter volume compared with patients with established bipolar disorder. The HR individuals showed increased neural response in the left superior frontal gyrus, medial frontal gyrus and left insula compared with controls. The overall results found no significant differences between individuals at high genetic risk and controls since the magnitude of the association as corresponds to an OR < 1.5 (low association)

Conclusion There is accumulating evidence for the existence of neurobiologic abnormalities in individuals at genetic risk for bipolar disorder at various scales of investigation. The etiopathogenesis of bipolar disorder will be better elucidated by future imaging studies investigating larger and more homogeneous samples and using longitudinal designs to dissect neurobiologic abnormalities that are underlying traits of the illness from those related to psychopathologic states, such as episodes of mood exacerbation or pharmacologic treatment.

* Corresponding author.

Introduction Bipolar disorder is a leading cause of hospitalization in psychiatric hospitals. It is known that early detection of bipolar disorder is associated with a better prognosis.

Objectives The aim of this study is to conduct a demographic analysis of patients hospitalized for bipolar disorder in a single center between 2003 to 2014.

Methods Retrospective cohort study of 1230 patients admitted with bipolar disorder diagnosis from 2003 to 2014 at Centre Assistencial Emili Mira i López of Parc Salut Mar of Barcelona. We divided the study in two periods: 2003–2008 and 2009–2014. We analyzed the following variables: frequency of admissions, age, sex and days of hospital stay, comparing both periods. Chi-square test for categorical variables and Student t test for quantitative variables were applied.

Results The mean ages at the first and second period are 52 and 47, respectively ($P < 0.001$). There are no significant differences in sex and days of hospitalization. The frequency of admissions on the first and third trimesters is higher than in the second and fourth, although the differences are not statistically significant.

Conclusions Despite the large number of patients in the study, there are limitations, such as being a retrospective study and not being adjusted for confounding factors. The average age of patients in the second period is lower than in the first. This could suggest an improvement in early detection of bipolar disorder in the last years. Further research is needed to confirm this hypothesis.

Disclosure of interest LG is funded by the Instituto de Salud Carlos III (CM14/00111).

² Vasile Goldis West University of Arad, Psychiatry, Arad, Romania

* Corresponding author.

Introduction Bipolar disorder usually has an atypical onset, either with a depressive or a psychotic (non-manic) episode. Potential predictive factors for bipolarity should increase diagnostic accuracy since onset.

Objectives Identifying the onset episode type in a Romanian bipolar patient sample.

Methods Seventy-two patients diagnosed with bipolar disorder according to ICD-10 diagnostic criteria, admitted in our hospital between 2009 and 2015, were included in this study. For assessing the type of the onset episode, we used the MADRS and YMRS (for affective symptoms) and the PANSS (for psychotic symptoms).

Results Out of the 72 bipolar patients, at onset: 24 had a moderate or severe depressive episode (without psychotic features), 19 had a severe depressive episode with psychotic features, 11 had a manic episode with psychotic features, 8 had a manic episode without psychotic features, 6 had the diagnosis of acute polymorphic psychotic disorder (5 without symptoms of schizophrenia and 1 with symptoms of schizophrenia), 3 had the diagnosis of other acute predominantly delusional psychotic disorder and 1 had the diagnosis of acute schizophrenia-like psychotic disorder.

Conclusions More than half of the patients included in this study had moderate or severe depressive symptom severity at onset. Identifying predictors for bipolarity in a depressive first episode should aid in more adequate treatment since onset.

* Corresponding author.

Introduction The way an individual responds to emotionally arousing information best describes cognitive emotional regulation. In affective disorders, emotional regulation strategies vary widely depending on the phase of the disorder and the episode type.

Objectives Identifying differences in cognitive emotion regulation of remitted bipolar patients (after a depressive episode), remitted schizoaffective patients (after a depressive episode), remitted unipolar patients and a healthy control group.

Methods This study was conducted between 2009 and 2015 and consists of outpatients from the Timisoara Hospital and Mental Health Center, diagnosed with either bipolar disorder ($n=35$), schizoaffective disorder ($n=29$) and recurrent depressive disorder ($n=39$), according to ICD-10 criteria and a healthy control group ($n=84$). For assessing cognitive emotional regulation, we used the CERQ.

Results Statistically significant differences between the patient groups and the control group were found in the following subscales: “selfblame”, “rumination”, “catastrophizing”, “blaming others” (negative emotional response strategies – higher mean scores than the control group), “positive refocusing” and “putting into perspective” (positive emotional response strategies – lower mean scores than the control group). When comparing the three patient groups, we found statistically significant differences in the following subscales: “self-blame” and “rumination” (higher mean scores for unipolar subject), “blaming others” (higher mean scores for bipolar and schizoaffective subjects), “positive refocusing” (higher mean scores for unipolar subjects) and “catastrophizing” (higher scores for schizoaffective patients).

Conclusions Cognitive emotional regulation strategies used by unipolar, bipolar and schizoaffective patients seem to differ and might be an insight to the medium and long-term outcome, thus potentially guiding future therapeutic strategies.

* Corresponding author.

Introduction Most studies selected euthymic patients with bipolar disorder in inter-episodic phase according to clinical remission criteria at least between 1 and 6 months. However, possible differences can exist in the course of clinical symptoms in bipolar patients related to the duration of clinical remission.

Objectives The main aim of this study was to evaluate the clinical status of bipolar patients after 6 months of clinical remission.

Methods We performed a cross-sectional study of bipolar outpatients in clinical remission for at least 6 months. Bipolar Depression Rating Scale (BDRS), Young Mania Rating scale, Pittsburgh Sleep Quality Index (PSQI) scale, Visual Analogic Scales (VAS) evaluated cognitive impairment were used to assess residual symptomatology of patients. Multivariate analysis (MANCOVA) was conducted for analysing possible differences between 3 groups of patients according to their duration of clinical remission (<6 months–1 year, <1 year–3 years, <3 years–5 years).

Results A total of 525 patients were included into the study. The multivariate analysis indicated a significant effect of the duration of clinical remission on the different residual symptoms (Pillai's trace: $F4.48, P<0.001$). The duration of clinical remission was associated with the significant improvement of the BDRS total score ($P=0.013$), the PSQI total score ($P<0.001$) and the cognitive VAS total score ($P<0.001$).

Conclusion These results support a possible improvement of residual symptoms according to the duration of clinical remission in bipolar patients. Any definition of euthymia should specify the duration criteria.

Introduction A large number of studies have found that patients with bipolar disorders have a poor performance in tasks assessing social cognition.

Objectives and aims The present study aimed to investigate whether euthymic bipolar patients (EBP) have a dysfunction in emotion processing when compared to controls. An additional objective was to determine whether there is association between emotion processing and psychosocial functioning.

Methods A sample of 53 EBP and 53 healthy controls matched for age, gender, education level and premorbid intelligence were studied. All subjects were assessed using the MATRICS Consensus Cognitive Battery (MCCB) and two additional executive function measures: the Trail Making Test–Part B and the Stroop Test. Emotion processing was examined using the Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT). Psychosocial functioning was assessed using the Global Assessment of Functioning (GAF) scale and the Functional Assessment Short Test (FAST).

Results For the MSCEIT, EBP obtained lower total scores ($P=0.001$), experiential area scores ($P=0.012$), strategic area scores ($P=0.000$), perceiving emotions branch scores ($P=0.008$), understanding emotions branch scores ($P=0.014$) and managing emotions branch scores ($P=0.000$) than controls. There were no significant differences between groups for the using emotions branch ($P=0.113$). In addition, partial correlations controlling for sub-clinical psychopathology in EBP showed the existence of a significant correlation of MSCEIT total score and MSCEIT strategic area score with FAST total score.

Conclusions EBP exhibit deficits in several areas of emotion processing. Performance in emotion processing tasks is associated with social functioning in these patients.

* Corresponding author.

Introduction Deficient prepulse inhibition (PPI) of the startle response, indicating sensorimotor gating deficits, has been reported in schizophrenia and other neuropsychiatric disorders.

Objectives and aims The present study aimed to assess sensorimotor gating deficits in euthymic bipolar patients. Furthermore, we analysed the relationships between PPI and clinical and cognitive measures.

Method PPI was measured in 64 euthymic bipolar patients and in 64 control subjects matched for age, gender, education level and smoking status. Clinical characteristics and level of functioning were assessed in all participants using the Hamilton Depression Rating Scale (HDRS), Young Mania Rating Scale (YMRS) and Functioning Assessment Short Test (FAST). Cognition was evaluated using the MATRICS Consensus Cognitive Battery (MCCB) and the Stroop Test as an additional measure of executive function.

Results Compared with controls, patients with bipolar disorder exhibited PPI deficits at 60- and 120-millisecond prepulse-pulse intervals. Among patients with bipolar disorder, PPI was correlated with the social cognition domain of the MCCB. PPI was not significantly correlated with other clinical or neurocognitive variables in either group.

Conclusions Our data suggest that PPI deficit is a neurobiological marker in euthymic bipolar disorder, which is associated with social cognition but not with other clinical, functional or cognitive measures.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA

* Corresponding author.

Introduction Sexual dysfunction is common in major depressive disorder (MDD), and frequently is worsened by antidepressant treatment.

Objectives/aims To evaluate the effect of lurasidone on sexual functioning as measured by the Changes in Sexual Functioning Questionnaire (CSFQ) in patients with MDD with mixed features.

Methods Patients meeting DSM-IV-TR criteria for MDD, who presented with 2 or 3 protocol-specified manic symptoms, were randomized to 6 weeks of double-blind treatment with either lurasidone monotherapy 20–60 mg/d ($n = 109$) or placebo ($n = 100$). Change from baseline in the Montgomery-Asberg Depression Rating Scale (MADRS) total at week 6 was the primary efficacy endpoint, analyzed by MMRM. The CSFQ was assessed at baseline and week 6, analyzed by ANCOVA (LOCF).

Results The mean CSFQ total scores at baseline were 36.5 and 34.1 in the lurasidone and placebo groups, respectively. Sexual function was rated as abnormal at baseline on the CSFQ by 77.8% of patients on lurasidone and 89.8% of patients on placebo. Treatment with lurasidone was associated with significant improvement in CSFQ total scores at week 6 (LOCF) compared with placebo (+5.1 vs. +3.1; $P < 0.05$; effect size, 0.28). Significant improvement was also noted on the CSFQ-pleasure sub-scale, and numerical improvement on the CSFQ-desire/frequency, desire/interest, arousal, and orgasm subscales. Sexual function was rated as abnormal at week 6 (LOCF)

on the CSFQ by 59.0% of patients on lurasidone and 70.1% of patients on placebo (odds ratio, 0.75).

Conclusion Lurasidone treatment of MDD with mixed features was associated with significant improvement in sexual function.

* Corresponding author.

Introduction Several studies suggested the involvement of sensory perception in emotional processes and major affective disorders. Similarly, cognitive capacities and coping strategies are reported to influence quality of life of patients with unipolar and bipolar disorders.

Objectives The main objective of this study was to investigate the nature of the association between sensory processing patterns, coping strategies, and quality of life among patients with major affective disorders.

Aims The study aimed to compare unipolar/bipolar patients concerning sensory processing, coping strategies and quality of life (QOL); examine correlations between sensory processing and QOL; investigate the relative contribution of socio-demographic characteristics, sensory processing, and coping strategies to the prediction of QOL.

Methods Two hundred and sixty-seven participants, aged 16–85 years (mean = 53.6 ± 15.7), 157 diagnosed with unipolar major depressive disorder and 110 with bipolar disorder type I and type II completed the Adolescent/Adult Sensory Profile, Coping Orientations to Problems Experienced, and Short Form 12 Health Survey 2.

Results The unipolar and bipolar groups did not differ concerning sensory processing, coping strategies, and QOL. Sensory processing patterns correlated with QOL independently of the mediation by coping strategies. Correlations between low registration, sensory sensitivity, sensation avoidance, and reduced QOL were found more frequently in unipolar patients than bipolar patients. Elevated physical QOL was mainly predicted by lower age and lower sensory sensitivity whereas elevated mental QOL was mainly predicted by coping strategies.

Conclusions Future studies should further investigate the impact of sensory processing and coping strategies on patients' QOL to enhance adaptive and functional behaviors related to affective disturbances.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Interictal dysphoric disorder – the bridge between epilepsy and bipolar disorder

R. Sousa*, M. Salta, B. Barata, J. Nogueira, J. Vieira, B. Ribeiro, R. Ribeiro, S. Mendes, R. Mendes, A. Gamito
 Setúbal Hospital Center, Department of Psychiatry and Mental Health, Setubal, Portugal
 * Corresponding author.

Introduction Psychiatric disorders are frequent among patients with epilepsy. The association between epilepsy and mood disorders is recognized since the classical antiquity. Recent studies demonstrated that the prevalence of bipolar symptoms in epilepsy patients is more significant than previously expected. In the first half of the twentieth century, Kraepelin and Bleuler were the first to describe a pleomorphic pattern of symptoms claimed to be typical of patients with epilepsy and recently Blumer coined the term interictal dysphoric disorder to identify this condition. Although for some authors, the existence of this condition as a diagnostic entity is still doubtful, for others, it represents a phenotypic copy of bipolar disorder.

Objectives In this work, we start from the phenomenological similarities between the interictal dysphoric disorder and the bipolar disorder, to explore the neurobiological underpinnings that support a possible link between epilepsy and bipolar disorder.

Methods Research of articles published in PubMed and other databases.

Results Interictal dysphoric patients have features that resemble the more unstable forms of bipolar II disorder and benefit from the same therapy used in bipolar depression. Epilepsy and bipolar disorder share features like episodic course, the kindling phenomenon as possible pathogenic mechanisms and the response to antiepileptic drugs. The study of possible common biological processes like neurogenesis/neuroplasticity, inflammation, brain-derived-neurotrophic-factor, hypothalamus pituitary adrenal axis, provided promising but not consensual results.

Conclusions Further efforts to understand the link between epilepsy and bipolar disorder could provide the insight needed to find common therapeutic targets and improve the treatment of both illnesses.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comparison of treatment response of typical and atypical antipsychotics in acute mania

C.R. Medici, L.M. Kai, C. Kirkedal, S.P.V. Straszek*
 Aarhus University hospital, Department Q, Risskov, Denmark
 * Corresponding author.

Introduction The medical treatment of acute mania today mainly includes atypical and typical antipsychotics, lithium or valproate. Atypical antipsychotics are often used as first-line treatment, while typical antipsychotics come with the risk of severe long-term side effects and less used today. However, typical antipsychotics may lead to a faster reduction in the severity of mania or a faster remission of symptoms.

Objective To investigate whether the acute effect of typical antipsychotics differs from atypical antipsychotics measured by a daily mania rating-scale (MAS-M) and duration of treatment in a real-life clinical setting.

Aim To help determine if short-term treatment with typical antipsychotics may still be of benefit in the acute treatment of mania.

Methods This is a retrospective case record study. Patients admitted to an acute hospital ward with acute mania between 2012 and 2015 were included ($n = 100$). The daily use of atypical and typical antipsychotics will be compared by daily change in Bech-Rafaelsen Modified Mania Scale (Mas-M) score and time to discharge. The change in mania over time is presented visually using graph curves.

Results The data extraction and data handling will be executed in the winter 2015–2016.

Conclusions Any preliminary findings will be presented at EPA 2016.

Introduction Metacognition is described as the set of human abilities that allows us to recognize and think about own and other people's mental states. We use these skills in order to overcome psychological and interpersonal issues and to cope emotional, cognitive and behavioral suffering. Studies that focusing on metacognition in bipolar disorder (BD) are still limited and data are controversial. Our purpose is investigating the difference between BD patients and BD patients with alcohol addiction (BD+A), in terms of metacognitive functions. In addition, we want to assess among BD+A whether the increase in metacognitive functions mediates the relationship between symptoms at T0 and T1.

Methods Forty patients were recruited for this study. A set of tests was performed on each patient to formulate a metacognitive and clinical evaluation. A single measurement was performed on 20 BD patients. Two measurements (T0–T1) were carried out on the 20 BD+A patients, after an integrated treatment.

Results Data shown significant differences between these two groups. As regards the treatment of BD+A patients, differences were found between T0 and T1. Among the BD+A patients, reduction in the Beck Cognitive Insight Scale (BCIS-SC, P 0. 042) scores between T0 and T1, leads to the prediction of symptom improvement.

Conclusions Our results confirm the existence of a specific profile of metacognitive functioning in these patients. Our results reveal that the metacognitive functions appear to be predictors of the improvement in the remission of symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Bipolar patients show broad cognitive deficits and low global functioning.

Objective Assessment of global functioning in bipolars with severe course of illness and cognitive deficits.

Aim Improving life quality of bipolar patients with cognitive deficits.

Methods One hundred and thirty-seven bipolar (depressive: Hamilton Depression Rating Scale score ≥ 17 , manic/hypomanic: Young Mania Rating Scale score ≥ 12 , mixed: HAMD score > 8 and YMRS score > 6 , euthymic: 6-month of remission, HAMD score ≤ 8 , YMRS score ≤ 6) patients (DSMIVTR). Cognitive battery included standardized test of IQ, attention, executive functioning, memory (working and verbal). GAF (Global Assessment Functioning Scale) scale assessed global functionality. Demographic data, psychiatric history, past/current treatment, length of illness, age of onset were collected. We evaluate global functioning in bipolar patients.

Results Cognitive deficits with low functioning are more frequent in bipolars with more severe course of illness (longer illness length, younger onset age, history of frequent manic episodes, higher number of hospitalization). Manic patients showed the most pronounced cognitive deficits. Despite high energy, impaired cognitive function does not support performance and final result is an important decrease of functionality. While for most manic and mixed patients, GAF scores were included between 41 and 50 (any serious deterioration in socio-occupational, school functioning), for majority of depressive patients, GAF scores were included between 51 and 60 (moderate difficulty in socio-occupational, school functioning) and for most euthymic patients, the GAF scores were comprised between 61 and 70 (some difficulty in socio-occupational, school functioning). Manic and mixed patients have similar employment percentages ($< 50\%$), and lowest employment percentage is obtained by depressive ones (40%).

Conclusions Severe course of bipolar disorder is associated with cognitive deficits and lower socio-occupational functionality.

Correlation of vitamin D to attention deficit hyperactivity disorder

M. Abouzed*, A. Moshref, A. Elsherbiny, M. Elsheikh
Al-Azhar Faculty of Medicine, Psychiatry, Cairo, Egypt

* Corresponding author.

ADHD is one of the most common neurodevelopmental psychiatric disorders. Many factors have been identified as the cause of ADHD. ADHD is thought to be the result of interactions between biopsychosocial factors leading to neurobiological change. The aim of this study is to investigate the association between serum level of vitamin D and symptoms of attention deficit hyperactivity disorder (ADHD).

Design This is a case-control study which was conducted in children below 12 years of age from June 2013 to May 2014 at

outpatient child psychiatry clinic at Elhussin Hospital Al-Azhar University, Cairo, Egypt.

Methods and subjects The study was based on 62 cases and 30 controls. The data collection instrument included socio-demographic & Children Attention and Adjustment Survey (House form){CAAS}. And interview by (Diagnostic Interview Kiddie-Sads-Present and Lifetime Version (K-SADS-PL) to exclude other psychiatric morbidity. clinical data, serum 25(OH) Vitamin D. Descriptive statistical analysis were performed, Pearson Chi² test (χ^2) and Student (*t*) test.

Result 1-Vitamin D level was much lower in ADHD children compared to healthy children, and was a significant difference in the mean values of vitamin D between ADHD(23 ± 13) and control group means (44 ± 12) and *P* value was > 0.001 and was significant difference between subgroup of ADHD, means of inattentive subtype was (20 ± 13) hyper active subtype (30.1 ± 5) and combined subtype (24.04 ± 4). *P* value 0.011*.

Conclusion Children with ADHD had significantly lower levels of VITAMIN D than healthy, and inattention subtype than other types of ADHD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence rate of psychiatric disorders among Saudi Female adolescents: School-based study from Riyadh City

Y. Alatiq*, O. Al-Modayfer

King Abdulaziz Medical City, Medicine, Riyadh, Kingdom of Saudi Arabia

* Corresponding author.

Introduction Studies have shown that mental health problems at an early age can lead to greater impairment in adult life. Epidemiological evidence on the prevalence and incidence of mental health disorders is fundamental for planning mental health services. However, these data are lacking in Saudi Arabia.

Objectives The objective of the study is to examine the prevalence of mental health problems in Saudi female adolescents attending high school in Riyadh City.

Aims The primary aim is to examine the prevalence rate of psychiatric disorders. Second is to examine some psychosocial variables as predictors of psychiatric disorders.

Methods This two-stage epidemiological study used the Strengths and Difficulties Questionnaire (SDQ) to screen all eligible participants for the presence of a possible psychiatric disorder. The screening was followed by the use of a structured psychiatric interview (MINI-Kid), which was administered to a sub-sample to confirm the presence or absence of psychiatric disorders.

Results A total of 4745 participants were screened in the first stage, and 692 participants underwent follow-up interviews. Agoraphobia was the most common disorder with a prevalence rate of (30.6%), followed by major depressive episode (29.9%), then separation anxiety disorder (27.1%). The only variables with a predictive power of having a psychiatric disorder were “having a private teacher” (OR = 1.86, 95% CI (1.13–3/07), *P* = 0.013).

Conclusion The rate of psychiatric disorders among Saudi female adolescents is within the wide range reported internationally but is associated with specific social predictive factors.

Psychological violence: A study with adolescents in a Brazilian Public Educational Institution

Z. Scherer^{1,*}, L. Cavalin¹, E. Scherer²

¹ University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto, São Paulo, Brazil

² Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, São Paulo, Brazil

* Corresponding author.

Introduction The healthy development of adolescents is favored by interactions involving reciprocity and balance of power, however, neglectful or abusive relationships can be found in educational practices in family or school psychological violence being the most recurrent and often associated with other types of abuse.

Objectives The goal of this study was to investigate the exposure of adolescents to psychological violence, as well as identify its association with other types of abuse, the perpetrator and the context of occurrence.

Aims Knowing the circumstances of adolescents' exposure to violence in school environment.

Method Therefore, we performed a cross-sectional study with 218 adolescents (aged 14–18 years) of a Brazilian public educational institution. These students completed a questionnaire and Psychological Violence Scale (EVP), whose data were analyzed using descriptive statistics.

Results The study showed that 96.3% of students suffered psychological violence, followed by physical violence (34.9%), sexual (7.3%) and neglect (2.8%). Over 90% of adolescents who suffered physical, sexual and psychological violence suffered neglect in mild and moderate form, which shows the co-occurrence of victimization. We observed that 94.5% of students were exposed to such violence in its mild and moderate and 1.8% severe form, and only 3.7% of adolescents never responded to the 18 items asked of psychological research.

Conclusion These data show that psychological violence, even if experienced with mild to moderate behavior is present in the relationship with significant people in the lives of most adolescents in this study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence and determinants of common fears in children and their socio-demographic characteristic

A. Bener

Istanbul University, Biostatistics & Public Health, Istanbul, Turkey

Objective Most children experience some degree of fear during their development. Excessive fears can create serious obstacles to children. The aim of this study was to identify the most common fears in a sample of children and adolescents and examine the socio-demographic correlates of fears.

Subjects and methods This cross-sectional study was conducted during the period July 2010 to February 2012 at Public and Private Schools of the Ministry of Education and Higher Education, in Qatar. Out of 2188 students approached, 1703 students agreed to participate in this study, with a response rate of 77.8%. The questionnaire includes socio-demographic information, academic performance, behaviour at home and various fears.

Results More than half of the children experienced fears (56.7%). Most of them were in the intermediate level, 12–15 years old (46.1%). Overall, reported fears were significantly more frequent

in girls (62.6%) than boys (37.4%) ($P < 0.001$). A significant difference was observed between girls and boys who experienced fears in their age group ($P < 0.001$), education of mother ($P = 0.04$), household income ($P = 0.008$) and academic performance ($P < 0.001$). The most frequent reported fears were fear of someone dying in the family (85.2%), parents getting divorced (84.5%), breaking religious law (82%), being kidnapped (78.2%), family members ill (78%) and dying (76.7%).

Conclusions The study findings revealed that fears were highly prevalent in Arab children and adolescents in Qatar. Girls reported more fears than boys. There was a significant difference observed between girls and boys in their age group and academic performance for the reported fears.

Anticipating the unknown: A mixed method study assessing French psychiatrists opinions towards prognosis in adolescent and young adult psychiatry

L. Benoit

Hôpital Cochin, maison des Adolescents, Paris, France

The early treatment of psychiatric disorders has become a central goal of mental health policies worldwide. Yet little is known about the attitudes of psychiatrists regarding prognosis in their daily work. When treating young patients with acute psychotic symptoms, how do psychiatrists manage diagnostic uncertainty? Do they anticipate the risk of schizophrenia or avoid making prognostications? To what extent do they communicate their expectations to patients and their families?

Methods This is a mixed method study. Firstly, a series of in depth interviews addressed French youth psychiatrists' opinions towards prognosis. Participants worked in a variety of settings, public institutions, private practice, and student help. Secondly, an online survey investigated French psychiatrists' opinion toward prognosis. The survey consisted of the presentation of a clinical vignette in which a psychiatrist communicates on prognosis to a young patient with acute psychotic symptoms. The vignette was randomly shown in four versions with different predictions and outcomes. Respondents were then asked questions regarding prognosis communication.

Results Qualitative analysis stresses psychiatrists' uncertainty in their daily work with teenagers presenting unclear symptoms that might be the sign of a beginning psychotic process or might as well reflect adolescent unease. Psychiatrists are reluctant to commit into prognosticating or using standardized tools. The contradiction between the expectations that psychiatrists be able to predict what will happen to a young patient and their impossibility to do so, raises an ambivalence that is only managed through a deep emotional involvement. The survey received more than 400 answers, and statistical analysis is in progress.

Psychosocial correlates of subjective sleep disturbances in an adolescent community population in South Korea

S.Y. Bhang^{1,*}, J.W. Hwang², M. Jeon¹

¹ Eulji Hospital, Psychiatry, Seoul, Republic of Korea

² Gangwon National University, Psychiatry, Chonchon, Republic of Korea

* Corresponding author.

This study examines the relationship between psychosocial factors and insomnia complaints in a community adolescent population. The aims of this study are:

- to find the prevalence of poor sleep quality complaints in Korean community students;
- to explore the relationship between poor sleep quality complaints and the psychosocial factors;
- to explore the relationship between the severity of poor sleep and the psychopathology in the adolescents in Korea.

It is a cross-sectional study of a stratified sample of 2307 South Korean middle and high-school students. Subjects were given the Adolescent Mental Health and Problem Behavior Screening Questionnaire-II (AMPQ-II), the Symptom Checklist scale (SCL-90-R) and a questionnaire concerning demographic characteristics. Adolescents classified as suffering from sleep disturbances (22.3% of the participants) presented higher levels of general psychopathology. Age, gender, academic and Internet use problems, peer relationship difficulties including school violence, rule violation experiences were identified as correlates of the sleep disturbances complaints. Psychosocial correlates such as suicidal ideation and Internet use problems are important factors to consider when faced with sleep disturbance complaints in this age group. It was found that psychosocial and psychopathologic problems had a positive correlation with severity of sleep disturbances. Regarding the culture of hiding the psychological distress and exhibit the somatic complaints, the level of subjective sleep quality is one indicator for the screening of the high-risk group. Large-scale prospective studies and neurobiological studies are needed for a better understanding of the complex relationship between sleep, psychopathology, and youth suicidal behavior.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Disorganized attachment and psychological symptoms in children with somatic symptoms disorders

F. Bizzi*, S. Charpentier Mora, D. Cavanna

University of Genoa, Department of Educational Sciences, Genoa, Italy

* Corresponding author.

Introduction Somatic symptoms disorders (SSD) are one of the most neglected areas in child and adolescent psychiatry (Mohapatra et al., 2014). SSD are characterized by multiple and variable physical symptoms without demonstrable pathophysiological processes. Literature has investigated the role of several psychological variables in SSD, with inconclusive data. Moreover, there is a paucity of studies on middle-childhood and early adolescence in this clinical condition.

Objectives We focus on the role of attachment and on psychological aspects in children with SSD.

Aims The aims are to verify the presence of:

- an overrepresentation of attachment disorganization in these children;
- an overrepresentation of psychological symptoms.

Methods Fifty-six consecutive Italian patients with SSD, aged from 8 to 15, were administered Child Behavior Checklist (Achenbach, 1991) and Child Attachment Interview (Shmueli-Goetz et al., 2000).

Results Findings showed:

- a significant presence of disorganized attachment with respect to both parents;
- high levels of anxiety and depression.

Conclusion This study extended previous research in middle-childhood and early adolescence in SSD. The findings support the influence of the disorganization aspects and the psychological problems surrounding the SSD. The clinical implications for future research directions are discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction An overlap between autism spectrum disorder (ASD), in particular Asperger Syndrome (AS), and high intellectual potential (HIP-Total IQ > 2 SD) is often discussed.

Objectives Explore differences between homogeneous and heterogeneous Wisc-profiles among HIP children, and between HIP and ASD children, on cognitive and clinical assessments.

Methods Forty-nine participants (mean age 11.2 years) were divided in 4 groups: High Functioning Autism (HFA), AS, Homogenous HIP and Heterogeneous HIP. Data of WISC-IV and questionnaires – Autism Quotient (AQ), Empathy Quotient (EQ), Systemizing Quotient (SQ), Children's Communication Checklist (CCC) – were compared.

(Preliminary) Results On the WISC-IV, the Z scores curves follow similar trajectories but highlight quantitative differences between AS and heterogeneous HIP: verbal comprehension is the highest index (+1,6 SD in AS; +3,1 SD in heterogeneous HIP) followed by perceptual reasoning, working memory, and processing speed indexes (–1,2 SD in AS; +0,5 SD in heterogeneous HIP), respectively. The questionnaires show that scores of Homogenous HIP children are all in the average. Heterogeneous HIP children score 2,1 SD above average on the AQ (+1,6 SD on “Social Skills” and +1,3 SD on “Local Detail” subscales), whereas ASD children score 4 SD above average on the AQ. In addition, heterogeneous HIP children show pragmatic difficulties (–2,4 SD on the CCC, with a peak on “Area of Interest” subscale), also present in ASD children (–4 SD).

Conclusions AS and heterogeneous HIP children show similar cognitive profiles on the WISC-IV. Furthermore, heterogeneous HIP children exhibit high scores on the AQ and have pragmatic difficulties.

What do we share during a meal? Exploratory study of shared stories in ADHD children

A. Boulard^{1,*}, C. Leclercq²

¹ *Faculté de psychologie, logopédie et sciences de l'éducation, Liège, Belgium*

² *Centre Hospitalier Régional de La Citadelle, Child Psychiatry Unit, Liège, Belgium*

* *Corresponding author.*

Introduction Many research focus on the study of language in ADHD children. However, the discourse is beyond the language and provides access to child representations of the world, to its own history. The aim of our study was to compare and analyze the self-narratives during a family meal.

Method Speeches of 5 children (6–10 years) were recorded, analyzed and then compared to a strictly matched control group. Once transcribed, the data were morphosyntactically annotated and processed using multivariate exploratory techniques. A thematic analysis was also realized to understand how ADHD children moved from one conversation topic to another.

Results Our first results showed that ADHD children have more difficulty in producing self-narratives while they are doing something else (eat). Moments of sharing common stories are less frequent compared to the control group. The transition from one topic to another is made by direct associations (e.g. the child talks about what he is eating, and this leads him to think about the next day's dinner). The construction of the self-narratives is poorer compared to the control group, both in content and in length of utterances.

Conclusion Interestingly, concerning ADHD children, it appears:

- That these self-narratives exist;
- but also that they are poorer;
- that they allow, less frequently than in the control group, projections into the future or recollection of past events.

If ADHD children cannot access to these moments, special attention should be paid to this sharing of family history outside of daily activities.

Aerobic exercise training reduces anxiety in children

H. Budde^{1,*}, F. Koutsandréou¹, M. Wegner²

¹ *Medical School Hamburg, Faculty of Human Sciences, Hamburg, Germany*

² *University of Bern, Sportscience, Bern, Switzerland*

* *Corresponding author.*

Introduction Aerobic exercise seems to decrease anxiety in children. However, those studies are subject to methodological deficiencies (e.g. no control group, cross-sectional study). Therefore, we conducted a longitudinal study where we investigated how 10-week of aerobic or coordination training affects the anxiety of primary school children.

Method Sixty-four children aged 9–10 years were randomly divided into an aerobic (AE; $n = 25$), a coordinative (CE, $n = 23$) and a control group (CON, $n = 20$). The intervention groups received three times a week for 10 weeks for 45 minutes additional physical education. The AE completed an aerobic exercise training at an intensity of 60–70% of maximum heart rate (HR_{max}). The CE completed a coordinative training, with an intensity of 55–65% of HR_{max} . Anxiety was measured by the external version of the State-Trait Anxiety Inventory for Children (STAIC PTD).

Results and discussion A repeated-measures ANOVA of group (AE, CE, CON) \times test time (pre, post) showed a significant reduction in anxiety over time, $F(1, 64) = 7.337$, $P = .009$, $\eta^2 = .103$. The interaction effect of group \times test time was also significant, $F(2, 64) = 3.445$, $P = .037$, $\eta^2 = .097$. Only participants in the AE showed decreased anxiety ($P = .009$). In the post-measurement, AE significantly differed from CE ($P = .023$); the difference to CON was marginally significant ($P = .081$). The results are discussed in terms of exercise type and the slightly different intensities of the experimental groups.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Internment of the mentally ill children in Spanish asylums (National Asylum of Leganés, 1852–1952)

A. Consejieri Gámez^{1,*}, P. Vázquez de la Torre Escalera², R. Candela Ramirez²

¹ *Hospital Universitario Infanta Cristina, Psiquiatría, Parla, Madrid, Spain*

² *Hospital Universitario de Fuenlabrada, Psiquiatría, Fuenlabrada, Madrid, Spain*

* *Corresponding author.*

Introduction The creation of a theoretical model and institutions for “abnormal childhood” was a relevant issue in various areas (medical and educational) in the first decades of the XXth century. In 1910, the first “official” attempt was carried out with the creation of the Patronato Nacional de Sordomudos, Ciegos y Anormales, and in 1925 with la Escuela Central de Anormales, devoted to these patients. Internment of infants in Spanish asylums was carried out amongst polemic and structural deficiencies. The Internal Regulation of the National Asylum of Leganés (1873 and 1885) established different departments for childhood; however, in reality, there is no evidence of an actual separation being carried out. In the Internal Regulation of 1941, the department disappeared, despite that from the Dirección General de Sanidad, all psychiatric institutions were obliged to have separate pavilions for children.

Objetives/aims Analyze the hospital admissions of children in the national asylum of Leganés.

Study the regulation regarding admission of children.

Methods Children internment in the Asylum of Leganés is analyzed (1852–1952), and compared with other Spanish asylums (SPSSv21). State documents regarding institutionalization of minors are reviewed.

Results During 1852–1952, this Asylum admitted 96 children under 18 (mainly epilepsy and oligofrenia), without any specific pavilion for them. Other institutions, such as Valladolid did have separate pavilions.

Conclusions Children were admitted in Spanish asylums although the Jefe de la Sección de Psiquiatría de la Dirección General de Sanidad in 1943 denounced that few institutions followed the regulation of having separate pavilions.

A longitudinal approach to the contribution of trauma and external shame on depressive symptoms in adolescence

M. Cunha^{1,*}, R. Almeida¹, S. Cherpe², S. Simões¹, M. Marques¹

¹ *Miguel Torga Institute, Clinical Psychology, Coimbra, Portugal*

² FPCE, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Trauma experiences during childhood and adolescence (Gibb, 2002; Ansel et al., 2011; Musliner et Singer, 2014; Hopwood et al., 2015), the experience of shame (Rubeis et al., 2008; Cunha et al., 2012; Rosso et al., 2014; Stuewig et al., 2015) and gender (English et al., 2004; Rosso et al., 2014) had been considered as predictors of depressive symptoms.

Objectives To observe intra-individual variability of trauma, external shame, gender (as predictors) and depressive symptoms (as dependent variable).

Aims To test the predictive value of trauma, external shame and gender on depressive symptoms at 6 months, in adolescents.

Method A sample of 325 adolescents (ages ranging from 12–18) completed the Child Depression Inventory, the Childhood Trauma Questionnaire and Other as Shamer, adolescents version. The results were analysed by the hierarchical multiple regression method (SPSS Inc., 22).

Results The model – shame ($b=0.63$; $P<0.001$); affective abuse ($b=0.15$, $P=0.001$), gender ($b=0.12$; $P=0.001$), sexual abuse ($b=0.12$, $P=0.002$), and emotional neglect ($b=0.10$; $P=0.013$) – explained 63% of depressive symptoms variance.

Conclusions The data indicate that the higher the level of shame and trauma, the higher the level of depressive symptoms at 6 months. The present study can add important information that sheds light to the role of mechanisms underlying the vulnerability to depressive symptoms and that might have impact in the existing therapeutic interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comorbid psychiatric symptoms in children with ADHD and/or AUTISM SPECTRUM DISORDER (ASD)

M. Davidsson^{1,*}, C. Särneö², C. Gillberg², E. Billstedt²

¹ Institution of Neuroscience and physiology, Gillberg Neuropsychiatry Centre, Gothenburg, Sweden

² Neuroscience and Physiology, Gillberg Neuropsychiatry Centre, Gothenburg, Sweden

* Corresponding author.

Introduction Co-existing problems are a rule rather than exception in child psychiatry, although rarely studied. Clinical experiences suggest that anxiety and depression are common co-existing problems in children with neurodevelopmental disorders, affecting communication, social adjustment and cognition. Research also implies that the correlation between self-reports and other sources of information is relatively low. In clinical practice, it is frequently presumed that only one source of information is correct, usually from the parents.

Objectives The objectives of the study are to view the self-reported mental health in a group of children with ADHD and/or ASD and its connection to global functioning. A second objective is to study the compliance between reports of mental health from the parents and from the child.

Aims The aim of the study is to examine the connection between mental health and function in a group of children with ADHD and/or ASD.

Methods The study includes 65 children (mean age=16) with ADHD ($n=24$), ASD ($n=24$) or ADHD/ASD ($n=17$). Instruments used are the self-report Beck Youth Inventories Scale and the parent report Five to Fifteen questionnaire. The measure for adaptive functioning was the Global Assessment of Functioning scale.

Results The study is currently in its final stage and we will present the results during the conference. We will report prevalence of

symptoms of anxiety and depression and its correlation to global functioning, as well as the compliance between parent and self-reports.

Conclusions The study emphasizes the importance of assessing psychiatric conditions in children with neurodevelopmental disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Social and family risk factors of self-injury in Polish population of psychiatrically hospitalized adolescents

I. Makowska, P. Kropiwinicki, A. Gmitrowicz*

Medical University of Lodz, Adolescent Psychiatry, Lodz, Poland

* Corresponding author.

Introduction During last 10 years, the number of non-suicidal self-injury patients (NSSI patients) in Department of Adolescent Psychiatry of Medical University in Łódź has doubled (from 20 to over 40%). According to DSM-5 criteria, NSSI are deliberate and superficial skin injuries. Such behaviours should be distinguished from suicidal behaviour disorder (SBD). However, the two display the high rate of co-occurrence.

Material and method The study covered 1300 patients (12–19 years of age) hospitalized during last 6 years. The analysis included various variables, e.g. demographic, familial, problems related to school and to peer relations, and variables describing NSSI.

Results and summary The analyzed group consisted of 60,4% girls and 39,6% boys. Out of 43% of patients who performed NSSIs, 45% also confirmed BDS. The patients with diagnosed mental retardation and with schizophrenic psychoses performed significantly fewer NSSIs. The instrumental motive was the most frequently declared reason of self-injury (76%). The reactive (65%), and the illness-related motives (only 15%) were less frequent. In comparison to patients without self-injuries, the NSSI patients significantly more frequently ($P<0.05$) experienced physical violence, unreciprocated love, played truant and repeated grades. Conflicts, delinquency, divorce, and lack of a sense of support were significantly more frequent in the family systems of NSSI patients. They more often experienced loss of their parent before age 15 and had close relatives suffering from mental disorders.

Conclusions NSSI is a multi-dimensional issue that requires further research. Indicating potential risk factors allows for implementing efficient prophylactic, diagnostic and therapeutic actions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Unhealthy behaviours and mental health among Italian adolescents

M. Iosue*, M. Sarchiapone, M. D'Aulerio

University of Molise, Department of Medicine and Health Sciences, Campobasso, Italy

* Corresponding author.

Introduction A great number of studies describe reciprocal associations between unhealthy behaviours, such as poor sleep and nutrition and lack of physical activity, and mental health problems.

Aims To investigate the relationship between unhealthy behaviours and depression, anxiety and well-being among Italian adolescents.

Methods The sample comprised 1195 high-school pupils (mean age 15.3 ± 0.6 ; 68% females) participating to the SEYLE (Saving and Empowering Young Lives in Europe) study, a randomized controlled trial, co-funded by the EU. Depression, anxiety and well-being were assessed using the Beck Depression Inventory II, the Zung Self-Assessment Anxiety Scale and the WHO-5 index. Unhealthy behaviours, such as short or long sleep, physical inactivity, skipping breakfast and not eating fruit and vegetables were also investigated.

Results Controlling for age and gender, the unhealthy behaviours, with the exception of not eating fruit and vegetables, were all associated with poor level of well-being ($P < .05$); while only short or long sleep hours ($P < .001$) and skipping breakfast ($P < .05$) were associated with depressive symptoms. No significant association were found between anxiety symptoms and unhealthy behaviours.

Conclusions Unhealthy behaviours are often established early in life and are likely to be maintained during adulthood implying negative consequences for both physical and psychological well-being. Early combined health and mental health promotion programme should be implemented in order to boost their effectiveness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction One in ten children and adolescents experience mental health difficulties at any given time, yet only one third of those suffering access treatment. Untreated mental illness predisposes to longstanding individual difficulties, and presents a great public health burden. Large scale initiatives to reduce stigmatization of mental illness in children and adolescents, identified as a key deterrent to treatment, have had limited success, and research is scarce.

Aims To gain a better understanding of the stigma experienced by children and adolescents with mental health difficulties.

Objectives We conducted a systematic review of the literature examining stigma and self-stigma towards children and adolescents with mental health difficulties, in order to better understand the extent and type of discrimination directed towards this particularly vulnerable group.

Methods Following PRISMA guidelines, the databases Pubmed, PsychINFO and Cochrane were searched for original research published between 1980 and 2014, assessing public stigma (i.e. the

reaction of the general public) and self-stigma (i.e. internalized public stigma) towards children and adolescents with mental health difficulties.

Results Thirty-seven studies were identified, confirming that stigmatization towards children and young people suffering mental health difficulties is a universal and disabling problem. There was some variation by diagnosis and gender, and stigmatization was for the most part unaffected by labelling. Self-stigmatization led to more secrecy and avoidance of interventions.

Conclusions The findings confirm that stigmatization of mental illness is poorly understood due to a lack of evidence and methodological discrepancies. Implications of the findings are discussed, and suggestions made for future research.

Objective The purpose of the study was to evaluate burden of main caregivers in children with epilepsy and to identify factors associated with caregiver burden.

Method Main caregivers of pediatric patients with epilepsy were enrolled four general hospitals in several cities of Korea. One hundred and twenty-four caregivers of patients were included in this cross-sectional study. Sociodemographic/clinical characteristics of patients and sociodemographic characteristics of caregivers were collected. The caregivers were assessed using the Korean version Zarit burden Interview (ZBI), Center for Epidemiological Studies of Depression Scale (CES-D) and social support/conflict scale. Multiple linear regression methods were used to evaluate factors contributing to burden of caregivers.

Results Of the 124 participants, 98(81.7%) were the mothers. The mean score on the ZBI and CES-D were $23.66 (\pm 19.15)$ and $13.87 (\pm 12.95)$ points, respectively. Factors affecting of caregiver burden were the number of antiepileptic drugs (AEDs), which patients are taking, and CES-D score by multiple linear regression analysis.

Conclusions Higher number of AEDs prescribed and depression of caregivers are main factors contributing to burden of caregivers in children with epilepsy.

Deficit in executive abilities as a risk factor for emerging weakness in grammar understanding in Russian-speaking children

S. Kiselev

Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

Introduction Weakness in grammar understanding is key future of specific language impairment (SLI) in children. There has been a considerable amount of work on the language abilities of children with SLI, but we still know relatively little about their other cognitive abilities – in particular their non-linguistic cognitive strengths and weaknesses.

Aims The aim of this research was to examine the hypothesis that Russian-speaking children at the age of 4 with deficit in executive abilities have a risk for emerging weakness in grammar understanding at the age of 6.

Methods One hundred and twenty-five children at the age of 4 were assessed with the NEPSY to reveal children with different level of executive abilities. We have revealed 21 children with deficit in executive abilities. The control group included 21 children with typical level of executive abilities. The children from experimental and control group were matched for IQ and gender. In the framework of longitudinal research, children at the age of 6 from both groups were assessed by Grammar Understanding Test from Luria's neuropsychological assessment technique.

Results Two-way ANOVAs with repeated measures revealed significant differences between groups for scores in the Grammar Understanding Test. Children from experimental group had weakness in grammar understanding.

Conclusions We have revealed that children at the age of 4 with weakness in executive abilities have a risk for emerging weakness in grammar understanding at the age of 6. In view of the obtained results, it can be assumed that executive abilities have influence on the development of grammar understanding in preschool children.

Neurocognitive deficits underlying attention-deficit/hyperactivity disorder (ADHD): A clustering/subgrouping analysis

P. Leung*, F. Chan

The Chinese University of Hong Kong, Psychology, Shatin, Hong Kong, China

* Corresponding author.

Introduction Neurocognitive deficits are assumed to be underlying the behavioral symptoms of ADHD. Research over the years has identified a host of these neurocognitive deficits, but no single one deficit appears to be dominant or pervasive in all ADHD children. This raises the query whether there can be further subgrouping of ADHD children at the neurocognitive level.

Objectives and aims This study aims at disentangling the heterogeneous neurocognitive deficits underlying ADHD. To achieve this, we explore if there are separable neurocognitive subgroups in ADHD children.

Methods One hundred and sixty-four Chinese ADHD boys and 163 typically developing controls, aged 6 to 12, were recruited in Hong Kong. A neurocognitive battery of executive function (EF) measures was administered. Cluster analysis was first conducted to identify subgroups of ADHD children based on their neurocognitive functioning. MANOVA was then employed to further explore the differences between subgroups.

Results Two ADHD subgroups were identified. One subgroup showed multiple EF deficits, including disinhibition, impaired interference control, distorted temporal information processing, slow processing speed, and delay aversion. The other subgroup, on the contrary, had intact EF but increased response variability. Both subgroups had comparable ADHD phenotypic severity and comorbidity pattern. However, ADHD children in the EF deficits subgroup were more responsive to medication (i.e., methylphenidate).

Conclusion Results support the neurocognitive heterogeneity of ADHD. EF deficits and response variability are two separable neurocognitive profiles underlying and subgrouping ADHD children of comparable severity. This subgrouping has implication for medication response and offers candidate endophenotypes for neuroimaging and genetic study.

Do children with autism spectrum disorder have impaired sleep patterns?

A. Memari*, S. Hafizi

Tehran University of medical science, sport-medicine, Tehran, Iran

* Corresponding author.

Introduction Literature has emerged to offer contradictory findings about sleep disturbances in autistic population and there is still insufficient data for the background and associations of sleep problems (e.g. demographic variables, severity of autism and comorbidities) in autism research and little attention has been paid to autism specific factors.

Objectives This study seeks to add further evidence on sleep patterns specific to autistic children and help answer some of the questions in this field in a population with a different culture (Middle East).

Methods Eighty-six children and adolescents with autism were enrolled. Parents were asked to provide medication history and other comorbidities. Behavior problems were assessed via autism treatment evaluation checklist. Sleep diary forms was completed by parents to record children nocturnal sleep over a 7-day period and in times in which Actigraphy™ were taken off. Moreover, we used GT3X monitor Actigraph™ to assess sleep problems.

Results The *T*-test analysis for sleep minutes revealed that females had slept marginally more minutes than males ($P=0.05$). *T*-test analysis showed no significant difference in sleep parameters between those using and not using any psychotropic agents. Comorbidities analysis showed that children with comorbid conditions slept more ($P=0.01$), went to bed later ($P=0.03$) and had more number of awakening ($P<0.001$) than participants without comorbid conditions. Sleep minutes were correlated with deficit in sensory cognitive awareness ($r=0.236$, $P=0.035$). Behavioural deficit and number of awakening ($r=0.246$, $P=0.028$) were correlated significantly.

Conclusion Our overall findings showed the association of sleep problems and behavioral deficit and comorbidities in autism.

Role of music and non-musical techniques in self-guided emotional regulation

R. Mohan*, N. Anand

Surrey and Borders Partnership NHS Foundation Trust, Child and Adolescent Psychiatry, Guildford, United Kingdom

* Corresponding author.

Introduction Studies on relationships between music, visual imagery or therapeutic techniques, like mindfulness and emotions have been undertaken with varying success in predominantly adult populations. Their role in the child and adolescent population remains unclear.

Aims and objectives We undertook a systematic literature review to assess current evidence in the use of music, guided imagery with/without therapeutic techniques for emotional processing in adults, children and adolescents.

Methods We identified 87 relevant papers (JSTOR, OVID Medline, Cochrane, PubMed, Science Direct, Taylor & Francis and Wiley). We excluded non-English papers and qualitative analyses. Nine studies used quantitative techniques (Neuroimaging) for assessing emotional change using musical and non-musical stimuli ($n = 77$). Of these, four studies used fMRI and two used PET scans.

Results fMRI demonstrates a significant relation between amygdalar activation and emotional response to visual imagery ($P < 0.05$, $n = 45$). Early information using PET scanning shows a significant association between activation of different parts of brain with varied visual imagery (one study, $n = 5$) and varied music (one study, $n = 10$). There is similarity in the activation of specific cortical areas using musical and non-musical stimuli. Two separate studies of patients with damaged amygdala due to disease ($n = 6$) showed significant impairment of emotional processing and response.

Conclusions There is early encouraging data providing evidence of possible relationships between music and visual imagery in emotional processing. Further studies are needed to examine these in detail, especially in children/adolescents. Music with visual imagery may be a useful adjunct in the self-guided processing of milder emotional disorders with components of anxiety, depression, adjustment and emotional dysregulation.

Introduction The long-term safety and efficacy of lisdexamfetamine dimesylate (LDX) in children and adolescents with attention deficit/hyperactivity disorder (ADHD) was evaluated in a European 2-year, open-label study (SPD489-404).

Objective To evaluate the time-course of treatment-emergent adverse events (TEAEs) in SPD489-404.

Methods Participants aged 6–17 years received open-label LDX (30, 50 or 70 mg/day) for 104 weeks (4 weeks dose-optimization; 100 weeks dose-maintenance).

Results All enrolled participants ($n = 314$) were included in the safety population and 191 (60.8%) completed the study. TEAEs occurred in 282 (89.8%) participants; most were mild or moderate. TEAEs considered by the investigators as related to LDX were reported by 232 (73.9%) participants with the following reported for $\geq 10\%$ of participants: decreased appetite (49.4%), weight decreased (18.2%), insomnia (13.1%). TEAEs leading to discontinuation and serious TEAEs occurred in 39 (12.4%) and 28 (8.9%) participants, respectively. The median (range) time to first onset and duration, respectively, of TEAEs identified by the sponsor as being of special interest were: insomnia (insomnia, initial insomnia, middle insomnia, terminal insomnia), 17.0 (1–729) and 42.8 (1–739) days; weight decreased, 29.0 (1–677) and 225.0 (26–724) days; decreased appetite, 13.5 (1–653) and 169.0 (1–749) days; headache, 22.0 (1–718) and 2.0 (1–729) days. Reports of insomnia, weight decreased, decreased appetite and headache were highest in the first 4–12 weeks.

Conclusions TEAEs associated with long-term LDX treatment were characteristic of stimulant medications, with the greatest incidence observed during the first 4–12 weeks.

* Corresponding author.

Introduction The problem of children’s mental health in Ukraine – it is one of the most pressing problems in the country’s health. This is due to the increasing number of extreme situations (military operations in the territory of Ukraine) for the last time that calls for the training of specialists capable of carrying out psychosocial rehabilitation to victims of “anti-terrorist operation”(ATO).

Objectives The mental and behaviour disorders in children affected of ATO. We studied 261 families: 107 adults and 154 children. The aim of the project was to optimize the provision of psycho-social support for children and adolescents with problems of the psychic sphere by developing a system of psychological adjustment and social education at the Centre for psychosocial rehabilitation of children, as well as the creation of the necessary conditions that expand the comfort and a safe space for the child to enhance positive impacts and mitigate negative impacts of the social environment.

Methods The leading role was played by a combination of two areas of work, namely the psychocorrection (trainings, art-, individual-, family-, hyppo-therapy) and social work.

Results In 85.4% of the children showed stabilization of mental and emotional state, reducing aggression, increasing motivation to social activity. In 56.3% of families – reducing conflict relations.

Conclusions The non-standard way of psycho-correction allowed organizing a fruitful and creative leisure, which resulted in the

reduction of aggression and anxiety, increased motivation for the successful development of new activities and problem-solving skills and conflict situations with peers and family members.

From Child and Adolescent to Adult Mental Health Services: The Intrepid Journey

M. Nascimento^{1,*}, C.C. Santos², G. Bastos Martins³

¹ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5, Lisbon, Portugal

² Centro Hospitalar Lisboa Central, Psiquiatria da Infância e da Adolescência, Lisbon, Portugal

³ Hospital Fernando Fonseca, Psiquiatria, Amadora, Portugal

* Corresponding author.

Background The move from Child and Adolescent Mental Health Services (CAMHS) to adults' services (AMHS) is likely to coincide with other transitions in the adolescents' life. Barriers affecting this transition have been referred in most countries, but there is a lack of studies on this matter.

Aims To evaluate the transitional process from CAMHS to AMHS in Portugal, focusing on four criteria: continuity of care, parallel care, a transition planning meeting and information transference. The continuity/discontinuity of the diagnosis and therapeutic plan made at CAMHS has also evaluated.

Methods Identification from a sample of adolescents transferred from Clínica da Juventude (adolescents' clinic) to 3 major AMHS, collecting information regarding the quality of the transition between these services.

Results Fifty-nine adolescents were discharged in 2014, average of 16.5 years old, after being followed in our clinic for an average of 7.44 months. Ten continued being followed in adult psychiatric services (17.5%), with different disorders: 4 depressive, 2 personality, 1 anxiety, 1 bipolar, 1 addiction to psychoactive substances, and 1 oppositional defiant disorder. Even in those cases the transition was far from optimal, with 4 of those presenting the need to use adult emergency facilities.

Conclusions Several barriers between CAMHS and AMHS might account for the ongoing problem with the transition between services. In addition, considering that the onset of severe and recurring mental disorders begins generally before the age of 25, this raises the discussion around the present distinction between child and adolescent mental health services and adult services at 18 years old.

Assessment of behavior and sleep pattern in school age children with generalized epilepsy

M. Negm

Suez Canal University, Neuropsychiatry, Ismailia, Egypt

Background Epilepsy affects 1% of the human population. Sleep disorders frequently coexist in patients with epilepsy. Whether sleep affects epilepsy or epilepsy modifies sleep has been extensively evaluated, but very little literature exists on the mutual interaction of epilepsy and sleep problems.

Objective and aims To assess the sleep pattern and behavior in school age children with generalized epilepsy.

Methods The current study was comparative case control study was carried on 60 school aged children 30 of them had generalized epilepsy on carbamazepine presented to neuropsychiatry department in suez canal university hospital and other 30 healthy children had no chronic illness. The Children's Sleep Habits Questionnaire and Vanderbilt assessment scale were applied on both groups.

Results the current study showed that epileptic children have a statistically significant difference in breathing problem like snoring ($P=0.001$), epileptic children had more common daytime sleepiness problem ($P=0.002$). Behavioral problems were more common in epileptic children like ADHD (P -value=0.001), anxiety and depression were highly frequent in epileptic children than normal children (P -value=0.001) and schoolastic achievement was more problematic in epileptic children.

Conclusions Epileptic children are more vulnerable to sleep problems, behavioral problems and poor schoolastic achievement is more common in epileptic children. Controlled fits and monotherapy decreased the effect of epilepsy in all aspects.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Predicting clinical outcome of stimulant medication in pediatric attention, deficit/hyperactivity disorder (ADHD): Single-dose changes in event-related potentials (ERPs)

J.F. Brunner

6 Department of Physical Medicine and Rehabilitation, St Olav's Hospital, Trondheim, Norway

Introduction One of four children and adolescents with ADHD treated with stimulants are considered non-responders (non-REs). So far clinically useful predictors of medication response do not exist.

Objectives and aims In this study, we examined if changes in event related potentials (ERPs) induced by a single dose of stimulant medication were different in responders (REs) and non-REs.

Methods Nineteen channel electroencephalography (EEG) was recorded twice during performance of a cued visual go/no-go task in 82 medication-naïve ADHD patients aged 8–17 years (26 girls). The second recording was completed within 12 weeks after test 1 on a single dose of stimulant medication, followed by a systematic trial on stimulant medication lasting at least 4 weeks. Based on data from daily ratings, the patients were categorized as REs ($n=58$) or non-REs ($n=24$). The two groups were then compared on ERPs reported to be associated with ADHD.

Results REs and non-REs differed significantly with a large effect size in their medication induced changes in the P3 no-go component. This was also found for ERP component contingent negative variation (CNV). A quartile based scale combining changes in P3 no-go amplitude and reaction time variability in the task showed 26% probability of a positive response in quartile-group 1, and 95% probability in group 4.

Conclusion A single dose of stimulant medication induced a significant increase in P3 no-go and CNV amplitudes in REs, but not in non-REs; probably reflecting improvements in aspects of executive function.

Mental health transition plans for older adolescents with autistic spectrum disorders – clinical profile of patients from a metropolitan Borough, North West of England

S. Olety

Pennine Care NHS Foundation Trust, Child and Adolescent Psychiatry, Rochdale, United Kingdom

Introduction The needs of people with Autistic Spectrum Conditions (ASC) are varied and complex. In order to improve outcomes for Adults with Autism, it is important to understand and evaluate the transition planning process and current services for adolescents/young Adults with ASC.

Aims and objectives Aim was to undertake the needs assessment audit of all young people (ages 16–19) open to a Child and Adolescent Mental Health Service. Objectives was to ensure that transition/discharge plan was in place for all the open cases and also identify any gaps in service provision.

Methods A retrospective case-note review of all open cases ($n=41$) aged 16–19 was undertaken. Data was obtained on diagnosis, co morbid problems, educational status, and transition/discharge plans.

Results Twenty-two percent of the cases had co morbid moderate to severe Intellectual Disability. Transition was not an issue for this group, with entitlement of support from secondary-care-teams. Seventy-eight percent of the cases had diagnosis of Asperger's Syndrome (AS)/high functioning autism (HFA). Seventy-five percent had co-morbid depressive/anxiety disorders, 12% had ADHD and 10% presented with repeated self-harm/suicidal behaviour. Nature of the co-morbid problems/risks did not meet thresholds for Community Adult Secondary Mental Health Services resulting in discharge to Primary Health Care Services.

Conclusions Better training to equip primary care staff, such as General Practitioners is needed to support the growing numbers of young adults with HFA/Asperger's syndrome being discharged to their care. Costs/benefits of providing specialist adult services for people with HFA and AS to be considered in order to improve outcomes for adults with autism.

Safeguarding foster care youth from overmedication

C. Pataki^{1,2,*}, C. Thompson^{1,3}, G. Crecelius², J. Tesoro^{2,4}, G. Polsky², P. Kambam²

¹ David Geffen School of Medicine at UCLA, Psychiatry & Biobehavioral Science, Los Angeles, CA, USA

² Los Angeles County Department of Mental Health, Juvenile Court Mental Health Service, Monterey Park, CA, USA

³ Los Angeles County Department of Mental Health, Juvenile Justice Mental Health Program, Los Angeles, CA, USA

⁴ University of Southern California School of Pharmacy, Pharmacy, Los Angeles, CA, USA

* Corresponding author.

Introduction There are increasing concerns regarding long-term psychotropic polypharmacy prescribed for foster care youth 3.5 to 5 times more often than in at-home youth (Kreider et al., 2014). Polypharmacy risks include weight gain, glucose intolerance and type 2 diabetes. (De Hert et al., 2011). In view of these risks, novel interventions are essential to safeguard foster care youth from overmedication.

Objectives To present guidelines for identification and management of polypharmacy in foster care youth.

Aims To demonstrate a novel intervention to monitor and diminish polypharmacy and enhance psychiatric care in foster care children.

Methods Polypharmacy is identified using LA County Juvenile Court Mental Health Service (JCMHS) Psychotropic Parameters* to review medication consent forms from treating psychiatrists. Polypharmacy triggers an in-person JCHMS consultation. *(Parameters 3.9 for JCMHS PMAF Review, Revised May 2015).

JCMHS Psychotropic Parameters (summary):

- age 0–5 years:
 - 2 or > psychotropic medications,
 - Any antipsychotic (*except Risperidone in ASD);
- age 6–8 years:
 - 3 or > psychotropic medications;
- age 9–17 years:
 - 4 or > psychotropic medications;
- All age youth:
 - 2 or > psychotropic medications in the same class (antipsychotics, antidepressants, stimulants, mood stabilizers, alpha agonists).

Psychotropic medication doses in excess of recommended (*LA County Department of Mental Health Parameters 3.8 for use of Psychotropic Medications for Children and Adolescents).

Results Approximately 25% of JCMHS annual psychiatric consultations were initiated by JCMHS parameters for polypharmacy. Corresponding consultations included education and recommendations discussed with treating psychiatrists regarding polypharmacy and optimal psychiatric management.

Conclusions JCMHS Psychotropic Parameters is a useful tool to identify polypharmacy and enhance psychiatric care of foster care youth.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background and aims The research is aimed at revealing clinical and psychological predictors of recurrent depression in children. Our study reflects the relationships of certain clinical and psychological markers in the development of recurrent depression (RD) in children at the stage of sexual maturation.

Materials and methods The study included 145 children in pre-puberty and 200 children in puberty with recurrent depression, in which manifestation of the first depressive episode occurred at the age of 7–11 years. The study design included: social, clinical, psychopathological, anamnestic, somatoneurological and neuropsychological monitoring (CDRS-R; MADRS; the Columbia-Suicide Severity Rating Scale (C-SSRS), Toulouse-Pieronne test to determine the presence and type of a minimal brain dysfunction, as well as Luria's Memorizing 10 words technique).

Results Analysis of the relationships between psychological trauma factors, which took place in children at the stage of the first depressive episode, and the risk of the recurrent depression development in children at puberty has established the significance of: school bullying ($r=0.13$), combination of stress events ($r=0.11$), father flight ($r=0.10$), lack of authority and environmental rejection

($r=0.12$). The study has established a correlation between neurocognitive deficiency of ($r=0.13$), hyperactivity ($r=0.10$), anxiety ($r=0.13$), poor academic progress ($r=0.11$), somatoneurological asthenia ($r=0.10$), self-underestimation ($r=0.13$), suicidal behavior history ($r=0.10$) and the development of recurrent depression in the pre-puberty and early puberty.

Conclusion The revealed regularities make it possible to work out a strategy for the prevention of recurrent depression in young adults.

* Corresponding author.

Research about adjustment of adopted children indicates that they have more emotional and behavioral problems than non-adopted children. We have examined 28 adopted minors that have been admitted to the inpatient unit in Hospital Clínico Universitario of Valladolid. We examine the gender, age, diagnose and the number of hospital admissions. In the sample of 28 patients, there are 15 males (53.57%) and 13 females (46.42%). The most common diagnosis is attention deficit hyperactivity disorder (57.57%), followed by reactive attachment disorder of infancy or early childhood (46.42%). Readmission rate is 44.2%. Male patients have higher rates of readmission (60.86%) than females (39.1%). Males have higher rates of readmission (60.86%) than females (39.1%).

Discussion Results indicate a higher rate of admissions in adopted males than females, being attention deficit hyperactivity disorder and reactive attachment disorder of infancy or early childhood the most common diagnosis. Rate of readmission is higher in males.

Do parents of children with autism show the same motor and mental problems as children with autism spectrum disorder?

M. Shayesteh Far^{1,*}, A. Memari², R. Kordi²

¹ Tehran, Iran

² Tehran University of Medical Sciences, Sport-Medicine, Tehran, Iran

* Corresponding author.

Introduction Mild expressions of autism spectrum disorder (ASD) that does not reach the diagnostic threshold in relatives of ASD individuals has been defined as the broad autism phenotype (BAP). Moreover, research in ASD families has shown a high prevalence of psychiatric disorders (such as mood and anxiety disorders) as well as mild social cognitive impairment. However, there are inconsistent findings and results are inconclusive. Furthermore, there are few studies investigating motor function in parents of children with ASD.

Objective We aimed to examine the mental health, social cognitive skills and motor ability of the parents of ASD children in comparison to parents of TD children.

Methods Forty parents who have a child with ASD and 40 parents with typical children (TD) (control group) were included in the study. We administered General Health Questionnaire and the Beck Depression Inventory. Furthermore, the social cognition of subjects were evaluated using the “Reading the Mind in the Eyes” (RMET) test. Finally, we measured grip strength, motor speed, coordination and praxis of the dominant hand.

Results Parents of ASD children scored significantly higher in GHQ test and Beck questionnaire ($P<0.001$). Parents of ASD children scored significantly lower than the control group in RMET test ($P=0.008$). Parents of ASD children scored significantly lower in motor speed measures ($P=0.001$), fine control ($P=0.01$) and longer in coordination time ($P<0.001$) than control group.

Conclusion Our model including depressive symptoms, social cognitive and motor abilities presented an endophenotype, which can be inherited, from parents with a broad autism phenotype.

Norm of the Chinese version of the Swanson, Nolan and Pelham, version IV Scale for ADHD in Chinese urban children

J.A. Shi^{1,*}, N. Du², G. Zhao³, X. Hu⁴

¹ Xi'an mental health center, Medical Clinic, Xi'an, China

² West China Hospital, Sichuan University, Department of Psychiatry, Chengdu, China

³ Jining Medical College, Department of Psychiatry, Jining, China

⁴ Shanxi Medical University, Department of Medical Statistics, Taiyuan, China

* Corresponding author.

Introduction The Swanson, Nolan and Pelham, version IV Scale (SNAP-IV) is widely used in the research of ADHD with great reliability and validity. Although the diagnosis and treatment of ADHD has improved significantly recently, the research of SNAP-IV Scale is still scarce in mainland of China.

Objectives The study aimed to develop the norm of the Chinese version SNAP-IV in Chinese urban children and to test the reliability and validity of this scale.

Methods A sample of 2110 students (1102 males and 1008 females) in grades 1 to 9 from cities of the 5 main areas of China were selected by cluster sampling and 107 children diagnosed with ADHD consecutively recruited from a medical center in Chengdu. Parents of subjects completed the Chinese versions of the SNAP-IV and Child Behavior Checklist (CBCL). A total of 231 members of sample group were retested after one month.

Results The Chinese version of SNAP-IV demonstrated similar three-factor structure (Inattention, Hyperactivity/Impulsivity, and Oppositional) as its English version, and satisfactory test-retest reliability (intraclass correlation = 0.61–0.73), internal consistency ($\alpha=0.88–0.91$), and concurrent validity (Pearson correlations = 0.67–0.76). Males scored higher on two subscales and total score than females. Inattention and Hyperactivity-Impulsivity subscale were rated higher in young age groups than older age groups. The SNAP-IV clearly distinguished children with ADHD from school-based participants.

Conclusion The Chinese version SNAP-IV is found to have good psychometrics properties. The findings suggest that it is a reliable and valid instrument for rating ADHD-related symptoms in Chinese urban children.

A study for development and validation of the computer-based working memory tasks for school-aged children

M.S. Shin^{1,*}, S.J. Oh², J.J. Lee³, J.E. Lee³

¹ Seoul National University College of Medicine, Psychiatry, Seoul, Korea

² Seoul National University Hospital, Psychiatry, Seoul, Korea

³ Seoul National University, Medical Research Center, Seoul, Korea

* Corresponding author.

Introduction Working memory (WM) is the ability to retain and manipulate information during a short period of time. According to previous studies, children who have neurocognitive dysfunctions, such as ADHD and learning disorder were found to have a WM problem, which was associated with frontal lobe dysfunction, especially dysfunctions in dorsolateral prefrontal cortex.

Objectives In the present study, we developed the computer-based WM tasks for school-aged children, which help to provide a timely assessment of risk and preventive intervention for children with subclinical attention problems.

Aims We evaluated the construct and concurrent validity of newly developed WM tasks.

Methods A hundred and fourteen 8- to 10-year-old children were recruited. The newly developed, computer-based WM tasks consist of two domains:

- auditory-verbal WM;
- visual-spatial WM.

We examined the construct validity of the tasks through examining the developmental trend of the WM abilities with age. To determine the concurrent validity of those tasks, we conducted correlation analyses between the participants' scores and their scores on well-known measures of verbal and visual WM; Arithmetic and Letter-Number Sequencing subtest of intelligence scale (KEDI WISC), and Corsi block test.

Results There are marked linear increasing trends of the response accuracy with age. Further, there were high correlations between the scores of two WM tasks and the corresponding scores of standardized assessment tools.

Conclusions This study showed promising evidence for the validity of computer-based tasks assessing WM, which might have the utility for school-aged children in research and clinical settings.

Consumption of medicines for attention deficit hyperactivity disorder treatment per patient in children and adolescents in Slovenia from 2003 to 2012

M. Stuhec^{1,*}, U. Vedernjak², L. Igor²

¹ Ormoz's Psychiatric Hospital, Clinical Pharmacy, Ormoz, Slovenia

² Faculty of Pharmacy Ljubljana, Social Pharmacy, Ljubljana, Slovenia

* Corresponding author.

Background According to the attention deficit hyperactivity disorder (ADHD) treatment guidelines, atomoxetine (ATX) is a second line treatment after stimulants and therefore a serious monitoring of ATX prescribing is necessary to avoid inappropriate prescribing.

Objectives In most countries in Central Europe, except Germany, there is no data on drug consumption for ADHD medicines (expressed in defined daily dose (DDD)/ADHD patient/year).

Aim The main purposes of this study were: calculate and present the pattern and evolution of national consumption in Slovenia expressed in the percentage of DDD/patient/year consumption for the period 2003–2012.

Methods The national consumption and population data for this period were obtained from Slovenian databases. A DDD/ADHD patient/year was calculated. Only immediate-release methylphenidate (IR-MPH), methylphenidate-osmotic release oral delivery system (OROS-MPH) and ATX have been available and included in this study.

Results Less than 50% of patients with ADHD are treated with medications in Slovenia. A total consumption rose rapidly from 41.3 in 2003 to 148.5 DDD/ADHD patient/year in 2012. The total consumption for ATX and MPH is almost equal (140.9 for ATX and 150.3 for MPH in 2012). This result is lower as it has been seen in Germany (208 DDD/ADHD patient/year in 2008 for MPH).

Conclusions In the last decade in Slovenia, the total consumption is increasing rapidly, which indicates a positive trend. This pattern (low total consumption) has not been seen in Germany. After the new drugs have been available on the Slovenian market, the total consumption rose rapidly.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Validation of BGaze method supporting ADHD diagnosis

F. Lorena Esposito¹, P. Varela², E. Ozan Alkan¹, I. Morata¹, N. de la Osa³, L. Ezpeleta³, J. Cañete Crespiello², H. Super^{1,*}

¹ Braingaze, R&D, Mataro, Spain

² Consorci Sanitari del Maresme, Mental Health Dept, Mataro, Spain

³ UAB, Dept Clinical and Health Psychology, Barcelona, Spain

* Corresponding author.

Introduction Eye movement recordings can provide information about higher-level processing of visual information. Recent evidence shows a novel role for eye vergence in orienting attention (Solé Puig et al., 2013). Based on such eye tracking data, the BGaze method (Braingaze; Spain) detects visual attention. The outcomes of the BGaze method have been applied to classify ADHD patients from healthy controls.

Aim In this study, we validated the BGaze method.

Objective We therefore recorded eye movements in children while performing a visual detection task.

Methods We evaluated the BGaze method using 4 types of supervised machine learning algorithms. In total, 138 different trained models were tested. Nineteen ADHD diagnosed patients (children 7–14 years of age) and 19 healthy age matched controls were used to build the 138 models. We performed 30 times repeated random sub-sampling validation. In each repeated random split, training set consisted of 80% of the data and test set of the remaining 20%. Finally, all the 138 models were tested with a validation set consisting of 232 children, including 22 ADHD patients.

Results Across all the 138 models, BGaze method showed an average accuracy of 90.84% (minimum 86.21%; maximum, 95.26%) and an average AUC of 0.95 (minimum 0.90; maximum, 0.97). Best models gave accuracies of 92%, AUCs of 0.96 and FN and FP rates of 4.3% and 7.5%, respectively. Mean scores during the training-testing phase averaged 99.63%.

Conclusion The BGaze method is robust, accurate, and can provide an objective tool supporting the clinical diagnosis of ADHD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sleep matters: Impact of tuberous sclerosis and co-morbidities on children's sleep.

A questionnaire-based study and review of current research

P. Sykioti*, H. Liang, F. McEwen, C. The, P. Bolton
King's College London, Institute of Psychiatry, London, United Kingdom

* Corresponding author.

Background Sleep problems are common in children with neuropsychiatric symptoms and are a major source of morbidity both for children and their families. TS is a multisystem genetic disorder with prominent central nervous system involvement. Neurological and neuropsychiatric symptoms are common in TS putting this group of patients at high risk for sleep problems.

Aims Describe sleep problems in children with tuberous sclerosis (TS), profile children most at risk, understand the interplay between the most common co-morbidities and sleep disturbance in TS and review the current knowledge for the impact of TS and co-morbidities on sleep.

Method This study uses data from the TS2000 Study, a population based, longitudinal study of TS. One hundred and twenty-five children diagnosed with TS between 2001 and 2005 were ascertained and genetic testing undertaken. In 2014–2015, consenting participants (85) were assessed using a parent report questionnaire, including items enquiring after ASD diagnosis, epilepsy severity, ADHD diagnosis, tumour count and sleep, which included the Composite Sleep Diagnostic Interview (CSDI) questionnaire.

Review We used PRISMA criteria to report our results.

Preliminary findings – TS and sleep: sleep problems were reported by 63.3% of parents. The mean total CSDI score was 4.2 ± 3.6 . Main problems were: sleep latency (36.7%) and total sleep hours < 7 (46.3%). Parental satisfaction was significantly affected by total sleep hours;

– co-morbidities and sleep: 95.7% of children with ASD had epilepsy, compared to 58.3% without ASD ($P=0.003$). Patients with ASD showed significantly higher mean CSDI scores compared to children without ($P=0.009$). ADHD data and tumour count need further analysis.

Conclusion Children with TS have difficulties with reduced sleep hours and increased sleep latency. Comorbid ASD causes more difficulties.

An innovative child psychiatry training program using a family-based model for at-risk military families

R. Szeftel^{1,2,*}, C. Pataki^{1,3}

¹ David Geffen School of Medicine at UCLA, Psychiatry & Biobehavioral Science, Los Angeles, CA, USA

² Department of Mental Health, Psychiatry, Los Angeles, CA, USA

³ Department of Mental Health, Juvenile Court Mental Health Service, Monterey Park, CA, USA

* Corresponding author.

Introduction Few child psychiatrists are well trained in family-based interventions for military families who experience significant trauma, intergenerational posttraumatic stress disorder, substance abuse, depression and high rates of suicide (Ramsawh

et al., 2014). The innovative VA/UCLA/LACDMH Child and Adolescent Psychiatry Training program, sponsored jointly by the VA Greater Los Angeles Healthcare System (VA) and the Los Angeles County Department of Mental Health (LAC DMH), will address unmet needs of at-risk military families using a family-focused model also applicable to other families exposed to trauma.

Objectives To present the curriculum of the VA/UCLA/LACDMH training program and details of the collaboration between the LA VA and LAC DMH.

Aims To highlight how innovative child psychiatry training programs can be developed through creative institutional collaborations.

Methods The VA/UCLA/LACDMH program family-based model and FOCUS (Lester et al., 2011) intervention were structured to meet regulatory standards of child psychiatry training programs.

Results A specialized family-based child training program was created to meet the needs of at-risk military families while providing rigorous child and adolescent psychiatry training. Components Early Intervention Family Clinic for At-Risk Children provides family psychoeducation, and identifies children and adolescents at risk.

Focus An evidence-based early intervention for at-risk military families to enhance resilience and mitigate stress through improved coping, increased problem solving, and effective communication.

Conclusions A successful collaboration between the LA VA and LAC DMH can lead to an innovative family-based child psychiatry training program.

Prevalence of attention deficit hyperactivity disorder in selected rural primary school children in Bangladesh

M.M.J. Uddin

National Institute of Neurosciences and Hospital, Psychiatry, Dhaka, Bangladesh

Introduction Attention deficit hyperactivity disorder (ADHD) is highly prevalent globally as well as developing country, like Bangladesh and there is a limited source of information regarding the prevalence of ADHD in rural primary school going children of Bangladesh.

Objectives To identify the prevalence of ADHD in rural primary school children.

Methods This descriptive cross-sectional study was done in three selected primary school of Shariatpur district of Bangladesh. Children aged between 5 and 12 years were taken purposively. After obtaining informed written consent, ADHD was assessed by using Bengali translated version of Conner's Abbreviated Rating Scale given to the parents and teachers.

Results Out of 587 respondents, 318(54.17%) were boys and 269(45.83%) were girls of lower class and lower middle class 503(85.69%) social status. Among the respondents, 38(6.47%) were found having ADHD. Prevalence was higher among boys 27(4.60%) than girls 11(1.83%).

Conclusion Results of the study indicate that early identification and proper management will help to the children. Further broad based study is required in this regard.

Protected children require comprehensive mental health care. These are results gathered from a sample of children in care evaluated in the UMERP (Madrid, Spain)

J. Vidal^{1,*}, C. Pagés², K. Pérez², M.J. Ramos¹, M. de Matteis¹, E. Serrano-Drozdowskyj¹, D.M. Moreno¹

¹ Gregorio Marañón Hospital, Psiquiatría del Niño y Adolescente, Madrid, Spain

² Hospital Universitario de la Princesa, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction The Community of Madrid protects more than 4000 children. These children have an elevated psychopathology (Fisher, 2015). In Hospital General Universitario Gregorio Marañón (Madrid) in 2004, the UMERP (Unidad de Menores en Riesgo Psíquico) was created to attend children in care throughout the Community of Madrid (Spain). Its aim is to identify and treat their Mental Health needs.

Objectives To carry out a descriptive analysis of the sample of patients evaluated in the UMERP and a literature review in recent years.

Methods SPSS was used for statistical analysis. Pubmed was utilised for literature search.

Results Twenty-nine patients were evaluated from March to September 2015. The age of contact was 13.41 years (SD 3.418). In total, 58.6% were male and 41.4% female, 72.4% had psychiatric history and 100% of the evaluated minors had at least one psychiatric diagnosis (ADHD $n = 13$, conduct disorder $n = 12$, depression $n = 7$ and drugs disorders $n = 7$, were the most frequent diagnosis). The school failure in the last year (51.7%) and absenteeism (27.6%) were very high. The 34.5% had at least a medical disease and 31.03% recognized drug consumption in the last month.

Conclusion All evaluated patients had psychopathology, so we suppose that an indefinite number of minors does not have access to treatment. We are beginning groups with children's homes staff to increase their knowledge of Mental Health so they can recognize psychiatric symptoms earlier. We have to coordinate with schools to strengthen access to interventions. We need to contact with other medical specialties and drug addiction centres.

¹ Psychiatric Hospital Sveti Ivan, Adult Psychiatry, Zagreb, Croatia

² Clinic for Psychological Medicine, University Hospital Center Zagreb, Adult Psychiatry, Zagreb, Croatia

³ Clinic for Psychological Medicine, University Hospital Center Zagreb, Child and Adolescent Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction Twenty percent of children and adolescent population are suffering from psychiatric disorders, according to World Health Organization. Above that, clinical work and previous published reports point to increase of self-harm behaviour incidence and prevalence in many countries, including Croatia.

Aims To compare defence mechanisms in adolescent patients with deliberate self-harm behaviour and without it.

Objectives To explore differences in adaptive and maladaptive defence mechanisms in adolescent patients with self-harm behaviour and without this behaviour; to gain better insight in

possible perception and functioning patterns in these two patient subgroups. To assess the effect of possible differences on early diagnostic procedure and therapeutic plan.

Methods Defence Style Questionnaire (DSQ) was administered to 150 patients aged between 14 and 18 years on their first visit to child and adolescent psychiatrist. Seventy-nine patients had history of self-harm behaviour and 81 patients had negative anamnestic data on such behaviour.

Results Comparison of defence mechanisms in these two patient subgroups showed a statistically relevant difference in using defence mechanisms.

Conclusion Results of this study showed significant difference between patients with self-harm behaviour and without such behaviour regarding used defence mechanisms. Awareness of specific mental patterns in patients with self-harm behaviour provides better assessment of suicidal risk and optimal individual approach planning.

* Corresponding author.

Introduction The cutaneous polymorphic eruption of pregnancy (PEP) is presented by skin lesions usually in the third trimester of gestation and about 13% of women also suffer from perinatal depression.

Objective To determine the frequency of pruritic urticarial papules of gestation with and without perinatal depression.

Aim To assess the maternal causes for polymorphic eruption of pregnancy (PEP) in patients with and without perinatal depression.

Methods Cases and controls were matched on the grounds of maternal weight gain in gestation, hormonal changes, deficit in iron and zinc, dysregulation of hypothalamic pituitary axis, pre-maturity, pre-eclampsia, pre-term labour. Univariate and multivariate analysis, adjusting for important demographic factors and comorbidities was conducted to assess the relationship of PEP with and without perinatal depression

in reduced and full models of ANOVA in regression analysis. (Reduced model $Y = \beta_0 + \beta_1 X_1 + \dots$ and the full model $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \dots$)

Results Polymorphic eruption of pregnancy with perinatal depression was statistically significant in maternal weight gain in gestation [odds ratio (OR) 1.20; 95% (CI): 1.15–1.30], hormonal changes [(OR) 2.78; 95% (CI): 2.52–2.82], deficit in iron and zinc [(OR) 2.18; 95% (CI): 2.04–2.38], dysregulation of hypothalamic pituitary axis [(OR) 1.37; 95% (CI): 1.18–1.49] and was not statistically significant in pre-maturity, pre-eclampsia and pre-term labour in cases and controls.

Conclusion Pruritic urticarial papules and plaques of gestation are commonly associated in patients with perinatal depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Biomarkers of response to transcranial magnetic stimulation in youth with treatment resistant major depression

T. Wilkes^{1,*}, Y. Jasau², A. Kirton³, L.M. Langevin², M. Sembo², F. MacMaster⁴

¹ Foothills Medical Centre, Psychiatry, Calgary, Canada

² Alberta Children's Hospital Research Institute, Behavioral Research Unit, Calgary, Canada

³ Alberta Children's Hospital Research Institute, Paediatric Stroke Program, Calgary, Canada

⁴ Alberta Children's Hospital Research Institute, Psychiatry and Paediatrics, Calgary, Canada

* Corresponding author.

Background Major depressive disorder (MDD) affects approximately 15% of youth, half of who do not respond to standard treatment. One promising intervention is repetitive transcranial magnetic stimulation (rTMS). However, response is limited, highlighting the need to focus on biomarkers to predict treatment response.

Objectives To explore baseline biomarkers of response associated with rTMS treatment in adolescent MDD.

Aims To determine the association between dorsolateral prefrontal cortex (DLPFC) glutamate levels, cortical thickness, and cerebral blood flow (CBF) with MDD symptomatology decrease after rTMS intervention.

Methods Twenty-four MDD youth underwent 3 weeks of rTMS, baseline and post-intervention magnetic resonance imaging scans, and short echo proton magnetic resonance spectroscopy. Response was determined by a 50% reduction of depression scores.

Results Depressive symptoms decreased with rTMS ($t = 8.304$, $P = 0.00$). Glutamate levels differed significantly between responders and non-responders ($t = 2.24$, $P = 0.0039$), where higher glutamate changes were associated with a better response ($r = 0.416$, $P = 0.038$). Responders also exhibited thinner DLPFC ($r = -0.797$, $P = 0.000$) and lower CBF levels.

Conclusions The development of biomarkers for rTMS represents a novel and encouraging technique for a personalized and effective treatment while reducing ineffective treatment costs and personal burden in adolescent MDD.

Adults with persistent ADHD: Gender and psychiatric comorbidities – a population-based longitudinal study

K. Yoshimasu^{1,*}, W.J. Barbaresi², R.C. Colligan³, R.G. Voigt⁴, J.M. Killian⁵, A.L. Weaver⁵, S.K. Katusic⁵

¹ Wakayama Medical University, Hygiene, Wakayama city, Japan

² Boston Children's Hospital, Medicine, Boston, USA

³ Mayo Clinic, Psychiatry and Psychology, Rochester, USA

⁴ Baylor College of Medicine, Pediatrics, Houston, USA

⁵ Mayo Clinic, Health Sciences Research, Rochester, USA

* Corresponding author.

Objective To evaluate in adults the associations between persistent ADHD and comorbid psychiatric disorders and gender differences, among subjects from a population-based birth cohort.

Method Subjects were recruited from a birth cohort of all children born during 1976–1982 who remained in Rochester, MN after five years of age. Participating subjects with research-identified childhood ADHD ($n = 232$; mean age 27.0 years; 72% men) and non-ADHD controls ($n = 335$; mean age 28.6 years; 63% men) were administered a structured psychiatric interview (MINI-International Neuropsychiatric Interview) to assess current ADHD status and comorbid psychiatric disorders.

Results Among the 232 with research-identified childhood ADHD, 68 (49 men and 19 women) had persistent adult ADHD. Compared to subjects without childhood ADHD, adults with persistent ADHD were significantly more likely to have any (81% vs. 35%, $P < 0.001$) as well as each of the specific psychiatric comorbidities. The associations retained significance when stratified by gender and there were no significant gender by ADHD interactions on psychiatric disorders except for dysthymia with which ADHD was more strongly associated in women than men. Among subjects with persistent ADHD, externalizing psychiatric disorders were more common in men (73%) and internalizing disorders were more common in women (53%).

Conclusion Persistent ADHD is associated with an increased risk of comorbid psychiatric disorders in both adult men and women. Clinicians treating adults with persistent ADHD need to be aware of comorbid psychiatric disorders, especially externalizing disorders for men and internalizing disorders for women.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical correlates of comorbid chronic tics and Tourette syndrome in a National Inpatient Children's Unit

S. Zinna^{1,*}, M. Kyriakopoulos^{1,2,3}

¹ South London and Maudsley NHS Foundation Trust, National and Specialist Acorn Lodge Children's Inpatient Unit, London, United Kingdom

² Tourette Syndrome Clinic, Great Ormond Street Hospital for Children, London, United Kingdom

³ Institute of Psychiatry Psychology and Neuroscience, Kings College London, Child and Adolescent Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Chronic tics and Tourette syndrome (TS) can be comorbid with several neuropsychiatric conditions and may add to the complexity of children's clinical presentation and need for inpatient input.

Objectives To review the clinical notes of all children admitted to a National Children's Inpatient Unit (aged up to 12 years) over a 5-year period and analyse their demographic and clinical characteristics including the presence of chronic tics/TS.

Aims To assess the clinical correlates of comorbid chronic tics/TS in an inpatient preadolescent population.

Methods A retrospective naturalistic study of all patients admitted to our unit from 2009 to 2014 was conducted. Children with and without chronic tics/TS were compared in terms of age, gender, family history of mental illness, history of neurodevelopmental problems in siblings, medication on admission and at discharge, length of admission and functional outcomes using Chi² and *t*-tests for categorical and continuous data respectively.

Results A total of 133 children (mean age = 11.2 years) were included. Twenty-five (18.8%) were diagnosed with chronic tics/TS. Autism spectrum disorder was the most commonly comorbid diagnosis (84%), with the second most common being an anxiety disorder/OCD (52%). Statistically significant higher percentages of learning disability, neurodevelopmental problems in siblings, medication at discharge and longer inpatient admissions were identified in children with tics compared with the rest of the sample. No other differences were found.

Conclusions The prevalence of chronic tics/TS in children needing inpatient treatment is significant. In our sample, chronic tics/TS seem to represent a marker of increased neurodevelopmental deviance and overall symptom severity.

Diagnostic stability of acute and transient psychotic disorder: A systematic review and meta-analysis

Á. López Díaz^{1,*}, S. Galiano Rus¹, A. Soler Iborte², J.I. Aznarte López², J.L. Fernández González¹

¹ Hospital San Juan de la Cruz, Mental Health Services, Úbeda, Spain

² Hospital San Agustín, Mental Health Services, Linares, Spain

* Corresponding author.

Introduction The validity and diagnostic stability of acute and transient psychotic disorder (ATPD) has been questioned by several authors, since its introduction in the International Statistical Classification of Diseases (ICD-10).

Objective To determine the overall diagnostic stability of ATPD in scientific literature.

Method A systematic review and meta-analysis of prospective studies and retrospective chart reviews. Computerized search was performed in MEDLINE/PubMed, EMBASE, and Google Scholar, using the terms: “acute and transient psychotic disorder”, or “acute psychosis”, and “stability”, or “outcome”, or “long-term”, or “follow-up”, or “course”. Search was restricted to works in English published between 1993 and 2015, according to ICD-10 criteria. Opinion articles, individual case reports, researches with less than ten subjects, and overlapping studies were excluded. Data analysis was conducted using MedCalc software, version 15.8. Statistical procedure was calculated for meta-analysis of proportions.

Results Twenty-six studies met the inclusion criteria ($n = 10852$). For methodological purposes, a distinction was made between short-term (less than 2 years), medium-term (between 2–7 years), and long-term stability (more than 7 years). For short-term group ($k = 5$), the overall stability was 60.69% (fixed effects model); Cochran's heterogeneity statistic $Q = 14.9$, $I^2 = 73.15\%$, $P = 0.0049$. For medium-term group ($k = 15$), it was 49.99%; $Q = 181.6$, $I^2 = 92.29\%$, $P < 0.0001$. For long-term group ($k = 6$), it was 61.86%; $Q = 35.12$, $I^2 = 92.29\%$, $P < 0.0001$.

Conclusion The global stability of ATPD indicates at the validity of the construct, but should be redefined in future revisions of ICD, to clarify better diagnostic criteria, and more predictive power.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Human factors in driving accidents: A cognitive investigation in the Gulf context

Y. Alotaibi

Qatar University, Social Sciences, Doha, Qatar

Introduction Human factors have been reported as the reason behind the majority of car accidents. However, to date, no studies at least in the Arab world generally and Gulf area specifically, conducted a comprehensive examination of cognitive functioning as potential predictors of car accidents and driving violations.

Objectives Examining the role of cognitive functions e.g., verbal working memory, attentional control as predictors of traffic accidents and driving violations.

Aims Examining the predictability of individual's cognition of occurrence of driving violations and accidents.

Methods The study was carried on a sample of hundred and thirty two participants whose age ranged between 24 and 31 years. They were classified into groups of violators and non-violators, accident free and accident involved as well. Cognitive functioning were measured using self-reports and task performance, and a series of ANOVAS as well as stepwise multiple regressions were conducted to test the research hypothesis.

Results Findings showed significant differences between violators and non-violators and between the accident free and accident involved groups in almost all of the considered factors, except for the decision making factor. Moreover, Pearson product-moment correlations showed that there were significant negative correlations between age, driving violations, and cognitive performance and the accidents.

Conclusions Human cognition such as executive functioning and mental planning are key factors for predicting driving behavior and traffic accidents. The study results have many implications in diagnosing and preventing or at least reducing driving violations and road accidents.

⁴ Hackensack University Medical Center, Psychiatry and Behavioral Medicine, Hackensack, NJ, USA

* Corresponding author.

Introduction Previous transcranial magnetic stimulation (TMS) studies indicate that exposing the subjects to an emotionally valent stimulus results in larger motor evoked potentials (MEP). Up to date, no TMS studies have been conducted in order to investigate the effect of personal memories with emotional value on corticospinal excitability.

Objects To investigate changes in corticospinal excitability and sensorimotor integration induced by retrieval of negative or neutral autobiographical memories (AM).

Aims To contribute to a further characterization of neural circuits involved during the evocation of negative AM.

Methods In 12 healthy volunteers, we recorded motor evoked potentials (MEPs) elicited by TMS pulses during the retrieval of negative AM or neutral AM. Furthermore, we also tested Short-interval Intracortical Inhibition (SICI), Intracortical facilitation (ICF), Short and Long afferent Inhibition (SAI and LAI) in the two different experimental conditions.

Results Retrieval of negative AM induced a larger increase in MEP amplitude (35.01%) compared to neutral AM ($F_{(1,22)} = 7.04$, $P = 0.013$). Furthermore we showed that retrieval of Negative AM increased ICF ($F_{(1,22)} = 5$, $P = 0.03$) and decrease SAI ($F_{(1,22)} = 7.04$, $P = 0.039$). The other TMS parameters were different between conditions.

Conclusions Our results indicate that evocation of negative AM induce a complex modulation of excitatory and inhibitory sensorimotor networks. Further studies are needed to explore the link of these electrophysiological biomarkers with the strength, valence and specificity of negative AM.

Differential effects of APOE genotypes on intrinsic functional connectivity of the entorhinal cortex associated with episodic memory in amnesic mild cognitive impairment

J. Chen*, H. Shu, Z. Wang, D. Liu, Z. Zhang
Southeast University, Department of Neurology, Affiliated ZhongDa Hospital, School of Medicine, Nanjing, China

* Corresponding author.

Background The apolipoprotein E (APOE) gene is a well-established genetic susceptibility factor for the conversion from amnesic mild cognitive impairment (aMCI) to Alzheimer's disease (AD). Moreover, entorhinal cortex (ERC) is one of the earliest brain regions of AD pathology that disrupts the formation of episodic memory. The present study was the first to investigate whether there are differential effects of APOE polymorphism on functional connectivity (FC) of ERC and cognition in aMCI.

Methods The FC analyses of ERC in whole-brain were performed in 83 aMCI and 88 healthy controls (HC).

Results In the ERC network, aMCI with APOE epsilon 4 ($\epsilon 4$)-carriers showed decreased FC with the bilateral middle temporal gyrus (MTG) and the right precuneus (PCUN), and the right precentral gyrus (PreCG), while APOE epsilon 2-carriers showed increased FC (except decreased FC with the right PreCG) compared to HC. The altered FC between ERC and right MTG correlated with the impairment of episodic memory in aMCI carried APOE $\epsilon 4$ and $\epsilon 2$ allele.

Conclusions These results provide novel evidence that APOE $\epsilon 4$ and $\epsilon 2$ alleles affect multiple physiopathologic pathways in the ERC network, which aMCI with $\epsilon 4$ -carriers can accelerate

the pathological progression of network-based mechanisms while $\epsilon 2$ -carriers may play a protective role in contributing to a compensatory mechanism. It further suggests that APOE can appear to indirectly mediate the ERC-MTG neural pathway associated with the impairment of episodic memory in aMCI.

* Corresponding author.

Introduction Humans learn how to behave both through rules and instructions as well as through environmental experiences. It has been shown that instructions can powerfully control people's choices, often leading to a confirmation bias.

Aim To compare learning parameters in reinforcement learning task with and without instructions.

Methods We recruited 52 healthy adult control subjects (21 males, 31 females, age 30 ± 6.5 years). Participants completed Repeatable Battery of Neuropsychological Status (RBANSS). Twenty-seven participants completed additionally Probabilistic Selection Task (PST) while twenty-five participants completed Instructional Probabilistic Selection Task (IPST). To analyze learning parameters, we used Q-learning model with 3 parameters: learning rate due to positive and negative reinforcements as well as exploration-exploitation parameter.

Results Both groups did not differ with respect to cognitive functioning measured with RBANSS (immediate and delayed memory, visuospatial abilities, language and attention); however, participants who completed PST had trend-level statistically faster learning rates due to positive ($P = 0.099$) and negative reinforcements (0.057) in comparison to participants who completed IPST. Both groups did not differ with respect to exploration-exploitation parameter (0.409).

Conclusion In healthy adults, interference of confirmation bias can influence learning speed independent of cognitive functioning (immediate and delayed memory, visuospatial abilities, language and attention).

Risk associated to subtypes of seizure disorders in dementia patients

M. Habeych^{1,*}, R.C. Castilla-Puentes²

¹ Center for Clinical Neurophysiology, Neurological Surgery, Pittsburgh, USA

² Johnson and Johnson, Global Medical Safety, West Chester, PA, USA

* Corresponding author.

Introduction Seizure disorders have been identified in patients suffering from different types of dementia. However, the risks

associated with the subtypes of those seizures have not been characterized.

Objective/aim To compare the occurrence of seizure disorders (partial and generalized) between patients with and without a dementia diagnosis from the OPTUM database.

Methods All ages, and patients with full eligibility between January of 2005 to December of 2014, were included. Data from OPTUM, a de-identified, HIPAA compliant database, made up of 40.7 million private insured patient individual electronic health records from the US, were utilized. Using ICD-9 diagnoses, the occurrence of generalized or partial seizure disorders was identified. A comparison between patients with and without dementia was performed.

Results A total of 150,516 patient records had a dementia diagnosis, and, 56.38% of them were females. Patients with dementia when compared to those without dementia had higher risk for seizure disorders [odds ratio (OR)=6.5 95% CI=4.4–9.5]; grand mal status (OR=6.5, 95% CI=5.7–7.3); partial seizures (OR=6.0, 95% CI=5.5–6.6); motor simple partial status (OR=5.6, 95% CI=3.5–9.0); epilepsy (OR=5.0, 95% CI=4.8–5.2); complex partial epileptic seizures (OR=4.9, 95% CI=4.6–5.2); generalized convulsive epilepsy (OR=4.8, 95% CI=4.5–5.0); localization-related epilepsy (OR=4.5, 95% CI=4.1–4.9); petit mal status (OR=4.2, 95% CI=2.9–6.1); fits convulsions (OR=3.5, 95% CI=3.4–3.6); and complex febrile seizure (OR=2.5, 95% CI=1.6–3.9).

Conclusions The present study confirms that patients with dementia have higher risks for either generalized or partial seizures disorders when compared with patients without dementia.

Effects of BET inhibitor JQ1 on neurotoxicity in rat primary cortical neurons: A potential therapeutic approach in Alzheimer's disease

S.H. Han^{1,*}, K.J. Kwon¹, C.Y. Shin², S.Y. Chung³

¹ Konkuk University Medical Center, Neurology, Seoul, Korea

² Konkuk University School of Medicine, Pharmacology, Seoul, Korea

³ The Catholic University of Korea Incheon St-Mary Hospital, Pediatrics, Incheon, Korea

* Corresponding author.

Introduction The neuropathological features of Alzheimer's disease (AD) are deposition of amyloid plaques, neurofibrillary tangles and neuro-inflammation. Among these, neuro-inflammation is a common pathological substrate of neurodegenerative disease, such as AD, and Parkinson disease.

Aims Herein, we tested whether the inhibition of bromodomain and extra-terminal domain (BET) protein, a critical regulators of transcription in neurons, could attenuate the neuronal cell death and amyloid beta aggregation using rat primary cortical neurons. We also investigated whether a BET inhibitor could prevent the inflammatory processes and cognitive decline in an animal model of AD.

Methods The effects of BET inhibition on neuronal cell death were assessed in the followings:

- cell viability and reactive oxygen species generation;
- enzyme activity of tPA/PAI-1 measured by casein zymography;
- the signal pathways including BDNF/CREB and MAPKs using western blotting;
- the effects on inflammatory responses in an animal model of AD using immunohistochemistry.

Results JQ1, an inhibitor of Brd2/4 protein, significantly decreased the neuronal cell death in mixed cortical neurons in concentration-dependent manner but not in pure neurons. JQ1 increased the enzyme activity of tPA, which decreased the expression of Brd2 protein. JQ1 also decreased the ROS generation

and decreased cleaved caspase-3 expression. Moreover, Brd2 inhibition by transfection of Brd2 siRNA reduced amyloid beta aggregation.

Conclusion Our results suggested that BET inhibition might have therapeutic potential for AD. That is, Brd2 inhibition by JQ1 can prevent the neuronal cell death and neuroinflammation as well as amyloid beta aggregation through regulation of tPA/PAI-1 system.

Cognitive engagement profile of the fluency tasks performance by patients with schizophrenia

H. Karakula-Juchnowicz^{1,*}, P. Krukow², J. Morylowska-Topolska², M. Flis³

¹ Medical University of Lublin, Department of Clinical Psychiatry, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland

² Medical University of Lublin, Department of Clinical Psychiatry, Lublin, Poland

³ Medical University of Lublin, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland

* Corresponding author.

Introduction Fluency tasks, e.g. verbal, design fluency test, etc. are often used in the evaluation of cognitive function in patients with schizophrenia. In the standard approach, the test result is the sum of stimuli generated in a given time period. However, this approach does not allow to determinate of what strategies are used by subjects to regulate the cognitive engagement during task execution.

Aim To investigate the specific dynamic profile of fluency tests performance comparing with healthy controls.

Methods Thirty patients diagnosed with schizophrenia and 30 demographically matched healthy controls took part in the study. Participants performed two tests: COWAT (3 trials) and Ruff Figural Fluency Test in accordance with the original instructions. During the generation of these stimuli, the investigator wrote down their quantity in 15-second intervals, which enables the assessment of cognitive engagement variability in different parts of the whole time (1 minute).

Results Comparison of cognitive engagement variation in both fluency tests showed statistically significant differences. The differences in repeated measures ANOVA with group as an independent variables reached $P < 0.0001$. Factor differentiating the profiles in verbal and figural fluency was first 15 seconds after the tasks started.

Conclusions The beginning of task was the most difficult part for patients with schizophrenia, which may indicate that the overall worse performance of fluency tests is associated with significant difficulties in mobilizing the cognitive activity.

Temporal correlates of intuition and cognitive control in moral decision, making in different social contexts

F. Keshvari^{1,*}, Z. Rezvani¹, F. Ghassemi², H. Pouretamad¹

¹ Shahid Beheshti University, Institute for cognitive and brain science, Tehran, Iran

² Amirkabir University of Tehran, Faculty of Bioelectric Engineering, Tehran, Iran

* Corresponding author.

In the stream of flurry of publications grappling different paradigms to tackle underlying mechanisms of moral decision-making, EVENT RELATED POTENTIAL (ERP) studies is beginning to explore psychophysiological components in the moral domain, focused on observing various moral behaviors in the experimental situations. This research was aimed at providing a new method of study investigating neural correlates of subjective moral decision-making in which we hypothesize that the social congruent or in-congruent context, could emerge a salience brain response in intuitive or cognitive control related responses toward moral dilemmas. Electrophysiological data were recorded from the scalp a 32-channel recording system complying with the international 10–20 system. The average N2 (175–300 ms) and LPP (300–600 ms) amplitude and latency were measured after the onset of putative counterpart response. Repeated measure ANOVA revealed that there was a difference between congruent versus in-congruent social response to high conflict scenarios in LPP amplitude in right lateral and frontal electrodes $F_{(4, 174)} = 5.812, P < 0.001$ (Fig. 1). The findings also, suggest that N2 latency in less conflict moral scenarios may appear earlier compared with high conflict moral scenarios during in congruent social response in frontal electrodes especially left area $F_{(3, 174)} = 3.013, P < 0.05$ (Fig. 2, figures are not available for this abstract). In conclusion, these results were either extend previous neurophysiological findings on classic moral scenarios and consistent with the notion that right hemisphere would be much more representative of cognitive control process during high conflict moral decision-making, while left frontal electrodes engaged in early intuitive process.

Keywords Moral decision-making; Cognitive control; Intuition; Social context; Late positive potential; N2

Depressive pseudodementia in Greek patients: How differential diagnosis can lead to early diagnosis

G. Lyrakos^{1,*}, N. Tsioumas², V. Spinaris¹, E. Margioli³, P. Sakka³, I. Spyropoulos¹

¹ General Hospital Nikaia "Ag. Panteleimon", Psychiatric, Nikaia, Greece

² City Unity College-Cardiff MET, MSc Health Psychology, Athens, Greece

³ Day Center of Alzheimer's Disease, Day center, Athens, Greece

* Corresponding author.

Background The term Pseudodementia, as presented by Kiloh, is being used to describe the clinical image characterized by depression combined with impairment in cognitive functions which reacts positively in treatment with antidepressants.

Aim To explore the aspects that make this condition unique, so that mental health professional will be able to use the proper psychometric tools when they face patients with confusing symptoms.

Method Hundred and thirty-one participants were recruited from the B' Psychiatric Clinic of G.H.N.P "Agios Panteleimon" and Day Center of Alzheimer's Disease in Amarousion, with 56 (42.7%) males and 75 (57.3%) females. All participants were administered the MoCA and the DASS21 questionnaires. Statistical analysis was performed with SPSS21.

Results The findings reported a significant difference in the scores of MoCA done by patients with dementia ($M = 13.9, SD = 5.4$) and patients with depression ($M = 20.5, SD = 4.9$) while both groups scored below the accepted scores indicating cognitive impairment [CI]. However, analysis showed that in the following sectors of MoCA, depressive patients scored significantly higher than demented ones: visuospatial ($MD = 0.651$), clock ($MD = 1.288$), orientation ($MD = 1.212$) and delayed recall ($MD = 1.329$).

Conclusion Findings shows a significant pattern in the difference between depressed and patients with cognitive impairment. These findings suggest that mental health professionals should use neuropsychological measurements like MoCA when evaluating such cases in order to be able to diagnose effectively cases of pseudodementia.

Hemispheric processing of idioms in schizophrenia and autism spectrum disorder

N. Mashal^{1,*}, R. Saban-Bezael¹, S. Hess², D. Dolfin², H. Hermesh²

¹ Bar Ilan university, Education, Ramat gan, Israel

² Geva Mental Health, Geva Mental Health, Petah Tikva, Israel

* Corresponding author.

Introduction Schizophrenia (SZ) and autism (ASD) have been historically considered as a related diagnostic category. Studies point to difficulties in comprehension of figurative language and a tendency to interpret it in a literal manner in both populations.

Aims To examine idiom comprehension and pattern of hemispheric processing of idioms in SZ as compared to ASD.

Methods Nineteen adults diagnosed with SZ, 24 adults diagnosed with ASD, and 22 typically developing (TD) adults participated in the study. The SZ and the ASD groups were matched by gender and verbal abilities. Participants performed a lexical decision task to either literally or idiomatically related target words presented to either the left or the right visual field using the divided visual field paradigm.

Results First, although both SZ and ASD groups performed worse than TD, they demonstrated relatively unimpaired comprehension of idiomatic expressions. No significant difference in idiom comprehension was found between the SZ and the ASD groups. Second, adults with SZ demonstrated a similar pattern of hemispheric lateralization (i.e. right lateralization) as TD participants during the processing of the literal interpretations of idioms. In contrast to SZ and TD participants, ASD participants demonstrated a bilateral pattern of hemispheric processing.

Conclusions Our findings suggest that brain lateralization is intact in adults with SZ but atypical in adults with ASD. The atypical hemispheric processing in addition to relatively unimpaired understanding of figurative language can point to a compensation mechanism in ASD. Thus, the current findings point to a different brain mechanism in each clinical group.

Do patients with better neuro-cognition have better theory of mind?

J. Mrizak*, A. Arous, R. Trabelsi, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction Theory of mind (ToM) has repeatedly been shown to be compromised in many patients with schizophrenia (SCZ). By contrast, the association between ToM deficits and neuro-cognitive functioning (NF) remains uncertain.

Objectives To investigate the association between ToM functioning and neuro-cognitive functioning in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the intention-inferencing task (IIT), in which the ability to infer a character's intentions from 28 short comic strip stories is assessed. They also completed a neuro-cognitive battery comprising the following tests: the Hopkins Verbal Learning Test–Revised (HVLT-R), the Letter Digit Substitution Test (LDST), the Stroop Test (ST), the “Double Barrage” of Zazzo (DBZ), the Modified Card Sorting Test (MCST), Verbal Fluency (VF), the Trail Making Test–Part A (TMT-A) and the Digit Span (DS).

Results The performance in the IIT significantly correlated with performance in some neuro-cognitive tests including efficiency in DBZ, number of uncorrected mistakes in ST, number of correct categories in MCST and the time needed to succeed the TMT-A. No correlations were found between performance in the IIT and in memory tasks (HVLT-R and DS).

Conclusions ToM may rely on some neuro-cognitive functions (mainly attention and executive functioning). Elucidating the exact relationship between ToM and NF may be useful as both are targeted in specific psychotherapeutic interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive, anxiety and depressive disorders in middleage subjects with metabolic syndrome are associated with elevated endocannabinoid plasma level

V. Piotrovskaya*, N. Neznanov

First State Pavlov Medical University, Psychiatry, St. Petersburg, Russia

* Corresponding author.

Obesity and metabolic syndrome (MS) are associated with an increased risk of developing psychiatric disorders, such as mood disorders and cognitive disorders. Endocannabinoids (EC) are neuromodulators which are involved in a plenty of physiological processes: regulation of motor activity, neuroprotection, modulation of immune function and inflammatory responses, antiproliferative actions in tumoral cells, control appetite. Endogenous cannabinoids play modulatory role in cognitive and emotional processes (1).

Aim of this study was to evaluate a possible association between EC plasma levels, such as anandamide (AEA) and 2-arachidonoylglycerol (2-AG), and mental processes such as, cognitive impairment and anxiety in obesity. And thus determine the participation of the EC system in the development of cognitive and emotional disorders with obesity.

Methods and results Data analyzed from 271 patients with MS according IDF criteria (aged 30–60 years). Current mild cognitive impairment (MCI), depressive (D) and anxiety disorders (A) were confirmed by psychodiagnostic interview according to the criteria of ICD-10. All patients passed through: MMSE test, scales HADS, HARS, HAM-A. Determining the ES level (anandamide, 2-AG) by liquid chromatography. Subjects were divided into 2 groups, group A – with D and/or A (139) and group B – without affective disorders (132). Using Mann-Whitney test significant connection between high levels of 2-AG level and affective disorders in group A were obtained. Subjects with D and A and MCI had higher level of 2-AG and AEA in comparison with only MCI.

Conclusion Increased levels of 2-AG and AEA provoke comorbidity of MCI depression and anxiety.

Neurocognitive and functional performance in psychotic and non-psychotic bipolar patients and schizophrenia patients

A. Aparicio^{1,*}, E.M. Sánchez-Morla², J.L. Santos³

¹ University of Castilla La Mancha, School of Nursery, Cuenca, Spain

² University of Alcalá, School of Medicine, Psychiatry, Alcalá de Henares, Spain

³ Hospital Virgen de La Luz, Psychiatry, Cuenca, Spain

* Corresponding author.

Introduction It has been suggested that psychotic bipolar patients have more severe cognitive deficits and lower functioning than non-psychotic bipolar patients.

Objectives To evaluate neurocognitive and functional performance in stabilized psychotic bipolar patients (BP+), non-psychotic bipolar patients (BP–) and schizophrenia patients (SZ).

Aims To examine whether BP+ might be defined as a more homogenous subtype of bipolar disorder with more severe cognitive deficit and more severe functional impairment.

Methods Fifty TB+, 50 TB–, 50 SZ and 51 controls were evaluated with a comprehensive neurocognitive battery (WCST, FAS, TMT-A and B, Stroop Test, Digits span, letters and numbers – WMS-III–, CVLT, ROCFT, CPT-DS). Moreover, patients were evaluated with clinical scales (PANSS, MADRS, YMRS) and functionality scales (WHOs Disability Assessment Scales, QLS and GAF). IBM SPSS Statistics (version 19.0) was used to the data analysis.

Results No significant differences were found between three patients' samples ($P < 0.0001$). No significant differences in neurocognitive measures were found between BP+ and BP–. Significant differences were found between both groups of bipolar patients and schizophrenia in working memory measures ($P < 0.0001$). BP+ and BP– showed significant higher functionality than SZ ($P < 0.0001$), without significant differences in functionality between BP+ and BP–.

Conclusions The pattern of neurocognitive and functional deficit is similar in BP+ and BP–. The neurocognitive deficit is very similar in both groups of bipolar patients groups in comparison to SZ; functionality is better in both bipolar groups than in schizophrenia patients.

Neurocognitive training in the complex therapy of patients with schizophrenia

A. Sofronov^{1,*}, A. Spikina²

¹ Saint Petersburg, Russia

² North West Medical University named by I.I. Mechnikov, psychiatry, Saint Petersburg, Russia

* Corresponding author.

Neurocognitive deficits in schizophrenia patients is a major health and social problem of modern psychiatry nowadays. Many patients with schizophrenia are of working age and there is a high enough percentage of their disability.

Objective To study the influence of neurocognitive training on higher cortical functions in schizophrenia patients and to evaluate their effectiveness in the treatment of schizophrenia.

Material and methods We formed groups of patients diagnosed with paranoid schizophrenia undergoing treatment in the departments of rehabilitation and day hospital. Patients of the main group (102 patients) additionally participated in the training of cognitive deficits. Patients included in the comparison group (48 patients) received only pharmacotherapy.

Study design Initial evaluation of patients was carried out at the first call, prior to the neurocognitive training. Follow-up study was conducted one month after completion of training programs and the final examination, after a year. In the comparison, group surveys were conducted with the similar frequency.

Results After training, the cognitive processes in schizophrenia patients were obtained by increasing the tempo of the performance, improving concentration, improving the adequacy of long-term thinking and memory have identified trend towards an increase in operational short-term memory. According to the survey indicated, with an increase in all indicators (the difference with the control group ranged from 3 to 26%), the maximum improvement falls on visual memory, and minimal attention to the function.

Conclusion The neurocognitive training showed itself as an effective method of correcting neurocognitive deficits.

Is empathy correlated to patients' level of cognitive impairment in schizophrenia?

R. Trabelsi*, A. Arous, J. Mrizak, H. Ben Ammar, A. Khalifa, Z. El Hechmi

Razi Hospital, Department Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction Empathy, which refers to the ability to understand and share the thoughts and feelings of others, may be compromised in schizophrenia (SCZ). Yet the relationship between empathy and neurocognitive functioning remains unclear.

Objectives To explore whether cognitive and affective empathy are associated with the neurocognitive functioning in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the Questionnaire of Cognitive and Affective Empathy (QCAE) comprising five subscales intended to assess cognitive and affective components of empathy. They also completed a neurocognitive battery comprising the following tests: the Hopkins Verbal Learning Test–Revised (HVLTR), the Letter Digit Substitution Test (LDST), the Stroop Test (ST), the “Double Barrage” of Zazzo (DBZ), the Modified Card Sorting Test (MCST), Verbal Fluency (VF), the Trail Making Test-Part A (TMT-A) and the Digit Span (DS).

Results Better affective and cognitive empathy correlated with better performance in the ST (less hesitations and less errors). Patients with better cognitive empathy performed better in the MCST (more categories achieved; $P=0.029$) and in the LDST (more substitutions per minute; $P=0.031$).

Conclusions Our results bolster support for the presence of an association between NF and the decreased cognitive and affective empathy in schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical symptomatology and empathy in schizophrenia: Which relationship?

R. Trabelsi*, J. Mrizak, A. Arous, H. Ben Ammar, A. Khalifa, Z. El Hechmi

Razi Hospital, Department Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction The impairment of cognitive and affective empathy among patients with schizophrenia (SCZ) may represent a significant feature of the illness. However, the relationship between those impairment and dimensions of psychosis remains unclear.

Objectives To explore whether cognitive and affective empathy are associated with severity of different psychotic symptoms.

Methods Cognitive and affective empathy were evaluated in 58 patients with stable schizophrenia with the Questionnaire of Cognitive and Affective Empathy (QCAE) comprising five subscales intended to assess cognitive and affective components of empathy. Symptomatology evaluation comprised the Positive and Negative Syndrome Scale (PANSS), the Calgary Depression Scale for Schizophrenia (CDSS) and the Clinical Global Impressions Scale Improvement and severity (CGI).

Results Patients with better cognitive empathy had less total CDSS scores ($P=0.036$, $r=-0.449$) and lower CGI-severity scale scores ($P=0.01$, $r=-0.536$). Patients with better affective empathy had lower scores (which means a better improvement) at the CGI-improvement scale ($P=0.03$, $r=-0.461$).

Conclusions Our results suggest that empathy with its different component is not totally independent of the clinical state of the patient. Further studies are required to confirm whether empathy deficits are state or trait aspects of SCZ.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depressive symptoms in patients with schizophrenia

T. Aladashvili

Tbilisi, Georgia

Introduction Depression is common among patients with schizophrenia and is associated with a wide range of poor outcomes, including psychotic relapse and suicide. The aim of the study is to evaluate the presence of depressive symptoms in patients with schizophrenia and to compare depression intensity in schizophrenic patients and patients with depressive disorder.

Methods In this cross sectional study were included 40 patients from both genders. Patients were divided in 2 groups: (1) examined group: 20 schizophrenic patients who presented depressive symptomatology. Depressive symptoms-evaluated with the 17-item Hamilton Rating Scale for Depression. Inclusion criteria: schizophrenic disorder by ICD-10 (F20.0-F20.9), total score higher than 7 on the HRSD-17 and age between 25 and 65; (2) control group: 20 patients with depressive disorder. Inclusion criteria: recurrent depressive disorder by ICD-10 (F33.0-F33.9), total score higher than 7 on the HRSD-17 and age between 25 and 65. Psychiatric rating scales for clinical evaluation of prominence of symptomatology: 17-item Hamilton Rating Scale for Depression (HRSD-17) and PANSS (Positive And Negative Syndrome Scale).

Results The prevalence of patients with depressive symptoms among the schizophrenic patients was 45% i.e. out of 20 evaluated patients with schizophrenia, 9 showed depressive symptoms. The total score in the remaining 11 patients on the HRSD-17 was lower than 7 and they were excluded. Difference between the two groups for gender difference was not statistically significant.

Conclusions The percentage of patients with depressive symptoms among the patients with schizophrenic disorder was 45%. Schizophrenic patients more frequently presented mild and moderate depression in comparison to the control group. In the majority of subjects with schizophrenia and depressive symptoms positive schizophrenic symptomatology was predominant.

Nalmefene in alcohol use disorder subjects with psychiatric comorbidity: A preliminary report

M. Di Nicola^{1,*}, L. De Riso¹, M. Pettorruso¹, L. Moccia¹, G. Martinotti², L. Janiri¹

¹ Institute of Psychiatry and Psychology, Catholic University of Sacred Heart, Rome, Italy

² Institute of Psychiatry, Department of Neuroscience and Imaging, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy

* Corresponding author.

Introduction Nalmefene is the first drug approved to reduce alcohol consumption in Alcohol Use Disorder (AUD) patients with a high drinking risk level. There is a high prevalence of concurrent psychiatric disorders in AUD patients, with an associated increased morbidity and poorer prognosis.

Objectives Despite high comorbidity rates, little attention has been paid to the clinical management of these patients.

Aims The aims of our study were to evaluate the use of nalmefene in AUD patients with psychiatric comorbidity, previously treated unsuccessfully for alcohol dependence, and to assess reduction in craving.

Methods Thirty AUD outpatients (M/F: 19/11) with stabilized anxiety and affective comorbid disorders were treated with as-needed nalmefene 18 mg plus psychosocial support for 24 weeks. Primary outcome measures were: changes in heavy drinking days (HDDs) and total alcohol consumption (TAC, g/day). Secondary outcome measures were: changes in Drinking Risk Level (DRL) and craving levels (Obsessive-Compulsive Drinking Scale [OCDS] and Visual Analogue Scale for craving [VASc]).

Results The reduction of HDDs and TAC over time was significant ($P < 0.001$). A decrease of DRL was reported. Moreover, a significant reduction in craving levels was observed (OCDS and VASc craving scores, $P < 0.001$). No patients dropped out of the study due to adverse events.

Conclusions As-needed nalmefene was well tolerated and useful in reducing drinking in AUD patients with stabilized psychiatric comorbidity that had not responded to previous interventions for alcohol dependence. Nalmefene also reduced craving, which is related to the motivation to consume alcohol.

Substance abuse and quality of life in chronic hepatitis C patients receiving antiviral treatment

E. Egmond^{1,*}, G. Oriolo¹, M. Cavero¹, K. Langohr², R. Solà³, R. Navines¹, R. Martin-Santos¹

¹ Hospital Clínic, Psychiatry and Psychology, Barcelona, Spain

² Polytechnic University of Barcelona, Statistics and Operation Research, Barcelona, Spain

* Corresponding author.

Introduction Chronic hepatitis C virus (HCV) is one of world's most important chronic infections. HCV can be treated using interferon-alpha (IFN α) and ribavirin (RBV). HCV, IFN α and RBV are known to impair mental and physical life quality. Many HCV-infected individuals have life-prevalence of substance use disorder (SUD).

Objectives To study life quality (SF-36) in HCV patients with SUD history during antiviral treatment.

Methods SF-36 questionnaire was assessed in 384 HCV patients at baseline, and at 4, 12, 24, and 48 weeks of treatment. ANCOVA models were used to study the association of SF-36 scores and

potential risk factors at baseline. Risk factors from baseline scores over time were studied through linear mixed models, adjusting for baseline scores.

Results At baseline, SUD men had worse mental ($P = 0.03$) and physical health ($P = 0.022$), and younger patients had worse social functioning ($P = 0.011$), and mental ($P = 0.001$) but better physical health ($P < 0.001$). Figs. 1 and 2 show the results of mental and physical life quality during treatment from baseline.

Conclusions This study emphasizes the decrease in life quality in HCV patients with SUD before and during antiviral treatment.

Grant Instituto de Carlos III-FIS: PSICOCIT-PI110/01827,EU "One way to make Europe", Ministerio de Economía y Competitividad (MTM2012-38067-C02-01), and support of SGR/2014/1135.

Challenging patients: Human misery

I. Ganhao^{1,*}, S. Paiva², J. Cardoso²

¹ Qta do Anjo, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria Geral e Transcultural, Lisbon, Portugal

* Corresponding author.

Introduction Psychiatry has seen significant progress in recent decades due to scientific advances. However, beyond genes, neurotransmitters and neurocircuits, there is a truly human dimension that escapes all the science. The choices each one makes, even if biologically mediated, and the consequences, even if mediated through individual vulnerabilities, dictate an outcome. That outcome may be a biopsychosocially ill individual. Health professionals trained and up-to-date on the latest research are confronted with challenges that far outweigh what they expected and know what to do with, defying the humanity of even the most humane.

Objective To reflect upon a clinical case of human misery.

Aims To promote growth at a professional and personal level through the process of treating challenging patients.

Methods Presentation of a clinical case.

Results A homeless person with a history of and current drug use, prostitution, untreated HIV-AIDS, hepatitis B and C, untreated *Mycobacterium lentiflavum* pulmonary infection, bleeding rectal prolapse, prolonged psychotic manic episode and a very difficult personality has trouble finding and ultimately rejects help from medical professionals and ends up involuntarily admitted to a psychiatric inpatient unit.

Conclusions Many unsolvable or only partially solvable puzzles end up under psychiatric care. The complexity of human nature escapes all scientific advances. We can put many pieces together but the whole often remains a challenge, a challenge of our values, our motivation, creativity and resilience.

The prevalence of aggressive behaviors among patients with psychiatric disorders: A case study analysis from Jordan

A. Hamdan-Mansour

University of Jordan, Faculty of Nursing-community health Nursing, Amman, Jordan

The study examined the prevalence behavior among patients with psychiatric disorders in psychiatric hospitals in Jordan. Case study analysis was employed through using a non-experimental descriptive survey design. Data were collected through using a modified overt aggression scale and additional information was obtained through a self-designed questionnaire containing socio-demographic and psychiatric illness variables. A total of 203 subjects satisfied the inclusion. The prevalence of aggression in this study was 23.6%. This is inconsistent with previous studies done elsewhere. The findings of this study showed that patients, prior admission, had higher frequencies of aggression than after being admitted and used the same forms of aggression prior to and after admission while reports after admission were less. Also it showed that beating and swearing were reported highly and a considerable number of patients were still attempting to self-harm and committing suicide by hanging themselves. The results are useful in raising the awareness of mental health nurses care providers and recommended that mental health nurses care should be equipped with necessary skills in managing aggressive behaviors among patients with psychiatric disorders (Table 1).

Table 1 Aggression among patients admitted to psychiatric care units in Jordan ($n = 203$).

Variable	Prior admission		Post-admission	
	<i>n</i>	%	<i>n</i>	%
<i>Aggression against</i>				
Himself	34	16.7	12	5.9
Father	26	12.6	2	1.0
Mother	39	19.2	4	2.0
Wife	21	10.3	2	1.0
Children	16	7.9	1	0.5
Relatives	44	21.7	2	1.0
Others	84	41.4	5	2.5

Agitation in the patient with dual pathology

L. Hernández Plaza^{1,*}, M. García Navarro², E. Delgado Parada¹, E. Ochoa Mangado¹, E. Salvador Vadillo¹, S. Molins Pascual¹

¹ Hospital Ramon y Cajal, Psiquiatría, Madrid, Spain

² Complejo hospitalario de Cáceres, Psiquiatría, Cáceres, Spain

* Corresponding author.

Introduction The consumption of toxic substances often causes agitation, which makes more difficult the pharmacological management of the symptoms.

Objective About one case, a search was performed of the different therapeutic options in the agitation takes place in the context of intoxication.

Methods Thirty-five-year-old male patient diagnosed of dual pathology under treatment since 2003 in our outpatient. The patient shows paranoid schizophrenia disorder due to alcohol, cannabis and cocaine use disorder, summing up different pharmacological treatments with no remission. Whilst the examination is taking place the patient is under alcohol and cannabis effects. His physical and verbal behaviour are aggressive showing psychotic instability. The therapeutic team administers loxapine to its patient.

Results The inhaled loxapine turned out to be a good alternative in the case given.

Conclusion Handling agitation when toxics are involved is complex. The new formulation of inhaled loxapine helps to control agitation quickly and it might be a feasible option for this kind of patients.

Comparing gaze related anxiety in adult subjects with autism spectrum disorder (ASD) or social anxiety disorder (SAD)

A. Jouni^{1,*}, A. Amestoy^{1,2}, M. Bouvard^{1,2}

¹ Centre hospitalier Charles-Perrens, centre ressource autisme, Bordeaux, France

² CNRS, INCIA UMR 5287, Bordeaux, France

* Corresponding author.

Social anxiety is frequently reported by individuals with ASD. If atypical eye gaze in ASD can not be fully explained by emotional

models, a subgroup seems to present an active gaze avoidance associated with the report of social anxiety symptoms. The main objective of our study was to examine the gaze related anxiety in a population of adults with ASD compared with what's observed in adults with SAD. The purpose was to confirm the experience of social anxiety for some individuals with ASD and quantify its impact on gaze functioning. We included adult patients diagnosed with ASD without intellectual disability ($n = 13$) or SAD ($n = 11$) from three outpatient clinics. Patients were divided in two groups, ASD and SAD, and filled three clinical scales: Gaze Anxiety Rating Scale (GARS, Schneier et al., 2011), Liebowitz Social Anxiety Scale (LSAS, Liebowitz et al., 1999), and Social responsiveness Scale-2 (SRS-2, Constantino et al., 2003). Patients with ASD presented higher scores on SRS-2 (M [SD]: 73.5 [8.9] vs 52.4 [10.4]; $P < 0.001$) and lower on LSAS (M [SD]: 58.6 (32.1) vs 83.8 [22.8]; $P < 0.05$) but no difference on GARS scores compared to people with SAD. Furthermore, a sub-group of ASD patients, presenting with more social anxiety, reported greater gaze related anxiety and avoidance than other patients with ASD (M [SD]: 57.8 (20.5) vs 19.4 [23.5]; $P < 0.05$). Social anxiety can be present in ASD with an impact on gaze functioning. The SRS-2 and LSAS seem to be efficient differentiating anxiety from social ability deficits and maybe useful to guide patients toward a specialised evaluation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW127

The influence of social comparisons made on Facebook and sociotropy on bulimia nervosa symptoms: A revised examination of the dual pathway model

I. Krug^{1,*}, F. Kalathas²

¹ University of Melbourne, Psychology, Melbourne, Australia

² University of Melbourne, Psychological Sciences, Melbourne, Australia

* Corresponding author.

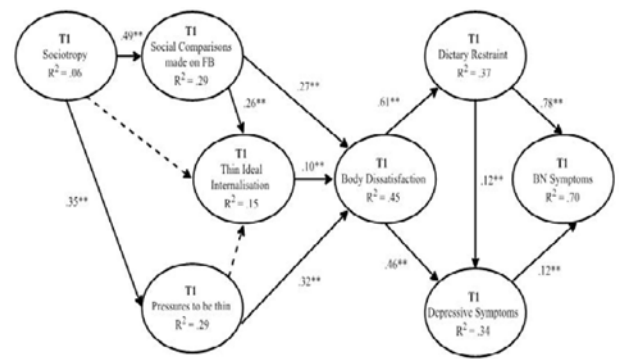

Background The dual pathway model (DPM) attempts to explain the processes that are etiological to the development of Bulimia Nervosa (BN) symptomology by examining both individual and sociocultural risk factors of BN. The DPM, however, is yet to incorporate the sociocultural factor Facebook, which is important given the widespread use of the social media website Facebook. In addition, research has suggested that the personality trait sociotropy may increase vulnerability to developing BN symptoms, however, there is limited evidence examining this factor in the DPM.

Objective To test a revised DPM with the inclusions of social comparisons made on Facebook and sociotropy both (a) cross-sectionally and (b) longitudinally.

Method Four hundred and seventy females participated at baseline (T1). Four weeks later, 274 females completed the follow-up assessment (T2), which assessed a subset of measures from the baseline assessment.

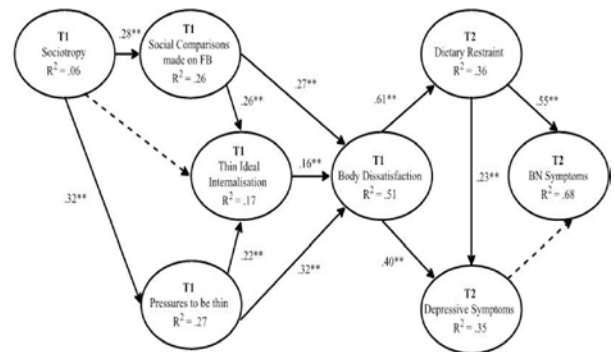

Results An acceptable fit for both DM models was obtained through Structural Equation Modeling (SEM) using MPlus (See Figs. 1 and 2).

Conclusions Prevention and early intervention efforts for both depression and BN should focus on addressing appropriate Facebook and social media use and these interventions should be tailored to individuals scoring high on sociotropy.

SEM fit statistics:
 χ^2 (df = 3970, N = 470) = 10530.76, $p < .001$
 CFI = .71
 RMSEA = .059
 SRMR = .07

Fig. 1 Revised cross-sectional DPM.

SEM fit Statistics
 χ^2 (df = 4530, N = 274) = 9244.12, $p < .001$
 CFI = .66
 RMSEA = .065
 SRMR = .10

A meta-analysis on the longitudinal relationship between eating pathology and depression

F. Puccio¹, M. Fuller-Tyszkiwicz², D. Ong¹, I. Krug^{3,*}

¹ University of Melbourne, Psychological Sciences, Melbourne, Australia

² Deakin University, Psychology, Melbourne, Australia

³ University of Melbourne, Psychology, Melbourne, Australia

* Corresponding author.

Background Despite the considerable number of studies that have assessed evidence for a longitudinal relationship between eating pathology and depression, there is no clear consensus regarding whether they are uni- or bi-directionally related.

Objective To undertake a meta-analysis to provide a quantitative synthesis of longitudinal studies that assessed the direction

of effects between eating pathology and depression. A second aim was to use meta-regression to account for heterogeneity in terms of study-level effect modifiers.

Results Meta-analysis results on 30 eligible studies showed that eating pathology was a risk factor for depression ($r_m = 0.13$, 95% CI: 0.09 to 0.17, $P < 0.001$), and that depression was a risk factor for eating pathology ($r_m = 0.16$, 95% CI: 0.10 to 0.22, $P < 0.001$). Meta-regression analyses showed that these effects were significantly stronger for studies that operationalized eating pathology as an eating disorder diagnosis versus eating pathology symptoms ($P < 0.05$), and for studies that operationalized the respective outcome measure as a categorical variable (e.g., a diagnosis of a disorder or where symptoms were “present”/“absent”) versus a continuous measure ($P < 0.01$). Results also showed that in relation to eating pathology type, the effect of an eating disorder diagnosis ($b = -0.06$, $t = -7.304$, $P \leq 0.001$) and bulimic symptoms ($b = -0.006$, $t = -2.388$, $P < 0.05$) on depression was significantly stronger for younger participants.

Conclusions Eating pathology and depression are concurrent risk factors for each other, suggesting that future research would benefit from identifying factors that are etiological to the development of both constructs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The personality dimensions, depression and tobacco smoking among detoxified male alcoholics

G. Mandić-Gajic*, A. Eror, G. Dedic, Z. Stojanovic, M. Dolic, D. Jokovic, Z. Spiric

Military Medical Academy, Psychiatry, Belgrade, Serbia

* Corresponding author.

Introduction The co-occurrence of tobacco smoking and depression among alcoholics is frequent and uncertain. Some findings suggest that there are some shared aetiological factors, but a few clinical researches of personality dimensions among patients with these comorbidities were done.

Objectives The differences of personality dimensions, the pattern of cigarette use and depression between inpatient alcoholics and healthy subjects were explored.

Methods The one hundred primary male inpatient alcoholics were consecutively recruited. Eighty-six completed study and were compared with thirty male age matched healthy subjects. Semistructured clinical interview for sociodemographics and the pattern of cigarette and alcohol use data was applied. The depression was assessed by HAMD scale (Hamilton, 1960). The Eysenck personality questionnaire EPQ was completed. Student *t*-test for differences and Pearson test for correlation were used.

Results There were no significant sociodemographic differences between groups. Alcoholics smoked significantly more frequently than healthy subjects (86% vs. 50%) and had average mild depression degree after detoxification. The HAMD score for alcoholics vs. controls was 15.37 ± 6.20 vs. 1.43 ± 1.55 respectively. All personality dimensions did not show differences between groups, except neuroticism. The neuroticism showed significantly higher level among alcoholics vs. controls (12.72 ± 5.19 vs. 5.00 ± 3.36). The depression significantly correlated only with neuroticism ($r = 0.487$, $P < 0.001$).

Conclusions The majority of detoxified alcoholics were smokers with mild depression and higher neuroticism compared to controls. Our results suggest that the alcoholics with high neuroticism may experience higher depression and may require more intensive integrative treatment.

Body image and eating disorders are common in professional and amateur athletes using performance and image-enhancing drugs (pieds).

A cross-sectional study

D. Piacentino^{1,*}, L. Longo¹, A. Pavan², S. Ferracuti¹, R. Brugnoli¹, P. Girardi¹, G. Sani¹

¹ Sapienza, University of Rome, NESMOS Neuroscience, Mental Health, and Sensory Organs Department, Rome, Italy

² Sapienza, University of Rome, Immunohematology and Transfusion Medicine, Rome, Italy

* Corresponding author.

Introduction The use of Performance and Image-Enhancing Drugs (PIEDs) is on the increase and appears to be associated with several psychopathological disorders, whose prevalence is unclear.

Objectives/Aims We aimed to evaluate the differences—if any—in the prevalence of body image disorders (BIDs) and eating disorders (EDs) in PIEDs users athletes vs. PIEDs nonusers ones.

Methods We enrolled 84 consecutive professional and amateur athletes (35.8% females; age range = 18–50), training in several sports centers in Italy. They underwent structured interviews (SCID I/SCID II) and completed the Body Image Concern Inventory (BICI) and the Sick, Control, One, Fat, Food Eating Disorder Screening Test (SCOFF). Mann-Whitney *U* test and Fisher's exact test were used for comparisons.

Results Of the 84 athletes, 18 (21.4%) used PIEDs. The most common PIEDs were anabolic androgenic steroids, amphetamine-like substances, cathinones, ephedrine, and caffeine derivatives (e.g. guarana). The two groups did not differ in socio-demographic characteristics, but differed in anamnestic and psychopathological ones, with PIEDs users athletes being characterized by significantly (P -values < 0.05) higher physical activity levels, consuming more coffee, cigarettes, and psychotropic medications (e.g. benzodiazepines) per day, presenting more SCID diagnoses of psychiatric disorders, especially Substance Use Disorders, Eating Disorders, Body Dysmorphic Disorder (BDD), and General Anxiety Disorders, showing higher BICI scores, which indicate a higher risk of BDD, and higher SCOFF scores, which suggest a higher risk of BIDs and EDs.

Conclusions In PIEDs users athletes body image and eating disorders, and more in general psychopathological disorders, are more common than in PIEDs nonusers athletes.

* Corresponding author.

Introduction Sensory deficits such as blindness and deafness are very common forms of disability, affecting over 300 million people worldwide according to World Health Organization estimates. These conditions can lead to misinterpretations of the environment, which may contribute to the development of a delusional disorder in predisposed people.

Objectives The objective of this study is to establish the prevalence of blindness and hearing loss across delusional disorder.

Aims The aim is to provide useful information regarding this frequent, often disregarded, comorbidity.

Methods Our results proceed from the Andalusian delusional disorder case-register (DelirAnda). We reviewed 1927 clinical histories of patients diagnosed of delusional disorder. Upon having verified the diagnosis following DSM-V criteria, we recollected data on the prevalence of blindness and hearing loss, which were defined based on clinical diagnosis.

Results One thousand four hundred and fifty-two patients matched DSM-5 delusional disorder criteria. Among them, 49.8% of our sample were women. The overall prevalence of sensory deficits was 7.4%, 3.5% of the patients with delusional disorder were blind, while 3.9% of them suffered from hearing loss.

Conclusions Our results are consistent with previous studies, such as the Deliremp study, which found a 5.7% prevalence of sensory deficit among delusional disorder patients. These results show a higher prevalence of sensory deficit among delusional disorder patients compared with the general population. However, causality could not be established. Further study should be undertaken regarding the relationship between these two conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comorbidity between delusional disorder and chronic physical conditions. Results from the Deliranda case register

A. Porras Segovia^{1,*}, C. Carrillo de Albornoz Calahorra², M. Guerrero Jiménez², J. Cervilla Ballesteros^{1,3}

¹ University Hospital San Cecilio, Mental Health Services, Granada, Spain

² Santa Ana Hospital, Mental Health Services, Motril, Spain

³ University of Granada, Psychiatry Department, Granada, Spain

* Corresponding author.

Introduction Mental disorders are often comorbid with chronic physical conditions. This relationship has been looked into in some mental disorders, such as depression or schizophrenia. However, very few studies have explored this comorbidity in the delusional disorder.

Objectives The objective of this study is to establish the prevalence of common chronic medical conditions across delusional disorder.

Aims The aim is to provide useful information regarding this frequent, often disregarded, comorbidity.

Methods Our results proceed from the Andalusian delusional disorder case-register (DelirAnda). We reviewed 1927 clinical histories of patients diagnosed of delusional disorder. Upon having verified the diagnosis following DSM-5 criteria, we recollected data on the prevalence of 10 different medical conditions, which were defined based on clinical diagnosis.

Results One thousand four hundred and fifty-two patients matched DSM-5 delusional disorder criteria. Among them, 49.8% of our sample were women. The overall prevalence of medical conditions was 66%. Thirty-one percent of the patients with delusional disorder had only one comorbid physical condition, 20% of them suffered from two conditions, and 15% of them had three or more chronic conditions. The most prevalent physical condition among delusional disorder patients was diabetes, affecting 16% of these patients.

Conclusions Chronic physical conditions are highly prevalent among patients with delusional disorder. Comorbid physical conditions may have an important impact on the course of delusional disorder. A correct diagnosis and treatment of this comorbidity should be made to help improve the prognosis and life quality of these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Punding in Parkinson's disease: To a better understanding of a common phenomenon between Parkinson's disease and addictions

A. Tremey*, I. de Chazeron, G. Brousse, P.M. Llorca
CHU Clermont-Ferrand, psychiatry, Clermont-Ferrand, France

* Corresponding author.

Introduction Punding is a stereotypical motor behaviour characterized by a repetitive, excessive and non-goal oriented activity that causes an important loss of time. Since its first description in psychostimulant addicts, data on punding has only derived from studies on Parkinsonian patients treated with dopaminergic drugs. Little is known in the literature about Parkinsonian patient's characteristics who suffer from punding.

Objective We propose to study characteristics of Parkinsonian "punders" in order to investigate the pathophysiology of this phenomenon.

Methods In this retrospective study, we use the "Arduin Scale of Behavior in Parkinson's disease" database. This database was initially used to design a global scale to detect changes in mood and behavior of Parkinson's disease (PD) patients. We compared different variables between Parkinsonian patients who suffer from punding with non-punder Parkinsonian patients.

Results Eighty of the 258 patients were identified as punders. In univariate analysis, the punder and non-punder groups differed statistically with regard to the age of diagnostic of PD, hypersexuality and dopaminergic agonist treatment. In multivariate analysis, the punder and non-punder groups only differed statistically with regard to dopaminergic agonist treatment ($P=0.05$).

Conclusion Dopaminergic agonist treatments appear to be more represented among patients with punding in our sample. Impulse control disorders (ICD) are known to be more common in patients treated by dopamine agonists. Punding could be considered as the most severe form of ICD that is linked to psychomotor stimulation and reward mechanisms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Alexithymia and asthma

M. Turki^{1,*}, R. Naoui¹, N. Moussa², S. Sellami², I. Gassrara¹, N. Halouani¹, N. Hamza¹, J. Aloulou¹, S. Kammoun², O. Amami¹

¹ Hedi Chaker University Hospital, Psychiatry Department, Sfax, Tunisia

² Hedi Chaker University Hospital, Pulmonary Department, Sfax, Tunisia

* Corresponding author.

Introduction Alexithymia refers to difficulties in verbal expression of emotions, commonly observed in patients with psychosomatic symptoms. In this context, asthma is described as one of psychosomatic diseases.

Objectives Identify clinical profile of asthmatic patients and assess the alexithymia level as well as associated factors.

Methods We conducted a cross-sectional, descriptive and analytic study, including 30 patients followed for asthma at pulmonary outpatient department, Hedi Chaker Hospital, Sfax, Tunisia, during September and October 2015. We collected socio-demographic and clinical characteristics. Asthma control level was assessed by

the Asthma Control Test (ACT). Alexithymia was measured using Toronto Alexithymia Scale (TAS 20).

Results The mean age was 51 ans. Sex-ratio F/M was 14. The mean duration of disease was 11 years. Long-term control medicines were: inhaled corticosteroids, long-acting beta agonists and theophylline respectively in 86.7%, 33.3% and 26.7%. Two thirds of our patients had a bad therapeutic adherence. The average ACT score was 16.8 points. Asthma was uncontrolled in 1/3 and well controlled in 1/3 of cases. The average TAS 20 score was 64.8 points. Twenty percent of patients were non-alexithymic, 13.3% had a probable alexithymia and 66.7% were alexithymic. This score was positively correlated to bad asthma control ($P < 0.001$), long term evolution ($P = 0.002$) and use of inhaled corticoids ($P < 0.001$). It was inversely correlated to ACT score ($P < 0.001$).

Conclusion Our study shows the high prevalence of alexithymia in patients with asthma and its negative impact in asthma control. Psychological support aiming specifically alexithymic dimension in these patients is indispensable.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Developmental Coordination Disorder (DCD) defines a heterogeneous class of children exhibiting marked impairment in motor coordination.

Objectives Explore in depth a general group of deficits in fine and gross motricity (subtype mixed group) common to all research subtyping studies. We aimed to highlight discriminant features and specific comorbidities.

Methods Data from DCD children aged between 6 and 13 years were eligible for inclusion in this study on DSM-5 criteria. All children were assessed with a neuropsychological evaluation of all brain functions and with developmental standardized physical tasks in the neuropsychomotor battery (NP-MOT) which include detection of minor neurological dysfunction (MND) and neurological soft signs (NSS) using tone examination, never considered in most previous studies.

Results Findings show in an unexpected way, a high incidence, in 33% of the children, of a motor pathway dysfunction, evidenced by mild spasticity of gastrocnemius muscles in the lower limbs, associated with NSS, for instance failure of standing tone ($P = 0.004$) and dysdiadochokinesia ($P = 0.011$) versus salient DCD markers of the mixed subtype as imitation of gestures, fingers digital perception,

digital praxia, manual dexterity, and upper and lower limbs coordination. This mild spasticity (MND) appears as a comorbid disorder increasing impairment of coordination between upper and lower limbs and manual dexterity. It could explain why DCD appears as a collection of motor disorders in a heterogeneous groups in numerous studies.

Conclusions Our results provide important new evidence to implement an extensive neuro-developmental assessment (mental and physical), including neuromuscular tone examination using appropriate standardized neurodevelopmental tools (common tasks across ages).

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background High rates of psychiatric comorbidity are subject of debate: to what extent do they depend on classification choices such as diagnostic thresholds?

Aims/objectives To investigate the influence of different thresholds on rates of comorbidity between major depressive disorder (MDD) and generalized anxiety disorder (GAD).

Methods Point prevalence of comorbidity between MDD and GAD was measured in 74,092 subjects from the general population according to DSM-IV-TR criteria. Comorbidity rates were compared for different thresholds by varying the number of necessary criteria from ≥ 1 to all 9 symptoms for MDD, and from ≥ 1 to all 7 symptoms for GAD.

Results According to DSM-thresholds, 0.86% had MDD only, 2.96% GAD only and 1.14% both MDD and GAD (Odds Ratio [OR] 42.6). Lower thresholds for MDD led to higher rates of comorbidity (1.44% for ≥ 4 of 9 MDD-symptoms, OR 34.4), whereas lower thresholds for GAD hardly influenced comorbidity (1.16% for ≥ 3 of 7 GAD-symptoms, OR 38.8). Specific patterns in the distribution of symptoms within the population explained this finding: 37.3% of subjects with core criteria of MDD and GAD reported subthreshold MDD symptoms, whereas only 7.6% reported subthreshold GAD symptoms.

Conclusions Lower thresholds for MDD increased comorbidity with GAD, but not vice versa, owing to specific symptom patterns in the population. Generally, comorbidity rates result from both empirical symptom distributions and classification choices and cannot be reduced to either of these exclusively. This insight invites further research into the formation of disease concepts that allow for reliable predictions and targeted therapeutic interventions.

Classical homocystinuria and psychiatric disturbances – A case report

T. Abreu^{1,*}, C. Freitas², A.R. Figueiredo³¹ Centro Hospitalar do Tâmega e Sousa, Department of Psychiatry and Mental Health, Penafiel, Portugal² Centro Hospitalar do Tâmega e Sousa, Department of Psychiatry and Mental Health, Amarante, Portugal³ Centro Hospitalar de Trás-os-Montes e Alto Douro, Department of Psychiatry and Mental Health, Vila Real, Portugal

* Corresponding author.

Introduction Classical homocystinuria (cystathionine beta synthase deficiency) is a rare autosomal recessive disease of methionine metabolism that causes accumulation of homocysteine in the blood and cysteine deficiency. It is characterized by intellectual disability, ectopia lentis, skeleton abnormalities resembling Marfan syndrome and thromboembolic episodes. The majority of patients have psychiatric disturbances as depression, behavioral disorders, personality disorders, obsessive-compulsive disorder and, less commonly, bipolar disorder and psychosis.

Objectives and aims To briefly review psychiatric disturbances in patients with homocystinuria and present a case report.

Methods Literature research and analysis of patient's clinical data.

Results A 22-year-old male was diagnosed with classical homocystinuria at age 4 due to intellectual disability and renal alterations. With aging, other problems emerged: epilepsy; postural tremor; dysesthesia; ectopia lentis; orofacial myofunctional disorder; asthma; and patellar instability. He went to a special education program. At age sixteen, he initiated Child Psychiatry consultations due to anxiety and behavioral changes, as difficulty in controlling impulses, establishing relationships and in the perception of the self. Nowadays, the patient is followed in psychiatric consultations, where he has demonstrated high difficulty to empathize. He is being treated with vitamin supplements; betaine; levetiracetam; clobazam; and propranolol, combined with a special diet.

Conclusions It is not practical to screen every psychiatric patient for Homocystinuria, but this disease should be considered when there is a family history, early and/or acute onset, intellectual disability, atypical symptoms, unusual response to treatment, progressive cognitive change and other organic disturbances present in this disorder.

Personality profile, anxiety, and sexual satisfaction: A comparison between implanted penile prosthesis and intracorporeal injection

H. Dessoki^{1,*}, M. Abas², M. Nasr³, O. Sleim⁴¹ Beni-Sewef, Egypt² Kaser Aini, Andrology, Cairo, Egypt³ Kasr Aini, Psychiatry, Cairo, Egypt⁴ Kase Aini, Andrology, Cairo, Egypt

* Corresponding author.

Purpose of the study To evaluate personality profile, anxiety, patient satisfaction in patients with erectile dysfunction treated

with penile prosthesis as compared to those on Intracorporeal Injection (ICI) home therapy.

Patients and methods A total of 40 male patients complaining of erectile dysfunction were classified into two equal groups according to the line of treatment: Intracorporeal Injection (ICI) and penile prosthesis. Patients were subjected to the following questionnaires: Beck Anxiety Scale, Eysenck Personality Questionnaire, Sexual Satisfaction Scale and International Index of Erectile Function Questionnaire (IIEF-5).

Results Results for Beck Anxiety Scale showed statistically significant difference between both groups ($P=0.000$), while for Eysenck Personality Questionnaire, no significant difference was found in Psychoticism ($P=0.056$), Neuroticism ($P=0.169$), in Extraversion ($P=0.225$), Lie scale ($P=0.159$), and in Criminality ($P=0.378$). Statistically significant difference between both groups was found in the results of Sexual Satisfaction Scale, ($P=0.013$) and for the results of International Index of Erectile Function Questionnaire (IIEF-5), ($P=0.000$).

Conclusion Patients who underwent penile prosthesis implantation showed lower level of anxiety, better sexual satisfaction and erectile function, while no significant difference was found when comparing personality profile five dimensions Psychoticism, Neuroticism, Extraversion, Lie scale and Criminality.

Familial multiple cavernomatosis and neuropsychiatric symptoms: Is there any relation?

V. Espirito Santo^{1,*}, R. Almendra¹, A.R. Figueiredo², A. Almeida³, I. Rego⁴, P. Guimaraes¹, A.G. Velon¹¹ Centro Hospitalar Trás-os-Montes e Vila Real, Serviço de Neurologia, Vila Real, Portugal² Centro Hospitalar Trás-os-Montes e Vila Real, Serviço de Psiquiatria, Vila Real, Portugal³ Centro Hospitalar Trás-os-Montes e Vila Real, Serviço de Neurologia, Neuropsicologia, Vila Real, Portugal⁴ Centro Hospitalar Trás-os-Montes e Vila Real, Serviço de Neurorradiologia, Vila Real, Portugal

* Corresponding author.

Introduction Cavernomas are clusters of abnormal blood vessels found in the brain and spinal cord. The familiar form is an autosomal dominant disorder associated with the presence of multiple cavernomas in both locations.

Clinical Case A 84-year-old man was admitted in our neurologic department for a sudden onset of difficulty in walking associated with loss of urinary sphincter control. Past history included a major depressive disorder with psychotic features since youth, epilepsy since 33 years old and, at 77 years old, he had a hemorrhagic stroke resulting from cavernous malformation haemorrhage. Medication consisted of clopidogrel 75 mg id, risperidone 3 mg id, venlafaxine 37.5 mg bid and clobazam 10 mg id. On neurological examination, he showed psychomotor slowing, dysexecutive syndrome, paraparesis and hypoesthesia with sensitive level by D10. Blood test was normal. Dorsolumbar spine-TC showed intradural hyperdensity by D12-L1, probably because of a hemorrhage lesion, that MRI revealed to be a cavernoma. Brain-MRI demonstrated 3 massive cavernomas in cortical-subcortical right occipital lobe, left lenticular nucleus and left pre-central gyrus and countless small infratentorial and supratentorial cavernomas. We inquired his family and we found out that one of his daughters also had multiple brain cavernomas, diagnosed after a hemorrhagic stroke when she was 55 years old.

Conclusion Familiar multiple cavernomatosis is associated with neuropsychiatric disorders. We enhance the impact that such a diffuse form of the disease has on the brain network causing atypical

psychocognitive symptoms. In all cases a detailed neuropsychiatric family history should be sought and all should be followed regularly clinically and by MRI.

Parkinson disease psychosis – A case report

M.D.C. Ferreira^{1,*}, S. Varanda², G. Carneiro², B. Santos¹, Á. Machado²

¹ Hospital de Braga, Psychiatry, Braga, Portugal

² Hospital de Braga, Neurology, Braga, Portugal

* Corresponding author.

Introduction Psychosis is one of the most prevalent non-motor complications in Parkinson's disease (PD). Risk factors for PD psychosis are advancing age, longer disease duration, severe motor symptoms, presence of dementia, sleep disorders, depression and autonomic dysfunction. Treatment is challenging in this setting because antipsychotic medications are known to worsen motor symptoms.

Objectives To highlight the therapeutic difficulties in PD-related psychosis.

Methods Case description and literature review.

Results We report a case of a 74-year-old woman with a 9-year history of PD, who presented a complex psychotic disorder consisting in auditory, olfactory and visual (gulliverian and lilliputian) hallucinations, persecutory and sexual delusions. Additionally, the patient presented euthymic mood, without evidence of cognitive impairment or impulse-control disorder. These symptoms began after dopamine agonist therapy (ropinirole 4 mg/day). Other medical conditions that could justify these symptoms were excluded. Initially, ropinirole was removed, but without psychotic remission. Then, she was treated with antipsychotic medication (clozapine 25 mg/day) with full psychotic remission and without significant worsening of motor symptoms.

Conclusions Clozapine treatment is frequently delayed, mainly for fear of its side effects, particularly agranulocytosis. However, this antipsychotic drug presents many benefits regarding the management of PD-related psychosis, namely few motor effects and even improvement of motor fluctuations.

Surgery-first or orthognathic surgery approach: Psychosocial and physical changes

E. Gambaro^{1,*}, C. Vecchi², C. Gramaglia², A. Losa², M. Giarda³, E. Broccardo³, A. Benech³, P. Zeppegno²

¹ Azienda Ospedaliera Universitaria Maggiore della Carità di Novara, Novara, Italy

² Università del Piemonte Orientale, Medicina Traslazionale, Novara, Italy

³ Università del Piemonte Orientale, Testa e Collo, Novara, Italy

* Corresponding author.

Introduction Two surgical approaches exist for malocclusion: in the surgery-first approach the orthognathic surgery precedes the orthodontic treatment, treating facial esthetics first and then occlusion, whereas in the conventional approach (the orthodontics-first approach) the orthodontic treatment precedes the orthognathic surgery, treating occlusion first and then facial esthetics. The advantages of the surgery-first approach include the fact that patient's

dental function, and facial esthetics are restored and improved soon after the beginning of treatment. Moreover, the entire treatment lasts only 1 to 1.5 years or less and orthodontic management is easier to achieve.

Aims Our study aims to compare patients undergoing surgery-first or orthognathic surgery approach as for as self-esteem, satisfaction with their appearance in the pre- and postoperative care, quality of life and psychosocial changes, are concerned.

Methods We recruited 50 patients undergoing surgery-first or orthognathic surgery approach at SC Maxillo-Facciale of Novara between October 2014 and December 2017. Assessment were performed at baseline (T0) and at follow-up (T1: 5 weeks; T2: 5–6 months), with Rosenberg Self-Esteem Scale (RSES), Temperament and Character Inventory (TCI: only at T0), Short Form Health Survey 36 (SF-36), Beck Depression Inventory (BDI-II), Resilience Scale for Adult (RSA), Psychosocial Impact of Dental Aesthetics Questionnaire (PIDAQ), Oral Health Impact Profile (OHIP-14).

Results Data collection is still ongoing. We expect to find a better quality of life and higher self-esteem in patients undergoing surgery first approach.

Conclusion Satisfaction is crucial for patients' adherence to treatment and to avoid revolving door. Clinical implications will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Descriptive study of hypothyroidism in an acute psychiatric unit in Barcelona

G. Hurtado*, E. Carrió, A.L. Palomo, M. Campillo, G. Mateu, A. Farre, J. Marti, R. Sanchez, J.R. Fortuny

Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions Centre Emili Mira, Santa Coloma Gramenet, Spain

* Corresponding author.

Introduction Behavioural, psychological and cognitive disturbance have been associated with hypothyroidism, even it has been suggested that this symptoms may remain despite adequate replacement therapy with thyroxine.

Objective To describe prevalence, sociodemographics and clinical features of patients with hypothyroidism in an acute psychiatric unit.

Aims To know about the relation between hypothyroidism and psychiatric symptoms.

Methods Data base collection of all patients admitted between 2010 and 2014 in the acute unit of our psychiatric hospital in Barcelona, was analyzed using SPSS program.

Results In all 3.1% of the 4536 total patients had hypothyroidism. Among them, 46% were duplicate cases. Mean age was 53 ± 14.27 years. A total of 82.7% were woman. Patients having a TSH lower than 0.30 were 12%, TSH normal were 60.2%, TSH higher than 5 were 27.8%. Most frequent Levothyroxine dosage was: 75 µg (22.1%), 100 µg (19%), 25 µg (12.5%) and 125 µg (12.5%). Diagnosis more frequently associated with hypothyroidism was: Bipolar (26.5%), Schizophrenia (20%), Depression (15.1%), Unspecified psychosis (10%), Personality disorder (10%), Schizoaffective disorder (7.2%), Paranoia 4.3%.

Conclusion Most of patients were stable of thyroid condition when had been admitted to our hospital. Hypothyroidism could be a relapse factor, even when treatment is adequate. Affective disorders are more frequently related with hypothyroidism (lithium has to be consider a confounding factor).

Which percentage of patients with coronary artery disease and depression has been referred a psychiatrist?

A. Ghanbari Jolfaei^{1,*}, M. Soltanabadi²¹ Hazrat-Rasool Hospital, Psychiatry, Tehran, Iran² Mental Health Research Center, Iran University of Medical Sciences, Psychiatry, Tehran, Iran

* Corresponding author.

Introduction Recent studies indicate high prevalence of clinical depression and use of antidepressants in patients with coronary artery disease, but the evidence and data about these topics is scant in our country.

Aims The aim of the present study was to investigate the prevalence and severity of depression, risk factors associated with depression, the prevalence of use of antidepressants, specialty of the physician who prescribed the antidepressants and type of antidepressants in patients with coronary heart disease.

Methods In this cross-sectional study, the information of 540 patients with coronary artery disease were collected through their records. In determining the frequency and severity of depression, Hospital Anxiety and Depression Scale (HADS) test was used.

Results From 540 patients, 321 cases (4/59%) were male. Prevalence of depression among patients with coronary heart disease was 29.6%. The average score of Hospital Anxiety and Depression Scale was 6.31 ± 3.91 . Also, the prevalence of antidepressant use was 14.6% and 8.7% had a history of using SSRIs. Depression was associated with severity of coronary atherosclerosis, hypertension and diabetes. In three forth of patients the antidepressants were prescribed by a cardiologist or internist without referral to a psychiatrist and only 25% reported were referred to a psychiatrist.

Conclusion Approximately one third of patients with coronary artery disease suffered from depression and this depression were associated with more severe coronary artery disease and hypertension and diabetes. Less than one in five patients taking antidepressants mentioned referral to a psychiatrist.

Keywords Depression; Coronary artery disease; SSRI

Burnout among Portuguese oncology healthcare providers – Differences between pediatric and adult teams

R. Gonçalves^{1,*}, J.M.V.D. Ferreira¹, C. Araújo¹, M. Gonçalves², S. Pedroso³, C. Pinho³¹ Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Child and Adolescent Psychiatry, Coimbra, Portugal² Centro Hospitalar e Universitário de Coimbra, Psychiatry Department, Coimbra, Portugal³ Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Child and Adolescent Psychiatry, Liaison Psychiatry Unit, Coimbra, Portugal

* Corresponding author.

Introduction Burnout is characterized by emotional exhaustion, depersonalization and reduced personal accomplishment, resulting from the inability to cope with chronic job stress. The literature suggests that staffs working in adult oncology are at risk of burnout. At the same time, research found that pediatric staff experiences a different set of stressors when compared with colleagues working in adult oncology. However, no studies were identified which directly compared prevalence and sources of Burn-out on pediatric and adult oncology staff.

Objectives To compare the differences on prevalence and sources of burnout between pediatric and adult oncology multidisciplinary teams.

Methods Pediatric and adult oncology professionals, including medical and nursing from a Portuguese oncology center completed the Portuguese version of the Copenhagen Burnout Inventory. Data was analyzed using SPSS.

Results Since the study is currently ongoing the authors will only be able to provide final results and conclusions by the time of submission of our work presentation, in March 2016. However, according to the literature available, we are expecting to found symptoms of Burnout in the superior limit of normality, with differences in the major sources of stress between adult and pediatric professionals.

Conclusion The differences in the challenges experienced by adult and pediatric teams highlight the importance of adequate prevention strategies to specific needs of each unit. Further investigation of stress across a wider range of professional disciplines is required in order to explore this gap.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Liaison psychiatry: Its impact in an intrahospital treatment for a psychotic patient

D. Goujon^{1,*}, D.E. Chouillard², D.B. Abdullah², D.B. Dew², D.L. Beer³, D.P. Grandin²¹ CASMP, Secteur 78G04, Conflans Sainte-Honorine, France² Centre hospitalier intercommunal Poissy–Saint-Germain en Laye, Department of Psychiatry, Poissy, France³ Institut “Théophile-Roussel”, Montesson, France

* Corresponding author.

Different manners of non-suicidal self-injuries are common ways to deliberately hurt oneself in order to alleviate suffering. It can be seen in various psychiatric affections. The ingestion of bizarre objects in psychotic patients is part of aggressive behaviour as a reaction to massive anxiety. We hereby present the case of a schizophrenic patient who presented to the Emergency Department for a second episode of ingestion of numerous metallic objects (screws, coins, knives, spoon, handles, . . .). Physical examination showed no abdominal guarding. CT scan revealed the presence of multiple metallic objects, which seemed impossible to go through the pylorus. Surgical transgastric extraction was performed. Outcome was uneventful. Patient was discharged and followed-up in a private structure. Three months later, the patient was readmitted for the same reason. Flexible endoscopy allowed this time complete extraction of the ingested objects. He recovered rapidly and was allowed to discharge from the surgical ward. The psychiatrist took decision with family to transfer him into a psychiatric hospital for the first time. His treatment was: chlorpromazine, Proton pump inhibitor, pain killers. Patient was treated by means of medication, psychotherapy, daily activities and family, preparation him for a day hospital.

Conclusion We discuss here the beneficial multifocal treatment of a 42-year-old man suffering from schizophrenia. The life threatening ingestion of sharp and other metallic objects three times in a year was treated surgically with success. The psychiatric affection including invalidating acoustic-verbal delusions and severe negative signs were treated in psychiatric hospital. The definite results will be discussed.

The prevalence of depression and its correlates in ankylosing spondylitis: A systematic review and meta-analysis

C. Hopkins^{1,*}, C. Moulton²

¹ Prospect Park Hospital, Berkshire Healthcare NHS Foundation Trust, Reading, United Kingdom

² Institute of Psychiatry Psychology & Neuroscience, King's College London, London, United Kingdom

* Corresponding author.

Introduction Ankylosing spondylitis (AS) is a chronic inflammatory disease, associated with significant pain, functional impairment, and diminished quality of life. However, there is significant uncertainty regarding the prevalence of depression in AS and its associations.

Objectives We performed a meta-analysis to examine the prevalence of depression in AS and its associated correlates.

Methods The study protocol was prospectively registered with PROSPERO (CRD42015019676). EMBASE, Medline, PsycINFO and Web of Science were systematically searched for cross-sectional studies with ≥ 50 adult AS patients, which reported depression prevalence using diagnostic criteria or a validated screening tool. Depression prevalence, tool and threshold used, age, gender, disease duration, as well as measures of disease activity, functional impairment, pain and innate inflammation, were abstracted. Open-Meta was used to calculate pooled prevalence estimates and to conduct meta-regression.

Results Eight hundred and seventy-seven texts were identified and 17 studies satisfied inclusion criteria, totalling 3187 participants (75.2% male). Six diagnostic tools and 10 different thresholds were reported, with depression prevalence estimates ranging from 4.9–55.5%. In studies using the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D), 37.1% of participants satisfied criteria for mild (≥ 8) and 8.2% met criteria for moderate depression (≥ 11). Multivariate meta-regression demonstrated significant positive correlations between depression and, respectively, disease activity ($P < 0.001$) and C-reactive protein ($P < 0.001$).

Conclusions The prevalence of depression in AS is comparable with that of other rheumatic and degenerative diseases. Moreover, depression demonstrates significant associations with age, inflammation and disease activity, which require further investigation in prospective studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Medically unexplained syndromes—Looking for common reasons

A. Kulik*, A. Smotrycka

The John Paul II Catholic University of Lublin, Department of Psychotherapy and Health Psychology, Lublin, Poland

* Corresponding author.

Approximately 15% of general practice doctor's patients and 50% of patients with chronic disease experience persistent physical symptoms, which do not have medical reasons. Those symptoms are often associated with high levels of distress, limited efficiency and consumption of health resources. Each set of symptoms has particular diagnostic features and own operational definition. However, there is a phenomenon of combination of different syndromes. Approximately 96% of patients have several concurrent diagnoses of different syndromes at the same time. One of the explicative hypotheses is the premise that there is a latent factor common for

all medically unexplained syndromes (Deary, 1999). The verification of the assumption about latent factor was based on studies of premenstrual syndrome (PMS) and chronic fatigue (CF). The aim of this study is to determine the relationship between selected sets of symptoms and their conditions in the biopsychosocial paradigm. Hundred and forty-nine young women (aged 18–27 years) were examined following questionnaires: PSST, CFSQ, NEO-FFI, PTS, TPI, KAS. The relationship between symptoms of PMS and CF is 0.517 ($P = 0.000$). The adopted model explaining variables: (1) the PMS 33.3% of the variability of results, the most important are: neuroticism ($\beta = 0.436$), the strength of excitation ($\beta = 0.229$) and negative emotions—anger ($\beta = 0.206$); 2) in CF 57.1% of the variability of results, the most important are: neuroticism ($\beta = 0.298$) and negative emotions—anxiety ($\beta = 0.275$). The relationship between the severity of different medically unexplained syndromes in women is moderate. Among biopsychosocial determinants the most important is the severity of neuroticism and negative emotionality.

Psychological factors influence the symptoms of Gastroesophageal Reflux Disease (GERD) and their effect on quality of life in Korean fire fighter

S.Y. Lee^{1,*}, D.I. Jon², M. Kyung-Joon³

¹ Wonkwang University and Hospital, Psychiatry, Iksan, Republic of Korea

² Hallym University College of Medicine, psychiatry, Chuncheon, Republic of Korea

³ Chungang University College of Medicine, psychiatry, Seoul, Republic of Korea

* Corresponding author.

Objective The aim of the study was to investigate the psychological factors influence the symptoms of gastroesophageal reflux disease (GERD) and their effect on quality of life in Korean Fire Fighters.

Methods This study examined data collected from 1217 fire fighters. Depression and Anxiety were identified using the Patient Health questionnaire-9 (PHQ-9) and the 7-item Generalized Anxiety Disorder Scale. Occupational stress and Stress coping were identified using the KOSS-26 and the Ways of Coping Checklist-Revised. Self-esteem and quality of life were identified using the Rosenberg's Self-Esteem Scale and World Health Organization quality of life scale abbreviated version (WHOQOL-BREF). The scores for anxiety, depression and QoL of the two groups were analyzed. The correlation between psychological factors and QoL was also analyzed.

Results Current psychological variables were associated with increased odds of concurrent GERD-related symptoms. Current depression, anxiety and stress were associated with increased odds of GERD-related symptoms. According to the WHOQOL-BREF, depression, anxiety, stress, stress coping and self-esteem were significantly correlated with quality of life in patients with GERD. Quality of life was obviously affected by psychological variables in patients with GERD.

Conclusions These results indicate that psychological symptomatology, depression, anxiety, occupational stress and self-esteem are associated with GERD-related symptoms. Acknowledging this common comorbidity may facilitate recognition and treatment, and opens new questions as to the pathways and mechanisms of the association.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The syndrome of irreversible lithium-effectuated neurotoxicity: Clinical case and review

F. Leite^{1,*}, H. Salgado², S. Viveiros³, P. Coya³¹ Matosinhos, Portugal² Hospital de Magalhães Lemos, Serviço C, Porto, Portugal³ Centro Hospitalar do Porto, Serviço de Psiquiatria de Ligação e Psicologia Clínica, Porto, Portugal

* Corresponding author.

Introduction Lithium is a mood stabilizer used in the treatment of bipolar disorder. Lithium has recently been associated to permanent neurological damage namely persistent cerebellar dysfunction as well as peripheral and central neuropathies.

Objectives To present a clinical case of a probable Syndrome of Irreversible Lithium-effectuated Neurotoxicity (SILENT) and a review of the literature concerning this rare syndrome.

Aims Increase awareness and knowledge of SILENT.

Methods Psychiatric and psychological evaluation of a probable clinical case of SILENT and review of the literature using the key words “lithium neurotoxicity” and “Syndrome of Irreversible Lithium-effectuated Neurotoxicity”.

Results A 54-year-old female patient was admitted in our hospital due to involuntary lithium intoxication, with acute renal and cardiovascular failure, neurological, metabolic and electrolytic dysfunction in an acute confusional state and in need of dialysis. The patient clinical picture rapidly improved although, when she achieved normal lithium seric levels, it was observed a worsening of the preexisting confusional state followed by two consecutive generalized tonic-clonic convulsions and a partial convulsion. A short time after, it was recognized the development of a persistent catatonic state. It was detected urinary incontinence and repetitive, monosyllabic, incoherent, short phrased speech featuring echolalia, together with emotional lability and incongruous affect. The patient slightly improved with the introduction of anti-Parkinson’s pharmacotherapy.

Conclusions This clinical case raises several differential diagnoses due to its psychiatric and neurologic characteristics. We conclude that the most probable diagnosis is SILENT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric symptoms as a presentation of central nervous system involvement in Chagas disease, a case report

G. Martinez-Ales*, A. Fraga, V. Bonan, E. Roman, A. Palao, B. Rodriguez-Vega, M.F. Bravo

Hospital Universitario La Paz, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Psychiatric symptoms set forth brain dysfunction at several levels. Behavioral disturbances, although frequently associated to primary psychiatric disorders, call for a previous discard of neurologic treatable causes.

Case report We report the case of a 30-year-old gentleman, receiving outpatient psychological treatment and follow-up for a 3-month history of low mood, abulia, apathy, generalized malaise, weight loss and insomnia. Non-structured jealous delusions were also present. No neurological deficit was found. After CT of the brain, a space occupying lesion, suggestive of glioblastoma multiforme, was found. Further studies, including biopsy and a MR, led to the diagnosis of central nervous system Chagas, related to a previously unknown HIV infection in AIDS status, and conditioning a secondary central hypothyroidism. Careful treatment of the

etiological factors, along with symptomatic relieve with low dose paliperidone, led to the resolution of the symptoms.

Discussion The majority of patients suffering from neurologic diseases develop psychiatric symptoms over the course of their illness, with or without the presence of classical disturbances, such as weakness, sensory loss or seizures. Modern psychiatry uses a complex disease model, therefore necessarily integrating anatomy, biochemistry and function during every diagnostic approach.

Conclusion It is necessary to rule out frequent treatable causes, thus involving both psychopathological and neuroscientific approach to psychiatric disturbances. However, while underlying causes are often difficult to treat, psychiatric symptoms respond to existing pharmacologic and nonpharmacologic therapies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychotic symptoms in a patient diagnosed with temporal lobe epilepsy and schizoaffective disorder

G. Martinez-Ales*, V. Baena, I. Rubio, B. Rodriguez-Vega, V. Bonan, E. Roman, M.F. Bravo

Hospital Universitario La Paz, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Epilepsy is considered a complex neurological disorder, and its clinical picture can resemble many different cerebral dysfunctions, including those associated to major psychiatric disorders.

Case report We report the case of a 52-year-old gentleman, with a 30-year history of schizoaffective disorder and of complex partial epilepsy with secondary generalization. He was admitted to an emergency room due to a voluntary overdose with 8 mg of clonazepam. The patient explained how he had recently experienced visual hallucinations and insomnia, symptoms that originally led to the psychotic diagnosis. He had previously presented these symptoms, along with stupor, delusions and lability, as a prodrome of complex motor epileptic decompensations. Thus, he took the overdose not to suffer seizures. After carefully reconstructing the clinical history, psychiatric admissions had shown seizures, and periods of clinical stability had been achieved by regulating antiepileptic medication. Eslicarbazepine and lamotrigine reintroduction, and quetiapine withdrawal, led to symptomatic remission.

Discussion Epilepsy and major psychiatric disorders show a high comorbidity. There has been an effort to even include epilepsy and psychosis in a unique diagnosis (alternant psychosis). Furthermore, polymorphism and restitutio ad integrum may resemble classic cycloid psychosis. In this case, chronological study showed all symptoms could be explained by one disorder.

Conclusion Epilepsy includes a variety of neuropsychiatric symptoms. It can be difficult to withdraw psychiatric diagnoses from patients after years of follow-up. However, a carefully taken medical history clarifies temporal criteria.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Traditionally psychomotor subtypes have been investigated in patients with delirium in different settings and it has been found that those with hypoactive type is the largest proportion, often missed and with the worst outcomes.

Aims and objectives We examined the psychomotor subtypes in an older age inpatients population, the effects that observed clinical variables have on psychomotor subtypes and their association with one year mortality.

Methods Prospective study. Participants were assessed using the scales CAM, APACHE II, MoCA, Barthel Index and DRS-R98. Pre-existing dementia was diagnosed according to DSM-IV criteria. Psychomotor subtypes were evaluated using the two relevant items of DRS-R98. Mortality rates were investigated one year after admission day.

Results The sample consisted of 200 participants [mean age 81.1 ± 6.5 ; 50% female; pre-existing cognitive impairment in 126 (63%)]. Thirty-four (17%) were identified with delirium (CAM+). Motor subtypes of the entire sample was: none: 119 (59.5%), hypo: 37 (18.5%), mixed: 15 (7.5%) and hyper: 29 (14.5%). Hypoactive and mixed subtype were significantly more frequent to delirious patients than to those without delirium, and none subtype more often to those without delirium. There was no difference in the hyperactive subtype between those with and without delirium. Hypoactive subtype was significant associated with delirium and lower scores in MoCA (cognition), while mixed was associated mainly with delirium. Predictors for one-year mortality were lower MoCA scores and severity of illness.

Conclusions Psychomotor disturbances are not unique to delirium. Hypoactivity, this “silent epidemic” is also part of a deteriorated cognition.

Use of antipsychotics and antidepressants in patients with HIV

P. Muñoz-Calero*, F. García Sánchez, N. Rodríguez Criado, R. Martín Aragón, J.F. Cruz Fourcade, S. Bravo Herrero, B. Sánchez Sánchez

Hospital Universitario de Móstoles, Psychiatry, Móstoles, Spain

* Corresponding author.

Introduction Psychological distress appears in the majority of people infected with HIV. Depression is the most important affection, the prevalence in comparison with general population arises to 37%. Psychotic symptoms in patients with HIV are a very frequent entity, in some cases, these symptoms are pre-existent in others the evolution of the infection or a medical cause related with the infection can cause its apparition. Psychosis and depression in patients with HIV have some clinical and therapeutical considerations. Antidepressants and antipsychotics have many pharmacological interactions with antiretroviral therapy.

Objectives Review the efficacy and safety of antidepressants and antipsychotics in patients with HIV infection.

Methods PubMed was searched for articles published between 1966 and January 1, 2015, using the search terms HIV, AIDS, depression, psychosis, antipsychotics, antidepressants, antiretrovirals. We selected randomized placebo controlled or active comparator control trials.

Results Twelve studies for depression treatment and 2 studies for psychosis treatment in patients with HIV infection. Selective serotonin reuptake inhibitors (SSRI) especially fluoxetine and tricyclic antidepressants are effective in treating depressive symptoms in patients with HIV infection. Testosterone and stimulants have

been used in patients with mild depressive symptoms, however studies with these agents had a small sample size. Haloperidol and chlorpromazine were effective for AIDS delirium, there are not controlled trials with other antipsychotics.

Conclusions Psychiatrists must be concern about the clinical particularities of patients with HIV and depression or psychotic symptoms. The election of antidepressant or antipsychotic has to be made very carefully because of their side effects and interactions.

Living with Parkinson disease – the central role of primary care physicians and a multidisciplinary approach

M. Oliveira*, M. Marinho, C. Santos

Centro Hospitalar São João - EPE, Psychiatry and Mental Health Clinic, Porto, Portugal

* Corresponding author.

Introduction Parkinson disease is a frequent neurodegenerative disorder. Presence of psychopathology is well described in this illness, nevertheless the etiology is still unknown.

Methods and aims The authors present a clinical case of a patient with idiopathic Parkinson disease with depressive symptoms after the decline of his functioning. We aim to emphasize the importance of a multidisciplinary approach and the central role of general physicians in screening these situations.

Results The patient is a male with 64 years old, reformed with a personal history of hypertension. With 62 years old he started with mild motor complaints that got worse over time, culminating after a year and half on him being almost dependant for most of his daily activities. He also started to express feelings of sadness, despair, and recurrent thoughts of death. He refused to seek out medical help, but was convinced by his wife to consult his general physician that observed the patient and referenced him to Neurology and Psychiatry consultations. He also started sertraline 50 mg/day. He was diagnosed with Parkinson disease and started medication with ropinirole, levodopa and carbidopa with a good response. In Psychiatry consultation the dose of sertraline was increased to 100 mg/day with improvement, and it was provided information on the disease to the patient and family and also supportive psychotherapy.

Conclusions General physicians have a privileged position on screening patients with psychopathology when other physical conditions or illnesses are present. The fast and correct referencing of these patients can improve the prognosis.

Psychological mechanisms of the formation of non-psychotic mental disorders in patients with hyperthyroidism

O. Pityk^{1,*}, M. Pityk², I. Kuzhda³

¹ Ivano-Frankivsk National Medical University, Department of Psychiatry- Narcology and Medical Psychology, Ivano-Frankivsk, Ukraine

² Ivano-Frankivsk National Medical University, Department of Neurology, Ivano-Frankivsk, Ukraine

³ Ivano-Frankivsk Regional Children Hospital, Department of Ophthalmology, Ivano-Frankivsk, Ukraine

* Corresponding author.

The application of a comprehensive, integrative, systemic approach to the examination of patients with abnormal thyroid gland has to lie in the basis of planning strategies and tactics of medical programs such patients. On this point of view we consider that non-psychotic mental disorders are developing on the basis of both organic and adaptation levels. Population researches showed that the majority of patients with endocrinological pathology suffer from one of the three DCPR syndromes: irritant mood, demoralization thrown in (desperation), persistent somatization. The task of our work was to investigate mechanisms of psychological defense in patients with hyperthyroidism with non-psychotic mental disorders. One hundred and twenty-five patients were examined. Non-psychotic mental disorders with different syndromologic structure were found in 76% of patients (study group), among which anxious-asthenic (38.95%), anxiety and depression (23.16%) were dominant. The method of Robert Plutchik for assessment of the mechanisms of defense was used. In asthenic syndrome we found excessive functioning of negation and regression, inadequate functioning of intellectualization. In patients with astheno-anxious syndrome inadequate functioning of negation, intellectualization, compensation, and excessive repression contributed to the formation of the sensations of anxiety. Excessive compensation, projection, reactive formation generally affected the structure of the asteno-depressive syndrome. The lack of displacing of reactive formation, repression and excessive intellectualization in a complex influenced to the structuring of anxious-depressive syndrome. In hypochondrical syndrome projection, regression and negation were the basis of the formation of clinical picture. Thus, meaningful relationships between intrapsychic level of functioning and syndromological structure of non-psychotic disorders were installed.

* Corresponding author.

Background Patients with schizophrenia have a higher prevalence of physical illness and a higher mortality from natural causes than the general population, which is a reason why they can be hospitalized for medical and surgical pathologies.

Aims To determine the demand, the reason for consultation and the sociodemographic characteristics of the psychotic patient admitted at the general hospital.

Methods Sociodemographic variables (age, sex, marital status, education, place of residence, residential housing, with who they live, work status) and health care (service of origin, type of request and its relevance, complaints, days of delay between the request and assistance, number of visits, average length of stay).

Study design Prospective epidemiological study of 80 psychotic patients (F.2 ICD-10), from the total of 906 consults solicited from 1 January 2012 until 31 December 2014. Bioethical considerations: compliance with these principles justice, non-maleficence, autonomy and beneficence.

Results The average age is 58.34 years old, 60% were male, 73.8% single, 81.3% with primary education, 52.5% living in urban areas;

and the 88.8% of cases were pensioners. The Departments that generate a greater demand are Internal Medicine (53.8%), Orthopaedic Surgery (10%), Pneumology (8.8%) and ICU (8.8%). The most frequent reasons for consultation are assessment/treatment setting (77.5%), abnormal behavior (30%), disorientation (18.8%) and psychotic symptoms (18.8%).

Conclusions The typical profile of psychotic patients hospitalized for medical-surgical diseases is a male, middle-aged, single, with primary education and pensioner; from whom it's sued consultation for adjusting of treatment, and secondly for abnormal behavior.

Inappropriate sinus tachycardia – cardiac syndrome or anxiety-related disorder?

P. Rasmus¹, E. Kozłowska², T. Sobow^{1,*}

¹ Medical University of Lodz, Medical Psychology, Lodz, Poland

² Medical University of Lodz, Experimental Immunology, Lodz, Poland

* Corresponding author.

Introduction Relation between psychology, psychiatry and cardiology are multidimensional and begin to have growing importance in the diagnosis and treatment of patients of cardiosurgery, electrocardiology and cardiac rehabilitation. Inappropriate sinus tachycardia (IST) is a rarely diagnosed clinical syndrome characterized by excessive resting heart rate (HR) or disproportional increasing HR during exercise. The mechanisms of IST are not well understood. It is speculated that psychological factors might be of importance.

Aims The purpose of the study was to evaluate possible relation between the level of anxiety, personality traits and control of emotions, emotional intelligence, coping with stress strategies and manifestation of IST.

Methods The participants were 23 women with a diagnosis of IST (age range 31.8 ± 8.72) and 23 women (28.7 ± 4.4) without cardiac diseases. The research applied psychological tools including: State-Trait Anxiety Inventory, NEO-Five Factor Inventory, Courtauld Emotional Control Scale, Emotional Intelligence Questionnaire, Coping Inventory for Stressful Situations and an originally developed sociodemographic questionnaire.

Results It has been found that that the group of women with IST received higher results in Trait Anxiety Inventory compared to the group of healthy women and the relation was highly statistically significant ($P = 0,009$). No other differences were found.

Conclusions Inappropriate sinus tachycardia can be considered as an anxiety related disorder. However, its pathogenesis and classification position remains elusive.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aspects of cardiac anxiety in patients with a myocardial infarction

M.H. van Beek^{1,*}, R.C. Oude Voshaar², G. Pop³, A.E. Speckens⁴

¹ Radboud University Medical Center, Psychiatry, Nijmegen, Netherlands

² University of Groningen- University Medical Center Groningen, University Center for Psychiatry- and Interdisciplinary Center

Psychopathology and Emotion Regulation, Groningen, Netherlands

³ Radboud University Medical Centre, Cardiology, Nijmegen, Netherlands

⁴ Radboud University Medical Centre, Psychiatry, Nijmegen, Netherlands

* Corresponding author.

Introduction When the heart is in danger – as is true during a myocardial infarction (MI) – this is life-threatening and as such can provoke specific fear: so-called cardiac anxiety. Both general anxiety and depression are associated with cardiac prognosis in MI-patients. However, as most treatment studies have not shown beneficial effects on cardiac prognosis, the need to examine specific aspects of anxiety and depression post-MI has been advocated.

Methods We examined whether cardiac anxiety can be reliably assessed with the Cardiac Anxiety Questionnaire (CAQ) in 237 hospitalized MI-patients. Cross-sectional associations were explored, as well as possible trajectories of cardiac anxiety in the year post-MI (by latent class-analysis) and its association with quality of life. Finally, the prognostic association of cardiac anxiety with major adverse cardiac events (MACE) including all-cause mortality was examined with cox-regression-survival analysis.

Results The CAQ is a valid and reliable instrument in MI-patients and assessed fear, attention, avoidance of physical exercise, and safety-seeking behavior. Higher cardiac anxiety was associated with more psychological distress but lower severity in cardiac injury. In the year post-MI four cardiac anxiety trajectories were identified; higher cardiac anxiety was associated with worse quality of life. CAQ score significantly predicted MACE in a five-year-follow-up period, even after adjustment for age, cardiac disease severity and depressive symptoms (HR_{baseline} : 1.60 [95% CI: 1.05–2.45], $P=0.029$; $HR_{3\text{-months}}$: 1.71 [0.99–2.59]; $P=0.054$).

Conclusion Cardiac anxiety is an important and potentially modifiable factor in the treatment of MI-patients: it is prevalent and associated with quality of life and cardiac prognosis.

The experience and impact of stigma in Saudi people with a mood disorder

D. Alateeq^{1,*}, A. AlDaoud¹, A. AlHadi^{1,2}, H. AlKhalaf¹

¹ King Saud University- College of Medicine, Department of Psychiatry, Riyadh, Kingdom of Saudi Arabia

² King Saud University- College of Medicine, SABIC Psychological Health Research & Applications Chair, Riyadh, Kingdom of Saudi Arabia

* Corresponding author.

Introduction Self-stigma plays a powerful role in attitudes toward mental illness and seeking psychological services. Assessing stigma from the perspective of people with mood disorders is important as they were ranked as major causes of disability.

Objectives To determine the extent and the impact of stigma experience in Saudi patients with mood disorder and compare them between depression and bipolar disorder patients. To test if stigma is a universal experience and has similar psychosocial impact across cultures.

Aim It's a part of multicenter international study comparing its results to the universal experiences in the perspectives of individuals with mood disorder.

Methodology We randomly interviewed 94 individuals with mood disorder at King Khalid University Hospital using valid reliable tool, Inventory of Stigmatizing Experiences (ISE), which has two components: Stigma Experiences Scale (SES) and Stigma Impact Scale (SIS).

Results ISE was validated in a population of Saudi patients with mood disorder. There were no significant differences in stigma between patients with bipolar or depressive disorder on SES or SIS. However, over 50% of all respondents tried to hide their mental illness from the others, and to avoid situations that might lead them to be stigmatized. In comparison with the Canadian population, Saudi participants scored lower on both SES and SIS, which may be due to cultural differences.

Conclusion Stigma associated with mood disorder is serious and pervasive. It's important first to understand how patients perceive stigma in order to conduct successful anti-stigma programs. The ISE is a highly reliable instrument among cultures.

Social skills training group with Turkish immigrants: Results of a pilot study

U. Altunoz*, S. Bozkurt, V. Bannasch, S. Castro-Nunez, I.T. Graeff-Calliess

Klinikum Wahrendorff Psychiatry Hospital, Transcultural Psychiatry, Hannover, Germany

* Corresponding author.

Introduction Social skills training (SST) is an element of cognitive-behavioral therapy, which focuses to improve verbal-nonverbal behaviors involved in social interactions.

Aims-objectives To assess the effectiveness of a standardised 8-sessions-SST-group therapy (Hinsch&Pfungsten) in Turkish Immigrants who have anxiety/depressive disorders.

Method German-Turkish translations-backtranslations of contents and materials of the standardised 8-sessions-SST-group therapy were performed. These weekly eight group sessions applied by two Turkish-psychotherapists to 8 voluntary Turkish-Immigrants (F/M=4/4, age=50±5.4), who were in treatment for anxiety/depressive disorders in our transcultural outpatient-clinic in Hannover, Germany. Symptom-Checklist-90 (SCL-90) and Insecurity Questionnaire (I-Q) administered before and after the treatment program. Seven patients completed pre-post scales.

Results Table 1 presents the scale scores. There was no significant improvement in global-symptom-severity and insecurity-profiles after the SST. One of the psychotherapists and one of the patients were interviewed to discuss qualitatively possible reasons of that. **Psychoherapist** I think patients were not comfortable with many pencil-paper homeworks. Daily-life-examples were too close to German culture. Therefore it's crucial to culturally modify the sessions.

Patient I found the sessions-homeworks strict and different from my thinking style and culture.

Conclusions Qualitative data of this study stated that no improvement may be caused by eurocentric nature of the psychotherapeutic approach. Berry (2006) suggested that such interventions may generate/exacerbate acculturative-stress and may not be beneficial for the patient. Further studies should investigate effectiveness of culturally-modified SST in Turkish immigrants.

Table 1 Scale scores before and after the SST.

	Pre (n = 7)	Post (n = 7)	Wilcoxon-Signed-Ranks-Test
SCL-90-Global-Symptom-Index	2.76 ± 0.5, min-max = 1.84–3.21	2.73 ± 0.8, min-max = 1.50–3.63	Z = -0.507, P > 0.1
I-Q	203 ± 44.6, min-max = 137–264	216.7 ± 44.8, min-max = 128–265	Z = -1.183, P > 0.1

Ethnopsychiatry and anorexia nervosa: Two clinical cases

N. Bragazzi^{1,*}, G. Del Puente²

¹ University of Genoa, School of Public Health-Department of Health Sciences DISSAL, Genoa, Italy

² University of Genoa, Section of Psychiatry-Department of Neuroscience-Rehabilitation-Ophthalmology-Genetics- Maternal and Child Health DINOGMI, Genoa, Italy

* Corresponding author.

Introduction Usually anorexia nervosa (AN) is considered to be typical only of Western societies, such as Europe and the USA. However, nowadays, this ethnocentric point of view and this position are no more valid, since more often new cases of AN are found and described in China, Singapore, Malaysia, Japan, India and in the Arabic countries. Subtle differences between the Western and the non-Western symptoms presentation of AN can be found concerning the psycho-pathological and psycho-dynamic mechanisms.

Objectives and aims Here, in this contribution, we report and compare the clinical cases of two African women from Tanzania suffering from AN.

Methods The diagnosis of AN was confirmed according to the criteria of DSM-IV TR. After obtaining the consent from the two women, they were administered a semi-structured interview. The psycho-social and anthropological contexts were also taken into account.

Results The first patient was a woman that, after some months spent in the USA, had adsorbed Western stereotypes and had begun to starve, obsessed by the skinny beauty of the American models. Doing this, she underlined the distance between her and her tribal identity and origin. The second patient refused to nourish after that her family had imposed her a planned marriage. Starvation was a strategy to lose her femininity and appeal, a kind of return to infant-hood, and an escape from the marriage.

Conclusion Cultural influences and ethnocultural models are of fundamental importance for properly diagnosing and treating AN, even though often overlooked or underestimated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Disparities Research Unit Massachusetts General Hospital, Psychology, Boston, USA

* Corresponding author.

Introduction Transnationalism provides a serious challenge in mental health care, especially due to the crucial role of communication. Emergency room interactions offer an opportunity to analyze the role of cultural competency among providers and how they relate to immigrants in the clinical encounter.

Objectives This study addresses three aims: to assess the level of provider-perceived accuracy of diagnoses; to evaluate the use of restraints; and to compare diagnoses rates between patients of diverse racial/ethnic groups.

Methods We examined patients' race/ethnicity and their relation to service use and perceived certainty of mental health diagnoses. Three hundred and forty-seven migrants and 67 natives as well as their providers were interviewed in psychiatry emergency rooms in Barcelona (Spain).

Results The perceived certainty of clinical diagnosis is lower for Asians (OR=0.2, 95% CI [0.07–0.63]), and higher when the clinician feels comfortable with the patient (OR=5.41, 95% CI [2.53–11.58]). The probability of restraints is higher for Maghreb patients compared to native born (OR=3.56, 95% CI [1.03–12.26]). The probability of compulsory admission is lower for Latinos compared to native born (OR=0.26, 95% CI [0.08–0.88]). The probability of receiving a diagnosis of psychosis is lower when the clinician can communicate in the patient's language (OR=0.37, CI 95% [0.16–0.83]).

Conclusions Cultural factors such as level of comfort and communication in the patient's language play a central role in diagnosis and treatment. This study highlights the importance of culture in psychiatric diagnosis and the role of cultural competency for mental health providers.

Case report: Hallucinations as depressive equivalents

E. Garcia^{1,*}, I. Vicente², R. Martínez²

¹ Ciudad Real, Spain

² Hospital General de Ciudad Real, USMIJ, Ciudad Real, Spain

* Corresponding author.

We comment the case of a 12 years old girl who started with visual and auditive hallucinations. Hallucinations are not a common symptom between children. They may also be linked to many conditions, some of them with poor outcome as schizophrenia. Symptoms appeared in a short time, after a previous normal development. She talked about a man who followed her and that was always behind, she also had heard some insults of undetermined voices. These symptoms were just of one-month duration and made her feel anxious and very afraid. After a normal organical study and a first proposal of medication they asked for our consultation. We found that the patient was alone at home every afternoon. Family, from other country, hadn't any social support, and the father had had to travel away some days before the child began to suffer hallucinations. Suspecting an affective disorder as the basis of anxious symptoms, and hallucinations as a cultural presentation of them, we started with a social intervention mixed with support therapy. After some sessions the patient could talk about her loneliness and fears, disappearing the other symptoms. We will resume this case and literature about other cultural presentations that may difficult diagnosis or treatment.

Gender differences in the manifestation of brain fog, depression and indices of anxiety among secondary school students in Nigeria

D. Igboke^{1,*}, B.A. Ola², R.J.E. Ndom³

¹ Covenant University, Psychology, Ota, Nigeria

² Lagos State University College of Medicine, Department of Behavioural Medicine- Faculty of Clinical Sciences, Lagos, Nigeria

³ University of Ilorin, Behavioural Sciences, Ilorin, Nigeria

* Corresponding author.

Introduction Secondary school students in Nigeria are under intense pressure to perform well in their academics so as to have competitive advantage in advancing their studies. This pressure has been linked to western derived psycho-pathologies such as depression, anxiety and culture bound syndrome such as brain fog syndrome.

Aim To examine gender differences in the manifestation of brain-fog syndrome, depression, and anxieties among students about to participate in Junior Secondary Certificate Examination (JSCE) and West African Senior School Certificate Examination (WASSCE) in Nigeria.

Methods Two hundred and nine (209) students (X age = 14.27, SD = 2.18) were administered a battery of tests comprising of the Brain Fog Syndrome Scale, Brain Fog Propensity Scale, State Trait Anxiety Inventory, Patient Health Questionnaire, Mathematics Anxiety Inventory and Test Anxiety Inventory. The data was subjected to a multivariate analysis of variance (MANOVA).

Results The result showed no significant gender differences in the manifestation of brain-fog syndrome, depression, and anxieties, $F(6, 202) = 0.947, P \geq 0.01$; Pillai's Trace = 0.03, partial $\eta^2 = 0.02$. In consonance with earlier studies, males reported higher brain fog mean scores than female participants (X = 5.46, SD = 2.06; X = 4.88, SD = 2.43).

Conclusions The study has shown that adolescents who are about to take their final examinations manifest brain fog propensity and go on to manifest symptoms of the brain fog syndrome. But, there is no significant gender difference in the manifestation of brain fog syndrome among males and females.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A brief exploratory synthesis of portrayal of mental health issues in the script and characters of TV series Wallander (Swedish Version)

S. Kumar

Liverpool, United Kingdom

Introduction The modern Swedish crime drama series Wallander by Henning Mankell presents a good portrayal of mental health issues in 21st century post modern world, including the contribution of biological, psychological and social issues in predisposing, perpetuating and maintaining them.

Aim The aim of the exploratory synthesis is to study the characters in Wallander focusing on the portrayal of their mental health with a view on formulating biological, psychological and social factors that play a role in their development. Furthermore, mental health is reviewed in first world culture acclimatizing itself to the themes emerging from post-modern globalised world.

Method The episodes of Wallander (Swedish Version) are reviewed focusing on the characters and the plots for each episode matching them with mental health diagnoses offered in International classification of diseases.

Discussion The results are collated and a general commentary is offered on the observations and motifs revealed in the portrayal. The focus will be on individual character formulations (both recurring main characters as well other side characters). In addition, there is a commentary on contributing to mental health problems in a post-modern industrial society.

Disclosure of interest The author has not supplied his declaration of competing interest.

Anthropology and psychiatry – perspectives on healing and metaphor

B. Lourenco^{1,*}, M. Duarte², M. Gonçalves¹, M.A. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, CP5, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, CP6, Lisbon, Portugal

* Corresponding author.

Introduction Despite different theoretical backgrounds, psychiatry and anthropology, always maintained an enriched dialogue. The understanding of cultural conceptualizations of disease and healing shed light on the symbolic dimension and the role of metaphor in the healing systems.

Objectives and aims To understand the effectiveness of the symbolic dimension and the role of metaphor in healing. To critically discuss the contribution of Anthropology to the field of Psychiatry.

Methods Review of selected literature.

Results Levi-Strauss (1958) formulates a theory of symbolic healing, where the myth plays a major role. The attempt to relive the experience through the reconstruction of the social myth allows its verbal expression. Without this language, the experience would be “chaotic and inexpressible”. The myth provides a coherent interpretation of the world system and thus enables a “psychological manipulation of the sick organ”. Recent studies suggest an hierarchical organization of bio-psycho-social levels on which different healing mechanisms act (Kirmayer, 2004). The metaphor, although it is a cognitive process, will mobilize motivational, emotional and even sensory aspects, working as an information vehicle between the different levels.

Conclusions Symbolic dimension is a highly pervasive aspect in all healing systems, even the biomedical. The hierarchical organization of bio-psycho-social levels, provides a convenient way of conceptualizing the efficacy of different healing systems, such as psychotherapy or shamanism.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Religious and spiritual implication in the assessment and management of bipolar disorder

L. Maia^{1,*}, A. Coutinho², I. Carvalho¹, B. Baptista¹, L. Carneiro³

¹ Hospital Center of Vila Nova de Gaia and Espinho, Department of Mental Health, Vila Nova de Gaia, Portugal

² Hospital Center of Vila de Gaia, Department of Mental Health, Department of Mental Health, Portugal

³ Hospital Center of Vila Nova de Gaia and Espinho, Department of Mental Health, Department of Mental Health, Portugal

* Corresponding author.

Introduction Religion/spirituality and medicine have been related in one way or another sense the beginning of our know History. Patients' beliefs, values and practices influence the way disease is perceived and managed. In order to provide adequate care the physician must have proper knowledge of the patients' spiritual/religious context, otherwise it may fall prey to errors

of diagnostic, inappropriate management and subsequent poor compliance.

Objectives To present the case of an adult male (a preacher whose beliefs include mediunity) with delusional ideation of mystical content and mood elation, identified during a religious ceremony.

Aims Questioning the frontier between spiritual/religious beliefs and psychopathology.

Methods A case report is presented and a literature review of the theme is shortly surveyed.

Results The case reports to a 53 years old man, who during a religious ceremony presented himself with agitation and disinhibition, removing all his cloths and living the church naked. Additionally it was identified the presence of insomnia, heteroaggressiveness, accelerated speech, mood elation and delusional ideation of mystical and megalomaniac content. Several studies demonstrate the importance of acknowledging the religious/spiritual beliefs of patients. This knowledge allows the psychiatry to correctly identify the existing psychopathology and organize an appropriate intervention plan for the patient.

Conclusions Spiritual and religious beliefs' influence the way disease is perceived and managed. Physician should collect a brief spiritual story of the patient and learn about the different religious/spiritual beliefs and practices of their community, in order to understand the full dimension of the individual illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Apotemnophilia: Psychiatric disorder, neurological disorder or not a disease at all?

C. Novais*, M.J. Peixoto, M. Mota Oliveira, A. Côrte-Real
Centro Hospitalar de São João, Psychiatry Department- Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction Apotemnophilia or body integrity identity disorder (BIID) is defined by the uncontrollable desire to amputate one or more healthy limbs or to be paraplegic.

Objectives/aims We reviewed the available studies of this condition in order to enhance the comprehension of this disorder and the possible need of a multidisciplinary assessment.

Methods Relevant papers from 2000 were identified using PubMed database, with the terms apotemnophilia, BIID and self-demand amputation.

Results Reports of the phenomenon of amputee attraction trace back to 1933 in a series of letters and articles published in journals and magazines by erotically-obsessed persons who wanted to become amputees themselves. The first scientific report of this issue only appeared in 1977, when John Money described two cases that requested an amputation of a healthy limb, a condition he named apotemnophilia. Would-be amputees – or “wannabes” – may appear in thousands and they have their own websites. Until now, the explanation of this phenomenon has been in favor of a psychiatric etiology: a pathological desire driven by a sexual compulsion. Recently, a neurological explanation has been proposed and defends that might exist a dysfunction of the right parietal lobe, leading to a distorted body image and a desire for an amputation.

Conclusions Apotemnophilia is a rare, uncommonly studied condition, which blurs the limits between psychiatry and neurology. We must be aware that this disorder is more frequent in unusual places like websites and others. A better understanding of this condition is crucial for the development of effective treatment.

“Makoki”: A view of electroconvulsive therapy in a Spanish comic of the early 80s

F. Pavez^{1,*}, A. Alcántara¹, E. Saura², P. Marset³

¹ Hospital General Universitario Reina Sofía, Psychiatry, Murcia, Spain

² Fundación Jesús Abandonado, Unidad de Asistencia Psicológica, Murcia, Spain

³ Unidad Docente de Historia de la Medicina, Departamento de Ciencias Sociosanitarias, Facultad de Medicina, Universidad de Murcia, Murcia, Spain

* Corresponding author.

Introduction Analysis from cultural products has been previously reported in psychiatry field. This approach provides an understanding of the social imaginary about psychiatry and its work over a determined period of time.

Objectives To describe the representations of ECT and insanity in an Spanish underground comic of the early 80s.

Methods We performed an analysis of complete production (1979–1994) of “Makoki”, comic by Gallardo and Mediavilla, looking for the aspects related with our interest scope (Fig. 1).

Results The comic analyzed is inscribed in the field of provocation and insolence. This is comprehensible in the historical context of Spanish transition, if we attend to almost forty years of cultural confinement as a result of a dictatorial regime. This cultural product could be seen as “politically incorrect” from the current perspective, given that reproduces some stigmatizing topics regarding mental illness, glorifying its alleged associations with violence and drug use, in addition to a negative view of ECT, represented as a sadistic instrument of punishment, control and subjugation (see Fig. 1).

Conclusions The material analyzed reproduces the prevailing social stigma in its epoch about psychiatry and mental illness. The analysis of cultural products that reflect and built the speeches about the psychiatry and its action field, can be a useful strategy to understand the views of the general population in a given era.

Introduction As the psychopathological constructs have been influenced by scientific and cultural paradigms of its time, culture reflects and determines the way of understanding health and disease. The knowledge generated is integrated to the cultural wealth and it continues its development by interacting with culture, thus the ideas of mental illness and its treatment vary according to culture and beliefs of a given population in a given time.

Objectives To propose a framework for analysis through the examination of cultural products. We argue that this strategy can give us some clues about how the general population understands mental illness and the psychiatric work.

Methods A review of the literature available about social representations of science, medicine, illness and psychiatry, through cultural products analysis.

Results There are many works that address the presence of these issues in the social imaginary by analyzing cultural products. In the field of psychiatry, the analysis of films, literature and music (the last, in a lesser extent) are the most frequent.

Conclusions The analysis of cultural products can be a source of additional knowledge that connects us with the social representations of our profession and its scope of practice, favoring a better understanding about what psychiatry and mental illness means for our patients and general population.

Hope and religiosity: Re-designing the placebo effectM. Salami^{1,*}, P.R. Khan²¹ Universiti Pendidikan Sultan Idris, Department of Psychology and Counseling, Kuala Lumpur, Malaysia² Universiti Pendidikan Sultan Idris, Department of Psychology and Counseling, Perak, Malaysia

* Corresponding author.

While hope helps to govern the prospects for optimal wellbeing. It also helps in attaining a purposeful and meaningful living. Moreover, the psycho-religious mechanism through which hope and religion may be explained, can be connected to the mind-body interaction, which explains the healing process of the placebo effect. Based on this paradigm, experts agree that what makes the healing process of the placebo comes to effect lies on the premise of how best the effectiveness of the treatment is conveyed to the client on one hand, and the degree of the client's confidence regarding the effectiveness of the treatment on the other. Hence, this paper explore the link between hope, religiosity and the placebo effect with the aim of redesigning the healing process that can be of benefit to both the client and the clinician and as an alternative means towards attaining optimal wellbeing and health. Implications and suggestions for future research are also discussed.

Band joy without hangover: Report of an experience of health promotion in the carnival of BrazilA. Teixeira*, J. Jaber, S. Cibreiros, A. Hollanda
Clinica Jorge Jaber, Addictions, Rio de Janeiro, Brazil

* Corresponding author.

Carnival is considered the most popular celebration in Brazil and millions of people take to the streets, looking for fun. However, studies have shown increased consumption of alcohol and illegal drugs during this period. Ten years ago, Jorge Jaber, psychiatrist, addiction specialist, created the carnival group "joy without hangover" preventive alcohol abuse and drug use, carrying the message that happiness is possible without the use of any substance chemistry. Band parades annually on Copacabana beach, in the city of Rio de Janeiro; with the support of the mayor, and in 2013, brought together several academic and community segments, besides hundreds of supporters to the cause. In 2015, a group of retired soccer players, the "Masters of Flamengo", from the very popular soccer team "Clube de Regatas do Flamengo", joined the Band "joy without hangover" with the slogan: "A real ace does not use crack", with the support of the Brazilian Psychiatric Association. The "joy without hangover" is inserted in the conceptual formulation of health promotion, as seen action on the individual, seeking behavioral change and lifestyle, according to the precepts of Verdi and Caponi (2005). Thus aims to contribute to change the view that associates the carnival the consumption of alcoholic beverages and drugs, showing the dangers of using these substances.

The effects of vitamin B1 on ameliorating of depression related to the premenstrual syndromeS. Abdollahifard^{1,*}, M. Maddahfar²¹ Jahrom University of Medical Sciences, Nursing & Midwifery Department, Jahrom, Iran² BHOWCO Trading GmbH- Int. Marketing & Business Services-Frankfurt- Germany, BHOWCO Trading GmbH- Int. Marketing & Business Services, Frankfurt, Germany

* Corresponding author.

Background & aim The premenstrual syndrome (PMS) is a series of physical, mental, and behavioral symptoms. Different treatments have been introduced for the syndrome due to its unknown complicated causes. Vitamin B1 (Thiamin) may reduce mental symptoms of the syndrome. This study was conducted to determine the effect of vitamin B1 on the Depression related to PMS in students residing at dormitories of Jahrom University in 2014.

Methods In this double-blind placebo-controlled clinical trial, 108 students with PMS residing at dormitories of Jahrom University were divided randomly into two groups, vitamin B1 and placebo. The severity of the depression related to PMS in two cycles, before the intervention and during the intervention, was recorded

by the students. The data were collected using an information collection form, PMS provisional diagnosis form, daily status record form, Beck Depression Inventory. The data were analyzed using descriptive and inferential statistics.

Results The comparison of vitamin B1 group before the intervention with that after the intervention showed that vitamin B1 reduced mean Depression related to PMS (42.06%) significantly ($P < 0.0001$). Moreover, there was a significant difference between vitamin B1 and placebo groups in terms of mean Depression, as mean symptoms in vitamin B1 group was significantly lower than that in the placebo group ($P < 0.0001$).

Conclusion It seems that vitamin B1 is effective in recovery of mental symptoms of PMS especially depression. Therefore, this vitamin can be used to reach a major goal of midwifery, that is, reduction of mental symptom severity of PMS, without any side effects.

The relationship between anxiety, depression and hopelessness among nonclinical sample

T. Alali

Kuwait University, Kuwait

Introduction This research aims at examining the relationship between anxiety, depression, and hopelessness among nonclinical Kuwaiti sample using Beck Anxiety Inventory, Beck Depression, and hopelessness inventories.

Objectives highlighting the relationship between anxiety, depression, and hopelessness among nonclinical sample of females and males and the common factor/s.

Methods The participants were 616 (308 females & 308 males), Kuwait University students. The two genders were matched in age (18.15 ± 0.36 & 18.18 ± 0.38 , $t = 0.94$, $P > .05$) and BMI (24.12 ± 3.27 & 23.50 ± 4.85 , $t = 0.54$, $P > 0.5$). The Arabic versions of the Beck Anxiety Inventory (BAI), Beck Depression Inventory-II (BDI-II), the Beck Hopelessness Scale (BHS), and demographic surveys were administered to participants during classes. All participants read and signed a consent form before participating. The correlation matrices, exploratory factor analysis, and reliability analysis are used in this study.

Results Internal consistency of scores were satisfactory for the BAI, BDI-II, & BHS inventories respectively (Cronbach's alpha (M)=0.88, 0.75, 0.74 & (F)=0.89, 0.84, 0.88). A correlation of ($r = 0.53$) between the BAI and BDI-II and ($r = 0.43$) with BHS. Meanwhile a correlation of ($r = 0.58$) between BDI-II & BHS. A principal-axis factor analysis with oblique rotation suggested one factor accounting for 67.73% of the common variance.

Conclusion The results indicate that there is a strong relationship between anxiety, depression and hopelessness. This highlights the important of examining common factors between anxiety, depression and hopelessness among nonclinical sample.

Can somebody listen to me?

E. Cortázar Alonso*, H. Guillén Rodrigo,

R. Remesal Cobreros, R. Alonso Díaz

Hospital Juan Ramón Jiménez, Salud Mental, Huelva, Spain

* Corresponding author.

Given the increase in depressive symptoms, as a mental disorder combined with an organic disease, we suggest a therapeutic

approach based on group therapy. The effectivity of this kind of therapy has been confirmed by multiple studies as a way to decrease the pressure in mental health units. The results reached in various studies confirm at least an equal effectivity as individual psychotherapy, thereby it optimizes the increasingly limited public health resources. The objective of the group therapy is to promote an active attitude in the patients and make them responsible of their condition and their treatment process too. The program is aimed to female patients with various kinds of clinical depression, ranging from 40 to 60, who come to the USMC Hospital Vazquez Diaz in Huelva. The group had 12 participants, it was led by a Clinical Psychologist with the help of the Clinical Psychology residents. The program consisted in 8 bimonthly sessions of 90 minutes with an assessment test/retest at the beginning and end of it. The work in the group therapy was based on the constructivist orientation. Different areas were treated as: identification and adaptive expression of emotions, strengthening self-esteem and providing adaptive coping strategies to the psychological distress. As a conclusion we can see how the individual changes in the patients go socializing and enhancing the change in the rest of the participants in a mutual support that promote a more active role that take the patients away of the initial passivity.

Phenotypes in patients with monopolar and bipolar depression

L. Dehelean^{1,*}, A.M. Draghici², R. Balint¹

¹ "Victor Babes" University of Medicine and Pharmacy, Neuroscience/Psychiatry, Timisoara, Romania

² Timisoara Psychiatry Clinic, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction Recurrent depressive disorder is heterogeneous in respect to its etiology (predominantly exogenous or endogenous). Patients with recurrent depressive disorder (RDD) may change diagnosis to bipolar disorder (BD). Regarding the "true" RDD there is the possibility that in most cases it is exogenous, and the prevalence of endogenous RDD might be similar to BD. There is still debate regarding useful criteria for distinguishing between bipolar and monopolar depression especially at the first episode.

Objectives The purpose of the study is to identify useful phenotypes that could help distinguishing between endogenous monopolar and bipolar depression.

Methods The study was carried out on patients diagnosed with RDD and BD according to ICD 10 criteria. The following data was analyzed: socio-demographic parameters, family psychiatric history, seasonality, suicidal attempts, and behavioral phenotypes such as nicotine, alcohol, or illicit drug use.

Results The study included 105 RDD and 74 BD patients. In the RDD sample the mean age at disorder onset was 45.93 years, while in the BD sample, was 32.45 years. Significant differences between the samples were found in: family psychiatric history (BD patients having more relatives with schizophrenia, $P = 0.01$), smoking habits (BD patients smoking more cigarettes than RDD patients, $P = 0.001$), and seasonal depression (mainly summer and winter in RDD, and mainly summer and autumn in BD). No differences were found regarding suicidal attempts, alcohol or illicit drug use.

Conclusions Onset age, family psychiatric history, smoking habits, and seasonality may reflect endogenous depression (BD or RDD) or different subtypes of BD or RDD.

Government employees and depressive and anxiety disorders: A systematic review

M.A. Dos Santos
Porto, Portugal

Introduction Depressive and anxiety disorders are common among working adults and costly to employers and individuals and their prevalence is high. Public sector employees are also vulnerable to poor mental health, mainly where have been occurring organisational changes similar to private sector concepts.

Objective To highlight the unmet mental needs for new vulnerable working population, government employees.

Methods The search was conducted using PubMed, Medline, Web of Science, Scopus, B-on, Science Direct with the terms “government employees”, “federal employees”, “depressive disorders”, “anxiety disorders”. Using the PRISMA methodology, 1374 articles were considered with the search terms and if were published in the last 10 years; after a review of the title and summary, 5 eligible studies in english were included.

Discussion Mental disorders are growing public health problem, and creating an enormous toll of suffering, disability and economic loss. There are few studies about depressive and anxiety disorders in public sector and those confirm that it would be to examine to what extent national characteristics can explain why individual and organizational characteristics are more related to them in some countries than in others, especially not including military or police officers who usually are submitted to high psychological distress.

Conclusions Workplace health promotion in addressing job stress is crucial to fight against to a range of mental health outcomes. Mental health screening in the public sector may contribute for changes to the traditional roles of government and its management structures and must be encouraged to find out the underlying mechanisms of developing depressive and anxiety disorders.

Decentering and avoidance: Mechanisms between external shame and depression symptomatology

C. Ferreira*, A.L. Mendes, J. Marta-Simões, I.A. Trindade
Faculty of Psychology and Educational Sciences - University of Coimbra, CINEICC - Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

It is widely accepted that shame plays a significant role in the development and maintenance psychopathology, namely depressive symptoms. In fact, the experience of shame is highly associated with the adoption of maladaptive strategies to cope with negative feelings, such as experiential avoidance (i.e., the unavailability to accept one's private experiences), and the inability of decenter oneself from unwanted internal events. The present study aims to explore a mediation model that examines whether external shame's effect on depressive symptomatology is mediated through the mechanisms of decentering and experiential avoidance, while controlling for age. Participants were 358 adults of both genders from the general population that completed a battery of self-report scales measuring external shame, decentering, experiential avoidance and depression. The final model explained 33% of depression and revealed excellent model fit indices. Results showed that external shame has a direct effect on depressive symptomatology and simultaneously an indirect effect mediated by the mechanisms of decentering and experiential avoidance. These data seem to support the association between shame and

depressive symptomatology. Nevertheless, these findings add to literature by suggesting that when the individual presents higher levels of shame he or she may present lower decentering abilities and tends to engage in experiential avoidance, which amplify the impact of external shame and depression. Furthermore, our findings seem to have important clinical implications, stressing the importance of developing intervention programs in the community that target shame and experiential avoidance and that promote adaptive emotion regulation strategies (e.g., decentering) to deal with adverse experiences.

Chronic illness-related shame and experiential avoidance mediate the impact of IBD symptomatology on depression

I.A. Trindade, C. Ferreira*, J. Pinto-Gouveia
Faculty of Psychology and Educational Sciences - University of Coimbra, CINEICC - Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Inflammatory bowel disease (IBD) is group of chronic diseases that cause symptoms such as abdominal pain, urgent diarrhoea and fatigue, as well as associated complications (e.g., arthritis). Literature has pointed that IBD may cause depressive symptomatology, which seems to aggravate physical symptoms in a cycle of depression and inflammation. This study's aims to examine the mediator roles of chronic illness-related shame and experiential avoidance in the relationship between IBD symptomatology and depression, while controlling for associated medical complications. The sample comprised 161 adult IBD patients (52 males and 109 females), with a mean age of 36.73 (SD = 10.93), that completed validated measures. The hypothesised model was tested through path analyses. Results (see Fig. 1) showed that although IBD symptomatology presented a direct effect of .13 on depression, the majority of its impact was mediated through chronic illness-related shame and experiential avoidance with an indirect effect of 0.22. Indeed, IBD symptomatology seemed to lead to higher chronic illness-related shame, which presented a direct effect on depression of .15 and an indirect effect mediated by experiential avoidance of 0.37. This model presented excellent goodness-of-fit indices. These findings suggest that targeting shame and experiential avoidance in IBD patients would have beneficial outcomes for patients' well-being. It thus seems that compassion and acceptance-based psychotherapies should be included in treatment programs for IBD.

Maladaptive emotion regulation mediating the link between the recall of early affiliative memories and depressive symptomatology

J. Marta-Simões*, C. Ferreira*, A.L. Mendes, I.A. Trindade
 Faculty of Psychology and Educational Sciences - University of Coimbra, CINEICC - Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

The inability of recalling warm and safe memories with parents and close relatives has been often associated in literature with a negative and judgmental sense of self, and a higher proneness to experience feelings of inferiority, inadequacy, and defectiveness. Thus, intending to deal with self-judgment and inferiority, individuals may become submissive as a way of compensating one's negative emotional states with other's positive attention and desirability. However, both early negative affiliative memories and submissiveness are associated with higher vulnerability to psychopathology, namely depression. Using a sample of 338 young women, the present study intended to examine the association between early affiliative memories and depressive symptomatology, and the mediator roles of self-judgment and submissive attitudes and behaviours on this association, through a path analysis. The tested model provided an excellent fit to the data, accounting for 41% of the depressive symptomatology's variance. Results revealed a direct effect of early affiliative memories on depressive symptomatology; and also on self-judgment and submissiveness, explaining 28% and 23% of their variances, respectively. Moreover, part of these memories' effect on depressive symptomatology was explained by self-judgment and submissiveness, which seems to suggest that submissiveness, although used to compensate feelings of inferiority and a judging attitude towards the self, may be a maladaptive strategy due to its positive association with depressive symptoms. This study's findings appear to emphasize the relevance of targeting submissiveness, especially in the context of a scarce recall of early affiliative experiences, when approaching women's depressive symptomatology on mental health promotion programs.

Monitoring of liver function in major depressive disorder treated with SSRI

P. Ifteni*, A. Teodorescu
 Spitalul de Psihiatrie si Neurologie, Psihiatrie Clinica III, Brasov, Romania

* Corresponding author.

Background Major depressive disorder is one of the most prevalent psychiatric illnesses in the world affecting more than 12% of men and more than 21% of women in their lifetime. Selective serotonin reuptake inhibitors (SSRIs) are worldwide prescribed to treat depression. SSRIs drugs can cause drug-induced liver injury (DILI). *Aims* The aim of the study was to evaluate the liver function in patients treated with SSRI in order to detect DILI.

Methods All the patients with first major depressive episode treated with the same SSRI antidepressant for at least 3 months between September 2013 and September 2015 were entered into the study. The hepatic function panel included aminotransferases, total and direct bilirubin, albumin, total protein, gamma glutamyl transferase (GGT), LDH cholesterol, hepatitis B virus (HBV), and hepatitis C virus (HCV).

Results Of 134 subjects with MDD according to The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)

who met inclusion criteria, 98 patients entered into study. Seventy-seven (76.5%) were treated with SSRI for at least 3 months with mean age were 45.4 (SD=6.3), 65 women (66.3%). Five patients (5.1%) were newly diagnosed with hepatitis, and 10 (10.2%) presented elevated values of ALT, AST. The mean duration of depressive symptoms was 9.2 months (SD = 6.9).

Conclusions The treatment with SSRI seems to be effective and safe in our sample. A relative small number of patients with MDD were diagnosed with viral hepatitis during this cross-sectional study. Further randomized and controlled trials are needed.

Biopsychosocial model of prevention of depression

M. Khan^{1,*}, S. Asghar², Z. Mukhtar³, S. Niaz⁴

¹ Lahor, Pakistan

² Sexual Health Institute Pakistan, Psychology, Lahore, Pakistan

³ Azm center, Psychology, Sargodha, Pakistan

⁴ Chase form, Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Depression is ranked third highest among disorders responsible for global disease burden. Preventive strategies are more cost effective than treatment alone. Depression is biological disease having serious psychological and social consequences comprehensive program based on biopsychosocial model can curtail its mortality and morbidity.

Method Pubmed search was made to study about prevention of depression.

Result Different studies suggested food, exercise relaxation and social support system to prevent depression. At biological level food is the first item. It should include omega 3, antioxidant, vitamin D3, B6, B12, folic acid, fiber. Foods with anti inflammatory effects too are recommended. Moderate exercise has biological effects mediated by endorphins. It is advised to avoid proinflammatory foods, refined sugar, smoking, and addiction. Whole some sexual life has anti anxiety and antidepressant effects. At psychological level high risk population is screened. Susceptible are taught cognitive restructuring and coping strategies for stress. At social level greater integration with family and friend can help the person.

Discussion Essential ingredients like omega 3 is derived from fish, nuts seed oils. Fruit and vegetable and beans are rich in antioxidant, vitamins and fiber. Healthy food maintains hippocampal volume, which gets shrunken by unhealthy food. Increased levels of homocystine due to inflammation can decrease monoamine neurotransmitters. Anti-inflammatory food include turmeric and garlic. Sex increase blood levels of oxytocin during arousal dopamine serotonin and endorphins at orgasm. Depression is less prevalent in peaceful societies.

Conclusion Every effort should be made to prevent depression.

Escitalopram orally-disintegrating tablets (ODT) in major depression treatment

M. Polikowska, B. Łoza*

Medical University of Warsaw, Psychiatry, Warsaw, Poland

* Corresponding author.

Introduction The growing rate of depressive disorders causes needs for more effective and more innovative solutions. The

modern patients' challenges make them fail mostly in the treatment compliance. Some reports have described that escitalopram orally disintegrating tablets (ODT) induce faster response and lower dropout rate than oral standard tablets (OST), although both forms have equal bioavailability.

Aim We tried to clarify effectiveness rates between escitalopram ODT and OST treatments in depressive patients.

Method An open-label, 6-month, randomized, flexible-dose study was conducted for direct comparison of the effects of escitalopram ODT (N16) and OST (N15) on dropout rate and clinical outcomes in patients with major depression.

Results Outcome measures included Hamilton Depression Rating Scale (HDRS), Drug Attitude Inventory-10 (DAI), Clinical Global Improvement Scale (CGI), and Psychological General Well-Being Scale (PGWB). The tolerability was assessed by the UKU scale. No significant difference was found in HDRS, CGI, PGWB and GAF between the two forms of tablets. No significant difference was found in any tolerability rates. However, dropout rate favored escitalopram ODT group (N5, 31.3%) vs escitalopram OST (N7, 47.0%). DAI-10 outcomes, both in patients' general attitude and subjective feelings, were significantly improved in ODT group ($P=0.000$), comparing with OST.

Discussion Escitalopram in its classical form (OST) has become a leader in a group of antidepressants, thanks to safety of use, efficacy and tolerability. In the ODT form, escitalopram can meet additional needs, both clinical and lifestyle. ODT may reduce dropout rate and costs of long-term treatment improving the patients' compliance.

Psychosocial and clinical characteristics of depressed patients with metabolic syndrome

M. Martinac^{1,*}, D. Babić², M. Pavlović²

¹ Public Health Centre Mostar, Centre for Mental Health, Mostar, Bosnia and Herzegovina

² University Clinical Hospital Mostar, Department of Psychiatry, Mostar, Bosnia and Herzegovina

* Corresponding author.

Introduction Depression is a complex disease associated with sleep, appetite and body weight disturbances as well as with the level of physical activity, all of which may be the risk factors for the development of metabolic disorders. Different physiological mechanisms as well as psychosocial factors such as gender, age, smoking, stress level, nutrition and level of physical activity can affect the metabolic syndrome (MS) development in depressed patients. It is considered that chronic stress causes depression and subsequent poor lifestyle that can lead to the MS development, which results in increased incidence of cardiovascular disease.

Aim To determine the psychosocial and clinical characteristics of depressed patients with MS diagnosis.

Methods Cross-sectional study was conducted on a sample of 80 patients suffering from depressive disorder. The structured socio-demographic questionnaire, MINI questionnaire, Hamilton Rating Scale for Depression (HAM-D-17) and the Clinical Global Impression Scale (CGI) were used as diagnostic instruments. MS diagnosis was made according to NCEP/ATP III criteria.

Results Depressive patients with MS diagnosis had a significantly higher frequency of suicide attempts, while MS diagnosis significantly more frequently was present in female patients. Increased intake of carbohydrates was an important characteristic of the depression as well as MS.

Conclusion Further studies are needed in order to explain the observed gender differences, and whether interventions focused on the treatment of depression may contribute to the acceptance

of healthy lifestyles, particularly in changing of dietary habits, and thus indirectly contribute to the reduction of MS frequency.

Self-esteem and emotional distress in a population of unemployed persons

K. Medhaffar*, I. Feki, R. Sellami, I. Baati, D. Trigui, I. Abida, J. Masmoudi

Hédi Chaker University Hospital, Psychiatry "A", Sfax, Tunisia

* Corresponding author.

Introduction For most individuals, basic life requirements are met through employment. It can satisfy creative urges, promote self-esteem, and provide an avenue for achievement and self-realization.

Objective To assess the level of depression, anxiety and self-esteem in a population of unemployed persons.

Method It was a cross-sectional study involving unemployed people we met in the office of employment of Sfax in Tunisia. The level of anxiety and depression was assessed by the Beck depression and anxiety inventories. The self-esteem Rosenberg scale allowed us to evaluate the level of self-esteem of our population.

Results The average age of our subjects was 33 years six months. The average duration of unemployment of our population was 4 years 7 months and 38.2% of them had never worked before. The anxiety level was moderate in 38.2%, while moderate to severe depression was found in 47%. Self-esteem was low to very low in 47.1%. A low level of depression was positively correlated with a low socioeconomic level ($P=0.000$), a low level of anxiety ($P=0.000$) and a high self-esteem level ($P=0.000$).

Conclusion People with strong support systems and greater self-esteem seemed to experience less unemployment stress. Identifying those who are at high risk for psychological and physical problems and finding ways of preventing them from suffering the adverse effect of unemployment are important areas for further study.

Religion and depression among Iranian college students

M.M. Naderi

Islamic Azad University- Azadshar Branch- IRAN, Psychology, Azadshahr, Iran

Objective The main aim of the present study is to investigate the relationship between religious attitudes and depression.

Method The statistical sample of this study is 129 students of Islamic Azad university Azadshahr branch selected randomly subjects have been asked to fill out the beck depression Inventory (1978) and religious Attitude Questionnaire (Serahzade, 1978). Pearson correlation coefficient and Multiple factor regression have been used to analyze the research hypothesis.

Results The findings suggested that there is significant relationship between depression and religious attitudes. Furthermore, religious attitudes could explain the depression variance significantly.

Conclusion Religion plays a major role in human life and mental health.

Revisiting melancholic depression: Review of the concept and clinical implications

L.A. Oliveira*, A. Machado, F. Polido

Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Major Depression Disorder (MDD) represents a major concern in mental and public health, being the most common psychiatric disorder and one of the most prevalent diseases in western societies. However, many studies demonstrate a significant heterogeneity in MDD evidenced by different clinical presentations (up to 227 different symptom combinations can be fulfilled to diagnose MDD), different sociodemographic variables, distinct outcomes and significant differences in treatment response. This data may suggest the existence of different ethiopathogenic mechanisms in the development of MDD, implying the review and readjustment of MDD criteria into more distinct and homogeneous subtypes of Depression.

Objectives and methods In this non-systematic review the authors sought to identify different subtypes of MDD concerning their 1) clinical features and outcomes, 2) neurocognitive and neurobiological correlates and 3) treatment outcomes.

Results An increasing number of studies is being published concerning MDD heterogeneity and its possible subtypes. However, most of the authors try to recognize MDD with Melancholic features (M-MDD) as an independent entity in opposition to the current diagnostic criteria. The suggestion of a distinct MDD subtype is based on several studies showing clinical, cognitive and neurobiological differences shared between M-MDD patients which will be further discussed in this review.

Conclusions M-MDD may represent an independent depressive disorder with distinct clinical and outcome implications. However, further research is needed to identify more homogeneous MDD subtypes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Apathy and depression: Which clinical specificities?

J. Palaric

Saint Ave, France

Introduction Apathy is a transnosographical symptom that is often described in psychiatric and neurological illness. The most known definition, proposed by Marin (1991), is a lack of goal-directed voluntary behavior. Apathy and depression may be present together but they are clinically independent. The confusion between signs of apathy and those of depression might reveal diagnostic and treatment issue. Our aim is to define a clinical profile of apathetic patients (Ap) with depression, hypothesizing there is a different clinic profile than non-apatetic patients (NAp).

Method Seventy adults diagnosed with depression were included in a comparative, non-randomized and open cohort, since November 2014. Clinical assessments targeted clinical scale evaluations (MINI, AES, MADRS, STAI, SHAPS). Patients were separated in two groups, Ap VS NAp, using a 42 points cut-off at AES score.

Results Ap represent 30%; n(Ap)= 21, n(NAp)= 49. Depressive severity scores (MADRS) are lower in the Ap group; W-test= 672, P= 0,044. State anxiety scores (STAI-A) are lower in Ap group; W-test= 739, P= 0,004. Anhedonia scores (SHAPS) are lower in Ap group; W-test= 412, P= 0,004. Pearson test show negative correlation between AES/STAI-A (r= -0,27; P= 0,02); AES/SHAPS (r= -0,45; P= 0,001).

Conclusion Apathetic patients suffering from depression seem to present different clinical pattern in term of anxiety and anhedonia. These results are high of interest for therapeutic and further studies focus on pathophysiological issues.

Systematic review of the association between interferon treatment and depression in patients with multiple sclerosis

L. Alba Palé*, B. Samsó Buxareu, J. León Caballero, V. Chavarría Romero, E.J. Pérez Sánchez, A.J. Palma Conesa, J.M. Ginés Miranda, P. Salgado Serrano, V. Perez Sola

Parc de Salut Mar, INAD, Barcelona, Spain

* Corresponding author.

Introduction Multiple sclerosis (MS) is a common chronic neurological disease. Interferon beta (INF-1b) was the first disease-modifying drug to be approved for the treatment of multiple sclerosis. During INF-1b pivotal trials, an association to depression was found. Later, in a study about its efficacy, three suicide attempts were accounted.

Objectives Depression lifetime prevalence in MS patients is 50%, almost three times the rate in the general population. Suicide rate is also significantly higher. Depression has the greatest impact on quality of life. Besides MS treatment, depression itself may be related to neuronal damage, immune dysfunction and lifestyle changes.

Aims The aim of this review is to assess the relationship between INF-1b and depression risk in MS patients.

Methods We performed a literature search on PubMed database using the following keywords.

depression, multiple sclerosis, interferon treatment. We included only human studies in English for the past five years. The abstracts were reviewed and also the full text when necessary.

Results We selected 8 articles. Regarding their design, there was 1 cross-sectional study, 1 retrospective analyses, 1 clinical trial, 1 case control-study and 3 cohort studies. No meta-analyses or previous reviews were found. Two of the studies showed a prejudicial effect, three found no differences and three reflected a beneficial effect.

Conclusions In conclusion, the link between INF-1b and depression is uncertain. Although some studies have found direct relationship, recent publications have seen no changes in mood, and even a positive effect. Studies' limitations are remarkable, which is why further investigation needs to be done.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of augmentation treatment with second-generation antipsychotics in major depression disorder—current evidence in the literature

E. Pereira*, F. Coutinho, M. Marinho, C. Hipólito-Reis

Centro Hospitalar de São João, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Major depressive disorder (MDD) is a chronic mental illness with a considerable lifetime prevalence in adult men and women. Only a third of MDD patients remit following adequate antidepressant treatment, while most suffer from significant

core depressive or residual symptoms during their clinical course. Augmentation treatment with second-generation antipsychotics (SGAs) has been one of the suggested approaches to overcome this shortage of efficacy of antidepressant therapy.

Objectives To review the role of SGAs as an augmentation strategy to antidepressant therapy in MDD.

Methods A search of the MEDLINE/Pubmed database was conducted for articles from 2010 to 2015, using the MeSH terms “antipsychotics”, “depression” and “treatment”.

Results There is a general consensus in the literature that antidepressant augmentation treatment with SGAs is more effective than placebo in the management of patients with MDD who failed to respond adequately to antidepressant therapy alone. The majority of studies found no significant differences between the different studied drugs (namely, aripiprazole, quetiapine, olanzapine and risperidone). On the other hand, discontinuation rates due to adverse effects are also higher with SGAs versus placebo. However, it remains unclear if augmentation with SGAs is more effective than other therapeutic strategies, such as combination or switching to other antidepressant or augmentation with other psychotropics.

Conclusions There is strong evidence that SGAs augmentation is an effective and generally safe therapeutic approach to patients with MDD who respond poorly to antidepressants. Nevertheless, more studies are needed to understand the efficacy of this treatment comparing other therapeutic approaches.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antidepressant-induced hyponatremia

L. Rodríguez Andrés*, S. Gómez Sánchez, A. Rodríguez Campos, R. Hernández Antón, L. Gallardo Borge, A. Álvarez Astorga
Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction Hyponatremia is one of the electrolytic disorders most commonly observed among general hospitalized populations (2% of hospitalized patients). A form of hyponatremia is the syndrome of inappropriate antidiuretic hormone secretion (SIADH). One of its diverse causes is medication. Selective serotonin reuptake inhibitors (ISRSs) can cause hyponatremia due to SIADH, particularly among elderly population.

Clinical case report A 81-year-old female treated with paroxetine 20 mg/day because of depression. Two weeks later she starts feeling nausea, somnolence and motor inhibition. The sodium level previous to the onset of treatment was normal but after two weeks it has decreased to 121 mEq/L, pointing to SIADH induced by ISRSs.

Discussion The incidence of hyponatremia among elderly patients treated with antidepressants of ISRSs class has increased. The prevalence varies between 0.5 and 25%. Although half of the patients are asymptomatic, the mortality rate may reach 25%. It generally develops during the first month of treatment and is reversible between 2 and 28 days after the suspension of the ISRSs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effectiveness of exercise on weight loss and postnatal depression: A systematic review

M. Saligheh^{1,*}, D. Hackett¹, P. Boyce², S. Copley³

¹ University of Sydney, Exercise and Sport Science, Lidcombe, Australia

² University of Sydney, Sydney Medical School, Camperdown, Australia

³ University of Sydney, Discipline of Exercise and Sport Science, Lidcombe, Australia

* Corresponding author.

Introduction Exercise has well-established benefits on depression and weight-management in normative populations. However, its effectiveness at postpartum phase remains uncertain.

Objectives Determine the effectiveness of exercise or physical activity (PA) interventions on postnatal depression (PND) and weight-loss.

Aims Identify exercise and PA modalities most effective in reducing PND symptoms and weight.

Methods Systematic review of RCTs and experimental studies comparing exercise or PA modalities (e.g., flexibility versus resistance training) against control or alternative interventions (e.g. social support, diet). Data search included Cochrane Library (CENTRAL), MEDLINE, PsycINFO, EMBASE, CINAHL, Scopus and Science Citation Index.

Results Of 8099 studies retrieved, six fulfilled inclusion criteria. Two implemented supervised exercise interventions, one using ‘Yoga & Pilates’ (1 × 60 mins/session × 12 weeks) and one using resistance (v flexibility) training focusing on major muscle groups (2/week × 18 weeks). Yoga & Pilates decreased PND and body mass index (BMI); though resistance training did not. Four studies implemented PA interventions (e.g., walking) with varying duration (i.e., 3–18 months (e.g., 30 mins per session × 1/week). Two studies showed significant declines in BMI but no changes in PND, while two showed no changes in PND and BMI.

Conclusion Limitations in the data available; research design quality; inconsistencies in application of exercise modalities as well as their structure and content; and, the standardization of PND diagnosis, constrain the ability to determine whether exercise or PA benefits PND and weight in postpartum women.

Keywords Exercise; Depression; Postpartum; Weight-loss

The impact of neuroinflammation and inflammatory cytokines in depression and suicidal behavior

G. Serafini^{1,*}, M. Pompili², P. Girardi², M. Amore¹

¹ Section of Psychiatry- San Martino Hospital- University of Genoa, Neuroscience DINOGMI, Genoa, Italy

² Sant’Andrea Hospital- Sapienza University of Rome, Neuroscience, Rome, Italy

* Corresponding author.

Introduction It has been suggested that neuroinflammation and inflammatory mediators may play a crucial role in the pathophysiology of both major depression and suicidal behavior. Immunological differences have been reported between both subjects with major affective disorders and suicidal behavior.

Objectives The main objective of this review was to deeply investigate the nature of the association between inflammatory cytokines in depression and suicidal behavior. **Aims:** The study aimed to conduct a systematic review of the current literature to investigate the association between inflammatory cytokines, depression, and suicidal behavior.

Results Generally, an imbalance between pro-inflammatory and anti-inflammatory cytokines has been documented in both major depression and suicidal behavior. The presence of major depressive disorder (MDD) with suicidal ideation/attempts was associated with differences in inflammatory cytokine profile when compared to that without suicidal ideation/attempts. However, not all

studies demonstrated a positive correlation between inflammatory cytokines and suicidal behavior.

Conclusions The mentioned association between inflammatory cytokines, depression, and suicidal behavior does not imply the existence of a causal relationship. Further additional studies should clarify the molecular mechanisms of the immune activation pathways underlying depression and suicidality.

N-methyl-D-aspartate antagonists in depression–15 years after the first ketamine clinical study what has changed?

J. Ribeiro*, D. Mota, L. Rosa

Coimbra Hospital and University Centre, Psychiatry Department, Coimbra, Portugal

* Corresponding author.

Introduction In the last decades, multiple studies have suggested evidences of disturbances within the glutamate system in depressed patients. The first clinical study using ketamine in depression treatment was conducted fifteen years ago. Since then several studies tried to understand the mechanisms underlying the antidepressant effects of ketamine, as well as discover new drugs with better pharmacodynamic profiles.

Objectives/aims Review the literature on the role of glutamate system in depression and novel approaches with glutamate N-methyl-D-aspartate receptor antagonists in depression.

Methods Search and review of scientific literature on PubMed database with the keywords.

“major depressive disorder”, “depression”, “ketamine”, “glutamate”, “NMDA”, “neuroplasticity”.

Results Abnormalities of the glutamate clearance at synaptic space and astrocytic dysfunction associated with glutamate metabolism have been associated with depressive symptomatology. In depressed patients, reduced levels of glutamate have been described by magnetic resonance spectroscopy in multiple cortical areas, amygdala and hippocampus, supporting the hypothesis of glutamate system involvement in the neurobiology of depression. Indeed, in the last 15 years, multiple clinical studies using ketamine provided some evidence that glutamate N-methyl-D-aspartate receptor antagonism could be an approach for refractory forms of depression. However, regardless all of the evidences, no drug targeting specifically the glutamate system has been approved for depression treatment.

Conclusions The glutaminergic system plays a role in the pathophysiology of depression, why it's a possible therapeutic target. So, it's of utmost importance that future studies keep the focus in this area, looking for new drugs active in this system.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Federal Research and Clinical Center of Physical-Chemical Medicine, Biophysical methods of diagnostics, Moscow, Russia

⁴ Moscow Research Institute of Psychiatry, Affective disorders, Moscow, Russia

* Corresponding author.

Introduction The last years it is became clear that disturbances in molecular processes in pathological conditions can be connected with conformational changes in protein structure.

Aim Investigation of blood albumin conformation in patients with melancholic depression.

Material and methods There were investigated 19 patients with melancholic depression (12 women and 7 men) and 25 health volunteers. Patient's state according to ICD-10 criteria was defined as a depressive episode in the frame of bipolar depressive disorder (type 2) (F32) and in the structure of recurrent depressive disorder (F33). Subnanosecond laser time resolved fluorescence spectroscopy (SLTRFS) (subnanosecond diapason) with K-35 fluorescent probe was used for the investigation of albumin conformation.

Results and discussion There were revealed 3 binding sites in albumin molecule with fluorescent decay time of 1, 3 and 9 nanoseconds (A1, A3 and A9 sites, respectively) in healthy volunteers using SLTRFS approach. There were found significant differences between albumin binding sites of volunteers and patients with melancholic depression, respectively, A1–117 ± 7 ns 142 ± 10; A3–358 ± 14 ns 420 ± 26; A9–371 ± 16 ns 433 ± 29.

Conclusion These findings point out that melancholic depression is followed by conformational changes of albumin molecule that can affect its functional properties. We can hypothesized that albumin binding properties can serve as a biomarker of the efficacy of psychopharmacotherapy.

Differential profile amongst patients with depressive disorder (DD) and adjustment disorder (AD)

J. Martínez Arnaiz^{1,*}, B. Vallejo-Sánchez¹, C. García Blanco¹, A.M. Pérez-García²

¹ Santa Barbara Hospital, Mental Health Unit, Puertollano- Ciudad Real, Spain

² UNED, Psychology Faculty, Madrid, Spain

* Corresponding author.

Introduction Adjustment disorder (AD) is a condition that includes both emotional or/and behavioral symptoms and occurs when individual is unable to cope with stress. It is a common diagnosis but few studies have been done due to controversial diagnosis related to their diagnostic criteria definition. It is often difficult to establish differential diagnosis with condition such as depressive and anxiety disorders or even normal reaction to stressful situations. There are limited tools to evaluate such condition and its definition is focused or based on lack of severity.

Objectives Study objective target is to analyse the differences between two groups, a first group with AD and another one with Major Depressive Disorder (MDD) (with different sociodemographic, clinical and triggering individual factors such as vulnerability or coping management).

Aims We try to have a better comprehension and management of depressive conditions.

Methods Two groups that belongs to Mental Health Community Team are compared. The first one with a diagnosis of AD, and another group with the diagnosis of MD. They have been diagnosed through a structured clinical interview and standard questionnaires to evaluate personality copying management. Other

pathologies (such as psychotic, organic, . . .) were excluded through a structured clinical interview. We analyzed variables considered through variance analysis.

Results Significant differences between groups were found in some of the variables considered.

Conclusions This study have important implications regarding evaluation, differential diagnosis and psychotherapeutic approach to patients with AD and MD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of GP services over a five-year period after an episode of depression

P. Verhaak

University Medical Center Groningen, General Practice, Groningen, Netherlands

Background Depression occurs frequently and is mostly treated in general practice. Little has been reported about its long-term course and long-term use of medical services.

Aim To follow up patients with these depression in general practice for five years, looking at the length and number of index episodes, prescribing behaviour and use of services within general practice and compare them with patients with psychological symptoms and mentally healthy patients.

Design and setting A case-control study based on data from Electronic Medical Records (EMR).

Methods Three cohorts of patients with depression ($n=453$), anxiety symptoms ($n=442$) and emotional distress ($n=185$) were compared against a cohort of control patients ($n=4156$) during a 5-year follow-up looking at the occurrence or recurrence of the index disorders, other psychological disorders and medical disorders, numbers of prescriptions and the number of contacts with the general practice.

Results The depression group had 1.1 follow-up episodes of depression, the anxiety group 0.9 follow-up episodes of anxiety and the emotional distress group 0.5 follow-up episodes of emotional distress during five years. All three groups had more consultations (for both psychological and somatic reasons) during each of the follow-up years than control patients. Furthermore, they are given more prescriptions for psychopharmacological treatment.

Conclusion Five years after the index episode in 2007, patients with an episode of depression, anxiety or emotional distress are still not comparable with control patients, in terms of the prevalence of psychological disorders, the number of prescriptions and healthcare use. Depression appears to be a chronic disease.

EW198

Anhedonic brain while attending sexual and emotional pictures

F. Von Duering

Heiligenthal, Germany

Anhedonia is defined as the inability to gain pleasure from normally pleasurable experiences and reduced sexual desire. Rees et al. (2007) showed that limbic and paralimbic areas are responsible for sexual arousal and that anhedonia is associated with frontolimbic inhibition. In major depression, reduced ventral striatum and increased ventral prefrontal cortex areas was associated with anhedonia (Gorwood, 2009). Walter et al. (2009) indicated that there is a deviation in the neuronal activation pattern of the pregenual anterior cingulate cortex in anhedonic depression which is related to

a glutamergic deficit. Glutamate was suggested to play a relevant role in reward system (Birgner et al., 2005). ACC is a key involved in affective state and glutamate mediates ACC activation to sexual attraction (Wu et al., 2009). Thus, a glutamatergic deficit might be related to reduced hedonic effect specific to major depression. Using an attention modulation of emotional and sexual pictures, we investigate the role of anhedonia on the ventral and dorsal systems in healthy volunteers and patients with major depression. They undergo an expectancy task in a 7T scanner and passively view sexual and emotional photographs and are asked to expect either high salient pictures or high erotic pictures. Half of these pictures are announced by an expectancy cue, whereas the other half are preceded by a fixation cross. Snaith-Hamilton-Pleasure-Scale and Hamilton Depression Rating Scale are employed to assess anhedonia and depressive symptom severity. Brain metabolites in the dorsal and pgACC are measured using MRS. We will show how anhedonia modulates the neural response to sexual arousal.

Oxytocin secretion in anorexia nervosa and bulimia nervosa: Investigation of its relationships to temperament personality dimensions

M. Nigro^{1,*}, A.M. Monteleone¹, L. Steardo¹, G. Patriciello¹, V. Di Maso¹, M. Cimino¹, U. Volpe¹, P. Monteleone²

¹ Department of Psychiatry, University of Naples SUN- Naples- Italy, Naples, Italy

² University of Salerno, Neuroscience Section- Department of Medicine and Surgery, Salerno, Italy

* Corresponding author.

Introduction Some temperament characteristics of personality seem to be modulated by oxytocin. Patients suffering from eating disorders (EDs) display aberrant personality traits.

Objectives and aims We investigated the relationships between plasma oxytocin levels and personality dimensions of patients with anorexia nervosa (AN) and bulimia nervosa (BN) and compared them to those of healthy controls.

Methods Plasma oxytocin levels were measured in 23 women with AN, 27 women with BN and 19 healthy controls and assessed their personality traits by means of the Cloninger's Temperament and Character Inventory-Revised (TCI-R).

Results AN patients showed plasma levels of the hormone significantly lower than BN and healthy controls. In healthy women, plasma oxytocin levels resulted significantly correlated negatively with novelty seeking scores and positively with both harm avoidance (HA) scores and the attachment subscale scores of the reward dependence: these correlations explained 82% of the variability in circulating oxytocin. In BN patients, plasma oxytocin resulted negatively correlated with HA, whereas no significant correlations emerged in AN patients.

Conclusions These findings confirm a dysregulation of oxytocin secretion in AN but not in BN and show, for the first time, that the association of circulating oxytocin to patients' temperament traits is totally lost in underweight patients with AN and partially lost or even inverted in women with BN. These findings suggest a role of oxytocin in certain deranged behaviours of ED patients, which are influenced by the subjects' personality traits.

Attachment style and salivary cortisol awakening response in eating disorders

F. De Riso^{1,*}, R. Giugliano¹, A.M. Monteleone¹, M. Nigro¹, F. Pellegrino¹, M. Calvanese¹, G. Patriciello¹, V. De Stefano¹, U. Volpe¹, P. Monteleone²

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Salerno, Neuroscience section- Department of Medicine and Surgery, Salerno, Italy

* Corresponding author.

Introduction Early life experiences can influence hypothalamus-pituitary-adrenal (HPA) axis regulation and adult attachment styles. Furthermore, several studies showed that in patients with eating disorders (EDs) there is a prevalence of insecure attachment. However, the relationship between adult attachment style, HPA axis functioning and onset of EDs is largely unknown.

Objectives and aims In order to evaluate possible associations between attachment styles and HPA axis functioning in EDs, we investigated Cortisol Awakening Response (CAR) in ED patients with different attachment styles.

Methods Twenty adult patients with EDs were classified in three groups, according to the Experience in Close Relationship questionnaire (6 with secure attachment, 6 with anxious attachment and 8 with avoidant attachment). Saliva samples were collected at awakening and 15, 30 and 60 minutes after.

Results There was a significant difference among the groups in both awakening and post-awakening cortisol concentrations. In particular, compared to secure and avoidant groups, the anxious group exhibited lower cortisol concentrations at awakening and post-awakening with a preservation of the timing of the CAR.

Discussion Present findings demonstrate that anxious attachment style is linked to flattened CAR in EDs. This pattern has been associated with other psychiatric disorders. Therefore, attachment style could influence the HPA functioning and it could play, although not specifically, a role in pathophysiology of EDs.

³ Università degli studi di torino, Dipartimento di Scienze della Sanità Pubblica e Pediatrica, Torino, Italy

⁴ Università del piemonte orientale, translational medicine, Novara, Italy

* Corresponding author.

Background Expressed Emotion (EE) can be described as a measure of the emotional temperature of the family climate and plays a role in disease course and outcome, especially in chronic illnesses. Overweight and obesity are severe problems with serious implications as far as health risks are concerned. The literature suggests

having a high EE caregiver correlates with a worse treatment compliance in obese patients.

Objectives To measure level of EE, stressful events and anxiety in obese patients and their caregivers; to investigate the possible correlations between treatment compliance and EE.

Methods We recruited 190 obese patients and 125 caregivers. Socio-demographic features were recorded. Assessment included: Level of Expressed Emotion Scale (LEE), one version for patients and one for relatives in order to evaluate 4 dimensions: Intrusiveness, Emotional Response, Attitude toward Disease, Tolerance and Expectation; the Paykel's Interview for Recent Life Events; STAI Y1 concerning state anxiety and STAI Y2 concerning trait anxiety; BMI (Body Mass Index) was measured at T0 and after 3, 6 and 9 months. **Results** We have found a correlation between gender and trait anxiety, and an inverse correlation between age and trait anxiety both in patients and caregivers. The decrease of BMI during follow-up is statistically significant and this reduction seems to be affected by tolerance and expectation perceived by patients and the emotional response on behalf of caregivers.

Conclusions Levels of EE should be considered when planning treatment interventions to enhance compliance in obese patients and to support change in their life-style.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How do obese people eat?

M.P. Felix-Alcantara^{1,*}, J. Perez-Templado², C. Banzo-Arguis¹, R. Martínez de Velasco¹, E. Ruiz-Velasco¹, J. Quintero³

¹ Hospital Universitario Infanta Leonor, Psychiatry, Madrid, Spain

² Fundación Psiformación, Psychiatry, Madrid, Spain

³ Hospital Universitario Infanta Leonor & Fundación Psiformacion, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction The recently published DSM-5 defines Eating Disorders (ED) as "a persistent alteration in the food supply or food-related behavior leading to an alteration in the consumption or absorption of food and cause a significant deterioration in health or psychosocial functioning" and, nevertheless, it does not include obesity as an ED due to the lack of enough evidence to include it. However, everyday more evidence supports that disordered eating could be a significant factor, at least, in development and maintenance of obesity.

Objectives Describe the eating behavior of a 180 obese sample.

Methods One hundred and eighty patients with obesity that went to the endocrinology service in order to lose weight are referred to the Psychiatry department to be assessed. To explore the eating behavior it was administered the Bulimic Investigatory Test of Edinburgh, BITE.

Results A total of 68.7% of patients showed a disordered eating pattern, 71.6% tend to eat a lot when feeling anxious, 63.8% eat rapidly large amounts of food, 72.8% worry about not to have control over how much eat, 40.5% consider that their pattern of eating severely disrupt their life, 40.7% eat sensibly in front of others and make up in private, 59.1% cannot stop eating when they want to and 58.3% admit binges of large amounts of food.

Conclusions Most of our patients showed a pattern of disordered eating, and then our findings support the idea of disordered eating as a significant factor in the development and maintenance of obesity. Therefore, obesity requires a multidisciplinary approach that goes beyond the traditional nutritional guidance.

Randomized controlled trial testing behavioral weight loss versus multi-modal stepped-care treatment for binge eating disorder

C. Grilo

Yale University School of Medicine, Psychiatry, New Haven, USA

Introduction Binge eating disorder (BED) is prevalent, associated with obesity and elevated psychiatric co-morbidity, and represents a treatment challenge.

Objective and aims A controlled comparison of multi-modal, stepped-care versus behavioral-weight-loss (BWL) for BED.

Methods One hundred and ninety-one patients (71% female, 79% white) with BED and co-morbid obesity (mean BMI 39) were randomly assigned to 6 months of BWL ($n=39$) or stepped-care ($n=152$). Within stepped-care, patients started BWL for one month; treatment-responders continued BWL while non-responders switched to cognitive-behavioral-therapy (CBT) and all stepped-care patients were additionally randomized to anti-obesity medication or placebo (double-blind) for five months. Independent assessments were performed by research-clinicians at baseline, throughout treatment, and post-treatment (90% assessed) with reliably-administered structured interviews.

Results Intent-to-treat analyses of remission rates (0 binges/month) revealed BWL and stepped-care did not differ significantly overall (74% vs 64%); within stepped-care, remission rates differed (range 40% - 79%) with medication significantly superior to placebo ($P<0.005$) and among initial non-responders switched to CBT ($P<0.002$). Mixed-models analyses of binge eating frequency revealed significant time effects but BWL and stepped-care did not differ overall; within stepped-care, medication was significantly superior to placebo overall and among initial non-responders switched to CBT. Mixed models revealed significant weight-loss but BWL and stepped-care did not differ overall; within stepped-care, medication was significantly superior to placebo overall and among both initial responders continued on BWL and non-responders switched to CBT.

Conclusions Overall, BWL and stepped-care treatments produced improvements in binge-eating and weight loss in obese BED patients. Anti-obesity medication enhanced outcomes within a stepped-care model.

Binge-eating disorder and major depressive disorder co-morbidity: Sequence and clinical significance

C. Grilo^{1,*}, D. Becker²¹ Yale University School of Medicine, Psychiatry, New Haven, USA² University California- San Francisco, Psychiatry, San Francisco, USA

* Corresponding author.

Introduction Binge-eating disorder (BED) is associated with obesity and with elevated rates of co-occurring major depressive disorder (MDD) but the significance of the diagnostic comorbidity is ambiguous—as is the significance of the onset sequence for MDD and BED.

Objective and aims We compared eating-disorder psychopathology and psychiatric comorbidity in three subgroups of BED patients: those in whom onset of BED preceded onset of MDD, those with onset of MDD prior to onset of BED, and those without MDD or any psychiatric comorbidity.

Methods A consecutive series of 731 treatment-seeking patients meeting DSM-IV-TR research criteria for BED were assessed reliably by doctoral-clinicians with semi-structured interviews to evaluate

lifetime psychiatric disorders (SCID-I/P) and ED psychopathology (EDE Interview).

Results Based on SCID-I/P, 191 (26%) patients had onset of BED preceding onset of MDD, 114 (16%) had onset of MDD preceding onset of BED, and 426 (58%) had BED without co-occurring disorders. Three groups did not differ with respect to age, ethnicity, or education, but a greater proportion of the group without MDD was male. Three groups did not differ in body-mass-index or binge-eating frequency, but groups differed significantly with respect to eating-disorder psychopathology, with both MDD groups having significantly higher levels than the group without co-occurring disorders. The group having earlier onset of MDD had elevated rates of anxiety disorders compared to the group having earlier onset of BED.

Conclusions MDD in combination with BED—with either order of onset—has a meaningful adverse effect on ED psychopathology and overall psychiatric co-morbidity.

ARFID in adults: Problems with the DSM 5 and ICD-11 conceptualization of restrictive eating disorders

R. Gupta*, V. Krishnan, K.S. Deb, A. Mahapatra, P. Sharan

All India Institute of Medical Sciences, Psychiatry, New Delhi, India

* Corresponding author.

Introduction The nosology of eating disorders is undergoing a vast change. As a part of the revision process, the new diagnostic category of “Avoidant/Restrictive Food Intake Disorder” (ARFID) replaces the “Feeding Disorder of Infancy or Early Childhood” of DSM-IV to include those patients who have restrictive patterns of diet, but do not endorse weight or body shape concerns as the primary reasons for these restrictions. DSM-5 broadened the scope of ARFID to also include adults with restrictive eating patterns, which cannot be explained otherwise.

Aims & objectives To highlight the nosological issues with ARFID as a diagnosis among adults.

Methods A case series describing four cases presenting with disordered eating causing significant dysfunction that occurred for the first time in adulthood.

Results In each case, anxieties regarding the consequences of eating multiple types of food led to significant restrictions of the quantity or kinds of diet which was associated with distress and dysfunction, and, significant weight loss. However, in all the cases, the restriction was secondary to the fear of physical symptoms which could be explained by underlying ICD-10 somatoform disorder. The cases do not match the classic western description of ARFID.

Conclusions This series highlights some of the issues relating to eating disorder, particularly its clinical and nosological status. Problems relating to classification in a non-western setting are also reflected by the difficulty in labeling eating-related problems amidst the interplay of somatization, culture and eating.

* Corresponding author.

Introduction Monitoring patient with anorexia nervosa (AN) include clinical, biological and psychological factors. In recent years many researchers criticize the BMI as useful measure for controlling evolution of AN.

Objectives Bioelectrical impedance analysis (BIA) is one of the main methods for nutritional status assessment.

Aims The aim of this study was the assessment of the nutrition status in a group of patients with anorexia nervosa in comparison to healthy population (HP).

Methods The study involved 37 participants: 21 patients with AN and 16 healthy volunteers constituting the control group (HP). The patients were divided into two groups according a BMI: I group $14 < \text{BMI} < 15.5$ ($n = 11$; age 18.0 ± 4.37) and II group: $15.5 < \text{BMI} < 17.5$ ($n = 10$; age 17.82 ± 3.68). The mean age of HP was 17.68 ± 1.57 and BMI $20.56 \pm 1.16 \text{ kg/m}^2$. BIA was performed by using ImpediMed bioimpedance analysis SFB7 BioImp. The parameters: phase angle (PA), TBW%, ECW, ICW, ECW/ICW were analyzed.

Results PA was decreased significantly in the I ($4.5^\circ \pm 0.6$) and II group ($4.7^\circ \pm 0.6$) of AN patients' in comparison with HP ($5.6^\circ \pm 0.7$). TBW was 9% higher in I group and ECW was increased 6% in the both AN groups compared with HP ($P < 0.01$). Additionally ECW/ICW ratio indicated the higher transfer of water into the extracellular compartment in AN group ($P < 0.01$).

Conclusions BIA is accurate tool to indicate the valuable indicators of detecting malnutrition in AN. Further studies are needed to validate the significance of these parameters for the full identification of the nutrition status of AN patients'.

Keywords Anorexia nervosa; Bioelectrical impedance; Phase angle; TBW; ECW; ICW

* Corresponding author.

Presence of NES increases frequency of comorbidity not only with anxiety and depression but also with other psychiatric disorders. The objective was to evaluate prevalence and comorbidity of NES with other psychiatric disorders in outpatient population. Participants were recruited from outpatients of Voronezh State Psychoneurological Dispensary and LLC «LION-MED». In total, 197 (male and female) psychiatric outpatients participated in the study. Results were controlled by comparison to a population of students of Voronezh State Medical University ($n = 227$, male and female). All participants were screened with Night Eating Questionnaire (NEQ). After assessment all subjects, who gathered more than 20 scores were invited for therapeutic interview with psychiatrist for diagnostic validation according to the criteria.

Results Thirty-five percent of patients were screened positive for NES. After therapeutic assessment only 19,3% were validated with diagnostic criteria. The results were significantly higher compared to control group (8%, $P < 0,05$). Comparison of prevalence of different disorders in NES and non-NES outpatients was conducted (Table 1).

Conclusion Prevalence of NES among psychiatric outpatients is 19,3%. Prevalence of alcohol addiction, panic disorder and mixed anxiety and depressive disorder is higher in NES group. Schizophrenia, generalized anxiety disorder is more prevalent in non-NES group.

Table 1

ICD-10	Diagnosis	NES (n = 38) %	Non-NES (n = 156) ^a %	χ^2 (df = 1)	P
F10.2	Alcohol addiction	34.21	23.08	8.592	0.003
F20	Schizophrenia	10.53	19.23	12.550	0.000
F41.0	Panic disorder	15.79	8.97	5.449	0.020
F41.1	Generalized anxiety disorder	2.63	6.41	8.693	0.003
F41.2	Mixed anxiety and depressive disorder	10.53	5.13	4.827	0.028

^a 3 patients refused to visit interview.

Trends of hospitalization for anorexia nervosa in USA: A nationwide analysis

Z. Mansuri^{1,*}, M. Rathod¹, P. Bansal², U. Mansuri³, S. Shambhu¹

¹ Drexel University, School of Public Health, Philadelphia, USA

² Mayo Clinic, Cardiology Research Fellow, Arizona, USA

³ Mount Sinai, Icahn School of Medicine Department of Public Health, New York, USA

* Corresponding author.

Objectives Anorexia Nervosa (AN) is an important cause of morbidity and mortality in hospitalized patients. While AN has been extensively studied in the past, the contemporary data for impact of AN on cost of hospitalization are largely lacking.

Methods We queried the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (HCUP-NIS) dataset between 1998-2011 using the ICD-9 codes for AN. Severity of co-morbid conditions was defined by Deyo modification of Charlson co-morbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, chi-square test, t-test and Cochran-Armitage test were used to test significance.

Results 28,150 patients were analyzed. 93.94% were female and 6.06% were male ($P < 0.0001$). 88.67% were white, 2.93% were black and 8.4% were of other race ($P < 0.0001$). Rate of hospitalization decreased from 1530/million to 1349.5/million from 1998-2011. Overall mortality was 0.78% and mean cost of hospitalization was 25,829.82\$. The in-hospital mortality reduced from 0.95% to 0.44% ($P < 0.0001$) and mean cost of hospitalization increased from 11,956.55\$ to 39,831.51\$. Total yearly spending on AN related admissions increased from \$145.33 million/year to \$420.61 million/year.

Conclusions While mortality has slightly decreased from 1998 to 2011, the cost has significantly increased from \$145.33 million/year to \$420.61 million/year, which leads to an estimated \$275.28 million additional burden to the US health care system. In the era of cost conscious care, preventing AN related hospitalization could save billions of dollars every year. Focused efforts are needed to establish preventive measures for AN related hospitalization.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objectives Bulimia Nervosa (BN) is an important cause of morbidity and mortality in hospitalized patients. While BN has been extensively studied in the past, the contemporary data for impact of BN on cost of hospitalization are largely lacking.

Methods We queried the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (HCUP-NIS) dataset between 1998–2011 using the ICD-9 codes. Severity of co-morbid conditions was defined by Deyo modification of Charlson co-morbidity index. Primary outcome was in-hospital mortality and secondary outcome was total charges for hospitalization. Using SAS 9.2, chi-square test, t-test and Cochran-Armitage test were used to test significance.

Results 19,441 patients were analyzed. 94.13% were female and 5.87% male ($P < 0.0001$). 85.72% were white, 4.55% black and 9.73% of other race ($P < 0.0001$). Rate of hospitalization decreased from 1136.99/million to 802.47/million from 1998–2011. Overall mortality was 0.20% and mean cost of hospitalization was 15,496.82\$. The in-hospital mortality reduced from 0.23% to 0.15% ($P < 0.0001$) and mean cost of hospitalization increased from 8,194.53\$ to 22,547.86\$. Total spending on BN related admissions have increased from \$73.96 million/year to \$139.93 million/year over the last decade.

Conclusions While mortality has slightly decreased from 1998 to 2011, the cost has significantly increased from \$73.96 million/year to \$139.93 million/year, which leads to an estimated \$65.97 million/year additional burden to US health care system. In the era of cost conscious care, preventing BN related Hospitalization could save billions of dollars every year. Focused efforts are needed to establish preventive measures for BN related hospitalization.

Current and emerging drugs treatment for night eating syndrome

M. Martellini^{1,*}, M. Barchiesi¹, M.G. Oriani², B. Nardi¹

¹ Polytechnic University of Marche, Clinica di Psichiatria, Ancona, Italy

² Dipartimento di Salute Mentale Ancona ASUR Marche, Dipartimento di Salute Mentale Ancona ASUR Marche, Ancona, Italy

* Corresponding author.

Introduction The night eating syndrome (NES) is a categorized in the diagnostic and statistic manual (DSM-5) as an "Other Specified Feeding or Eating Disorder" and it is characterized by a reduced feeding during the day, evening hyperphagia accompanied by frequent nocturnal awakenings associated with conscious episodes of compulsive ingestion of food and abnormal circadian rhythms of food and other neuroendocrine factors. Frequently it is associated with obesity and depressed mood.

Objectives The purpose of this review is to investigate the state of art concerning the psychopharmacological treatment of NES.

Methods A Medline enquiry of published articles from 2005 to October 2015 was performed using the following keywords: "NES,

pharmacological treatment, SSRI, antidepressants, antipsychotic, sertraline, citalopram, escitalopram, duloxetine, venlafaxine, paroxetine, fluoxetine, fluvoxamine, topiramate". Reviews, single case studies and RCT were also analyzed.

Results Only few studies met the selection criteria. A recent 8-week double-blind placebo controlled study, in 34 patients with NES, has confirmed the efficacy of sertraline. Sertraline was associated with significantly greater improvement than placebo in overall symptomatology.

Conclusions SSRIs should be considered the drug of choice for the treatment of NES not only because of evidence in the literature but also since they display the best pharmacological profiles with fewer adverse events. More evidence of efficacy is shown for some SSRIs such as paroxetine, fluvoxamine and especially sertraline. Topiramate should be reserved for cases resistant to treatment with SSRIs.

Childhood trauma and cortisol awakening response in eating disorders: A dose-dependent trauma effect

F. Monaco^{1,*}, A.M. Monteleone¹, F. Pellegrino¹, F. De Riso¹, G. Patriciello¹, M. Cimino¹, M. Calvanese¹, U. Volpe¹, P. Monteleone²

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Salerno, Department of Medicine and Surgery-Neuroscience Section, Salerno, Italy

* Corresponding author.

Introduction A role for the hypothalamus-pituitary-adrenal (HPA) axis has been suggested in the pathophysiology of anorexia nervosa (AN) and bulimia nervosa (BN), and childhood trauma experiences have been detected frequently in patients with AN and BN. Since trauma exposure in the childhood may persistently affect HPA axis functioning, we explored HPA axis activity in AN and BN patients with and without childhood trauma history.

Objectives and aims We aimed to examine possible associations between childhood traumatic experiences and HPA axis functioning, as assessed by the cortisol awakening response (CAR), in adult patients with AN or BN as compared to adult healthy controls.

Methods Saliva samples were collected by 41 patients with symptomatic AN, 32 with symptomatic BN and 45 healthy controls at waking and after 15, 30 and 60 min. They filled in the Childhood Trauma Questionnaire (CTQ), which assesses five specific types of childhood trauma.

Results As compared to the control group, the no-maltreated AN patient group exhibited an enhanced CAR whereas the no-maltreated BN patient group showed a similar CAR. On the contrary, both AN and BN patients with a positive history of childhood maltreatment exhibited statistically significant blunted CAR as compared to no-maltreated patients. Moreover, in maltreated ED patients the CAR tended to decrease when the number of trauma types increased.

Discussion Present findings confirm a dysregulation of the HPA axis activity in symptomatic patients with AN and BN and suggest a dose-dependent effect of childhood adverse experiences on the CAR of adult ED patients.

Trauma, impulsiveness and inflammatory dysfunction in eating disorders

M. Díaz Marsá^{1,*}, A. Navalón¹, A. Rodríguez Quiroga², K. McDowell³, J.C. Leza³, M. Soto⁴, C. Prado¹, J.L. Carrasco¹

¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

² Hospital Gregorio Marañón, Psiquiatría, Madrid, Spain

³ Universidad Complutense De Madrid, Farmacología, Madrid, Spain

⁴ Hospital provincial de la Misericordia, Psiquiatría, Toledo, Spain

* Corresponding author.

Introduction Links between impulsiveness and eating disorders (ED) is widely studied. The relationship between stress response and inflammatory mechanisms in ED have also been suggested in several studies.

Objectives To clarify role of impulsivity in ED and to relate it with inflammatory response observed in previous studies.

Methods This study belongs to a larger one in which inflammatory parameters in white blood cells were investigated in 50 female patients with ED. Subjects were selected at the Eating Disorders Unit of a general hospital. The psychopathology of the disorder was evaluated by using different eating disorders assessment tools. A neuropsychological battery test was also applied. In this study, we used Barratt Impulsiveness Scale (BIS-11) to characterize impulsiveness. We also divided sample in subgroups: impulsive ED and non-impulsive ED in order to study differences in clinical variables and inflammatory response between groups.

Results A significant increase in plasma levels of the proinflammatory cytokine IL1b that correlates with scores in BIS-11 (Cognitive impulsiveness) was showed. We also found correlation between psychoneurological test and inflammatory response. A relationship between clinical assessment: trauma questionnaire (TQ), and BIS-11 was also found. Subgroup impulsive ED had significant higher scores in trauma than non impulsive ED.

Conclusions Impulsiveness correlates with greater dysfunction of the inflammatory system. The increases in plasma levels of IL1b are related to impulsive response, that indicates an inflammatory and oxidative-nitrosative status in this particular clinical settings. This study continued the investigation of a new line of inflammatory biomarkers in patients with eating disorders.

³ Catholic University of Leuven, Mind-Body-Unit- University Psychiatric Center, Leuven, Belgium

* Corresponding author.

Introduction Individuals with eating disorders (EDs) often report a history of early traumatization. Although a great attention has been paid to sexual and physical trauma, less is known about emotional one, especially neglect.

Objectives/aims We aimed to estimate the prevalence of sexual, physical, and emotional trauma-occurring under 18 years of age-in ED patients vs. healthy controls, focusing on emotional abuse and neglect.

Methods We consecutively recruited 57 DSM-V ED outpatients (91.2% females; age range = 18–42 years) at the Psychiatric Outpatient Clinic of our University Hospital and 90 healthy controls (78.9% females; age range = 20–39 years). Among ED patients, 43.9% had restrictive anorexia nervosa (AN), 29.8% binge/purging AN, 26.3% bulimia nervosa. Individuals completed the Eating Disorder Inventory-2 (EDI-2) and the Traumatic Experiences Checklist (TEC). We used Mann-Whitney U test and χ^2 test for comparisons.

Results ED patients scored significantly higher than controls on all EDI-2 subscales (P -values < 0.05). On the TEC, emotional trauma was more frequent than sexual/physical ones in both ED patients and controls. Emotional trauma, and to a lesser extent physical one, were significantly more frequent in ED patients than controls. Distinguishing between emotional abuse and neglect, the latter had a higher prevalence than the former in both groups. Additionally, ED patients reported significantly more neglect, but not emotional abuse, than controls.

Conclusions Our findings show a high prevalence of emotional trauma in EDs, mainly neglect, i.e., a lack of care and attention potentially contributing to EDs. Thus, it is crucial to investigate emotional neglect in ED patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction A high proportion of individuals with eating disorders (EDs) report childhood abuse and neglect. The prevalence of traumatic events in ED patients has been extensively investigated; less is known about their self-perceived-and reported-severity. **Objectives/Aims:** We aimed to assess in ED patients vs. healthy controls the severity, i.e., duration, perpetrator, and subjective impact, of sexual, physical, and emotional traumas suffered from 0 to 18 years, paying particular attention to emotional neglect.

Methods Fifty-seven consecutive DSM-V ED patients (91.2% females; age range: 18–42 years) were recruited at the Psychiatric Outpatient Clinic of our University Hospital. Ninety controls (78.9% females; age range: 20–39 years) were also recruited. Among ED patients, 43.9% had restrictive anorexia nervosa (AN), 29.8% binge/purging AN, 26.3% bulimia nervosa. Individuals completed the Eating Disorder Inventory-2 (EDI-2) and the Traumatic Experiences Checklist (TEC).

Results The severity of all traumatic events, according to the TEC total score, was significantly higher in ED patients than controls ($P < 0.001$). Moreover, ED patients showed significantly higher scores with regard to emotional neglect ($P < 0.001$) and emotional abuse ($P < 0.001$). The same can be said for physical traumas ($P < 0.01$) and physical abuse ($P < 0.01$), although with a lower significance, and for sexual abuse ($P < 0.05$), with an even lower significance. No difference in the severity of sexual harassment was found.

Conclusions All types of traumas, especially neglect, can occur in ED patients and controls, however they are reported as more severe by ED patients.

The relationship of perfectionism with changes in body dissatisfaction in eating disorders treatment outcome

T. Rodriguez Cano^{1,*}, L. Beato Fernandez¹, B. Mata Saenz¹, L. Rojo Moreno², F.J. Vaz Leal³

¹ Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

² Professor of Psychiatry. HUIP la Fe, Catedrático de Psiquiatría, Valencia, Spain

³ University of Extremadura Medical School Head, Mental Health and Eating Disorder Unit, University Hospital Network Badajoz, Professor of Psychiatry, Badajoz, Spain

* Corresponding author.

Introduction Body dissatisfaction is one of the core psychopathological components in Eating Disorders (EDs) and it tends to persist over time regardless treatment interventions. Perfectionism is considered as a mediator and moderator between body dissatisfaction and disordered eating.

Objectives To study the influence of Perfectionism in EDs outcome.

Aims To analyze changes in body dissatisfaction at one year follow-up in patients with eating disorders and the effect of perfectionism over these changes.

Methods Participants were 151 patients with eating disorders. DSM-IVTR diagnoses were as follows: 44 (29.1%) Anorexia Nervosa (AN), 55 (36.4%) Bulimia Nervosa (BN) and 52 (34.4%) Eating Disorders no Otherwise Specified (EDNOS). Perfectionism was assessed with the Edinburg Investigatory Test (EDI-2). The Body Shape Questionnaire (BSQ) was also distributed. One year after the beginning of their treatment, patients were reassessed.

Results Patients with BN showed significantly higher scores on BSQ than those with AN. There was a significant improvement in BSQ after one year of treatment regardless the diagnostic (repeated measures ANOVA: $F = 8.4$, $P < .01$). Perfectionism was a co-variable that influenced in those changes.

Conclusions The results confirm the interaction between perfectionism and body dissatisfaction in the treatment outcome of EDs. It has been described an interplay between Perfectionism, body dissatisfaction and disordered eating attitudes and behaviours, being Perfectionism a moderator factor. The results highlight the need of dealing not only with the core symptoms of EDs, but also with the moderator factors such as Perfectionism to enhance the outcome.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW216

Perfectionism in eating disorders: Temperament or character? Does perfectionism improve on treatment outcome?

T. Rodriguez Cano^{1,*}, L. Beato Fernandez¹, B. Mata Saenz¹, L. Rojo Moreno², F.J. Vaz Leal³

¹ Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

² Universidad de Valencia, HUIP la Fe, Professor of Psychiatry, Valencia, Spain

³ University of Extremadura Medical School Head, Mental Health and Eating Disorder Unit, University Hospital Network Badajoz, Professor of Psychiatry, Badajoz, Spain

* Corresponding author.

Introduction Perfectionism is considered a risk factor and is very close related to Eating Disorders (EDs). It estimates heritability of 29–42%. However, it has also been related to psychosocial factors such as the insecure attachment style.

Objectives To study the relationship of perfectionism with personality dimensions, its likelihood of improvement and its treatment.

Aims To analyze if Perfectionism is associated with dimensions of Temperament or dimensions of Character and therefore more psychosocial.

Methods Participants were 151 female outpatients who consecutively started treatment at the Eating Disorders Unit (Ciudad Real University General Hospital). Personality was assessed by using the Temperament and Character Inventory (TCI). Perfectionism was assessed by using the Edinburg Investigatory Test (EDI-2) subscale (t0). One year later, patients were re-assessed with the EDI-2 (t1).

Results The scores on Perfectionism significantly improved from t0 to t1, (repeated measures ANOVA, $F = 6.6$, $P < 0.01$). At baseline, Perfectionism was related to any of the Temperament dimensions, but the Character variable Purposefulness (SD2) ($\beta = .25$ 95% CI .17, .98), 2.7% of variance). Responsibility (SD1) and Self-Acceptance (SD4) were inversely associated with Perfectionism. At t1, Responsibility still was a protective factor for Perfectionism, regardless the effect of Perfectionism at t0.

Conclusions Perfectionism is also related to psychosocial and developmental factors. People with an internal locus of control tend to take responsibility for their own actions and are resourceful in solving problems. Thus, Self-directedness, mainly Responsibility for their own actions, is a protective factor for Perfectionism in EDs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Co-occurrence of gender dysphoria and eating disorders: A systematic review of the literature

A. Calderera¹, P. Brustia¹, E. Gerino¹, L. Dimitrios², L. Rollè^{1,*}

¹ University of Torino, Psychology, Torino, Italy

² Filistos Psychosocial Testing and Consulting, Psychology, Athens, Greece

* Corresponding author.

Introduction According to DSM-5, gender dysphoria (GD) is the “distress that may accompany the incongruence between one’s experienced or expressed gender and one’s assigned gender” (p. 451). Research showed that it may be associated with different social, psychological and psychiatric difficulties. It is clear how body is central in GD. Eating Disorders (ED) are strongly related too with the body, and, although they may co-occur with GD, a systematic review of the studies about this association is not available.

Objectives and aims To carry out a review of the published studies about co-occurrence of GD and ED.

Methods Literature research in 12 databases was performed, and the papers analyzed.

Results Nine papers about case studies and four empirical studies are available. Results of the clinical reports suggest a link between GD and ED may be the strong body uneasiness perceived by these people. The empirical studies support this hypothesis, outlining that usually adolescence, when secondary sexual characteristics develop, is a crucial phase for the onset of ED. Restrictive eating behaviors may function as a way of modifying the body shape and the hormone system. Differences between Female-to-Male and Male-to-Female transsexuals are outlined, as well as persistence of ED symptomatology after sex reassignment surgery.

Conclusions Body becomes an expression of the inner conflicts linked to gender incongruence, shifting the focus of the suffering

from mind to body. In the light of these results, specific indications for the clinical practice with transgender people and for future directions in research are outlined.

Internet and smartphone application usage in eating disorders: A descriptive study in Singapore

T. Tan*, A. Kuek, S.E. Goh, K.W. Ng, S.M. Tan, A. Gudi, H.Y. Lee, E.L. Lee, K. Victor

Singapore General Hospital, Psychiatry, Singapore, Singapore

* Corresponding author.

Introduction Eating disorders are associated with significant morbidity and mortality. The Internet is a popular medium for individuals with eating disorders to discuss and reinforce their affliction. However, the available literature on Internet usage and eating disorders is scarce, especially in the area of social media and smartphone application (“app”) usage.

Objectives & aims To look at the Internet and smartphone app usage patterns of participants who presented with an eating disorder in Singapore, and whether it corresponded to severity of illness.

Methods Individuals who presented to the Eating Disorders clinic at the Singapore General Hospital from 13th June 2013 to 20th December 2013 completed a self-reported questionnaire on Internet and app usage. They also completed the EDE-Q, EAT-26 and CIA 3.0.

Results Fifty-five participants completed the study. A total of 41.8% had anorexia nervosa, 34.5% had bulimia nervosa, and 9.1% were ED-NOS. 41.8% felt that apps helped to perpetuate their illness, while 32.7% felt that apps were helpful for recovery. Overall, any smartphone application usage was associated with younger age and greater eating disorder psychopathology and psychosocial impairment. While 30.9% had encountered eating disorder-related content on Facebook, only 12.75 visited Facebook groups related to eating disorders. For YouTube, “Cooking and Food” and “Beauty and Fashion” videos were among the top 3 types of videos that participants watched.

Conclusions Internet and smartphone app usage is significant, and they are used to prolong or worsen eating disorder behavior in those with greater severity of illness. It is necessary to include interventions in this aspect as part of treatment.

Symptoms of eating disorders in at term pregnancy: The influence of body mass index

F. Volpe^{1,*}, L. Giliberti², G. Soldera², G. Tesolat², G. Straface², V. Zanardo²

¹ Padova, Italy

² Policlinico Abano Terme, Medicina Perinatale, Abano Terme, Italy

* Corresponding author.

Introduction Weight gain in pregnancy has been associated with body image dissatisfaction.

Aims This study analyzed symptoms of ED in pregnancy by the Eating Disorder Examination Questionnaire (EDE-Q 16.0; Fairburn & Beglin, 2008) in connection with body mass index (BMI).

Materials and methods The research involved 616 consecutive, at term, Italian-speaking healthy puerperae, who delivered at the

Division of Perinatal Medicine of Policlinico Abano Terme, Italy from January to August 2015. The mean (\pm SD) maternal age was 33.06 (\pm 4.07), 540 (87.5%) followed a Mediterranean diet, 16 (2.5%) were vegetarian and 3 (0.4%) were vegans. At the end of pregnancy, 204 (33.06%) had a normal weight; 295 (47.81%) were overweight and 117 (18.96%) were obese. Before discharge, mothers completed the EDE-Q to measure the Global Score (GS) and the four EDE-Q subscales (Restrain, Eating Concern, Shape Concern, and Weight Concern).

Results EDE-Q Global Score significantly increased with BMI increase. Compared to normal-weight mothers, both overweight (0.94 \pm 1.59 vs 1.80 \pm 2.34; $P < .001$) and obese puerperae (0.94 \pm 1.59 vs 2.35 \pm 2.30; $P < .001$) had significant higher Global Score. Both overweight and obese mothers had also significant higher scores than normal in all subscales.

Conclusions In our study population, symptoms of eating disorders were associated with excessive increase in gestational BMI: EDE-Q scores were elevated in overweight mothers and in obese; in addition, obese puerperae have higher scores than overweight. Routine controls and prevention plans could help women from the beginning of pregnancy to avoid ED symptoms appearance.

Eating disorders: What has the society to do with it?

B. Wimmer-Puchinger^{1,*}, S. Blahout², K. Waldherr³

¹ Wien, Austria

² Vienna Program for Women's Health, Municipal Department, Public Health Services of the City of Vienna, Vienna, Austria

³ Ferdinand Porsche Distance Learning University of Applied Sciences, Vienna, Austria

* Corresponding author.

The prevention of eating disorders is a main concern of the Vienna Women's Health Programme, which was adopted by the Vienna City Council in 1998. Eating disorders are very serious mental health problems in adolescence. There is evidence that media exposure of the thin ideal body image leads to uncertainty, low self-esteem and dieting. To examine the current state of body (dis-)satisfaction and the risk of eating disorders among Viennese adolescents, we surveyed 1427 participants at the age of 12 to 17, using a self-assessment questionnaire that included the Eating Disorder Inventory (EDI-2), the SCOFF-questionnaire and the Rosenberg self-esteem scale. Results support our hypothesis. The highest concern among adolescents is about their weight and body shape. 76% of the girls surveyed wanted a skinny body, 31% were afraid of gaining weight, and 32% have already been dieting - 13% took appetite suppressants, 5% used vomiting, 3% took laxatives. According to the SCOFF-questionnaire, 30% of the girls were at risk of having eating disorders. Trends were evaluated via regression analysis. In 2012 girls used less dieting and had lower scores in the EDI-2 subscales ‘body dissatisfaction’, ‘drive for thinness’ and ‘bulimia’ than in 2001. Boys had less conspicuous scores than girls in total, but have shown an alarming increase in body dissatisfaction. School prevention programmes are indicated to enhance media literacy and encourage self-esteem among adolescents. To be successful, an interdisciplinary approach has to be established. The City of Vienna has already launched several awareness campaigns to counter unhealthy body ideals.

Perceived stress and coping strategies among Jordanian nursing students during clinical practice in psychiatric/mental health courses

A. Alzayyat

College of applied medical sciences-mohial, Nursing, abha, Kingdom of Saudi Arabia

Introduction Clinical practice in the psychiatric/mental health nursing (PMHN) field is considered a highly-stressful experience for nursing students.

Aim The purpose of the present study was to identify the degrees of stress, the types of stressors, and coping strategies perceived by undergraduate nursing students during their clinical practice in PMHN courses.

Methods A descriptive, longitudinal design was used. Sixty-five students registered in PMHN clinical courses were recruited from five Jordanian universities using a systematic random-sampling method. Data collection was conducted in the second semester of the 2012–2013 academic year at two points of time: pre-PMHN clinical training and post-PMHN training. The Basic Information Questionnaire, Perceived Stress Scale, and Coping Behavior Inventory were administered. Students' ages ranged from 20 to 25 years.

Results The findings illustrate that the highest reported types of stressors at both data-collection times were taking care of patients, stress related to teachers and nursing staff, and from assignments and workloads. The most utilized coping strategy at both data-collection times was problem solving.

Conclusion The findings of the present study are useful for clinical educators in identifying nursing students' stressors, easing their learning in the clinical setting, and establishing an efficient PMHN course programme.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Professional stress among psychiatrists—a Delphi study

A. Dhandapani*, S.S. Armugam, S.K. Chaturvedi

National Institute Of Mental Health & Neuro Sciences, Psychiatry, Bangalore, India

* Corresponding author.

Introduction Professional stress is a misfit between a person's skills and demands of the job. It has been found to be common among psychiatrists and affects their personal and professional life. **Objectives** To rank order the factors and manifestations of professional stress among Indian psychiatrists.

Aims To determine the factors and manifestations associated with professional stress among Indian psychiatrists.

Methods A qualitative ranking type Delphi study was conducted at National Institute of Mental Health & Neurosciences, Bangalore. The Delphi team comprised of 43 randomly selected Indian psychiatrists with at least 10 years of clinical experience in psychiatry. Questionnaires were mailed & the replies were analyzed and a consolidated list was sent back to rank order them. Agreeability was assessed & the final list of factors and manifestations was shared with the experts.

Results Forty-eight percent of the experts completed all 3 stages of the study, 53% opined that age & gender were not a factor; however 58% & 44% opined that personality attributes & relationship

status were significant factors contributing to professional stress (Table 1).

Conclusion Professional stress in Indian psychiatrists is largely secondary to increased workload and inadequate support system. System level changes, like increase in manpower and handling stigma regarding psychiatry, is required.

Table 1 Top 3 factors & manifestations associated with professional stress.

Sl no.	Factors	Manifestations
1	Not enough time to complete all tasks satisfactorily	Emotional exhaustion
2	Too much work to do / too many different things to do	Poor communication with the patients
3	Lack of adequate staffing/ inadequate technical / clerical back up	Loss of idealism / zeal

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The European Federation of Psychiatric Trainees (EFPT) is an independent Federation of Psychiatric Trainees and represents the consensus of psychiatric trainee's organizations across European countries and advocates for what training should look like, regardless of the country. Spain was one of the last countries to be part of the Association. Finally, and after months of hard work and networking, on September 2015 the Spanish Society of Psychiatry Trainees (SERP), was founded and Spain became a observer member of the EFPT.

Objectives One of the main goals of the SERP, is creating a program of clerkships, in both directions, from other trainees to come to Spain, and for Spanish Trainees to go abroad.

Methods Our idea in this poster is to explain a first look of which Hospitals/Units would be appropriate to make a rotation, and to explain the first steps in order to create a database with information about the nightshifts, possible accommodation and other aspects related to the organization. We want to use this poster to present to Europe our new Association.

Results On September 25 at the National Congress of Psychiatry in Santiago de Compostela, a Group of Spanish trainees founded the SERP, organized the first Board and signed the Founding Amendments.

Conclusions After two previous failed attempts, finally on 25th September 2011; the Spanish Society of Psychiatry Residents (SERP) was founded, an important part of the activity of this company is promoting exchanges between residents of member countries in Spain.

www.saudemental.pt - Online Mental Health Literacy

B. Lourenco^{1,*}, B. Ferreira², M. Gonçalves¹, M.A. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, CP 5, Lisbon, Portugal

² USF, São João Evangelista dos Lóios, Lisboa, Portugal

* Corresponding author.

Introduction Health Literacy promotes the understanding of basic health information and services. Online health information has been searched by 80% of the internet users, according to a 2006 survey (Fox, 2006). www.saudemental.pt is an online mental health platform, set up in 2015 by a multidisciplinary team, composed by family physicians, psychiatrists and psychologists. It establishes a two-way information flow, because the analysis of the users profile and the pattern of use of the website allows future adaptations on the communication strategy.

Objectives and aims Understand the importance of Online Health Literacy in psychiatric diseases. Present www.saudemental.pt and characterize its activity during the first six months of operation.

Methods Review of selected literature. Descriptive statistical analysis of the site's activity during the first six months of operation.

Results There is a known association between level of education and health, and recent studies suggest that health literacy is one of the factors that mediates this relationship (Heide, 2013). www.saudemental.pt is a simple tool, with great potential to reach a wide audience, providing information and support to patients and caregivers. Preliminary results suggest an average of 30 users/day (80% new users), mainly from Portugal (79%), followed by Brazil (5%). The most visited content was related to mental health; anxiety was the most consulted pathology.

Conclusions Psychoeducation is an essential tool in clinical practice. Mental Health services should seek alternative means of information diffusion. Despite being at an early stage of implementation, www.saudemental.pt has proved to be an effective strategy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Advanced practice nursing students' use of screening and brief intervention in the clinical setting

A. McNelis^{1,*}, J. Agle², J. Carlson³, R. Schwindt¹, C. Clark¹, K. Kent¹, K. Lay³, R. Gassman², D. Crabb⁴

¹ Indiana University, Nursing, Indianapolis, USA

² Indiana University, Public Health, Bloomington, USA

³ Indiana University, Social Work, Indianapolis, USA

⁴ Indiana University, Medicine, Indianapolis, USA

* Corresponding author.

Introduction More than 30% of US adults are estimated to drink at risky levels or meet criteria for harmful or dependent alcohol

use. Screening, brief intervention and referral to treatment (SBIRT) in primary care settings is recommended and nurses, particularly advanced practice nurses (nurse practitioners), are being called upon to perform SBIRT for alcohol. This study assessed if knowledge, attitudes, and beliefs about SBIRT, evaluated after a three-part, educational training, predicted whether 21 family nurse practitioner (FNP) students screened for alcohol use during subsequent patient encounters in their clinical practice.

Objectives Learners will be able to:

- describe the general purpose and procedures of SBIRT;
- identify three strategies for integrating SBIRT into current practice setting.

Aims To help in development of SBIRT skills, the Substance Abuse and Mental Health Services Administration expanded training grant opportunities in 2013, for education programs to multiple groups of medical professionals. Findings from this study are presented to show the effectiveness of the training for nursing professionals.

Method Immediately following training, students completed a survey and then documented implementation of SBIRT during their clinical practice.

Results Students who reported higher levels of perceived "Competence" in their post-training surveys were more likely to screen patients for alcohol use in their clinical practice settings.

Conclusion Screening for alcohol use and identifying patients at risk for or engaged in hazardous drinking meet important NP practice competencies. Further research is needed to explore training programs that specifically emphasize activities to increase competence, knowledge, and comfort regarding SBIRT.

⁵ Institute of Mental Health, psychiatry, Belgrade, Serbia

⁶ Hospital de Magalhães Lemos, University of Porto, Porto, Portugal

⁷ EFPT, EFPT, Brussels, Belgium

* Corresponding author.

Introduction Despite efforts to unify psychiatric education among European member countries, there are still considerable variations between national training programmes. To ensure equivalence of training standards the current tendency of recommended guidelines and reports is steering psychiatric training towards becoming more competency focused.

Objectives The research group of the European Federation of Psychiatric Trainees (EFPT) conducted a multi-national study on postgraduate psychiatry training. The aims are to assess the psychiatric trainees' experiences and opinions on their national training and assessment methods in respect to the Union européenne des médecins spécialistes (UEMS) 2009 competencies framework.

Methods This study surveyed 745 psychiatric trainees from 10 EFPT member countries using a questionnaire designed specifically for assessing this issue.

Results In this sample, the majority are aware of having a competency based training programme but 86.5% are poorly acquainted with the UEMS competencies framework. All key competencies were rated as being important but not all as being relevant in the assessment process. One's level of preparedness and the degree of education one's receives during their training differs from one competency to another. Trainees who aren't satisfied with their national training would be in favour of taking an end of training Pan-European exam which differs from the one's that are satisfied and wouldn't be interested in undergoing this assessment method.

Conclusions This sample isn't fully acquainted with the competency-based concept for postgraduate training. The ones satisfied with their postgraduate psychiatric education seem to be less inclined to take an end of training Pan European exam.

Developing simulated training in old age psychiatry to recognise and assess medical problems in a psychiatric setting (RAMPPS)

U. Narayana^{1,*}, O.J. Corrado², P. Rowlands³, S. Kaur⁴

¹ Health Education Yorkshire and Humber, Leadership fellow-ST5 Old Age Psychiatry, Hull and East Yorkshire NHS Trust, United Kingdom

² Leeds Teaching Hospitals NHS Trust, Consultant Geriatrician, Leeds, United Kingdom

³ Head of School of Psychiatry, Health Education Yorkshire and Humber, Derbyshire Healthcare Foundation Trust, United Kingdom

⁴ Bradford District Care Trust, Clinical Audit, Bradford, United Kingdom

* Corresponding author.

Introduction Older people with mental ill health are more likely to receive lower quality of health care, inappropriate prescriptions and reduced access to services, leading to increased rates of mortality [1–3]. There is increase focus on supporting people with multiple long-term physical and mental health conditions, particularly by embracing opportunities created by technology [4] (references are not available for this abstract).

Objectives To identify the common medical comorbidities on the Old Age Psychiatry Wards.

Aims To develop simulation training from the medical scenarios.

Method We audited all patients referred to the Liaison Geriatrician from 2008 to October 2015 from the Mount Hospital Leeds, which consists of 4 Old Age Psychiatry wards. Data was collected in October 2015 and included referral date, patients' age and sex, number of referrals, reason for referral and the outcome.

Results We assessed 339 (142 F, 197 M) patients with a mean age of 77 (range: 56–94). The cardiovascular problems constituted the majority (34%) of the referrals, central nervous system (11%), respiratory (8%), gastrointestinal (8%), infection (8%), musculoskeletal (7%), renal (3%), others (19%) and the reasons were unknown in (2%) of the 440 referrals. Some unusual problems were diagnosed including a spontaneous pneumothorax, primary biliary cirrhosis.

Conclusion The audit highlights the essence for more training in recognising and assessing medical problems in psychiatric settings - the simulation programme (RAMPPS) in Old Age Psychiatry. As a result of the service model, we are developing a simulation-training course tailored to the mental and physical health needs of the elderly.

Indicators in psychiatric assessments; an evidence-based practice

Y. Rumalean^{1,*}, C. Parfitt²

¹ UK National Health Service & London Metropolitan Police, General Psychiatry and Forensic & Legal Medicine, Goffs Oak- Hertfordshire, United Kingdom

² Global Insurance- UK, Statistics and Engineering, London, United Kingdom

* Corresponding author.

There are subtle signs and symptoms that can function as strong, significant and evidence-based indicators to improve upon diagnosis of mental illness as a primary clinical issue. With the well-being of patients at stake and services experiencing mounting pressure on their time and resources, the accuracy of such a diagnosis is critical. The data used in this study was obtained from the Hampshire Police of individuals arrested under Section 136 of the Mental Health Act 1983 (Amended 2007). Documented observations by the arresting officers were transferred onto a list of signs and symptoms, adapted for clinicians and non-clinicians. Answers to all 23 indicator questions were assigned a binary coding and became the input data. A logistic regression model (LRM), sensitivity and specificity analysis, analysis of maximum likelihood estimates, and confusion matrix, were applied. Three significant evidence-based indicators for primary mental illness diagnosis: "fixed stare/looking (possibly) confused" (perplexed), "calm/seemingly calm", and "poor attention and concentration, not able to follow instructions easily" (distracted). There was suggestion that when all three identified indicators are absent within the same assessment period, primary mental illness should not be diagnosed. A correlation was observed between the presence of one, two, or all three indicators and the increased chance of patients suffering from moderate-to-severe primary mental illness. The indicators would very likely be particularly helpful in cases where signs and symptoms of primary mental illness are less obvious and made more complex by actual underlying problems of drugs/alcohol, difficult personality traits, and/or criminal behaviour.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Lessons from a Balint group scheme led by psychiatry trainees for year 3 bristol medical students on their medicine/surgery placements

K. Wood^{1,*}, A. Kothari², J. Malone³

¹ Southmead Hospital, North Bristol Trust, Bristol, United Kingdom

² Callington Road Hospital, Avon and Wiltshire Mental Health Partnership, Bristol, United Kingdom

³ Retired consultant psychiatrist, North Bristol Trust, Bristol, United Kingdom

* Corresponding author.

Background The UK General Medical Council highlights the centrality of effective communication, reflective practice and the doctor-patient relationship in medical practice. A decline in empathy has been documented as occurring within clinical and early postgraduate years, potentially affecting diagnostic processes and patient engagement. Access to Balint groups can enhance awareness of the patient beyond the medical model, but remains limited at many UK medical schools. This scheme offered Balint groups to

Bristol medical students in their first clinical year, demonstrating that this method is relevant beyond psychiatry.

Methods Initial focus groups with medical students indicated that many felt unable to discuss distressing aspects of clinical encounters. During 2013–2014, a Balint scheme run by psychiatry trainees was started for 150 students in their psychiatry placements. During 2014–15, the scheme was introduced to all third-year medical students on their medicine/surgery placement. Balint leaders have group supervision with a psychoanalytic psychotherapist. Evaluation of the scheme was based on pre- and post-group questionnaires and leaders' process notes.

Results Sixteen groups led by 12 trainees were run twice over the year to serve 246 medical students. Two example cases are discussed here. Students appreciated the chance to discuss complex encounters with patients in a supportive peer environment, and work through a range of emotionally challenging issues.

Conclusions Novel aspects of this work include the implementation of Balint groups within medicine and surgery placements; the enrolment of psychiatry trainees as leaders with group supervision and leadership training workshops from the UK Balint Society; and the scale of the scheme.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Right to decide: Preferences and satisfaction with treatment in women and men patients with agitation and bipolar or schizoaffective disorder

J. Arenaza*, S. Hernandez, M. Gutierrez Fraile, A. Gonzalez-pinto Arrillaga, I. Zorrilla

Hospital Universitario de Alava, Psiquiatria, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Current recommendations on agitation management advocate for involving patients in deciding the therapeutic plan. Verbal de-escalation is directed to calming the patient while clinical evaluation is performed, and allows agreeing treatment. However, research on patients preferences and satisfaction is scarce.

Objectives To assess patients preferences and satisfaction related to treatment of agitation.

Methods Prospective observational study among patients that were agitated during hospitalization in 2014. Patients with bipolar disorder, schizoaffective disorder or schizophrenia were offered to choose between inhaled loxapine or usual treatment (intramuscular antipsychotic). Satisfaction with treatment was measured at 7 and 14 days and satisfaction with hospitalization was measured at discharge.

Results A total of 180 patients were agitated during 2014, but the majority of agitations were attended in the emergency room. Eighty patients presented agitation during hospitalization. Sixty of them had bipolar disorder, schizophrenia or schizoaffective disorder, and 90% had comorbidity with substance abuse, alcohol abuse or personality disorder. Forty patients were not able to deem their preferences and were treated with intramuscular antipsychotics. Twelve patients chose inhaled loxapine. Eight refused any treatment and received IM antipsychotics. Satisfaction with treatment was higher in patients receiving loxapine. More women than men received loxapine. Satisfaction with hospitalization was higher in women.

Conclusions It is important to consider patient opinion in order to increase satisfaction with treatment and patient collaboration. Inhaled loxapine is a new therapeutic option that facilitates this approach.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Goal of study Our aim was to examine whether cerebral frontal cortex O₂ desaturation may be related with the development of delirium symptoms' after cardiac surgery in the elderly during the intensive care unit (ICU) staying.

Materials and methods A prospective, before and after, longitudinal study in II-IV ASA class patients scheduled for cardiac surgery and undergoing intravenous general anesthesia with remifentanyl plus propofol was done. Clinical and surgical parameters, cardiopulmonary function, intraoperative cerebral oxygen saturation (rSO₂) and bispectral index were continuously recorded and corrected throughout the surgery. Severity of delirium was represented as a score of the Intensive Care Delirium Screening Checklist (ICDSC) during the patients' stay in the ICU under the assumption that higher ICDSC score indicated severe delirium.

Results and discussion Patients, $n = 44$, 77.3% male, aged 59.9 ± 1.9 years old, scheduled to coronary (36.4%), aortic valve replacement (18.2%), mitral valve replacement (13.6%), coronary plus valve replacement (13.6%) and others (18.2%) surgery, on pump 98.4% were enrolled. A reduction of the rSO₂ higher than 10% at the end of the surgery compared with basal values was detected in a 46.5% of the patients. Reduction of rSO₂ higher than 10% at the end of the surgery was related with significantly higher values of delirium symptoms' development during the intensive care unit post-surgery staying (rSO₂ higher $\geq 10\%$ 68.8 vs. rSO₂ higher $< 10\%$ 31.3%, $P < 0.05$).

Conclusion Delirium symptoms' development during the intensive care unit post-surgery staying is related with reduced intraoperative cerebral oxygen saturation in the elderly subjected to cardiac surgery.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction The assessment and management of psychomotor agitation may result in the use of coercive or sedative treatments. In the absence of conclusive evidence, the consensus of experts can guide clinical decisions.

Objectives To seek consensus recommendations on the assessment and management of psychomotor agitation.

Methods An international expert task force in this field developed consensus using the Delphi method. Twenty-seven experts were invited to participate and 91% of them agreed. Initial survey items were gathered from the content of literature search (systematic review). This included open-ended questions inviting participants to add suggestions by e-mail correspondence. After this initial first round, the Delphi study was conducted online using Google Forms. Survey items were rated on a 5-point scale. Items rated by at least 80% of experts as essential or important were included. Items rated as essential or important by 65–79% of experts were included in the next survey for re-rating. Items with consensus below to 65% were rejected and excluded.

Results The initial survey included 52 items. The second web-based survey included 33 items. The briefer third survey consisted of 6 items that needed rerating. Twenty-two of the initial 33 items were endorsed and formed the clinical recommendations on the assessment and management of the psychomotor agitation. The endorsed items were categorized into 5 domains forming the clinical recommendations.

Conclusions The panel expert generated 22 recommendations on the assessment and management of agitation. The Delphi method is a suitable formal iterative process for reaching consensus on relevant and controversial issues.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The suicide attempt is a real challenge for the clinician who works at the emergency department in order to identify and propose an adequate care.

Aims To estimate the prevalence of the suicide attempts, to describe the sociodemographic and clinical characteristics and to identify the predictors of recurrence.

Methods Our cross-sectional study was conducted at the medical emergency department of the university hospital of Mahdia and lasted for 12 months. Data were collected using a questionnaire of 51 items exploring the general and clinical characteristics and providing information of the treatment.

Results Among the 513 consultants, 90 had attempted suicide (17,5%). We found an average age of 26 years old, a sex-ratio (M/F) of 0,3, a secondary education level (53,3%), an unemployment and a single status (38,9% and 75,6%). The presence of psychiatric personal history and/or suicide attempts was found in 31,1% and 33,3% of cases. Suicide attempts were taken place in all cases at home, between 18 and midnight (43,3%), without premeditation (82,2%),

in the presence of triggering factor (95,6%), during the last 3 months of the year (34,4%). In 70,2% of cases, the type of the suicide attempts was a drug intoxication. 67,8% of the suicide attempters regretted and criticized their acts.

Conclusion A good assessment of the suicide risk determines the type of intervention that should be established and allows an adequate care.

Ensuring patient safety: Physical health monitoring in rapid tranquillisation for aggression and violence of adult acute inpatients

R. Talukdar, M. Ludlam, L. Pout, N.P. Lekka*

Sheffield Health and Social Care Foundation Trust, Acute Inpatient Services, Sheffield, United Kingdom

* Corresponding author.

Introduction Intramuscular (IM) medications used in rapid tranquillisation (RT) to manage violent/aggressive behaviour can cause serious physical side effects including sudden death, therefore comprehensive physical health monitoring is advised.

Objectives To assess whether physical health monitoring of patients who received IM medication for RT was completed as per the Aggression/Violence NICE-guideline based local Policy.

Methods All patients that received IM benzodiazepines or antipsychotics for RT were identified amongst 822 discharges from February 2014 to February 2015. Demographics, diagnoses, non-pharmacological interventions, types/doses of medication, and associated seclusion/restraint episodes were recorded. Notes were examined to determine whether physical health monitoring protocols involving blood pressure, pulse, temperature, oxygen saturation, respiratory rate and level of consciousness were followed.

Results There were a total of 218 episodes where these medications were used, in which only 19 (8.8%) had any physical observations completed; only one case (0.5%) was completed fully as per the protocol. Of the cases that did not have observations taken, in 12 (5.5%) cases observations were attempted but the patient was too agitated/aggressive. A doctor was contacted in only 53 (24.3%) cases and an ECG was completed in 120 (55%) cases, of which only 11 were completed within 24 hours.

Conclusions The results show poor compliance (or at least recording) with the guidance, demonstrating the need for further education of nursing and medical staff on the potential dangers of RT and for better physical health monitoring of patients on RT. To improve patient safety, staff training and well-timed recording of physical observations on electronic tablets will commence.

Mental health problems in the aftermath of earthquakes in Nepal

N.P. Luitel*, J. Kene, M. Jordans, B. Kohrt, W. Tol

Transcultural Psychosocial Organization TPO Nepal, Research, Kathmandu, Nepal

* Corresponding author.

Introduction Mental health problems may increase in populations affected by humanitarian emergencies, such as the 2015 earthquakes in Nepal.

Objectives We assessed mental health and psychosocial problems (depression, anxiety, post-traumatic stress disorder, alcohol

use disorder, suicidal ideation), and available mental health resources to deal with these problems 4 months after the earthquakes.

Methods The study was conducted in three affected districts: Kathmandu, Gorkha, and Sindhupalchowk. The study used a mixed methods design with both qualitative and quantitative approaches. The outcome measures used in the study were locally validated Hopkins Symptoms Checklists (HSCL), PTSD Checklist-Civilian version (PCL-C), Alcohol Use Disorder Identification Test (AUDIT), and a functioning impairment scale. We used a stratified multi-stage cluster sampling method to select 513 adults (171 from each districts).

Results 32.4% (26.7–38.7; 95% CI) of participants met threshold criteria for depression, 30.8% (24.5–37.9) for anxiety, 5.2 (3.9–6.8) for PTSD, and 20.4% (17.1 – 24.3) for alcohol use disorder. Prevalence of suicidal ideation was 11%. Despite high rates of mental health problems, few participants reported impaired daily functioning.

Conclusion We found elevated prevalence estimates of mental health problems but overall daily functioning was good. The need for trauma-specific treatments for PTSD do not appear to be widespread. However, support services to address anxiety, depression, and substance abuse could benefit large numbers of earthquake-affected communities.

Survivors of gender-based violence and role of official psychiatry in recovery process

E. Molchanova

American University in Central Asia, Psychology, Bishkek, Kyrgyz Republic

Consequences of events in the Southern region of the Kyrgyz Republic continue to have impact on communities to the present day. One of the most significant is a number of undiagnosed cases of rapes and other types of gender-based violence (GBV), which happened during the events of 2010. Accurate prevalence rates of GBV cases is still unknown. According to official data of Ministry of Internal Affairs, there were only seven cases of rape, however, according to the crisis center reports, there were 325. Even more alarming, witnesses of the Osh events suggest one out of three women in Osh and Jalal-Abad were either raped or suffered from other types of GBV. Those acts included undressing and unveiling, and cutting women's hair to a shamelessly short length. Cultural stereotypes dictate women hide their 'shame', which is why only a small percentage of victims with PTSD symptoms that developed after GBV sought out services from professionals, such as from crisis centers, psychologists and psychiatrists and, of course, police. Author analyzed several cases of women raped during the Osh massacre and suffered from PTSD signs afterwards. The previous painful experience of GBV was uncovered during treatment. The problem is that mental health care specialists are the last stop for applying for help. This paper analyses several ways of solving the problem, including creating a number of normative documents in collaboration with Ministry of Internal Affairs and Ministry of Health of the Kyrgyz Republic.

⁶ Hospital Universitari Germans Triás i Pujol, Farmacologia Clínica, Barcelona, Spain

* Corresponding author.

Introduction New Psychoactive Substances (NPS) appear to be increasing in popularity because they mimic the effect of traditional drugs. DOB is a world-wide controlled phenethylamine, with agonist activity in 5HT_{2A} receptors. Its effects are comparable to those of LSD, with dosage range 1.0–3.0 mg and duration 18–30 h.

Objective To assess the presence of DOB in the substances submitted to, and analyzed by, energy control.

Materials and methods All samples presented to Energy Control (EC) from August 2009 to August 2015 were analyzed. EC is a Spanish harm-reduction non governmental organization that offers to users the possibility of analyzing the substances they intend to consume. Samples in which DOB was detected using gas chromatography-mass spectrometry were selected for this study.

Results From a total of 20,062 samples, 13 contained DOB (0.06%), with no clear variations among the years studied. The samples were mostly sold as DOC(8), DOB(2) and LSD(2). Nine out of total 13 samples presented as blotter.

Conclusion Results suggest that availability of DOB in the Spanish drug market is anecdotic. Nonetheless, a number of the samples containing DOB were not sold as such, increasing the possibility of side effects, as users may ignore which substance they are actually using. When a patient presents at an Emergency Department with persistent hallucinogenic symptomatology after ingesting a blotter, psychiatrist should be aware of long-lasting psychedelics such as DOB.

Incidence and management of agitation in emergency medical services in Spain – “SOSEGA” Study

R. Rodríguez Calzada^{1,*}, M.A. Suarez Fuentes², P. Roset Arisso², S.G.O.R. Sosega Group Of Researchers³

¹ Gerencia Emergencias Castilla Y Leon, Prehospital Emergency Ume 1 Valladolid, Valladolid, Spain

² Ferrer, Medical Department, Barcelona, Spain

³ Ferrer, Department Of Medical Research, Barcelona, Spain

* Corresponding author.

Introduction Agitation is a frequent and complex emergency. Its early detection and adequate treatment are crucial to ensure

the best outcomes. Pre-hospital management of agitation requires appropriate measures to preserve patients' safety, stabilize the patient and alleviate suffering, and transfer to the hospital psychiatric services, including involuntary admission if needed.

Objectives To describe the management of agitation by the Emergency Medical Services (EMS) in Spain.

Methods Observational retrospective survey on the protocols and procedures used, the number of in-calls received and the resources dedicated to attend emergencies in 2013.

Results Seven out of the seventeen EMS in Spain provided information. All of them registered in a database in-calls and actions taken. Four of them had a specific protocol to attend psychiatric emergencies and agitation in-calls, and five coded the initial diagnostic with ICD-9. Paramedics attending emergencies register the diagnostic in 3/7 EMS. Nursing and Medical staff code the final diagnostic with ICD-9 in all. Emergency Coordination Centres received 4,437,388 in-calls (209/1000 inhabitants); 2.6% classified as psychiatric (6.2/1000 inhab.). Healthcare teams attended 2,028,467 emergencies, 84,933 (4.2%) were psychiatric (4.0/1000 inhab.) and 37,951 (1.9%) were patients with agitation (2.0/1000 inhab.). General practitioners attended 17% of all psychiatric emergencies, while ambulances attended 61%.

Conclusions The incidence of acute agitation accounts for almost half of the total psychiatric emergencies in the pre-hospital setting. Since there are different healthcare providers in charge, specific protocols as well as treatment procedures are needed to provide the most adequate management, in order to ensure the best Psychiatric Emergency Chain.

² Klinikum Chemnitz gGmbH, Klinikum Chemnitz gGmbH, Chemnitz, Germany

³ Intenta GmbH, Intenta GmbH, Chemnitz, Germany

* Corresponding author.

Introduction After legal restrictions regarding coerced medication in Saxony, we monitored significant increases in aggressive behaviour and regarding the use of physical restraints at our closed psychiatric ward. Alternative measures for managing dangerous behaviour were discussed.

Objectives There are limitations regarding the use of treatment interventions in emergency psychiatry, e.g. the use of constant observation is limited in its efficiency generally and video surveillance is prohibited by law in high-risk areas (e.g. bathroom).

Aims To find appropriate solutions for patient safety improvement in emergency psychiatry including high-risk areas, prospects of the field of "technical assistance" entered the limelight of interest.

Methods In 2014, a cooperation of Chemnitz University of Technology, Intenta GmbH, Eckstein Design and the affiliated partner Klinikum Chemnitz started a project*, which focuses on the development of a technical assistance system for recognizing high-risk behavioural patterns (e.g. suicide attempt) in risk areas in

emergency psychiatry. The system is based on a smart-sensor technology and waives a recording and storing of sound and vision.

Results In the 1st half of the project technical development and the design of the system were the focus of attention. Special requirements regarding use cases, user acceptance, data protection and ethical concerns were processed by our psychiatric department. Testing and further development of the system in clinical settings are planned.

Conclusions The development of the system must be seen as a big challenge in many regards. Further research is indispensable.

Does psyche pain manifest as agitation in the emergency setting?

L. Zun^{1,*}, L. Downey²

¹ Mount Sinai Hospital, Emergency Medicine, Chicago, USA

² Roosevelt University, Health Care Policy, Chicago, USA

* Corresponding author.

Objectives The objective was to determine a patient's level of psyche pain when they present to an emergency department (ED) and whether there was a relationship between this psyche pain and the patient's level of agitation.

Methods This was a prospective study using a convenience sample of 300 patients presenting to an ED with a psychiatric complaint. This study was conducted in an urban, inner-city trauma center with 60,000 ED visits a year. After obtaining consent, a research fellow administered validated tools for assessing agitation, BAM, PANSS-EC, ACES, assessment of psyche pain, MBPPAS and a self-assessment of agitation at admission. SPSS version 22 was used for statistical analysis and the study was IRB approved.

Results A total of 74 patients were enrolled at this time. The most common ED diagnoses were depression, schizophrenia, or bipolar disorder. Majority of patients were African-American (59%), falling in the 25–44-year-old age range (56%). Fifty-two percent male and 48% female. Psyche pain was rated by MBPPAS as marked (18.9%) or moderate (67.6%). The self-reported tool demonstrated 20% none, 16% mild, 21% moderate and 42% marked level of agitation. The agitation rating varied by the tool with self-reported level of agitation having the highest correlation with level of psyche pain ($P < 0.05$).

Conclusions Psychiatric patients frequently present to the emergency department with a high level of psyche pain and high level of self-reported agitation. This correlation may signal the need to address a patients' level of agitation early in evaluation process.

Health related quality of life in adults with ADHD symptoms: A population survey using 15D and AAQoL

L. Alaheino^{1,*}, S. Leppämäki², T. Partonen¹, M. Sainio²

¹ National Institute for Health and Welfare, Mental Health Unit, Helsinki, Finland

² Finnish Institute for Occupational Health, the development of work and work organizations, Helsinki, Finland

* Corresponding author.

Introduction Health related quality of life (HRQoL) can be measured and compared, to give us an understanding of the impact different diseases have on health. The diagnostic tests for attention-deficit/hyperactive disorder (ADHD) in adulthood fail to catch the diversity of ways the condition affects one's life. Disease-specific quality-of-life scales try to reach beyond the typical symptoms of the condition, to find those specific difficulties a person subjectively grades as challenging.

Objectives To assess the levels of general and disease-specific HRQoL in adults with ADHD-like symptoms.

Aims To understand the impact ADHD-like symptoms have on adults' HRQoL.

Methods A random, nationwide sample of 3000 Finnish speaking citizens (aged 18–44 years) was drawn from the national population register. A subsample of 171 people, 57 screener (Adult ADHD Self-Report Scale [ASRS]) positive cases and two age- and sex-matched controls for each case, participated in a telephone interview. General HRQoL was measured with 15D, and disease-specific HRQoL with Adult ADHD Quality-of-Life (AAQoL) scale.

Results The 15D score was 0.866 for the screener positives, 0.943 for the controls, and 0.945 for the Finnish population reference. The difference between the screener positives and controls was significant ($P < 0.001$). The AAQoL sum score was worse for the screener positives than controls (61.9 vs. 82.1, $P < 0.001$), and all the sub-scales were affected accordingly.

Conclusions Adults with ADHD-like symptoms have a lower quality of life, as measured both on the general and on the condition-specific quality of life scales.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric disorders in mass media and social networks: A media impact study

M.Á. Álvarez de mon^{1,*}, R. Sánchez², P. Molero³

¹ Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

² University Hospital, University of Navarra, Medical Oncology, Pamplona, Spain

³ University Hospital, University of Navarra., Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction Every year, 1 million people commit suicide in the world. Major Depressive Disorder is the first cause of loss of Disability-Adjusted Life Years (DALYs) in developed countries.

Objective To study the references to psychiatric disorders in the media and to measure their media impact compared with other topics such as politics, sports and tabloids.

Methods We focused on the top-six journals in terms number of readers in the USA. Our research strategy included the introduction of several terms of interest (ex: "anxiety") on each journal's Twitter account. The search was restricted to 2014, and yielded a database of 6296 news, which was categorized in four areas: health, politics, sports and tabloids.

Results Six hundred and eighty-one (10.8%) news dealt with psychiatric disorders. The term with the highest impact in mass media was "suicide", present in 1 of every 3 Psychiatric-related news. Anorexia was the psychiatric disorder with the lowest impact (just 1 tweet). We noticed certain peaks-patterns in the number of tweets coincidentally with the suicide of any famous person. Within the total of terms included in our study, suicide ranked the 8th position regarding media impact.

Conclusions Social networks can be a useful tool for the divulgation of mental disorders and their awareness among the general population. Despite psychiatric disorders are very prevalent and cause high morbidity, they have a relatively low media impact. Despite the WHO recommendation of avoiding specific information regarding the suicide of famous people, for preventive reasons, suicide is the psychiatric disorder with the highest media impact.

The Psychiatry consultation in primary health care setting at an Oporto Area: Sociodemographic and clinical data

A. Dias Amaral^{*}, M.J. Peixoto, A. Cortiñas, S. Fonseca, R. Curreal
Centro Hospitalar de São João, Psychiatry and Mental Health Clinic, Porto, Portugal

* Corresponding author.

Introduction The Psychiatry consultation is a collaborative approach between primary health care services and community mental health teams. Our clinic provides support to three Oporto areas (Bonfim/Paranhos, Campanhã and Maia/Valongo) corresponding to a population of 350,000 inhabitants.

Objectives To analyze and collect Psychiatry consultation data of the first semester of 2015 in Maia/Valongo region. We aim to describe our population's sociodemographic characteristics, the most common referral motive, diagnosis and therapeutics, and orientation.

Methods Psychiatry consultation data of the first semester of 2015 were collected and analyzed using SPSS software (version 20).
Results One hundred and sixty-one patients were evaluated. A total of 26.09% were male and 73.91% were female. The mean age was 51.61 years old. The most frequent referral motives were depressive (47.82%) and anxiety (23.60%) symptoms. The two most common diagnostic groups according to the International Classification of Diseases (version 10) were F30-F39–Mood affective disorders (57.76%) and F40-F48–Neurotic, stress-related and somatoform disorders (18.63%). 22.36% of the patients were referred without medication, but only four were discharged drug-free, corresponding to bereavement situations. 34.16% of our population were previously prescribed two or more psychotropic drugs, increasing to 63.98% after assessment. Only 18.63% met criteria to hospital referral.

Conclusions The Psychiatry consultation selects the most severe patients and allows a faster evaluation of mentally ill patients awaiting hospital consultation, thus preventing unnecessary access to the emergency room. Authors consider that all the patients referred to a hospital consultation should be previously evaluated by a consultant psychiatrist on a primary health care setting.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Memory abilities and maladaptive schemas among Moroccan students

K. Mammad^{1,*}, F.Z. Azzaoui², A. Ahami¹, S. Boulbaroud³

¹ Faculty of science, department of biology, Kenitra, Morocco

² Faculty of science Ben M'sik, department of biology, Casablanca, Morocco

³ Polydisciplinary faculty, department of biology, Beni Mellal, Morocco

* Corresponding author.

Introduction Schemas are the organized general representations of the experience intended to facilitate information processing. Any dysfunction in these schemas could affect the normal neurocognitive abilities, as memory.

Aim To evaluate the forward and backward memory span abilities among Moroccan students and to study the impact of maladaptive schemas on the memory.

Methods The present study is a cross-sectional study conducted among 212 students, aged 17 to 25 years, randomly selected from the IBN TOFAIL University (Kenitra, Morocco). Two neurocognitive tests are used; the first one is the short version of the Early Maladaptive Schemas Questionnaire to evaluate the activated and deactivated schemas and the sub-test of Wechsler to evaluate the working memory among these subjects.

Results The obtained results of forward memory span showed that 53% of students had a normal memory, 47% had an excellent memory and no one had pathological forward memory. However, 63% of students had a pathologic backward memory span, 28% had normal memory and 9% had an excellent backward memory. Also, significant negative correlations are registered between good forward memory span and activated schema of alienation ($r = -0.17$; $P < 0.05$), self-sacrifice ($r = -0.17$; $P < 0.05$), abandonment ($r = -0.16$; $P < 0.05$). Moreover, significant negative correlations are registered between good backward memory span and activated schema of emotional deprivation ($r = -0.14$; $P < 0.05$).

Conclusion The students' memory appeared in connection with activation of some maladaptive schema. Deeper investigations are needed to understand this relationship and also to study the other possible factors that could affect this important neurocognitive function.

Unemployment and the rate of new contacts with mental health services in South London

V. Bhavsar^{1,*}, M. Hotopf², J. Boydell¹, S. Hatch², SELCOH Investigators²

¹ Institute of psychiatry, department of psychosis studies, London, United Kingdom

² Institute of psychiatry, department of psychological medicine, London, United Kingdom

* Corresponding author.

Introduction Unemployment is a risk factor for later development of mental health problems, but characterisation of this in real world clinical data is limited. This study aimed to investigate the association between employment status and time-to-first-contact with mental health services using survey data linked to electronic health records (EHR).

Methods SELCOH ($n = 1698$, 2008–2010) was a representative population survey of South East London, with a 71.9% household participation rate. Anonymised survey data for participants was linked with EHR, generating survival data for time-to-first-contact. Cox regression was used to assess associations between unemployment and time to first contact with mental health services.

Results The rate in the unemployed was 22.84 contacts per 1000 person-years, and in those not unemployed, it was 10 contacts per 1000 person-years. The crude (age-adjusted) hazard ratio (HR) for unemployment was 3.09 (95% CI: 1.66–5.75). The HR for contact for unemployment, after adjusting for age, gender, ethnicity and education, was 2.8 (95% CI: 1.44–5.47). On addition of symptoms of common mental disorder, post-traumatic stress, psychosis and suicide attempts, to the model, unemployed participants remained at elevated risk (HR: 2.65, 95% CI: 1.33–5.27). Finally, illicit drugs and alcohol had minimal influence on estimates, giving a fully-adjusted

estimate for the association between unemployment and rate of contact of 2.6 (95% CI: 1.31–5.14).

Conclusions Unemployment was associated with a greater than two-fold increase in risk of accessing mental health care for the first time within the observation time, after adjustment for sociodemographic confounders, psychopathology, and substance use. Explanations for this association could include unobserved confounding, health behaviours associated with unemployment or effects of unemployment on stress processing.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Social environment may lead to emergence and persistence of psychotic experiences.

Objectives Testing differential impact of social environments on emergence and persistence of subclinical psychotic experiences.

Aims To assess different social environments that predicts emergence and persistence of subclinical psychotic experiences in a 6-year follow-up of a representative general population sample.

Methods A longitudinal prospective cohort study (the TürkSch - The Izmir Mental Health Survey for Gene-Environment in Psychoses) was conducted with a general population sample ($n = 4011$) from Izmir-Turkey, who were 15–64 years of age at baseline. Sociodemographic factors, social environmental exposures (deprivation and social capital of neighbourhoods, and familial dysfunction and relationships), and measures of psychopathology (subclinical psychotic experiences) were assessed across two waves (T₁-2008 and T₂-2014; $n = 2192$) using the Composite International Diagnostic Interview.

Results Measures of wider social environment at T₁ (high social control and social deprivation within neighbourhoods) was associated with emergence (OR = 1.6; 95% CI = 0.6–2.4) and persistence (OR = 1.8; 95% CI = 0.6–2.4) of psychotic experiences at T₂. Also, measures of familial dysfunction and relationships were associated with emergence (OR = 2.1; 95% CI = 1.2–3.3) and persistence (OR = 3.3; 95% CI = 1.4–6.7) at T₂. The associations between wider social environment and psychotic experiences were not significant after adjusting for measures of family dysfunction relationship.

Conclusions The association between wider social environment and psychosis may be partially a result of dysfunctional relationships within the narrow environment including family. Current and past difficult family relationships may be an important contributing factor.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction One hundred and twelve emergency medical staff are faced with many physical and mental problems due to the deterioration of their sleep-wake cycle and getting out of their usual work and social life.

Objectives The aim of this study was to examine the effects of anxiety, depression, day time sleepiness on the quality of life in 112 emergency medical staff.

Methods Target population of this cross-sectional study was the 112 emergency medical staff in the province of Rize. We tried to obtain all the universe ($n = 154$), so the sample was not selected. One hundred and four people (67%) participated in the study. In the data form, Epworth sleepiness scale, Beck Anxiety Inventory, Beck Depression Inventory and the SF-36 quality of life questionnaire were applied.

Results The prevalence of pathological sleepiness was 14.4% ($n = 15$), the prevalence of anxiety was 39.8% ($n = 41$), the prevalence depression was 20.2% ($n = 21$), respectively (Table 1).

Conclusion Based on high levels of anxiety and depression that reduces quality of life compared to the general population in 112 emergency services workers, motivational programs, coping strategies, psychological counseling services are required. Also, against the psychosocial risk factors forming anxiety and depression in the working life, organizational measures must be taken.

Table 1 The correlation between depression, anxiety and sleepiness scores with the subscores of the quality of life scale in 112 emergency medical staff.

Is body weight dissatisfaction associated with depression?

M. Eichholzer*, A. Richard, S. Rohrmann

Epidemiology- biostatistics and prevention institute EBPI- university of Zurich, chronic disease epidemiology, Zurich, Switzerland

* Corresponding author.

Introduction Body image dissatisfaction is a risk factor for depression. Research has focused on female adolescents; yet little is known about sex and age differences.

Objectives/aims The aim of our study was to evaluate the association of body weight dissatisfaction, a component of body image, with depression overall, and for different sex and age-groups independent of body weight.

Methods We analyzed data of 15,975 individuals from the cross-sectional 2012 Swiss Health Survey. Participants were asked about their weight satisfaction. Patient Health Questionnaire (PHQ-9) was used to ascertain depression. Age was stratified in three groups ($\geq 18-29$; $\geq 30-59$; ≥ 60 years). Body mass index (BMI) was self-reported and categorized into normal weight (BMI: 18.5-24.9 kg/m²), overweight (BMI: 25.0-29.9 kg/m²), and obesity (BMI: ≥ 30 kg/m²). The association between weight dissatisfaction and depression was assessed with logistic regression analyses and adjusted for known confounders (including BMI).

Results Weight dissatisfaction was associated with depression in the overall group (OR: 2.04, 95% CI: 1.66-2.50) and in men (1.85, 1.34-2.56) and women (2.25, 1.71-2.96) separately, independent of body weight (multivariable adjusted). Stratification by age groups revealed associations of weight dissatisfaction with depression in young (1.78, 1.16-2.74), middle-aged (2.1, 1.61-2.74) and old individuals (2.34, 1.30-4.23) independent of BMI. A sub-analysis in the overall group revealed statistically significant positive associations of weight dissatisfaction with depression in underweight, normal weight, overweight and obese individuals.

Conclusion Body weight dissatisfaction is associated with depression in men, women, young, middle-aged and old individuals independent of BMI.

Fraction of suicides attributable to alcohol in Belarus

Y. Razvodovsky

Grodno state medical university, pathological physiology, Grodno, Belarus

Introduction Suicide is one of the main causes of premature mortality in Belarus. There is strong evidence of a crucial role of alcohol in explanation of high suicide rate in this country.

Objectives The aim of the present study was to estimate the suicides mortality attributable to alcohol abuse in Belarus using aggregate- and individual-level data.

Methods The alcohol effect will be expressed in terms of alcohol-attributable fraction (AAF). The results of AAF estimates were compared with the data on BAC (blood alcohol concentration)-positive suicides based on the autopsy reports of the Bureau of Forensic Medicine.

Results The proportion of BAC-positive suicides and AAF estimates are presented in Table 1. BAC-positive suicides were found more frequently in men (60.2%) than in women (30.6). Similarly, the estimates of AAF for males (63.4%) were considerably higher than the estimates for females (35.2%). We also found that the relationship between alcohol consumption and suicides was stronger for male age groups 30-44 and 45-59 years.

Conclusions The outcome of this study provides support for the hypothesis that alcohol plays an important role in Belarusian suicide mortality crisis. The fact that the AAF estimated from aggregate-level data is similar to individual-level estimates suggests that this method produces reliable estimates of alcohol-attributable suicides.

Table 1 The proportion of BAC-positive suicides and AAF for different age groups.

Age	Males		Females	
	AAF	BAC+	AAF	BAC+
0–75+	63.4	60.2	35.2	30.6
15–29	27.8	54.4	20.6	48.8
30–44	67.2	65.4	47.2	41.7
45–59	67.2	65.1	44.1	38.4
60–74	50.6	58.8	20.6	19.6

* Corresponding author.

Introduction Women living in HIV-affected communities in sub-Saharan Africa are at increased risk for anxiety and depression.

Objective We aimed to assess the effect of a year-long parenting program in rural Eastern Uganda on caregiver's depression and anxiety symptoms and assess their functioning.

Methods One hundred and twenty-two caregivers and their HIV-infected preschool children (2–5 years) were randomly assigned to biweekly Mediation Intervention for Sensitizing Caregivers (MISC) training or a health and nutrition curriculum (treatment as usual-TAU). Dyads were assessed at baseline, 6-, 12- and 24-months. Primary outcomes were caregiver's depression and anxiety symptoms (Hopkins Symptom Checklist) and functional impairment. Treatment arms were compared using mixed effects models adjusting for outcome values at baseline, age, sex, and ARV status.

Results Fifty-eight child-caregiver dyads received the intervention and 60 received TAU. Most (75%) caregivers were the biological mothers of children and had a mean age of 37 years. At baseline, 63% of women had clinically relevant symptoms of depression or anxiety. Compared to TAU, caregivers in the treatment arm had a reduction in depressive symptoms at 24-months (HSCL-25 score=0.75 vs. 0.92, $P=0.06$), and functionality significantly increased at 6-months (0.32 vs 0.49; $P=0.02$) and was sustained at 12-months (0.24 vs 0.39; $P=0.04$).

Discussion Findings show that caregiver mental health and functioning was significantly better in those who received the parenting training, compared to those who received TAU.

Conclusions Parenting training interventions can be useful to promote both maternal mental health and child development in low-income countries.

* Corresponding author.

Perspectives of an individual in life are determined by effective socialization. Nowadays, much attention should be paid to the psychological nature of social adaptation and how effective socialization relates to the literal perception. This study aims to determine the relationship between personal adjustment, temperament traits, emotional burnout and reactions to emotion-laden social stimuli. Forty-one healthy volunteers (36 women and 11 men), students aged 17 to 26 years, participated in this study. We asked them to watch an emotional video. We used the following tests: the Method of Diagnostics of Social-Psychological Adaptation by Rogers & Dymond, Maslach Burnout Inventory (MBI), Cloninger's Temperament and Character Inventory (TCI), and Syndrome of Emotional Burnout by V. Boyko. Twenty-seven participants had a low level of personal adjustment and experienced burnout the most. There was an inverse correlation between social adjustment and harm avoidance, which reflects the activity of the serotonergic brain system. On the contrary, exploratory activity, which depends on the dopaminergic brain system, directly correlated with social adjustment. We found also a direct correlation between the formation of emotional burnout (depersonalization) and the perception of the negative video as pleasant, and inverse correlation of the latter with the level of social maladjustment and reward dependence (which reflects activity of the noradrenergic brain system). Thus, our results suggest that the balance of the activity of serotonin and dopaminergic brain systems may contribute to the development of social adaptation, burnout syndrome, and the adequacy of the negative view of the world.

The relationship between non-consensual sex and risk of depression in female undergraduate students at universities in Maritime Canada

D. Langille^{1,*}, B. McDougall², A. Steenbeek³, M. Asbridge¹, P. Andreou¹

¹ Dalhousie University, Community Health and Epidemiology, Halifax, Canada

² Dalhousie University, Department of Psychiatry, Halifax, Canada

³ Dalhousie University, School of Nursing, Halifax, Canada

* Corresponding author.

Introduction Sexual victimization and depression are common on university campuses, especially among females, and both are associated with negative health outcomes. Most studies of relationships between non-consensual sex and depression have used broad definitions of victimization and/or have controlled poorly for confounding.

Objectives This study examines whether there is an independent association between non-consensual sex and current risk of depression after controlling for related factors.

Aims To better inform university health services about the psychological sequelae of non-consensual sex.

Methods Cross-sectional data collected online from female students younger than age 30 at eight universities in Maritime Canada were analyzed. Non-consensual sex while at university was measured using one dichotomous item and risk of depression was measured using the Center for Epidemiologic Studies Depression (CES-D) Scale. All analyses were weighted and data were imputed using the Sequential Regression Multivariate Imputation (SRMI) Method. Analyses involved basic descriptive statistics, a series of unadjusted logistic regressions, and an adjusted multiple logistic regression.

Results In total, 36.7% of students were at risk of depression and 6.8% had been victims of non-consensual sex while attending university. After adjusting for covariates and confounders, females who had been victimized were 2.11 times more likely to be at risk of depression than females who had not been victimized ($P < .0001$).

Conclusions This study points to the need for more mental health support for victims of sexual victimization and more efforts to prevent sexual violence. These findings can be used to help inform university mental health services and health promotion activities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Type A personality and its association with mortality: Considering different analysis approaches of the Bortner Scale

T. Lohse^{1,*}, D. Faeh², M. Bopp², S. Rohrmann²

¹ Epidemiology, Biostatistics and Prevention Institute EBPI, Zurich, Switzerland

² Epidemiology, Biostatistics and Prevention Institute EBPI, Chronic Disease Epidemiology, Zurich, Switzerland

* Corresponding author.

Introduction Type A behaviour pattern (TABP) is defined as the combination of competitive need for achievement, sense of time urgency, aggressiveness, and hostility. Studies raised evidence for an association between TABP and cardiovascular disease. Recent studies on its association with mortality showed contradicting results and used different methods to measure TABP.

Objectives/aims Investigating the association between TABP and all-cause, CVD, and all-cancer mortality.

Methods We used data of the MONICA and the NRP1A studies that were linked with the Swiss National Cohort (SNC) ($n = 7997$). Essentially, the SNC is an anonymous record linkage of census, migration and mortality data. TABP was measured by the Bortner Scale. To determine the all-cause, CVD, and cancer mortality risk a Cox regression was performed. Following Edwards et al. (1990), we analysed the Bortner Scale in two different ways: all items and its two dimensions (speed and competitiveness) separately.

Results We found a significant association of the Bortner Scale with all-cause mortality in women (adjusted for sociodemographic factors HR 1.02, 95% CI 1.00–1.03, additionally adjusted for lifestyle factors—smoking, alcohol intake, physical activity, BMI category—1.01, 1.00–1.03). The subscale of competitiveness was associated with all-cause and CVD mortality in women. Interestingly, stratifying for lifestyle variables revealed that the association was only present in those having a healthy lifestyle, e.g. non-smoking or non-hazardous alcohol intake.

Conclusions The Bortner Scale and its subscale of competitiveness were associated with mortality in women. In those having

great health awareness, this might offer potential for further reduction of mortality risk.

* Corresponding author.

Introduction Social withdrawal is a major health problem that has been related with higher morbidity and mortality rates. There are few studies about the relationship between suicidal behavior and social isolation.

Aim To describe the existence of suicidal risk in subjects with social isolation.

Method Participants were 187 subjects referred to a Crisis Resolution Home Treatment because of social isolation. The inclusion criteria were: home isolation, avoiding of social situations and relationships, for at least 6 months. Suicide risk was assessed by the item of the Severity of Psychiatric Illness, dividing in four groups (from absence to high suicide risk). Socio-demographic and clinical data were also analysed.

Results Most cases ($n = 132$, 70.5%) had absence of suicide risk. They were predominantly young males in all groups. There were no statistically significant differences in sociodemographic or clinical variables. The mean age at onset of social isolation was lower in the high suicide risk group, having lower socially withdrawn period. This group had also lower rates of child abuse and suicide attempt history. The more frequent diagnosis in all groups was psychotic, affective and anxiety disorders. Those cases with mild and high suicide risk needed more frequently hospitalization.

Conclusions Social isolated people attended by CRHT do not have high frequency of suicide risk. Cases with higher suicide risk are younger and have a shorter period of isolation. The absence of child abuse history or previous suicide attempts contrasts with previous suicidal behavior research. These data can be influenced by the characteristics of functioning of CRHT and the small sample size.

Diagnosed depression and utilization of healthcare and preventive services in the general adult population in Germany

U. Maske^{1,*}, J. Maren², U. Hapke¹, D. Kleiber², M.A. Busch¹

¹ Robert Koch Institute, Department of Epidemiology and Health Monitoring, Berlin, Germany

² Freie Universität Berlin, Department of Education and Psychology, Division Public Health: Prevention and Psychosocial Health Research, Berlin, Germany

* Corresponding author.

Introduction Depressive disorders have been related to increased health service utilization, but specific information about associations between health professional-diagnosed depression and the utilization of health care and preventive services in the general population is limited.

Objectives To compare the use of health care and preventive services among men and women with and without diagnosed depression in the general population in Germany.

Aims To examine the association of diagnosed depression with the utilization of healthcare and preventive services.

Methods Cross-sectional analysis of data from the representative telephone survey German Health Update (GEDA) 2009 and 2010 ($n = 43,312$ residents in private households 18 years and older). We analyzed associations between self-reported health professional-diagnosed depression (past 12 months) and the use of a range of healthcare services and preventive services covered by statutory health insurances using multivariable regressions adjusted for age, socio-economic status, marital status, employment and number of chronic somatic conditions.

Results Twelve-month diagnosed depression was associated with increased health care service utilization (physician contacts, hospital admissions, rehabilitation) in both sexes. Of the preventive services, diagnosed depression was associated with increased use of general health check-ups, cancer screening and flu vaccination among women, while there was no association with dental check-up and tetanus and pertussis vaccination. Among men, no association of diagnosed depression with any preventive service was found except for cancer screening.

Conclusions Health professional-diagnosed depression is associated with increased health service utilization independent of somatic comorbidity and socio-demographic confounders. This includes some preventive services in women and only one preventive service in men.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between mental health problems of stunted children and common mental disorders of their mothers in Brazil: A case control study

C. Miranda^{1,*}, L. Santos², C.S. Paula³, W. Ribeiro⁴, T. Florencio⁵

¹ Maceio, Alagoas, Brazil

² Universidade Federal de Alagoas, Instituto de Ciencias Basicas da Saude, Maceio, Alagoas, Brazil

³ Universidade Presbiteriana Mackenzie, Programa de Pos Graduação em Distúrbios do Desenvolvimento, Sao Paulo, Brazil

⁴ Kings College London, Institute of Psychiatry, London, United Kingdom

⁵ Universidade Federal de Alagoas, Faculdade de Nutrição, Maceio, Alagoas, Brazil

* Corresponding author.

Introduction In deprived environments, mental health problems for both the mother and her stunted child may be related.

Objective To verify possible association between a child's nutritional and mental health status with common maternal mental disorders (and associated impairment).

Aims To contribute to management of malnutrition and mental health in low-income populations.

Methods Case-control study in which 48 malnourished children (aged 48 to 72 months) were compared with 50 eutrophic children. The child's nutritional status, the children's mental health, the maternal mental health, and the associated disability were evaluated by using the WHO criteria, the "Strengths and Difficulties Questionnaire" (SDQ), the "Self-Report Questionnaire"-20

(SRQ-20), and the "Sheehan Disability Scale" (SDS), respectively. In addition, selected socio-economic aspects were considered.

Results Variables with significant odds ratio (OR) in the univariate analysis were: maternal education (OR: 2.96, 95% CI: 1.30–6.75), number of residents in the household (OR: 0.32, 95% CI: 0.14–0.74), number of children in the household (OR: 0.25, 95% CI: 0.10–0.61), and social class (OR: 2.30, 95% CI: 1.02–5.18). The only SDQ dimension that tended to be associated with malnutrition was conduct problems ($P = 0.08$). The disability associated with probable common maternal mental disorders (CMD) also showed statistically significant association ($P = 0.02$). In the logistic regression, child malnutrition remained associated with child conduct problems and disability associated with probable CMD.

Conclusions Conduct problems in stunted children are positively associated with CMD and related disability. Longitudinal studies are necessary to confirm these hypotheses.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Workforce migration of mental health professionals seems to have a significant impact on mental health services, both in the donor and host countries. Nevertheless, information on migration in junior doctors within Europe is very limited. Therefore, the European Federation of Psychiatric Trainees (EFPT) has conducted the Brain Drain Survey.

Objectives To identify, in junior doctors training in psychiatry, the impact of international short-term mobility experiences, towards a future workforce migration across countries, exploring its patterns and reasons.

Methods In this cross-sectional international study, data were collected from 2281 psychiatric trainees in 33 countries. All participants answered to the EFPT Brain Drain Survey reporting their attitudes and experiences on mobility and migration.

Results Only one-third of the trainees had a short-mobility experience in their lifetime, being education the main purpose for these experiences. Interestingly, the main predictors for future migratory tendency were not only the having a income and being dissatisfied with this income, but having a short-mobility experience. In fact, people that had short-mobility experiences were two times more likely to express a migratory tendency. Trainees that went abroad were predominantly satisfied with their experiences,

reporting that these influenced their attitudes towards migration, positively.

Conclusions These findings show that short-term mobility has a positive impact into future long-term migration, increasing its probability.

⁶ University of Manchester, Institute of Brain, Behaviour and Mental Health, Manchester, Australia

* Corresponding author.

Introduction Role functioning is key to optimal health and inoculates against life-long inequality. Depression is a leading cause of functional disability. In most cases, improved symptomatology corresponds with improved functioning; however, functioning does not always return to "normal", despite symptom remission. Furthermore, the relationship between symptom remission and the likelihood of being Not in Employment, Education or Training (NEET) is unknown.

Objectives and aim To examine the temporal associations between depression course, functioning, and NEET status in young adults with mental health problems.

Methods A prospective and multisite clinical cohort study of young people aged 15–25 years seeking help from a primary mental health service ($n=448$). Participants completed a clinical interview (incl. QIDS-C16) and self-report battery (incl. WHODAS 2.0, employment, education) at baseline which was repeated at 12-month follow-up whilst continuing treatment as usual.

Results Remitted depression was significantly associated with improved functioning; however, 12 month functioning was still lower than the normative ranges for age-matched peers. Remittance of depression did not change the likelihood of being NEET. Only 10% of those who were NEET had received vocational support during the study.

Conclusion Remittance of depression was associated with improved functioning but it did not reduce the likelihood of being NEET. This may be explained by economic influences or alternatively, a time lag may exist where improvements in functioning do not immediately correspond with reduced NEET rates. Lastly, there may be a scarring effect of depression such that change in NEET status requires an additional intervention to depression treatment.

Association of family stress with other psychosocial factors in female population 25–64 years in Russia: WHO program MONICA-psychosocial

V. Gafarov, D. Panov*, E. Gromova, I. Gagulin, A. Gafarova
FSBI Institute of Internal and Preventive Medicine, Collaborative laboratory of cardiovascular diseases epidemiology, Novosibirsk, Russia

* Corresponding author.

Aim To explore association of family stress with other psychosocial factors in female population aged of 25–64 years in Russia.

Methods Under the third screening of the WHO "MONICA-psychosocial" program random representative sample of women aged 25–64 years ($n=870$) were surveyed in Novosibirsk. Questionnaire "Awareness and attitude towards the health" was used to estimate levels of family stress. Chi-square (χ^2) was used for assessment of statistical significance.

Results The prevalence of high family stress level in women aged 25–64 years was 20.9%.

High family stress was higher in age groups 25–34 years and 45–54 years: 27.6% and 30.5%, respectively. Among women with family stress, 58.7% had high level of trait's anxiety. Women with stress at family had high rate of major depression (11%). There were tendencies of higher prevalence of hostility and vital exhaustion in those with stress (41.1% and 27.4%, respectively). Among those in female population with stress at family, 60.6% had sleep disturbances. Social support like close contacts and social network tended to be lower in women with family stress: 59.1% and 80.3%, respectively. Rates of serious conflicts in family were more often in younger age groups and reached 48.6%. In women aged 25–34 years, 54.9% have no possibilities to have a rest at home after usual working day ($P<0.001$).

Conclusions The prevalence of high stress in family in female population aged 25–64 years is more than 20% in Russia. High family stress closely associated with anxiety, major depression, high hostility and vital exhaustion, poor sleep and low social support.

Prenatal depression in women hospitalized for threatened preterm labour: A prospective study in Greece

G. Papazisis^{1,*}, T. Dagklis², I. Tsakiridis², F. Chouliara², A. Mamopoulos², D. Rousso²

¹ Faculty of Medicine, Aristotle University of Thessaloniki, Pharmacology and Clinical Pharmacology, Thessaloniki, Greece

² Faculty of Medicine, Aristotle University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Hippokrateion hospital, Thessaloniki, Greece

* Corresponding author.

Introduction Pregnancy complications may require admission in a high-risk pregnancy unit (HRPU). A complicated pregnancy and hospital admission might negatively affect the pregnant woman's mental health.

Objectives To screen for depressive symptoms in pregnant women admitted in a high-risk pregnancy unit due to threatened preterm labour and also to investigate for associated risk factors.

Aims Early identification of prenatal depression will decrease the risk of pregnancy complications and postnatal depression.

Methods A prospective study enrolled pregnant women admitted at ³24 gestational weeks due to threatened preterm labour in a university hospital HRP, between 9/2014 and 11/2015. The Edinburgh Postnatal Depression Scale (EPDS) was used to assess depressive symptoms and a cut-off score ³13 was considered as indicative of depression. Test results were then correlated with the indication for admission, demographic and socio-economic parameters.

Results Overall, 80 of the women admitted in the HRP were eligible for the study and agreed to complete the questionnaire. The mean age was 29.4 ± 6.23 years and the mean gestational week at the admission was 31.6 ± 3.33 weeks. The prevalence of prenatal depression (score ³13) was 25% (20/80). In the multivariable model, depression was significantly correlated with the existence of thoughts for pregnancy termination [*P* = .03 OR = 4.560 95% CI: (1.162–17.892)].

Conclusions One quarter of pregnant women admitted in the HRP with the indication of threatened preterm labour may suffer from clinically significant depression. An unwanted pregnancy was found to be independently associated with prenatal depression whereas no association was found with any obstetric parameters.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Descriptive epidemiology of depressive and anxiety disorders, cognitive impairment and dementia in a sample of elderly patients in the geriatric unit of a general hospital

A. Pater^{1,*}, Y. Espolio Desbaillet², D. Peris³

¹ Hôpital Neuchâtelois, Gériatrie, Neuchâtel, Switzerland

² Centre Neuchâtelois, Gériatrie, Neuchâtel, Switzerland

³ Centre Neuchâtelois de Psychiatrie, Hôpital de Préfargier, Neuchâtel, Switzerland

* Corresponding author.

Introduction Studies have demonstrated the high prevalence of depressive disorders amongst elderly people and their underestimation and mistreatment.

Objective The aim of this study is to describe epidemiological issues in a sample of elderly hospitalized patients, giving special attention on the prevalence of depressive and anxiety disorders and the detection of potential risk factors.

Material and methods The sample included 168 elderly patients referred for the geriatric unit of a general hospital. Epidemiological and clinical data were collected. Geriatric Depression Scale (GDS), Mini Mental State Examination (MMSE) and Functional Independence Measure (FIMTM) were used. Data were analyzed with XLSTAT program.

Results The 39% of the sample were men and the 61% women, with an age range between 65 and 95 years. Nine percent of patients aged 65–84 had a diagnosis of depressive or anxious-depressive disorder, compared to 13% within the age range 85–95. However, 14% of patients aged 65–85 had a GDS higher than 5 and 19% for the patients aged 85–95, which could confirm the underestimated rate of depression diagnosed in elderly patients. Item “feeling loneliness” was pointed out in 75% and item “feeling bored” in 64% of all GDS higher than 5. Prevalence of dementia was 8% in the whole sample.

Conclusions High prevalence of depressive and anxious disorders amongst the elderly is to be taken in account. Potential risk factors could be loneliness and lack of daily activity. The development of social primary prevention interventions in order to

decrease the prevalence of these pathologies amongst elderly is needed.

Making sense of economic deprivation as a predictor of suicide and homicide: A nationwide register-study

M. Pompili^{1,*}, M. Vichi²

¹ Rome, Italy

² National Institute of Health, National Centre for Epidemiology, Surveillance and Health Promotion, Rome, Italy

* Corresponding author.

Introduction Classical work on lethal aggression often viewed suicide and homicide as sharing a common source.

Objective The present investigation explores the association between measures of social deprivation on the relative incidence of suicide over homicide in Italian provinces.

Methods Data refer to official government sources on lethal violence rates and measures of social deprivation. The central dependent variable is termed SHR or the suicide rate expressed as a proportion of the sum of the suicide and homicide rates Data were available for the 103 Italian provinces.

Results The SHR had three significant predictors. The greater the percentage of the population with low education, the lesser the tendency towards suicide. The tendency towards suicide was also predicted by rental housing, the greater the percentage of the population living in rental housing the less the tendency towards suicide. The inverse of the unemployment rate also predicted the SHR. Given that the measure follows an inverse function, the greater the unemployment rate the lesser the tendency towards suicide relative to homicide (SHR). We can interpret the results relative to a homicidal tendency in the SHR: the greater the low education percentage of the population, the greater the homicidal tendency, and the greater the rental housing percentage, the greater the homicidal tendency in the SHR.

Conclusion The results are consistent with a stream of previous research that connects deprivation with a relatively high probability for disadvantaged populations to direct aggression outwardly in the form of homicide rather than inwardly in the form of suicide.

Structure and function of social networks, loneliness, and their association with mental disorders among older men and women in Ireland: A prospective community-based study

Introduction Interpersonal stressors and social isolation are detrimental for emotional health, but how these factors are related

to loneliness and altogether influence risk for mental disorders is not well understood.

Objectives To examine the mediating role of loneliness in the associations of relationship quality and social networks with depressive symptoms, anxiety, and worry among a sample of Irish men and women in late-life.

Aims To determine the gender-specific risk for mental disorder associated with poor social relationships and loneliness among older adults.

Methods Data came from the Irish Longitudinal Study on Ageing (TILDA). Nationally representative data on 6105 community-dwelling adults aged > 50 years were analyzed. Follow-up data was obtained two years after cohort inception. Multivariable linear regressions and mediation analyses were used to assess the associations. Analyses were stratified by gender.

Results Better spousal relationship quality was protective against depressive symptoms and worry for men. For both genders, support from friends was protective against depressive symptoms, and better relationship quality with children was protective against depressive symptoms and worry. Social network integration was inversely related to depressive symptoms for men. Loneliness significantly mediated most associations (Tables 1–3).

Conclusions High quality spousal relationships and social integration appear to play a more central role for mental health among men than for women. For both genders, poor social relationships increase feelings of loneliness, which in turn worsens mental health. Interventions to improve relationship quality and social networks, with a focus on reducing loneliness, may be beneficial for the prevention of mental disorders among older adults.

Suicidal events due to overdose and medical comorbidities in psychiatric disorders of ICD-10 classes F1–F4: A comparative overview of five studies in general hospital admissions

D. Schoepf^{1,*}, R. Heun²

¹ University Hospital of Bonn, Psychiatry, Bonn, Germany

² Royal Derby Hospital, Radbourne Unit, Derby, United Kingdom

* Corresponding author.

Introduction General hospital-based studies may help towards improving the treatment of psychiatric disorders.

Objectives and aims Based on five representative studies in general hospital admissions, we will represent a comparative overview of suicidal events due to overdose and of the most common medical comorbidities in psychiatric disorders of ICD-10 classes F1–F4.

Methods In secondary analysis one-way Anova and Tukey HSD test were used for comparisons of interval variables. Suicidal events and medical comorbidities with prevalences > 10% were compared between studies using the OR and the 95% CI.

Results Individuals with psychiatric disorders of ICD-10 classes F1–F4 were young (44.7–50.0 years), had an extended length of hospital stay at initial hospitalization (3.8–8.1 vs. 2.9–3.4 days), and significantly more likely suffered of suicidal events due to overdose than controls, contributing from 4.1% (OR = 4,1) to 11,6% (OR = 25.2) to general hospital admissions. Additionally, individuals with schizophrenia (SCH) significantly more likely suffered of type-2 diabetes mellitus (OR = 2.3, 95% CI 1.5–3.6) than individuals with major depressive disorder (MDD), anxiety disorder (ANX), and alcohol dependence (AD), but equal likely as individuals with bipolar disorder (BD). Asthma and hypertension contributed significantly more to hospitalizations in the MDD and ANX samples compared to the SCH, BD, and AD samples. In the AD sample, alcoholic liver disease was more prevalent than in all other samples.

Conclusions In psychiatric disorders, the frequency of suicidal events due to overdose in general hospitals is significantly determined by the diagnostic class. Additionally, different medical comorbidities contribute more than other medical comorbidities to general hospital admissions in various psychiatric disorders.

The projected number and prevalence of dementia in Japan: Results from the Toyama Dementia Survey

M. Sekine^{1,*}, M. Suzuki², H. Kido³, M. Yamada¹, T. Tatsuse¹

¹ University of Toyama, Department of Epidemiology and Health Policy, Toyama, Japan

² University of Toyama, Department of Neuropsychiatry, Toyama, Japan

³ Kido Clinic, Department of Psychiatry, Imizu, Japan

* Corresponding author.

Purposes The increasing number of dementia is of major public health concern. This study aims to calculate the projected number and prevalence of dementia in Japan, using data from the Toyama Dementia Survey.

Methods The Toyama Dementia Survey was conducted 6 times in 1983, 1985, 1990, 1996, 2001, and 2014. In the 2014 survey, the subjects were randomly chosen from residents aged 65 or more in

Toyama prefecture, with a sampling rate of 0.5%. Of those, 1303 men and women agreed to participate (participation rate: 84.8%). An interview with a screening questionnaire was conducted by public health nurses. Psychiatrists and public health nurses further investigated for the suspected cases of dementia and diagnosed whether the cases had dementia. The 1985–2001 surveys were conducted in a similar way, and, therefore, data from the 1985–2014 surveys were used in the analysis.

Results The prevalence of dementia in Toyama prefecture increased from 4.7% in 1985 to 15.7% in 2014. Using the age and sex-specific prevalence of dementia in the 2014 survey, the projected number of dementia is approximately 4.8 million (prevalence rate: 14.1%) in 2015, 6.1 million (16.7%) in 2025, and 7.2 million (19.2%) in 2035. Using the age and sex-specific prevalence of dementia as estimated by linear regression models, the projected number of dementia is approximately 4.7 million (13.9%) in 2015, 7.1 million (19.5%) in 2025, and 9.7 million (25.8%) in 2035.

Conclusions The number of dementia in Japan could double in the next 20 years, which corresponds to 1 in 4 elderly people.

Duration of the compulsory psychiatric forensic hospital treatment compared to maximum penalty sentences in the Republic of Croatia

M. Curkovic*, K. Radic, N. Buzina, G. Arbanas, V. Jukic

University Psychitric Hospital Vrapce, Centre for Forensic Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction Legal system, by the nature of its involvement, has the tendency to create boundaries of forensic psychiatric (in)patient care. In 2014, after the introduction of the new Law of the Protection of Persons with Mental Disorder in the Croatia new boundaries were created within the article: “compulsory hospitalized treatment of insane person cannot be longer that maximum penalty sentence prescribed for that offense”.

Objectives To analyze the duration of hospitalization of forensic psychiatric inpatients at the University Psychiatric Hospital Vrapče’s Centre for Forensic Psychiatry and compare these findings to a prescribed maximum penalty sentence.

Aims To test appropriateness of the new regulative introduced with the new Law.

Methods Available data from all forensic psychiatric inpatients that committed crimes of murder, attempted murder, grave murder, threat, personal injury or domestic violence that were dismissed within 10 years before the introduction of the new Law were analyzed.

Results The analysis included a total of 168 inpatients. The mean durations of hospitalizations for all six categories of crimes did not exceed maximum penalty sentences prescribed by the latest corresponding law, although in some rare individual cases they did. This was present within the categories of crimes of domestic violence (mean duration: 20.6 months with maximum duration: 68 months), and threat (mean duration: 24, maximum duration: 89).

Conclusion Although arguably with the best intentions (“unacceptability of negative discrimination”), legal system created

unnecessary tension as it imposes legal principles over clinical and moral ones. Deeper analysis of possible mediators of the duration of hospitalization are identified and presented.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Long-stay in high and medium secure forensic psychiatric care – Prevalence, patient characteristics and pathways in England

R. Edworthy*, B. Vollm

University of Nottingham, School of Medicine Division of Psychiatry and Applied Psychology, Nottingham, United Kingdom

* Corresponding author.

Introduction Forensic psychiatric services are costly and highly restrictive for patients. Clinical experience and the limited research available indicate some patients stay for too long in these settings. A proportion of patients may, however, require long-term (potentially life-long) secure forensic psychiatric care but their needs may not be met by existing service provision designed for faster throughput.

Objectives We conducted a national, multi-centre, cross sectional study exploring the prevalence of long-stay and characteristics of long-stayers in high and medium secure forensic psychiatric care in England.

Aims (1) Estimate the prevalence of long-stay in secure settings in England (length of stay over 5 years in medium secure care or 10 years in high secure care); (2) describe the characteristics, needs and care pathways of long-stay patients. Develop recommendations following the exploration of international models for this patient group.

Methods We employed a mixed-methods approach including the analysis of administrative data, case file reviews, patient interviews, consultant questionnaires, interviews with clinicians and commissioners and a Delphi survey.

Results Twenty-five percent ($n=401$) of our sample were experiencing long-stay. This patient group has a heterogeneous set of characteristics and needs relating to their diagnosis, offending history, risk and therapeutic need and have experienced a variety of care pathways through secure care.

Conclusions We found a greater number of long-stay patients than originally estimated with a set of characteristics and needs that are arguably different to that of the general forensic population, therefore calling for a specific care pathway and service provision for this patient group with a greater focus on autonomy and quality of life.

³ Hospital Ramón y Cajal, Psiquiatría, Madrid, Spain

⁴ Hospital Ramón y Cajal, Enfermedades Infecciosas, Madrid, Spain

* Corresponding author.

Introduction There are many studies of HIV-infected patients where have found higher prevalence of substance use disorders than in general population. Moreover some factors, like presence of

legal problems, substance abuse and HIV are also frequently related with poorer clinical results.

Objectives/aims The aim of this study is to analyze the relationship between substance consumption and presence of legal problems among HIV-infected patients.

Methods Our study is a cross-sectional case-control survey. Cases were defined as HIV-infected patients who referred presence of legal problems in a sociodemographic questionnaire. Controls were defined as HIV-infected patients who denied presence of legal problems. Both groups were interrogated about illegal substance use (cocaine, heroin, cannabis, stimulants or benzodiazepines) and alcohol problematic use during previous year. Logistic regression was employed as statistical analysis. Results were adjusted for age, gender and race.

Results Our sample was compound by 63 patients: 44 controls and 19 cases. A statistical signification was found between illegal substance use variable and presence of legal problems ($P=0.003$) but not with alcohol problematic use. The condition of illegal substance use during previous year increased the risk to have legal problems 5.353 times. Another important result was found in gender, the condition of male increased the risk to have legal problems 2.32 times than female condition.

Conclusions In our sample, substance use (cocaine, heroin, cannabis, stimulants or benzodiazepines) during previous year was related to have more legal problems. Gender, specifically male condition, also was linked with more risk to have legal problems.

Introduction and objective Description through a survey of physical aggressions suffered by Spanish Medical Trainees of all specialties.

Methods We developed a survey through an online platform that was distributed to all Spanish trainees of all medical specialties. In that survey, we ask residents if they ever have been physically assaulted, for how many times, the year of residence when it occurred, if they have in their hospital an aggression protocol, and if it included a specific topic for trainees. We also asked them about their feelings after they have been assaulted.

Results We collected 282 answers from the survey. We could observe that 12.9% of respondent trainees had been assaulted at least once. Fifty-one percent of times, it occurs during the first year of residency. Among assaulted residents, 25.5% were psychiatric trainees, and 44.4% were medical trainees, but no psychiatrist. Twenty-three percent were psychiatric trainees, and the 35% of them had been assaulted once. Only 25.2% of the residents knew the aggression protocol of their work center, but the majority (65.5%) did not know it. About how do they feel after being assaulted, most of them responded that they felt anxiety, helplessness, fear and they had even thought of leaving de residency or change it.

Conclusions Aggressions during the trainee period seems to be prevalent (12.9%). Most trainees don't even know if there is a

aggression protocol in their hospitals, we think that a prevention and supporting guideline should be design for improve this prevalent situation.

* Corresponding author.

Introduction Pedophilia is a disorder where sexual preferences of adults are directed towards children. This disorder impacts society with 1–2 out of every 10 children being sexually approached by an adult, often resulting in prolonged negative psychological effects. Prior research reported structural and functional amygdala alterations in pedophilia. As the neurophenomenological model of sexual arousal suggests the importance of the amygdala in the emotional component, we focused on amygdala functional connectivity in pedophilia.

Aims To investigate amygdala functional connectivity (FC) modulated by expectancy and salient stimuli in pedophilic patients.

Methods Thirteen pedophilic patients and 13 matched healthy controls underwent a salience expectancy task in a 7T ultra high fMRI study. Subjects perceived pictures of naked adults and children. Half of the pictures were preceded by an expectancy cue. Participants were instructed to actively expect the picture depending on the cue. We conducted psychophysiological analysis (PPI) to examine amygdala FC changes in two amygdala sub-regions for child/adult stimuli during the expectancy period and the visual stimuli consummation period using as seed regions the basolateral (BLA) and central nucleus of the amygdala (CeA).

Results Healthy controls, relative to patients showed significant stronger left CeA to right post-central gyrus FC during expectancy of adult > child picture. For picture condition (adult > child picture) we found significant stronger left CeA to left dorsolateral prefrontal cortex FC in patients compared to healthy controls.

Conclusion These findings add to the recent literature by indicating that amygdala dysfunctional connectivity is involved in development of deviant sexual behavior.

Restrictive measures in psychiatry

M. Rodríguez Merino*, J.J. Arechederra Aranzadi, M.I. López-Ibor Alcocer

Dr. López Ibor Neuropsychiatric Institute, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Informed consent is guarantor of the three principles that guide the professional activity of physicians concretely, information, comprehension and volunteerism, based on bioethical values of autonomy, non-maleficence, beneficence and justice. Psychopathological alterations undermine the capacity to consent treatment, requiring, sometimes, restrictive measures for risk prevention and treatment, including involuntary admission, intramuscular medication and physical restraint.

Objectives This study aims to analyze the therapeutic measures of restriction, according Spanish legislation, article 763 of Civil Procedure Law, under the condition of a mental disorder.

Method We will proceed to the descriptive statistical analysis of total cohort of hospital admissions in the Dr. Lopez Ibor Neuropsychiatric Institute in the calendar year 2014 and we will review the coercive measures to the treatment of those patients who have decline of the ability to provide informed consent.

Results Of the cohort of income, 10.5% has been involuntary admission, 51% men versus 49% women. Forty-one percent of patients have been diagnosed with schizophrenia, schizotypal and delusional disorder; the other 30% with affective disorders (21% bipolar disorder or manic disorder); and the 12.2% with disorders of adult personality and behaviour. Eighteen percent have needed intra-muscular medication and physical restraint.

Conclusions The proportion of patients with decline of the decisional-making capacity is less than that found in studies in other countries of the European Union. The involuntary commitment is more frequently associated with severe mental disorders and the use of restrictive measures is associated to situations of danger to the patient or others.

Not just 'callous-unemotional': Psychopathic traits are associated with emotion dysregulation dimensions

P. Velotti^{1,*}, M. D'aguanno², C. Garofalo³, G. Rogier²

¹ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

² University Sapienza, Psychology, Rome, Italy

³ Tilburg University, psychology, Tilburg, Netherlands

* Corresponding author.

Introduction Historically, psychopathic individuals have mainly been described as characterized by pervasive callous-unemotional traits, with dramatic implications for clinical and forensic practices – such as the tendency to deem psychopathic individuals as untreatable. However, recent evidence with community samples have highlighted that psychopathic traits may be in fact related to emotion dysregulation rather than being the mere reflection of an underlying 'unemotionality'. Yet, it is no clear if this association extends to populations with more severe forms of psychopathy (i.e., offenders).

Objectives We wanted to replicate previous evidence of an association between emotion dysregulation and psychopathic traits in a sample of incarcerated offenders.

Aims To investigate the associations among emotion dysregulation dimensions and psychopathic traits, exploring similarities and differences between the Interpersonal-Affective and the Antisocial-Lifestyle facets of psychopathy.

Methods A sample of male offenders incarcerated in Italian jails completed the Self-Report Psychopathy Scale (SRP-4; Paulhus, Neumann, & Hare, 2015) and the Difficulties in Emotion Regulation Scale (DERS; Gratz & Roemer, 2004).

Results In line with the expectations, emotion dysregulation dimensions did predict higher levels of psychopathic traits. Structural Equation Modelling revealed that selected dimensions of emotion dysregulation were associated with different facets of psychopathy.

Conclusions Based on our findings, we argue that psychopathic traits may be associated to a certain extent with emotion dysregulation, and thus a focus on improving emotion regulation skills may hold the promise to dampen the therapeutic pessimism when dealing with psychopathic offenders.

Lifetime abuse among male inmates in an Italian prison: Psychiatric clinical correlates

N. Verdolini^{1,*}, L. Attademo¹, R. Garinella¹, L. Pauselli¹, M. Piselli², P. Moretti², R. Qartesan³

¹ University of Perugia, School of Specialization in Psychiatry, Department of Medicine, Perugia, Italy

² University of Perugia, Section of Psychiatry, School of Specialization in Psychiatry, Department of Medicine, Perugia, Italy

³ University of Perugia, Director of the School of Specialization in Psychiatry, Section of Psychiatry, Department of Medicine, Perugia, Italy

* Corresponding author.

Aim to evaluate the prevalence of lifetime abuse in inmates of the Spoleto prison (Umbria, Italy) as well as the association with psychiatric disorders, Axis I or II, lifetime drug abuse, self-harm in the inmates and the history of legal problems or lifetime drug abuse in their parents.

Subjects and methods Five hundred and twenty-six convicted males incarcerated in the Spoleto Prison between October 2010 and September 2011 were evaluated by trained interviewers with the SCID-I, the SCID-II, the ASI-X and the DSHI. Chi² tests were performed to examine the relation between the history of lifetime abuse and the different clinical features.

Results Ninety-seven (18.4%) inmates reported a lifetime history of abuse. Among them, 65 (67%) suffered from an Axis I diagnosis and 65 (67%) were given an Axis II diagnosis. Inmates that reported a lifetime history of abuse were more likely to have an Axis II diagnosis ($P = .002$) but not an Axis I diagnosis ($P = 0.086$) or a lifetime drug abuse ($P = 0.060$) than those without abuse. Furthermore, there was a significant relationship between history of abuse and lifetime self-harm in inmates ($P < .001$) and legal problems or lifetime drug abuse in their parents ($P < .001$).

Conclusion Even though a lifetime history of abuse is not so frequently reported in our sample of inmates, the high rates of psychiatric disorders among those abused and the correlation with self-harm should be taken in consideration when needs of inmates are evaluated, mainly in those who require psychiatric treatments.

⁴ Institute of Molecular Medicine, University of Southern Denmark, Department of Neurobiology Research, Odense, Denmark

* Corresponding author.

Introduction The diagnoses of autism spectrum disorders (ASDs) are based on a phenotype, characterized by impaired social interaction and communication and by repetitive and restricted interests. However, this might not represent a single clinical entity, but a behavioral manifestation of different neurodevelopmental deficits with a multifactorial etiology. Small studies have shown elevated levels of oxidative stress and lower levels of anti-oxidants in patients with ASD, and correlations with the severity of ASD. Therapies targeting oxidative stress have shown improvements regarding behavior, social interaction and verbal communication in patients with ASD, supporting the oxidative stress theory.

Objectives To evaluate the importance of oxidative stress in the neurobiology of adults with ASD.

Aims There is a need to understand the neurobiology of ASD, therefore this study analyzes the level of oxidative stress in a larger cohort of patients with ASD and compares to controls.

Methods The study includes 350 patients over 18 years of age diagnosed with ICD-10 diagnoses F84.0, F84.1, F84.5 or F84.8 and compared to gender and age matched neurotypical controls. The included probands will have their serum and plasma analyzed for levels of oxidative stress (superoxide dismutase 1 and 2, catalase, glutathioneperoxidase, malonaldehyde, thiobarbituric acid reactive substances and xanthinoxidase).

Results The preliminary results will be presented at the EPA in March 2016 in Madrid.

Conclusion With this study we aim to elucidate some of the neurobiology in ASD. This could lead to new potential targets for treatment and prevention of the disorders.

Plasma micro-RNA profiles in patients with major depressive disorder (MDD)

V.R. Enatescu^{1,*}, I. Papava¹, I. Enatescu², M. Antonescu³, A. Anghel³, E. Seclaman³, I.O. Sirbu³, R. Romosan¹, C. Marian³

¹ "Victor Babes" University of Medicine and Pharmacy Timisoara, Department of Psychiatry, Timisoara, Romania

³ "Victor Babes" University of Medicine and Pharmacy Timisoara, Department of Biochemistry, Timisoara, Romania

* Corresponding author.

Introduction Micro-RNAs (miRs) are involved in processes associated with MDD such as neural plasticity, neurogenesis,

synaptogenesis and stress response. MiRs are detectable in biological fluids; however, no data is available regarding the use of plasma circulating miRs as markers of MDD, only whole blood or serum being reported so far.

Objectives We investigated plasma miR profiles as potential markers for MDD in patients treated with antidepressants.

Aims To detect and characterize differentially expressed miRs in the plasma of MDD patients, before and after treatment with escitalopram.

Methods Blood was collected from patients with MDD before and after 12 weeks of treatment. Plasma profiles of 1008 miRs were measured by real time PCR. The fold change of expression between time points was calculated and a paired *t* test was used for statistical significance. Gene targets and pathways were assessed in miRWalk2.0.

Results From 222 plasma miRs expressed, 40 were significantly different after treatment. Upregulated miRs (23) belonged to 43 pathways, down-regulated miRs (17) belonged to 46 pathways; the top 5 significant pathways identified being pathways in cancer, Wnt signalling, endocytosis, axon guidance and MAPK signalling. Six of these miRs are common to all five pathways: miR-146a-5p, miR-146b-5p, miR-221-3p, miR-24-3p, miR-26a-5p.

Conclusions Our analysis of significant changes in plasma miRs after escitalopram treatment of MDD might open new avenues for the understanding of its mode of action and its side effects. To our knowledge, this is the first study to assess miRs affected by antidepressant treatment in plasma of MDD patients.

⁴ Max Planck Institute of Psychiatry, Clinical Research, Munich, Germany

* Corresponding author.

Gene expression profiling may be a tool to identify markers of antidepressant treatment response and new potential drug targets. In a first step, we selected 12 males, age- and severity-matched pairs of remitters and non-responders, and analyzed expression profiles in peripheral blood at admission and after 2 and 5 weeks of treatment using Illumina expression arrays. We identified 127 transcripts significantly associated with treatment response with a minimal *P*-value of 9.41×10^{-4} (false discovery rate-corrected). Analysis of selected transcripts in an independent replication sample of 142 depressed inpatients confirmed that lower expression of retinoid-related orphan receptor alpha (RORa, $P = 6.23 \times 10^{-4}$), germinal center expressed transcript 2 (GCET2, $P = 2.08 \times 10^{-2}$) and chitinase 3-like protein 2 (CHI3L2, $P = 4.45 \times 10^{-2}$) on admission were associated with beneficial treatment response. In addition, leukocyte-specific protein 1 (LSP1) significantly decreased after 5 weeks of treatment in responders ($P = 2.91 \times 10^{-2}$). Additional genetic, in vivo stress reactivity data and murine hippocampal gene expression findings corroborate our finding of RORa as a transcriptional marker of antidepressant response. In summary, using a genome-wide transcriptomics approach and subsequent

validation studies, we identified several transcripts including the circadian gene transcript RORa that may serve as biomarkers indicating antidepressant treatment response.

Markers of neurodegeneration in patients with severe neuropsychiatric disorders

T. Dokukina*, M. Makhrov, P. Korolevich, A. Pinchuk, A. Astashonok, T. Budko

Republican Scientific and Practical Centre for Mental Health, Department of mental and behavioral disorders, Minsk, Belarus

* Corresponding author.

The high frequency of occurrence and serious social consequences of cognitive impairment allow us to consider them as an actual general medical problem.

Objective To describe the quantitative ratios of markers of neurodegeneration (Aβ40, Aβ42, phosphorylated tau protein) in patients with severe neuropsychiatric disorders.

Material and methods The study included 82 patients with different cognitive impairment. Three groups: 35 patients with schizophrenia, 26 patients with epilepsy and 21 patients with autism. The results showed differences in the expression profile of tau protein in patients with early and late onset of schizophrenia. Variations of the quantitative ratio in plasma of amyloid peptide Aβ40 were detected in the second experimental group (epilepsy). Aβ40 concentrations were 13.8–38 pg/mL in the age group 28–39 years. At the same time, this protein was not detected in persons older than 40 years. Amyloid Aβ42 was not detected in any of the cases. Tau (concentration 30 pg/mL) is defined only in 1 patient. Most of the persons with autism noted the presence of two markers simultaneously: tau protein (concentration 27.4 pg/mL) and amyloid Aβ40 (concentration 23–138 pg/mL).

Conclusion It is shown that there is a high variability of the proportion of the amyloid Aβ40 in patients with schizophrenia, epilepsy and autism. Tau protein is detected only in the group of patients with early-onset schizophrenia and in one case in a patient with epilepsy. The results are important for the improvement of diagnostic methods and development of etiopathogenic therapy.

Alterations of the POMC-promoter-methylation and its derivative alpha-MSH in a rodent model for alcohol dependence

M. Muschler*, M. Rhein, H. Frieling, T. Hillemacher, S. Bleich

Medical School Hannover, Department of Psychiatry, Social Psychiatry and Psychotherapy, Hannover, Germany

* Corresponding author.

Introduction Till this day the molecular mechanisms underlying alcohol dependence are far from being understood in its entirety. Repeatedly the HPA-axis got in the focus of research for alcohol dependence. Many of these works show an association between alcohol dependence and the answer of the HPA-axis on its different levels. POMC and its derivative alpha-MSH as part of the HPA-axis are supposed to mediate alcohol craving. To investigate the role of alpha-MSH for craving we used a rodent model for alcohol dependence.

Methods To prove our hypothesis we used a rodent model with 90 male wistar-rats which were housed individually in single cages. Water, 3 alcohol-solutions (5%, 10% and 20%) and food were offered to the animals ad libitum for one year (4 bottle paradigm), whereas control groups got 4 bottles filled with water. The continuous alcohol consumption of the animals was interrupted by scheduled alcohol-deprivation-phases. During the animal trial a manifest alcohol dependence was induced. The blood and tissues, obtained at the end of the trial, were analysed using direct bisulfite-sequencing (methylation status) and Elisa (alpha-MSH protein levels).

Results and discussion The group of alcohol dependent animals showed an altered methylations status of the POMC-gene-promoter and altered levels of alpha-MSH compared to the control group. These findings are in line with our previous results showing a significant correlation between symptoms of alcohol craving and POMC-promoter methylation. These new data confirm our results from humane materials and clarify the meaning of alpha-MSH for craving in alcohol dependence.

Characterizing rare mis-sense variations of CACNA1I identified in a Swedish schizophrenia cohort

J. Pan*, A. Allen, L. Huang, D. Daez

Broad Institute of Harvard and MIT, Stanley Center for Psychiatric Research, Cambridge, USA

* Corresponding author.

CACNA1I (hCav3.3) encodes the $\alpha 1$ pore-forming subunit of human voltage-gated T-type calcium channels. Cav3.3 is expressed in a limited subset of neurons including GABAergic neurons of the thalamic reticular nucleus (TRN) where they support oscillatory activity essential for sleep spindle generation. *CACNA1I* is implicated in schizophrenia risk by emerging genetics including genome-wide association studies (PGC, 2014), and exome sequencing of trio samples (Gulsuner et al., 2013). In order to understand the impact of disease-associated sequence variation on the function of Cav3.3, we set out to analyze a complete set of rare mis-sense coding variations in *CACNA1I* in a Swedish cohort, including 15 variations identified in patients, 20 identified in control subjects, and 23 in both. We established a heterologous expression system of isogenic cell lines, each carrying single-copy inducible cDNA variants of hCav3.3, and evaluated their functional impact on channel function by electrophysiology, calcium imaging, and biochemistry. We found at least five coding variations impaired overall channel protein abundance, as well as whole cell current density. In addition, we identified hCav3.3 variants with altered voltage-dependence of channel activation and inactivation. Overall, we found that reduced calcium influx through hCav3.3 is associated with the group of variants identified in patients, compared to those in both patients and controls. Our findings suggest that patient-specific rare variations of *CACNA1I* may influence channel-dependent functions, including rebound bursting in TRN neurons, with potential implications for schizophrenia pathophysiology.

* Corresponding author.

Objective To study the association gene of candidate NPSR1 rs324981 with sleep disorders in the open population of men 45–64 years of Novosibirsk.

Materials and methods The study of the association candidate gene polymorphisms with sleep disorders was carried out during the examination of a random representative sample of men 45–69 years ($n = 1770$). The response rate was 61%. The median age is 56.5 year. Every 12 a man was selected for genotyping ($n = 147$). To assess the level of sleep was used a questionnaire which was filled with self-test. Statistical analysis was performed using SPSS-11.5.

Results The level of sleep disorders in the male population of 45–64 years was 79.9%. The frequency of homozygous C/C genotype of neuropeptide S (gene *NPSR1* rs324981) was 19.4%, T/T genotype occurs in 27.8%, C/T genotype –52.8%. Men dominated the T allele of –54.2%, and the C allele –45.8% growth trend Fnd dissatisfaction with the quality of their sleep among men. Men T-allele carriers, most evaluated their sleep as “satisfactory” in 69% of cases, ($\chi^2 = 15,713$ df=8, $P < 0.05$).

Conclusion Association found men carrier T-allele of neuropeptide S (gene *NPSR1* rs324981), a sleep disorder.

Methylomic changes in individuals exposed in utero to diethylstilbestrol

F. Rivollier*, O. Kebir, B. Chaumette, M.O. Krebs

Sainte-Anne Hospital, Service Hospitalo-Universitaire, Paris, France

* Corresponding author.

Background In the Western world, more than 2 million people were exposed in utero to diethylstilbestrol. In exposed individuals and in their descendants, several adverse outcomes have been linked to such exposure, like cancers, genital malformations and, less consistently, psychiatric disorders. Disruption of epigenetic homeostasis was proposed as the molecular substratum of this environmental factor but was not fully proven.

Methods We selected 69 siblings from 30 families. In each family, at least one sibling was exposed in utero to diethylstilbestrol. We analyzed DNA methylation using Human Methylation 450 DNA Analysis BeadChip®. We performed a methylome-wide association analysis searching for specific methylation changes in exposed versus unexposed individuals. Secondary, we compared exposed individuals with and without genital malformation, and with and without psychosis.

Results No differentially methylated regions were identified between exposed and unexposed individuals. Yet, our analyses showed that exposed individuals with genital or psychotic abnormalities have several specific differentially methylated regions compared with exposed individuals without complication. These CpGs were located in genes relevant for cancer (ADAMTS9), genital abnormalities (HOOK2) and psychiatric diseases (ZFP57).

Conclusions In utero exposure to diethylstilbestrol is not associated with changes in methylation profiles. In exposed individuals though, specific traits are associated with methylomic modifications encompassing genomic regions, mostly involved in cancer and neurodevelopment, leading to heterogeneous consequences.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ University Hospitals of Geneva, Department of Mental Health and Psychiatry, Geneva, Switzerland

⁵ University of Geneva, Department of Psychiatry, Geneva, Switzerland

⁶ Geneva University, Department of Psychiatry, Geneva, Switzerland

* Corresponding author.

Early life adversity plays a critical role in the emergence of borderline personality disorder (BPD) and this could occur through epigenetic programming. In this perspective, we aimed to determine whether childhood maltreatment could durably modify epigenetic processes by the means of a whole-genome methylation scan of BPD subjects. Using the Illumina Infinium[®] Human Methylation 450 Bead Chip, global methylation status of DNA extracted from peripheral blood leucocytes was correlated to the severity of childhood maltreatment in 96 BPD subjects suffering from a high level of child adversity and 93 subjects suffering from major depressive disorder (MDD) and reporting a low rate of child maltreatment. Several CpGs within or near the following genes (IL17RA, miR124-3, KCNQ2, EFN1, OCA2, MFAP2, RPH3AL, WDR60, CST9L, EP400, A2ML1, NT5DC2, FAM163A and SPSB2) were found to be differently methylated, either in BPD compared with MDD or in relation to the severity of childhood maltreatment. A highly relevant biological result was observed for cg04927004 close to miR124-3 that was significantly associated with BPD and severity of childhood maltreatment. miR124-3 codes for a microRNA (miRNA) targeting several genes previously found to be associated with BPD such as NR3C1. Our results highlight the potentially important role played by miRNAs in the etiology of neuropsychiatric disorders such as BPD and the usefulness of using methylome-wide association studies to uncover such candidate genes. Moreover, they offer new understanding of the impact of maltreatments on biological processes leading to diseases and may ultimately result in the identification of relevant biomarkers.

Effect of Disrupted-in-Schizophrenia 1 gene on treatment response in patients with a first episode of psychosis

J. Vázquez Bourgon*, R. Ayesa Arriola, P. Suarez Pinilla, R. Roiz Santiañez, D. Tordesillas Gutierrez, V. Ortiz-García de la Foz, B. Crespo-Facorro
University Hospital Marqués de Valdecilla-IDIVAL, CIBERSAM, Psychiatry, Santander, Spain

* Corresponding author.

Introduction There is substantial evidence suggesting that individual variability in antipsychotic treatment response could be genetically determined. Disrupted-in-Schizophrenia 1 (DISC1) gene has been previously associated to the illness and to treatment response in a sample of patients suffering from psychosis. However, there is a lack of studies on the effect of DISC1 on treatment response in samples of first episode psychosis.

Objectives The aim of this study was to explore the relation between variations in DISC1 gene and treatment response to antipsychotics in a sample of drug-naïve patients with a first episode of psychosis.

Methods Two hundred and twenty Caucasian drug-naïve patients experiencing a first episode of non-affective psychosis were genotyped for rs821616 (Ser704Cys), rs6675281 (Leu607Phe) and rs1000731. Early (6 weeks) response to antipsychotic treatment was assessed with the Brief Psychiatric Rating Scale, the Scale for the Assessment of Positive Symptoms, and the Scale for the Assessment of Negative Symptoms. Other clinical and socio-demographic variables were recorded to eliminate potential confounding effects.

Results We found a significant association between rs1000731 and treatment response. Thus, those patients homozygous for the G allele of rs1000731 were more frequently non-responders, measured with SANS, after 6 weeks of treatment, than those carrying the A allele ($X^2 = 4.019$; $P = 0.032$). Moreover, when analysing the clinical improvement longitudinally, we observed that those patients carrying the A allele for the rs1000731 presented a greater improvement in positive symptoms dimension ($F = 8.905$; $P = 0.003$).

Conclusions Our results suggest a minor contribution to antipsychotic drug response of genetic alterations in the DISC1 gene.

Agreement and equation between Mini Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) in an old age psychiatry outpatient clinic population

D. Adamis^{1,*}, L. Helmi², O. Fitzpatrick¹, D. Meagher³, G. McCarthy²

¹ Sligo Mental Health Services, Psychiatry, Sligo, Ireland

² Sligo Mental Health Services, Sligo Medical Academy, NUI Galway, Psychiatry, Sligo, Ireland

³ Medical School, University of Limerick, Psychiatry, Limerick, Ireland

* Corresponding author.

Introduction Both MMSE and MoCA are two widely used cognitive screening test. Comparison of the two tests has been done in specific populations (Parkinson) but not in general elderly psychiatric populations. In research, equating methodologies has been used to compare results among studies that use different scales, which measure the same construct.

Aims To explore their level of agreement within a particular clinical setting.

Objectives (a) To find MoCA and MMSE agreement. (b) To derive a conversion formula between the two scales and test it in a random population of similar setting.

Methods Prospective study of consecutive community dwelling older patients who attend outpatient clinic or day hospital. Both tests were administered from the same researcher the same day in random order.

Results The total sample ($n = 135$) was randomly divided in two. One from where the equating rule derived ($n = 70$) and a second ($n = 65$) in which the derived conversion was tested. Agreement of the two scales (Pearson's r) was 0.86 ($P < 0.001$), and

Lin's Concordance Correlation Coefficient (CCC) was 0.57 (95% CI 0.45–0.66). In the second sample, we convert the MoCA scores to MMSE scores according to equating rule from the first sample and after we examined the agreement between the converted MMSE scores and the originals. The Pearson's r was 0.89 ($n=65$, $P<0.001$) and the CCC 0.88 (95% CI 0.82–0.92).

Conclusions Although the two scales overlap considerably, the agreement is modest. The conversion rule derived showed promising accuracy in this population but need further testing in other populations.

Burden of care among relatives of people with dementia attending tertiary care in Oman

M. Al Maqbali*, H. A-Sinawi

Sultan Qaboos University Hospital, Behavioral Medicine, Muscat, Sultanate of Oman

* Corresponding author.

Introduction Providing care to people with dementia is a stressful experience and has been associated with high burden of care. Such issue has been under-researched in Arabic/Islamic parts of the world.

Aims and objectives The aim of this study is to determine the degree of burden of care among caregivers of people with dementia attending the Old-Age clinic, Sultan Qaboos University Hospital, Oman.

Methods Fifty patients with dementia and their primary care caregivers were included in the study. The diagnosis of dementia was based on DSM 5 criteria and the severity was rated according to the Global Deterioration Scale for Assessment of Primary Degenerative Dementia and Clinical Dementia Rating. Level of dependency was measured using the Katz Index of Independence in Activities of Daily Living (ADL) and Lawton Instrumental Activities of Daily Living (IADL) Scale. For the caregivers, burden of care was determined by Zarit Burden Interview (ZBI).

Results The majority of caregivers were adult children (90%) who are supported by other relatives. Overall, 70% of caregivers demonstrated high degree of burden as quantified by ZBI. Factors such as patient's age, duration and severity of dementia, level of dependency and female gender of the caregiver were associated with higher burden.

Conclusion Burden is common among dementia caregivers and several factors interplay to influence the perceived stress. As increased burden was evidenced to be associated with higher incidence of mental disorders, screening and early intervention will impact positively on the caregiver as well as the patient.

First psychiatric hospitalization in patients older than 65 years

J. Ballesteros, A. Uría, P. Rico*

Hospital Universitario de Getafe, Psychiatry, Getafe, Spain

* Corresponding author.

Introduction Medical assistance for elderly people with mental health problems increases at the same time that life expectancy does.

Objectives The aim of this work is to describe several demographic and clinical characteristics of elderly patients admitted for the first time to an acute inpatient psychiatry unit.

Methods Observational, descriptive, and retrospective study from June 2013 to May 2015, where it is analysed patients older than 65 years admitted to the acute psychiatric ward of Hospital de Getafe in that period without psychiatric hospitalization in their personal background.

Results Seventeen patients were included of a total of 428 patients admitted in that period (3.97%). Mean age: 70.7 ± 4.7 . A total of 10 male (58.9%). The average stay in the studied group was 18.5 days, slightly lower than general average stay in that period (19.2 days). No psychiatric background was found in 4 patients. The most common diagnoses was depressive episode (5 patients) followed by manic episode (4 patients) and delusional disorder. Every of them but one, were taking at least one antipsychotic drug at discharge.

Conclusions Elderly patients represent a low percentage of the total of patients admitted to an acute inpatient psychiatry unit. Many of them, despite having long-term ambulatory psychiatric follow-up, require a first psychiatric hospitalization after 65 years, as well as other patients begin their treatment in the mental health services in that hospitalization. It is noteworthy that antipsychotic drugs are used very commonly in those patients.

Comparison of the frailty phenotype and the Tilburg Frailty Indicator regarding the prediction of quality of life in a two-year follow-up

T. Coelho^{1,*}, C. Paúl², L. Fernandes³

¹ School of Allied Health Technologies, Polytechnic Institute of Porto, Department of Occupational Therapy, Vila Nova de Gaia, Portugal

² Institute of Biomedical Sciences Abel Salazar, University of Porto, UNIFAI/CINTESIS, Porto, Portugal

³ Faculty of Medicine, University of Porto, UNIFAI/CINTESIS, Porto, Portugal

* Corresponding author.

Introduction Frail individuals are highly vulnerable to minor stressful events, presenting a higher risk for adverse health outcomes (e.g. falls, disability, hospitalization), which can lead to a decline in quality of life (QoL). In this context, an early screening of elderly frailty is of crucial importance.

Objective To compare how the Frailty Phenotype (FP) and the Tilburg Frailty Indicator (TFI) predict QoL in a two-year follow-up.

Methods A longitudinal study was designed recruiting 110 community-dwelling elderly (≥ 65 years). The presence of frailty was assessed at baseline (FP ≥ 3 and TFI ≥ 6), whereas QoL was measured two years later with two different scales: the WHOQOL-OLD and the EUROHIS-QOL-8. Hierarchical regressions were conducted. **Results** The mean age of the participants at baseline was 77.7 ± 6.9 years, and most were women (75.5%). According to FP, 33.6% of the participants were classified as frail, while the TFI detected frailty in 50% of the elderly. After adjusting for age and gender, the TFI significantly predicted QoL (WHOQOL-OLD: $\beta = -18.9$, $t(106) = -6.97$, $P < 0.001$; EUROHIS-QOL-8: $\beta = -6.1$, $t(106) = -6.71$, $P < 0.001$), whereas the effect of the FP on the outcome measures was non-significant.

Conclusions Frailty at baseline was associated with a lower QoL at follow-up. A multidimensional frailty operationalization (TFI) showed a stronger predictive validity than an exclusively physical one (FP). The option of which frailty measure to use in a clinical setting should take into account its ability to predict specific adverse outcomes, conducting to targeted and effective interventions.

Physical activity, salivary cortisol and psychological well-being in institutionalized elderly women – A preliminary study

M. Figueiredo-Braga^{1,*}, G. Furtado², M. Uba-Chupel², J.P. Ferreira², A.M. Botelho²

¹ Faculty of Medicine, University of Porto, Clinical Neurosciences and Mental Health, Porto, Portugal

² Faculty of Sport Science and Physical Education, University of Coimbra, Portugal, Centro de Investigação do Desporto e da Actividade Física, Coimbra, Portugal

* Corresponding author.

Introduction Aging is a process of morphologic and physiologic changes that naturally predisposes elderly persons to progressive health decline. Vulnerability to poor resolution of homeostasis after a stressor event may represent the common pathway of elderly cognitive, physical and psychological fragility. Regular physical activity (RPA) has been shown to have positive effects in cognitive performance, stress and mood state.

Aims We aimed to study the relationship between RPA, salivary cortisol, emotional and cognitive state in institutionalized elderly women.

Methods A cross-sectional study was performed in 35 institutionalized women (mean age of 81.5 [7.5] years). Participants were divided in active (ACT, $n=20$) and insufficiently active (IACT, $n=15$) according with the International Physical Activity Questionnaire (IPAQ-sv). The Center for Epidemiological Studies Depression Scale (CES-D), Subjective Happiness Scale (SHS) and Mini-mental State Exam (MMSE) were applied. Salivary levels of Cortisol were analyzed by Elisa. The t -student test was used to compare groups and associations between variables were detected using Pearson's correlation coefficients.

Results Participants from the ACT group presented higher MMSE ($P=.037$) and lower CES-D scores ($P=.028$). Although Cortisol presented similar levels in both groups, a negative correlation was detected between cortisol and the CES-D score. A negative association was also found between the presence of depressive symptoms and MMSE.

Conclusion A higher physical activity was associated with lower cognitive impairment and less depressive symptoms, reinforcing the positive influence of RPA in the elderly. Furthermore, higher subjective well-being is associated with the maintenance of cortisol levels and an adequate stress response.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ ASL Foggia, Mental Health Department, Foggia, Italy

* Corresponding author.

Introduction Patients with serious psychiatric illness (SMI) have a reduced quality of life and life expectancy than the

general population. Metabolic syndrome (MS) is a clinical aspect determining who should be considered to reduce the risk of serious and chronic organic factors, even more significant in the elderly.

Objectives To evaluate metabolic screening of elderly patients with severe mental illness (SMI).

Aims To evaluate the importance of routine screening of metabolic parameters in elderly guests of residential facilities with or without SMI; metabolic screening at baseline and after two of hospitalization.

Methods Elderly inpatients (44 Tot) with Severe Mental Illness (SMI: bipolar disorder: 34%; schizophrenia: 46%; other: 20%) vs elderly inpatients (78 Tot). Data collected at baseline: psychiatric diagnosis; any previous diagnosis of hypertension, diabetes, dyslipidemia; ECG. At baseline and for two years were administered following scale: BPRS; PANSS; Qli; MMSE, ADL.

Results After two years metabolic screening has recorded at least one of the new interactions between the five factors of MS (ATP III) in 50% of patients with: one (34%); two (21%); three (11%); four (3%) new altered parameters. In MS inpatients, 53% of new metabolic alterations were recorded in 53% (MS inpatients) vs 23% without MS after two years.

Conclusions Our results showed a higher frequency of MS in patients with SMI than comparison subjects. Haloperidol was the antipsychotic medication that caused minor impact on the development of metabolic disorders.

Cognitive deterioration and depressive symptoms in elderly people living in the community

M.D.C. García Mahía*, Á. Fernández Quintana, M. Vidal Millares
CHU A Coruña, Psychiatry, A Coruña, Spain

* Corresponding author.

Introduction Depression is a prevalent illness in elderly people. Cognitive deterioration associated to depressive symptoms is frequently considered as Dementia, especially in primary care. The study of the relation between both pathologies is necessary to correct treatment of mental illness in elderly people.

Aims The aim of this study is to investigate whether depressive symptoms are related to certain areas of cognitive decline in elderly people.

Methods The sample included community people older than 65 years ($n=927$), mean age 72.9; 55.1% were women and 44.9% men. Instruments used were Beck Depression Inventory (BDI), Blessed Dementia Scale (BDS), Mini Mental State Examination (MMSE), verbal fluency test, clock drawing task, Wechsler digit substitution test and Wechsler similarity test.

Results Of the sample, 15.2% presented cognitive deterioration in Blessed Dementia Scale, with statistical significance in relation between growing age, female sex and cognitive deterioration ($P<0.005$). Twenty-eight percent of the sample present cognitive decline, finding the same relation between sex, age and cognitive condition. Of the sample, 33.5% presented mild depression, 9.1% moderate depression and 1.4% presented severe depression using BDI. Correlations between depression and cognitive tests were analyzed. In demographic factors, social support was significantly correlated with depression but marital status, occupation and education were not correlated.

Conclusions There is a high prevalence of depressive symptoms and cognitive deterioration in elderly people. High levels of

depressive symptoms are associated with cognitive deterioration, especially in comprehension and judgment, delayed recall, verbal memory and visuospatial coordination in elderly people.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A description of clinical profile of over 65-years-old patients in acute psychiatric hospitalization unit at Hospital Universitario Central De Asturias (Oviedo, Spain)

I. Abad-Acebedo, L. Gonzalez-Blanco*, E. Torio-Ojea, S. Bestene-Medina, J. Rodriguez-Revuelta
Servicio de Salud del Principado de Asturias, Psiquiatría, Oviedo, Spain

* Corresponding author.

Introduction Older patients with psychiatric conditions often have other disorders that include different levels of cognitive impairment, modifying the presentation of psychiatric symptoms and requiring treatment adaptations [1].

Objective To describe clinical profile of hospitalized patients > 65 years, and its relationship with the presence of cognitive impairment and the length of hospital stay.

Methods Descriptive and comparative study. Sample: 71 inpatients > 65 years (mean \pm SD Age: 72.42 \pm 5.96), admitted to "Hospital Universitario Central de Asturias" (Spain) from August 2014 to June 2015. Age, length of hospitalization, diagnosis, cognitive impairment and treatment data were collected (Table 1).

Results Days of hospital stay (mean \pm SD) = 15.89 \pm 11.53. No variable showed significant relation except number of antipsychotics taken ($r=0.307$, $P=0.009$). Cognitive impairment was significantly more frequent in men than women (45.5/15.8%; $\chi^2=7.46$; $P=0.006$). No other variable showed significant differences.

Conclusions A high percentage of psychiatric inpatients > 65 years present a cognitive impairment (29.6%) which was more frequent in males (45.5%). The length of hospital stay seems to be similar than in the rest of patients and not being affected by any of studied variables. More studies should be carried on to compare those results with similar variables in younger population and to analyze if there are differences between subgroups (65–75 vs > 75) [1].

Table 1 Sociodemographic/clinical features.

		PERCENTAGE(%)
Gender	Female/Male	53.5/46.5
Admission reason	Suicide-risk/ Agitation-psychosis	23.9/38
Main psychiatric diagnosis	Schizophrenia/Schizoaffective dis.	18.3
	Other Psychosis disorders	18.3
	Bipolar disorder	29.6
	Other Affective disorder	19.7
	Personality disorder	1.4
	Cognitive impairment	9.9
	Other	2.8
Cognitive impairment	Present	29.6
Treatment	Antipsychotics(LAI)	74.6(11.3)
	Antidepressants	57.7
	Mood stabilizers	25.4
	Anxiolytics(BZD)	57.7(54.9)

LAI: long-acting injections.

Introduction The problems and costs associated with aging and the aged pose a major challenge to the future. The elderly portion of our population is constantly expanding. No single health issue will demand more attention than aging, challenging our healthcare system.

Objectives and aim This study aims at assessing functional and cognitive independence in a sample of elderly patients in a private care setting.

Methods The sample is composed of 38 elderly patients undergoing treatment in a private healthcare setting, mean age 76.32 (SD: 7.46), 22 females; 16 males. The Functional Independence Measure Scale was applied in order to assess physical and cognitive disability. The scale focuses the level of disability indicating the burden of caring for these patients. The scale contains 18 items (13 motor tasks and 5 cognitive ones) of basic activities of daily living.

Results The symptomatic pattern is marked by main scores in dimensions of a cognitive profile, namely, Problem solving (mean value: 2.64), Cognitive comprehension (2.88), Memory (3.12) followed by motor-gait disability and physical dependence items, as Bathing (3.24), Upper body dressing (3.92), Lower body dressing (4.06), Toileting (4.38), Shower transfer (4.60) and Locomotion (4.68).

Discussion and conclusions Cognitive items are underlined as the most impaired ones. Physical limitation is related to common daily tasks even in indoor activities. Questions remain concerning the independence of cognitive and physical variables. Are cognitive problems the real trigger of body functional disability? Or do they have an independent onset? Future research could answer properly these questions.

Facial emotion recognition in elderly patients with bipolar disorder: Comparison with healthy controls

M. Herrmann^{1,*}, C. Padovan^{1,2}, I. Rouch³, J.M. Dorey¹

¹ Centre Hospitalier Le Vinatier, Geriatric Psychiatry, Bron, France

² Centre de Recherche en Neurosciences, Inserm U1028, CNRS UMR5292, Bron, France

³ Hospices Civils de Lyon, Hôpital des Charpennes, Centre Mémoire Ressource et Recherche, Villeurbanne, France

* Corresponding author.

Background The ability to recognize facial emotion is considered as an important skill for social interaction. There is evidence of impairments of this ability in psychiatric diseases such as schizophrenia. The fact that this could be the same in bipolar disorder (BD) is controversial. Moreover, no studies address the impact of aging on social cognition in BD.

Objective The main objective of this study was to evaluate facial emotion recognition (FER) in euthymic elderly patients with BD compared to healthy elderly volunteers. The secondary objective was to search for correlations between FER, clinical and neurocognitive features.

Methods Sixteen subjects with BD, in a euthymic state, with a mean age of 73.94 years were included. They were assessed for FER along with 16 healthy elderly volunteers. Neurocognitive abilities were also assessed. A gender facial recognition task was used as control.

Results BD patients had lower FER performance compared to healthy controls, more specifically in fear, disgust and anger recognition. No difference was found for happiness or for the gender task. Additionally, correlations were found between disgust, recognition and certain executive function (EF) abilities.

Limitations The main limitation is the small size of the sample. Also, we were not able to account for an influence of treatments.

Conclusions FER in BD seems to weaken with aging, especially for negative emotions, maybe with an impact of EF decline. Longitudinal studies with larger samples are required to investigate this issue and to explore possible correlations with cognitive decline or psychosocial functioning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ School of Medicine, University of Belgrade, Psychiatry, Beograd, Serbia

⁵ The Public Health Institute of Uzice, Public Health, Uzice, Serbia

* Corresponding author.

Introduction Recent research in dementia was focused on determining risk factors that can be prevented. There is strong evidence that these risk factors are: low levels of education, smoking, unregulated high blood pressure, blood sugar levels, blood lipid levels, diabetes.

Objectives Following some of the risk factors for cognitive impairment that can be prevented.

Aim Evaluating the connection between cognitive impairment and education levels, blood glucose, cholesterol (chl) and triglyceride (tgl) levels.

Methods Two hundred and thirty-seven subjects (162 women and 75 men), with an average age of 80.75 ± 6.69 were included in the research. Based on the MMSE score (single cutoff, <24 is abnormal), they were divided to a control group (without cognitive impairment) and experimental group (with cognitive impairment).

We used Accu-Check Active appliance for determining blood levels of tryglicerides, cholesterol and glucose.

Results Subjects in the experimental group were significantly older ($\chi^2 = 2.13, P < 0.01$). Glucose levels were higher in the experimental group but the difference was not statistically significant ($\chi^2 = 0.13, P = 0.56$). Cholesterol and trygliceride levels were significantly higher in subjects with cognitive impairment ($\chi^2 = 3.56, P < 0.05$; $\text{tgl}-\chi^2 = 8.78, P < 0.05$). In the experimental group, there was a statistically significant prevalence of subjects with less than one year of education ($\chi^2 = 13.8, P < 0.01$).

Conclusion Confirming the connections between cognitive impairment and education levels, glucose, cholesterol and trygliceride blood levels can lead towards potential strategies for prevention of those parameters. Even though our research confirmed the results from previous scientific studies, the connection should be tested in future randomized controlled trial.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background As many as three-quarters of patients with major depressive disorder presenting to old age psychiatrists have late-onset depression. Late-onset depression was conceptualized as a neurologic disease and more often associated with cognitive impairment than early-onset depression.

Objectives To compare cognitive functions between early-onset (<60 years) and late-onset (≥ 60 years) depression in geriatric patients to detect white matter hyperintensities via MRI using modified Fazekas score.

Design A cross-sectional, comparative study with a consecutive sample.

Subjects Eighty elderly patients with depression were recruited from the Geriatric Outpatient Clinic-Psychiatry and Addiction Hospital in Al Kasr Al-Ainy, Cairo University. They were divided according to the age of onset of depression into 2 groups: Late onset group (A) and Early onset group (B) depression, they were subjected to the following: SCID-I, HDRS (Hamilton Depression Rating Scale), BCRS (Brief Cognitive Rating Scale), GDS (Global deterioration Scale), ACE-R (Addenbrook's Cognitive Examination-Revised), Trail B Test, Digit symbol coding and Digit span subtest of Wechsler Adult Intelligence Scale, MRI-Brain to assess white matter hyperintensities by using modified Fazekas rating.

Results Group A had worse performance than group B in trail B test, total memory score, verbal fluency test, total language score, visuospatial abilities, the total (ACE-R) and ischemic changes periventricular and in deep white matter were more in group A than in group B.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Efficacy of memantine for elderly patients in the mild stage of Alzheimer's and vascular dementia in Ukraine

V. Kholin*, N. Bachinskaya, I. Rozhelijuk
D.F. Chebotarev Institute of Gerontology NAMS of Ukraine, Age Physiology and Pathology of Nervous System, Kiev, Ukraine
* Corresponding author.

The aim of our research was to investigate the effectiveness of memantine treatment of Ukrainian patients with Alzheimer's (AD) and vascular dementia (VaD) depending on existing ApoE genotype. **Methods** It was a complex examination of 60 elderly persons (72.40 ± 1.35 years) with mild stage of AD and VD. The effectiveness of response to (20 mg/day) memantine intake was studied during the first 3 months of treatment. Efficacy of short-term treatment was determined by MMSE and the numbers of positive statistically significant changes ADAS-cog subtests. Genetic ApoE polymorphism was investigated too (using the of the PCR technique). Statistical Anova analysis was done.

Results After 3 months of treatment significant changes in the overall score of Adas-cog was observed in both groups with some differences in subscale profiles. For AD patients, statistically positive changes ($P < 0.05$) were found in comprehension of spoken language, naming objects, commands, ideational praxis and delayed recall subtests. For VaD patients, statistically positive changes ($P < 0.05$) were found in comprehension of spoken language, naming objects, word finding difficulty and delayed recall subtests. There was established a significant prevalence of individuals with genotype $\epsilon 4/\epsilon 4$ among patients with AD compared with patients with VD. The main differences, according to the memantine efficacy treatment in carriers ApoE3 and ApoE4 genotypes, were in remembering test instructions subtest.

Conclusions The memantine treatment efficacy in AD and VaD patients in mild stage of dementia was not significantly associated with an existing of Apo-E genotype polymorphism.

EW297

A systematic literature review to ascertain the effectiveness of using bed-exit alarm in the prevention of bed falls in a psycho-geriatric ward

C. Koh
Alexandra Health System, Khoo Teck Puat Hospital, Gericare@North, Singapore, Singapore

Background and objectives Bed exit alarms detect motion and send alarm signals to alert caregivers when a patient is attempting to exit a bed. Its use renders an opportunity for timely staff response to a fall risk situation associated with unplanned/unassisted bed exits. The utility of these devices is often appraised around the concepts of preventing patient falls and related injuries. To acquire further knowledge, a systematic review of literature was carried out to generate practice-based evidence in relation to the use of bed-exit alarms/monitors. This study was conducted: (1) to examine evidence-based articles regarding the use of bed exit alarms in psycho-geriatric settings; and (2) to obtain and apply newly-acquired knowledge towards assessing the effectiveness of such devices in reducing bed fall incidents and injuries among elderly inpatients in a psychiatric hospital in Singapore.

Methods A systematic review of literature was the main method used to generate evidence-based results.

Results Due to lack of random clinical studies, all five studies (conducted in the USA) find evidences offered on the effectiveness of bed exit alarms as inconclusive. Its overall reliability in detecting movements out of bed has not been established. The use of bed exit alarms is useful but it should not compromise staff vigilance in any way.

Conclusion These findings indicate the there was little evidence to show that bed-exit alarms have the capacity to prevent falls totally. Decisions to use bed exit alarms as an assistive tool for fall prevention remain open to the full discretion of any hospital management.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Understanding adverse health effects of widowhood in old age – A cross-countries mixed methods study

C.B. Kristiansen^{1,*}, P. Munk-Jørgensen², C. Mattisson³, K. Andersen²

¹ Aarhus University hospital, Psychiatric Research Academy – Department of Affective Disorders, Risskov, Denmark

² Odense University Hospital, Psychiatric Department, Odense, Denmark

³ Lund University Hospital, Department of Clinical Sciences, Lund Division of Psychiatry, The Lundby Study, Lund, Sweden

* Corresponding author.

Introduction Widowhood in old age increases mortality and adverse health effects, particularly depression and need for psychiatric care. The causes of this are poorly understood. To study risk factors and mechanisms, theories about what to study are needed. A qualitatively approach to widowhood from the widow/widower's perspective may uncover important knowledge.

Objectives To investigate risk factors of the adverse health effects associated with widowhood in old age from the perspective of the widower/widowers and to test the generalisability of the theories quantitatively.

Methods This is a cross-country mixed methods study combining narrative interviews with Danish widows/widowers and a 50-year follow-up study from Sweden – The Lundby Study. Widows/widowers above 65 years of age referred to in- or out-patient treatment at the Department of Psychiatry at Odense or Aarhus University Hospital are included. Narrative interviews are conducted and analysed according to grounded theory. The qualitatively developed theories will then be tested quantitatively through the Lundby Study by comparing widows/widowers above 65 years with age-matched controls, who are still married.

Results In the Lundby Study, 597 persons above 65 years were identified in the latest follow-up: 176 (29.5%) were widow/widowers, 421 (70.5%) were married/cohabitating. Depending on the theories developed a total of 384 possible variables regarding physical health, mental health and general living circumstances are tested. Further results will be presented.

Conclusions The causes of adverse health effects in widowhood are poorly understood. This study will potentially contribute to unravelling these by identifying possible risk factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Anticholinergic burden in inpatient psychogeriatric population – Do we care?

M. Lee*, A. Warren, B. Zolotarev, J. Henderson, M. George
 West Moreton Mental Health, Older Person, Ipswich, Australia
 * Corresponding author.

Background Although recent studies have found that there is significant association between anticholinergic and cognitive impairment, especially in the elderly population, there seems to be minimal emphasis on anticholinergic burden (ACB) when prescribing medications to the inpatient psychogeriatric population.

Aim To evaluate the prescribing patterns in Older Person Mental Health Inpatient Unit (OPMHU), whether the ACB Score on admission has been reviewed for lowest possible ACB while maintaining therapeutic effects. A protocol will be developed to ensure that ACB is reviewed for future admissions and discharges.

Methodology Fifty patients admitted and discharged from OPMHU are recruited retrospectively from 30th September 2015, excluding outliers and deceased patients. For those who had multiple admissions during that period, only the most recent admission would be included for evaluation. Individual ACB score is calculated on admission and discharge based on pharmacist final medication summary. Their mental health records are also audited for any documented ACB review by the treating team, while making note for any pre-existing cognitive impairment.

Result ACB has not been taken into consideration in all patients by the treating team on admission as well as when prescribing medications on discharge. Hence, it is unsurprising that the ACB score showed an increment of 30% on discharge (3.25) when compared to the admission score (2.5).

Conclusion The study found that although ACB poses significant risks on cognitive impairment, this knowledge has not been employed pragmatically. A protocol should be developed to ensure that ACB is evaluated and managed accordingly.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Delirium related distress in family: A non-systematic review

S. Martins^{1,*}, L. Fernandes²

¹ Center for Health Technology and Services Research/CINTESIS, Faculty of Medicine of University of Porto, Porto, Portugal

² Center for Health Technology and Services Research/CINTESIS, Faculty of Medicine of University of Porto, Psychiatry Service, CHSJ Porto, Porto, Portugal

* Corresponding author.

Introduction Delirium is a common neuropsychiatric syndrome, particularly in elderly hospitalized patients, and is associated with an increase in morbidity and mortality. Although these negative consequences are well documented, only a few studies describe the experience of delirium from the families' perspective.

Aims To analyze studies regarding the experience and distress caused by delirium in the families/caregivers of adult/elderly hospitalized patients.

Methods A non-systematic review of published articles until October 2015 in the database PubMed was carried out. The keyword "Delirium" was combined with: "experience", "distress", "anxiety" and "family", "carer" and "relatives". Inclusion criteria were: standardized diagnosis of delirium, systematic/prospective assessment of distress level. Clinical cases were excluded.

Results Sixteen studies met the inclusion criteria for analysis. In most of them, family members (mostly younger) showed high levels of distress, even higher than health care professionals and

patients. Several predictors of family distress were found, including poor functional status, psychomotor agitation, delusions, emotional lability, incoherent speech, inattention and disorientation. Higher distress was associated with long-term consequences (e.g. generalized anxiety). In the qualitative research, family members interpreted delirium as a sign of approaching death, result of pain/discomfort or an effect of medication. In addition, distress was associated with rapid and unexpected changes or unable to recognize the loved ones.

Conclusions Delirium in patients was associated with significant distress in family members. These findings underline the importance of providing information and the development of appropriate supportive and psychoeducational interventions in order to help families throughout this process and reduce the associated distress. This work is supported by FCT (SFRH/BPD/103306/2014).

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The ageing population and the resulting increase in chronic diseases, including dementia, make the evaluation of their emergent needs a crucial step in psychogeriatric care. Unmet needs are found to be important clinical targets that should be followed by active management in order to improve health status and survival. **Objectives** To analyze the relation between unmet needs and cognition, and explore the nature of these needs across dementia severity stages.

Methods A cross-sectional study was conducted in three nursing homes. Residents were excluded if they were terminally ill, unresponsive or presented delirium. All participants were assessed by Mini-Mental State Examination/MMSE (cognition) and Camberwell Assessment of Need for the Elderly/CANE (needs). Additionally, cognitive decline was staged as: absent (MMSE = 30), questionable (26–29), mild (21–25), moderate (11–20) and severe (≤ 10).

Results The study included 175 elderly with a mean age of 80.6 (SD = 10.1) years, of which 58.7% presented cognitive decline. For these, the mean number of unmet needs was greater than for those without (4 vs 3, $P < 0.001$), and they differed significantly in the domains of daytime activities ($P < 0.001$), memory ($P < 0.001$) and psychotic symptoms ($P = 0.005$). A significant negative correlation was found between MMSE and number of unmet needs ($r_s = -0.369$, $P < 0.001$). Considering the severity stages, unmet needs also differed: more needs in early stages in daytime activities (73.3%), and in advanced ones in memory (63.9%) and psychotic symptoms (23%).

Conclusions Greater cognitive decline was related with more unmet needs, which agree with previous studies. The different nature of needs across severity stages also suggests that interventions should be tailored comprising this specificity and complexity, when effective care is planned.

Burden of informal carers in northwest Ireland: A pilot study of factors that influence burden

G. McCarthy^{1,*}, I. Gresswell², D. Adamis³

¹ Sligo Medical Academy NUI Galway, Psychiatry, Sligo, Ireland

² NUI Galway, Psychiatry, Galway, Ireland

³ Sligo Mental Health Services, Psychiatry, Sligo, Ireland

* Corresponding author.

Introduction Research has shown that approximately 67% of carers experience extreme mental tiredness, a decrease in their quality of life and a deterioration in their physical health since taking on a care-giving role.

Aims and objectives This study aims to identify factors that influence carer burden and in doing so, identify the sub-populations of carers who are most susceptible to burden.

Methods In northwest Ireland, 53 informal carers referred to the Carers Association, Sligo were contacted and met for a face-to-face interview. Measurements used included demographic data, the Neuropsychiatric Inventory, Zarit Burden Interview, Social Network Index and Brown's Locus of Control Scale.

Results Of the 53 carers, 43 were females and 10 males (age range: 32–81 years, mean age of 64.5 years). Of the corresponding 53 patients, 21 were females and 32 males (age range: 17–92 years, mean age of 72.1 years). Multiple linear regression analysis showed that sex of carer, marital status and the patient's behavioural problems were statistically significant independent factors, which influenced carer burden ($p < 0.01$). Female sex and greater patient behavioural problems increased susceptibility to burden and being married increased resilience towards burden.

Conclusions The ability to predict which carers are more susceptible to burden allows physicians to more quickly identify "higher risk" carers, facilitating routine check-ups by physicians and carer support services. Further research should explore why female and unmarried carers are more susceptible to burden and whether it is possible to tailor support services to their individual needs.

Attachment representations in a population of elderly subjects

M. Moalla^{1,*}, I. Feki¹, A. Ktata², R. Sellami¹, D. Triqui¹, I. Baati¹, I. Abida¹, J. Masmoudi¹

¹ CHU Hédi Chaker S department of psychiatry "A", Sfax, Tunisia

² Manzel Bouzayen Hospital, consultation, Sidi Bouzid, Tunisia

* Corresponding author.

Introduction According to attachment theory, attachment relationships have a lasting impact on the functioning of the individual. If this impact has been much studied in children, few studies have been conducted in the elderly.

Objectives Explore the representations of attachment in a population of elderly subjects.

Methods The sample consists of 90 consultants over the age of 65. Each participant filled out demographic questionnaire, Relationship Scale Questionnaire (RSQ): questionnaire of 13 items, each item rated from 1 to 5, a lower score attests a more secure attachment and Adult Attachment Questionnaire: a categorical scale of 3 statements. Statement 1 corresponds to secure attachment style, 2

to avoidant attachment style and 3 to anxious-ambivalent attachment style.

Results The age of participants ranged from 65 to 95 years with an average of 68.14. The sex ratio M:F was 0.8. The RSQ Score ranged from 16 to 56 with an average of 37.27. Of the participants, 72.2% have secure attachment style, 24.4% have an avoidant attachment style and 3.3% have an anxious-ambivalent attachment style. The study of correlations showed strong correlation between the two scales ($P = 0.00$) and the RSQ score was significantly associated with poor satisfaction of married life ($P = 0.025$), presence of psychological trauma in childhood ($P = 0.016$) and a separation experience ($P = 0.029$).

Conclusion Our study highlights the importance of early childhood experiences that may impact late adult life. These findings are in accordance with attachment theory.

A proactive geriatric liaison service to assess and manage medical problems on old age psychiatry wards

U. Narayana^{1,*}, O.J. Corrado², S. Kaur³

¹ Health Education Yorkshire and Humber, ST5 Old Age Psychiatry and Leadership fellow, Hull and East Yorkshire NHS Trust, United Kingdom

² Leeds Teaching Hospitals NHS Trust, Consultant Geriatrician, Leeds, United Kingdom

³ Bradford District Care Trust, Audit Officer, Bradford, United Kingdom

* Corresponding author.

Introduction Older people with mental ill health are more likely to receive lower quality of healthcare, inappropriate prescriptions and reduced access to services, leading to increased rates of mortality^{1,2,3}. The NHS mandate 2015 to 2016 emphasises the need to deliver care, which is joined up and seamless for users of services⁴.

Aims and objectives To identify the common medical comorbidities on the Old Age Psychiatry Wards and to assess the management outcomes.

Methods We audited all patients referred to the Liaison Geriatrician from 2008 to October 2015 from the Mount Hospital Leeds, which consists of 4 Old Age Psychiatry Wards. Data was collected in October 2015 and included referral date, patients' age and sex, number of referrals, reason for referral and the outcome.

Results We assessed 339 (142 F, 197 M) patients with a mean age of 77 (range: 56–94). Cardiovascular problems were the biggest group of referrals (in particular oedema, hypotension and rhythm disturbances) (34%) followed by central nervous system problems (11%), respiratory (8%), gastrointestinal (8%) and infection (8%). Some unusual problems were diagnosed including a spontaneous pneumothorax, primary biliary cirrhosis. The most common intervention was advice on treatment or investigation, very few patients needed acute admission and some unnecessary admissions were aborted as a result of the physician's intervention.

Conclusions This audit emphasises the need for a joint coordinated approach between psychiatry and medicine in managing health problems in older people. A dedicated Geriatric Liaison service can improve care, avoid unnecessary acute admissions and is more convenient for patients who would otherwise attend repeated outpatient appointments.

Depression, physical illness and mortality in a Spanish community-dwelling elderly people

J. Olivera-Pueyo^{1,*}, S. Benabarre-Ciria², T. Lorente-Aznar³, M. Rodríguez-Torrente³, C. Pelegrín-Valero¹, A. Acín-Sampietro³, J. Aguaviva-Bascuñana³, C. Alastrué-Pinilla³, J. Alcubierre-Cura³

¹ Hospital San Jorge, Psychiatry, Huesca, Spain

² Fundación Agustín Serrate, Psychology, Huesca, Spain

³ Atención Primaria, Unidad Docente, Huesca, Spain

* Corresponding author.

Objectives The aim of this study is to investigate the association between depression, physical factors and mortality in elderly people living in the community.

Methods Prospective longitudinal multicenter study for 5 years. Cohort of 293 people aged 65 years and older living in the province of Huesca (Spain). Individual face-to-face interviews and with appropriate caregiver. The following information was collected:

- demographic data;
- psychosocial factors: sex, age, education, marital status, live-in family members, social relationships, life events;
- physical factors: severity of physical illness, comorbidity (Cumulative Illness Rating Scale);
- psychiatric factors: cognitive function (Spanish version of Mini-Mental State Examination), depression (Geriatric Depression Scale), diagnostic criteria according DSM-IV-TR.

Statistical analyses:

- a bivariate analysis;
- a multivariate analysis. Cox regression model (explanatory variables).

Results Two hundred ninety-three participants, simple representative of people aged 65 years old or more in province of Huesca (Spain). Monitored 5 years follow-up study. Sixty-four people died (21.8%), annual mortality rate: 5.3%. Depression: 66 people (22.5%), (32.2% women, 13.3% men). Cognitive impairment: 51 people (17.4%). Bivariate: factors associated ($P < 0.005$) with mortality: functional impairment, living in nursing home, sensorial impairment, polypharmacy, severe physical illness and psychiatric comorbidity: depression (34.8 vs 18.1%), cognitive impairment (49.1 vs 15.8%). Association between some factors and mortality was nullified after multivariate statistical model; the case for depression (Hazard Ratio: 1.1), cognitive impairment (HR: 1.2) or functional impairment (HR: 1.3).

Conclusions Depression and cognitive impairment are associated with mortality in elderly community living people in bivariate analysis, therefore, this association disappears after multivariate analysis. Severity physical illness seems to nullify the effect of other variables, such as depressive symptomatology.

Delirium as 12-month mortality predictor

K. Paschalidis^{1,*}, P.P. Dalli², P. Argitis³, C. Chatzidai², I.Z. Chaviaras²

¹ Papanikolaou General Hospital, Psychiatric Hospital of Thessaloniki, Thessaloniki, Greece

² General Hospital of Corfu, Psychiatric Department, Corfu – Ionian Islands, Greece

³ University Hospital of Ioannina, Psychiatric Clinic, Ioannina, Greece

* Corresponding author.

Introduction The delirium of the elderly is defined as an acute confusional state, with variation during the day, characterized by

impaired consciousness, orientation, memory, thinking, attention and behavior. It is a clinical syndrome with poor prognosis in hospitalized patients over 65 years.

Purpose The purpose of this research is to investigate whether the organic psychosyndrome of the elderly is a mortality predictor. **Material** It was used material from patients with organic psychosyndrome older than 60 years, who were hospitalized in pathological clinics of the Hospital of Corfu and it was diagnosed by the linker portion of the Psychiatric Clinic.

Methodology During the research, it was studied that the medical record of the patient and telephone calls were made for more complete monitoring at intervals of 3, 6 and 12 months. The patients diagnosed with organic psychosyndrome neither suffered from a psychiatric disorder psychotic type in the past, nor previously preceded anaesthesia in the context of physical disease.

Results According to the analysis of the data of the study, 50 patients met the criteria of research. Eight percent of patients died during hospitalization, in the first 3 months after diagnosis 28% of the initially hospitalized patients, in 6 months 42%, while in the year, 48% of the initial total patients.

Conclusions The analysis of the survey results shows that about half of the patients die from pathological causes in the first 12 months after the diagnosis of the organic psychosyndrome, which means that the organic psychosyndrome could be considered as a poor prognostic marker for the pathological cases.

EW307

Religiosity and its influence on mental health of late age persons

L. Pishchikova

Moscow, Russia

Christian anthropology considers personality as a unity of spiritual, emotional and corporal manifestation. Spirituality is defined as highest level of development and self-control of mature personality, ignoring which leads to moral dissonance and spiritual conflict. For the believing person, it is indisputable that belief, church sacraments and practices are capable to facilitate not only corporal, but also spiritual diseases. Clinical and expert analysis of 235 late age patients (> 60 years), who underwent forensic psychiatric examination in criminal and civil cases, helped to identify the influence of religiosity on mental health of late age persons. At late age, appeal to spirituality defines further evolutionary development of the person and favorable forms of aging. It is noted that elderly believers have no expressed cognitive and emotional frustration. When developing mental disorders, they resort to church sacraments and prayers. Thus, a patient with visual hallucinosis noted that during a prayer “visions calmed down, left or started listening”. A patient with acoustical hallucinosis (“blasphemous” voices) considered them as manifestation of “dark powers”, fought them by appeal to the icon of the Mother of God. A patient with menacing acoustical hallucinations read Psalmbook, dawned on them a cross sign with “consecrated hand” (venerated to Sacred relics) and “locked” them in room corner. Ignoring spirituality, which is observed in psychiatry, is connected with incompatibility of representations based on science and belief; low level of religiousness among psychiatrists; underestimation of religion role in life of patients; lack of special knowledge of this area.

Abnormal Stroop-related event related potentials in patients with late onset depression in remission period

M. Pišljari^{1,*}, Z. Pirtošek²¹ Psychiatric Hospital Idrija, Geriatric department, Idrija, Slovenia² University Medical Centre, Department of Neurology, Ljubljana, Slovenia

* Corresponding author.

Introduction Depression in late life follows a relapsing course and it has been related to impaired cognitive control. Information processing speed, memory and executive abilities are most frequently impaired.

Objectives Cognitive changes are difficult to confirm during depressive episode, as signs of both disorders largely overlap. Therefore, it makes more sense to assess cognition after a remission has been reached. Electrophysiology may be particularly convenient as a tool in such studies, as it can separate central cognitive processing from the motor processing.

Aims The study of cognition was focused on executive function and speed of information processing. It was measured with Stroop-related event related potentials (ERPs) and reaction times (RTs) in a modified computer version of the Stroop test which is highly sensitive to frontal functions.

Methods Thirty-four patients with late-onset depression were included after they had reached remission. They were compared to twenty-four age-, gender- and education-matched healthy controls. Each participant completed a single item computer version of the Stroop task using verbal response mode. EEG and RT were simultaneously recorded.

Results Revealed abnormal late positive Stroop-related potentials in the period of about 500–600 ms period corresponding to the latency of the so-called P300b wave.

Conclusion Study supports the view that patients with late onset depression are also cognitively impaired and that this impairment persists in the period of early remission. Using more sensitive ERP measurement of the Stroop task, we demonstrated impaired information processing at an earlier, pre-response related stage.

Cognitive screening in the acute hospital: Preliminary findings from a cognitive screening program in a university-affiliated, tertiary-referral hospital with 6-month interval outcomes

C. Power^{1,*}, H. Bates², M. Healy², P. Gleeson², E. Greene²¹ St James's Hospital, Memory Clinic- Mercer's Institute for Research in Ageing, Dublin, Ireland² St James's Hospital, Psychiatry of the Elderly, Dublin, Ireland

* Corresponding author.

Introduction Cognitive impairment impacts on patient outcomes [1] but is under-recognised in acute hospitals [2]. Data on rates and degree of impairment among hospital inpatients remain sparse. This information is vital for strategic planning of health services as the European population ages.

Objectives To examine the rates and degree of cognitive impairment among patients aged 65 and older who were admitted to an acute general hospital and to assess its impact on patient outcomes.

Methods All patients aged over 65 who were admitted over a 2-week period were invited to participate. Those who met the inclusion criteria were screened for delirium then underwent a

cognitive screening battery. Normative values for age and level of education were obtained from the TILDA study [3]. Demographic and outcome data were obtained from medical records.

Results One hundred and forty-eight patients underwent cognitive screening. Thirty-nine over 148 (26%) met the DSM-IV criteria for dementia of whom only 16 (41%) had a previously-documented impairment. Thirty over 148 (20%) had evidence of cognitive impairment that did not meet criteria for dementia, only 3 (10%) of whom were previously documented. Seventy-three over 148 (49%) were normal. Six over 148 (4%) were not classifiable. The impact of cognitive status on length of hospital stay, number of readmissions in 6 months and discharge destination was investigated. Impact on length of stay was significant ($P=0.017$) but significance was not achieved against number of readmissions or discharge destination.

Conclusions Cognitive impairment is pervasive and under-recognised in the acute hospital and impacts on length of hospital stay. Longer interval analysis is necessary to investigate further implications.

Clinical and cognitive outcome, course of late onset depression – A study from geriatric services of a tertiary care center in India

S. Rajur^{1,*}, M. Varghese¹, P.T. Sivakumar¹, K.J. Kumar²¹ National Institute of Mental Health & Neurosciences, Psychiatry, Bangalore, India² National Institute of Mental Health & Neurosciences, Clinical Psychology, Bangalore, India

* Corresponding author.

Introduction Literature on outcome studies of late onset depression (LOD) is inconsistent and long-term follow-up over LOD is lacking from India.

Aims and objective To study the course, outcome in LOD and to compare the cognitive performance between patients with LOD and healthy controls.

Methodology Study design was a naturalistic follow-up study. Two hundred and ten case files of LOD between 2007 and 2012 were reviewed. Physical follow-up was done for fifty patients. Depression was assessed using GDS and MADRS, follow-up data using Longitudinal Interval Follow-up Evaluation (LIFE) and cognitive functions using HMSE, neuropsychological battery for Indian elderly, which was compared with matched healthy controls.

Results Among 210 file reviews, 22.4% cases dropped out after initial visit. Among 79 cases, where follow-up information was available, 3 cases converted into BPAD, 1 had MCI and 1 of them was converted to dementia who was missing. Thirty-three were still symptomatic, 5 patients attained partial remission, 40 attained complete remission. Among 50 where in person evaluation was done, only 28% of patients had regular follow-up and 66% had attained remission from index episode out of which 54% had at least one relapse at follow-up. Subjects in LOD group had significantly inferior performance in Wordlist {IR ($P<0.001$), DR ($P<0.001$)}, Design {Construction ($P=0.013$), IR ($P=0.040$)}, DR ($P=0.014$)}, DigitSpan {Forward ($P=0.014$), Reverse ($P=0.012$)}, CorsiSpan {Forward ($P=0.011$), Reverse ($P=0.039$)}, Verbal fluency total ($P=0.010$) and Total time for Tower of Hanoi ($P=0.009$). However, remitted LOD patients performed better in executive functions and memory.

Conclusion Patients with LOD appear to have poorer outcome with fewer remission rates, longer duration to achieve remission, high probability of relapse and poorer performance in cognitive functions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dementia in acutely-ill medical elderly patients

P. Sá Esteves*, D. Loureiro, E. Albuquerque, F. Vieira, L. Lagarto, S. Neves, J. Cerejeira

Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Dementia is one of the leading causes of disability and burden in Western countries. In Portugal, there is a lack of data regarding dementia prevalence in hospitalized elderly patients and factors associated with in-hospital adverse outcomes of these patients.

Objectives Determine dementia prevalence in acutely-ill medical hospitalized elderly patients and its impact in health outcomes.

Methods All male patients (>65 years) admitted to a medical ward (>48 h) between 1.03.2015 to 31.08.2015 were included in the study. Patients were excluded if unable to be assessed due to sensorial deficits, communication problems or severity of the acute medical condition. Baseline evaluation included socio-demographic variables, RASS, NPI, Barthel Index and Confusion Assessment Method.

Results The final sample consisted of 270 male subjects with a mean age of 80.9 years, 116 (43%) having prior dementia. Dementia patients were significantly older (83.5 vs 78.9; $P < 0.001$) and had lower values of Barthel Index (dementia: 34.8 vs non-dementia: 85.8; $P < 0.001$). Mortality rate (9,3%) and length of hospitalization (11.2 days) were similar between groups (12.1 vs 7.1; $P = 0.204$ and 11.9 vs 10.6; $P = 0.218$, respectively). Patients with dementia had higher rates of all neuropsychiatric symptoms except depression, anxiety and mood elation. The level of consciousness (measured by RASS) was impaired in 50% of patients with dementia, which was significantly higher than in non-demented subjects (12.3%; $P < 0.001$). Delirium rates were 29.5% in dementia compared with 7.1% in controls ($P < 0.001$).

Conclusions There is a high prevalence of dementia and an appreciable rate of delirium among these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depression and mild cognitive impairment – Comorbidity and/or continuum?

G. Sobreira^{1,*}, M.A. Aleixo¹, C. Moreia², J. Oliveira³

¹ Centro Hospitalar Psiquiátrico de Lisboa, First Psychotic Episode Unit, Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Schizophrenia and Schizoaffective Disorders Unit, Lisboa, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Neuropsychiatry and Dementia Unit, Lisboa, Portugal

* Corresponding author.

Introduction Depression and mild cognitive impairment are common among the elderly. Half the patients with late-life depression also present some degree of cognitive decline, making the distinction between these conditions difficult.

Objectives To conduct a database review in order to understand the relationship between these entities, and treatment approaches.

Aims To create and implement clinical guidelines at our institution, to evaluate and treat elderly patients presenting with depression and mild cognitive impairment.

Methods A PubMed database search using as keywords “late life depression”, “depression”, “cognitive impairment”, “mild cognitive impairment” and “dementia” between the year 2008 and 2015.

Results Late-life depression and cognitive impairment are frequent among the elderly (10–20%). Depression is also common in the early stages of dementia decreasing as the cognitive decline progresses. The causal relationship between these entities is not well understood and some authors advocate a multifactorial model (genetic risk factors; neuroendocrine changes; vascular risk factors) and the cognitive impairment of said changes is dependent on the individual's cognitive reserve. Regarding treatment of depression in patients with cognitive impairment, most authors advocate a stepped approach with watchful waiting and then, if symptoms persist, the introduction of pharmacotherapy and psychosocial intervention.

Conclusions The relationship between cognitive impairment and depression is still not clear and probably multifactorial. The diagnosis of depressive symptoms in patients with severe cognitive impairment can be difficult and most forms of pharmacological treatment in this population are not beneficial, making it important to carefully evaluate the benefits of introducing new medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Anosognosia in dementia – Relevance for clinical-practice in a memory clinic

S. Verhülsdonk*, B. Höft, T. Supprian, C. Lange-Asschenfeldt

Heinrich Heine University, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

* Corresponding author.

Introduction Anosognosia is a common symptom in patients with dementia, although data on prevalence vary widely. It is associated with decreased compliance to medical diagnosis and treatment. The rejection of assistance challenges professionals as well as caring relatives.

Objectives Anosognosia increases with progression of disease but is also found in early stages. The underlying mechanisms are not completely understood; past studies described an association with executive dysfunction.

Aims Our study aims to identify the frequency of anosognosia in our memory clinic.

Methods We evaluated disease awareness using the Clinical Insight Rating Scale in 124 patients presenting with diagnosis of Alzheimer's disease in our memory clinic. We correlated the degree of awareness with standardized cognitive, affective, and functional parameters.

Results One hundred and fourteen patients (90.9%) showed decreased awareness, in 51.7% of our sample awareness was seriously impaired or even entirely lacking. In accordance with the literature, anosognosia correlated significantly with the result of the Mini-Mental-Status-Examination as indicator of global cognitive functioning ($r = -0.291$, $P < 0.05$) and with the need for assistance in everyday-life ($r = .364$, $P < 0.05$). We found no correlation with depressive symptoms or age.

Conclusion The phenomenon of anosognosia is frequent in the setting of a memory clinic and has special impact on clinical practice as it is well correlated with executive functioning and global cognition and, thus, is a relevant factor for the initiation of medical care for patients with dementia.

Ebola virus disease (EVD) outbreaks create widespread panic, fear and anxiety. Psychological disorder and distress has been demonstrated among survivors and contacts of EVD and their relations, potentially having a negative effect on contact tracing. In the recently controlled outbreak in Nigeria, mental health professionals played active roles in case management, contact tracing, operational research and development of an emergency response plan. At-risk countries need to have a proactive intervention strategy that involves mental health professionals in response to disease outbreaks. This ensures comprehensive support for people during outbreaks that address mental health as well as physical needs of the community.

⁶ University College London, Department of Statistical Science, London, United Kingdom

* Corresponding author.

Introduction Cardiovascular risk prediction tools are important for cardiovascular disease (CVD) prevention, however, which algorithms are appropriate for people with severe mental illness (SMI) is unclear.

Objectives/aims To determine the cost-effectiveness using the net monetary benefit (NMB) approach of two bespoke SMI-specific risk algorithms compared to standard risk algorithms for primary CVD prevention in those with SMI, from an NHS perspective.

Methods A microsimulation model was populated with 1000 individuals with SMI from The Health Improvement Network Database, aged 30–74 years without CVD. Four cardiovascular risk algorithms were assessed; (1) general population lipid, (2) general population BMI, (3) SMI-specific lipid and (4) SMI-specific BMI, compared against no algorithm. At baseline, each cardiovascular risk algorithm was applied and those high-risk (> 10%) were assumed to be prescribed statin therapy, others received usual care. Individuals entered the model in a 'healthy' free of CVD health state and with each year could retain their current health state, have cardiovascular events (non-fatal/fatal) or die from other causes according to transition probabilities.

Results The SMI-specific BMI and general population lipid algorithms had the highest NMB of the four algorithms resulting in 12 additional QALYs and a cost saving of approximately £37,000 (US\$ 58,000) per 1000 patients with SMI over 10 years.

Conclusions The general population lipid and SMI-specific BMI algorithms performed equally well. The ease and acceptability of use of a SMI-specific BMI algorithm (blood tests not required) makes it an attractive algorithm to implement in clinical settings.

Intellectual disability among delusional disorder: A case series register

C.M. Carrillo de Albornoz Calahorra*, M. Guerrero Jiménez, A. Porras Segovia, J. Cervilla Ballesteros

Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

* Corresponding author.

Introduction The quoted prevalence of intellectual disability (ID) among adults with psychiatric illness varies widely. Some believe that these people are protected from certain intellectual and psychological stress by having ID, and therefore, are less prone to develop psychiatric illness. However, in the past decades, the more prevailing view is that people with ID are more vulnerable to psychosocial stress than people without ID, and therefore, are more likely to develop psychiatric symptomatology. According to various population surveys the probability of suffering a mental disability increase with age. Delusional disorder is as well a disease related to advanced stages of life.

Objectives/aims The aims of the present study is to establish the prevalence of functional intellectual disability among adults who fulfil DSM 5 delusional disorder criteria.

Methods Our data come from a case register study of delusional disorder in Andalucía (Spanish largest region). By accessing digital health data, we selected 1927 cases, which meet criteria DSM 5 for delusional disorder collecting whether in its history intellectual disability was registered by the referent psychiatrist.

Results Of our sample, 2.6% had reflected some kind of intellectual disability in their digital clinical record.

Conclusion These percentage has been found to concur with other epidemiological studies linking mental retardation and psychotic spectrum disease although there are no epidemiological data

published to the best of our knowledge that correlate delusional disorder specifically and intellectual disability.

The weight of borderline intellectual functioning on the capacity of integration and social adaptation of patients with borderline personality disorder

D. Galletta*, A.I. Califano, N. Vangone, S. De Simone, A.M. Mastrola, V. Suarato

University of Naples Federic II, Neuroscience, Naples, Italy

* Corresponding author.

From the analysis of current scientific literature are still few studies on the relationship between personality disorders and borderline intellectual functioning, since the latter, without its own specificity, has always been considered as a kind of undefined zone between intellectual functioning medium and intellectual disabilities. Several studies have shown the presence of comorbidity of the personality disorders with BIF, emphasizing a higher frequency of Borderline Personality Disorder. BIF is considered a significant risk factor for the development of a broad spectrum of neuropsychiatric disorders, in particular in our observations ongoing since 2003, it assumes an important weight on the global functioning of patients with personality disorder as we have stated in the intervention SOPSI 2012. In detail, this study focuses on the relationship between BPD and BIF, noting the weight the latter on the social adaptability, job placement and creation of bonds of individuals with Borderline Personality Disorder. Patients included in this study were 52 (40 F and 12 M), of which 27 belonging to the first group had a borderline intellectual functioning in comorbidity with BPD and 25 individuals belonging to the second group with BPD without BIF. The results show that 33% of individuals included in the first group did not find a job working compared to 16% of the second group, showing further falls in attention and concentration, therefore, in the ability to anticipate and generalization, impacting strongly on the degree of adaptation to social life, while there are not significant differences in the ability to create emotional ties between the two groups.

EW318

Family burden and quality of life of mothers of children and adolescents with mental retardation or borderline mental capacity

L. Utas Akhan

Bulent Ecevit University, Health College, Zonguldak, Turkey

Introduction Studies have found that the cognitive function levels of intellectually challenged children add a burden to the family and affect quality of life.

Objectives The purpose of this study was to determine the family burden felt by mothers of children, ages 6–16, whose mental capacity evaluation indicates an IQ of 35–79 to explore the mother's quality of life and discover the factors that yield an impact in this context.

Aims The main objective of this study therefore was to ascertain the family burden and quality of life experienced by the parents of children with mentally retarded or borderline mental capacity.

Methods The WISC-R test was used in the research to determine the intellectual capacity of children, 6–16 years of age. The sample comprised 131 children and adolescents between the ages 6–16 with IQs in the interval of 35–79 and their mothers. The parents accompanying their children were assessed using the Family Burden Assessment Scale, the World Health Organization Quality of Life instrument and a sociodemographic questionnaire that was filled out during face-to-face interviews.

Results The quality of life of the mothers was found to be average. At the same time, as the IQ level of the children went up, the less the mothers felt they were under a family burden. It was seen that the mothers experienced the most difficulty in the domains of “perception of inadequacy” and “emotional burden.”

Conclusion Mothers with intellectually disabled children need psychosocial support. Providing all members of the family with counseling services to help them cope with the issues and responsibilities involved in the care of disabled children may make a significant difference in quality of life.

* Corresponding author.

Introduction Low-income countries have a critical shortage of health professionals. In countries such as Pakistan, Community Health Workers (CHWs) can play an important role in improving access to healthcare services and hence improve health outcomes.

Aims To explore the efficacy of a training program; Learning Through Play Plus, a combination of Learning Through Play (LTP) and Thinking Healthy Program (THP) on knowledge and attitudes of CHW's regarding child development, maternal depression and cognitive behaviour.

Objectives To use focus groups and the training programmes to increase the knowledge of CHWs method: a qualitative approach was used to explore experiences of CHWs who delivered the intervention. Three-day training was provided to 216 CHWs on LTP and THP. Trained facilitators conducted focus groups before and

after the training to explore their prior knowledge and expectations. A semi-structured topic guide was developed for this. All the focus groups were audio-recorded. The data were analysed using framework analysis principles.

Results Four key themes emerged from the focus groups; the psychosocial context these women live in (poverty, work-overload, interpersonal conflicts, lack of support from family, lack of awareness of depression and scarcity of mental health services) CHWs perception of depression (role of negative thoughts in depression), the impact of maternal depression on children and the impact of training for CHWs (improvement in CHWs knowledge related to children).

Conclusion Training CHWs improves their knowledge about child development and psychological therapies. This can contribute to improving access to maternal healthcare services and improving child development outcomes.

600 Greek people's attitudes towards family hosts for mentally ill persons

P. Kloni*, D. Angelopoulou, E. Vardari, A. Zotos, A. Psychogiou, M. Theodoratou

Technological Institute of Patras, Social Work, Patras, Greece

* Corresponding author.

Introduction Family hosts for people with mental diseases is a quite new institution in Greece [1,2].

Objectives The study investigated Greek people's attitudes toward mentally ill people and their institutionalisation

Aims The survey investigated Greek society's attitudes and bias concerning Family Host Programs for the mentally ill.

Methods Questionnaires were administered to a sample of six hundred (600) people in the cities of Patras, Pyrgos and Mesologgi, Southern Greece from May the 27th to June the 12th

Results Of the respondents, 47.3% were men while 52.7% were women. Most citizens were not familiar with the term "Host Family" and were not aware of this new institution (62.7%). However, many knew a person that suffered from mental illness environment (35.7%), but they thought that mentally ill people would be rather a "burden" to foster families (32.2%).

Conclusions Although many people knew well a person with mental illness, they were not aware of psychiatric reforms and community based programs. In conclusion, psycho-educational programs contributing to repel bias towards psychiatric patients should be implemented.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objectives The elderly persons continue to invest substantially in emotional relationships.

Aim The overall objective of this research study was to investigate the attitudes of elderly persons towards family relations.

Method One hundred and ninety-seven healthy elderly individuals participated to the present study from different region in Greece. The age range was 66–93 years old. The questionnaire included: (a) the Family Environment Scale (Family Environment Scale, Form R-FES), (b) The Experience of Shame Scale (ESS), (c) the Other As Shamer Scale (OAS), (d) Quality of Life (SF-36).

Results Univariate and multivariate analysis was applied for the statistical analysis of the data, which showed that: the elderly persons who are satisfied with their lives in past, they exhibit lower overall price external shame feelings of emptiness (empty – OAS) ($P = .002$), they perceived reaction of others when they make mistakes (Mistakes – OAS) ($P = .000$), conflict (Conflict – [Form R-FES]) ($P = .000$). Elderly persons who are satisfied with their life in this time show higher levels of orientation towards active recreational activity (Active-Recreational Orientation – R-FES) ($P = .000$). Elderly persons who declared that family relation is important for them exhibit lower levels of feeling vacuum (empty – OAS) ($P = .009$), and higher levels of orientation for achievements (Achievement Orientation) (R-FES) ($P = .010$), social role (SF – SF36) ($P = .000$), Mental Health summary Scale (SF_MCS-SF36) ($P = .000$).

Conclusion From the findings of this study, it is apparent how important is the study of the quality of life in old age.

Patients with anxiety disorders: Pathways of care and their outcomes in Germany – A secondary data analysis

S. Kowitz*, J. Zielasek, W. Gaebel

Heinrich-Heine-University Duesseldorf, Department of Psychiatry and Psychotherapy, Duesseldorf, Germany

* Corresponding author.

Introduction Anxiety disorders are among the most common mental disorders in Germany. Different sectors and disciplines participate in mental healthcare of these patients, but there is a lack of empirical evidence of the treatment outcomes in different settings.

Objectives The study focuses on analyzing the care pathways of patients with anxiety disorders and the effects of such pathways on critical events like sick leave, early retirement and mortality.

Aims The analysis aims at developing recommendations for optimizing treatment with a view to minimize the rate of occurrence of critical events during the care pathway.

Methods Secondary data of three statutory health insurance companies and of the German Pension Funds of the years 2005–2007. The analyses are based on 744,742 persons with at least one diagnosis of an anxiety disorder.

Results The analyses reveal a low rate of changes between primary and specialized care. There was a high number of care pathways ($n = 2.608$). The most common type was care by primary care physicians/somatic specialists only (60.5% of patients), followed by a treatment by a psychiatrist only (9.5%). Patients, who

were only treated by general practitioners/somatic specialists, had significantly lower rates of sick leave and early retirement. This may indicate that cases with more favourable prognoses are found with this care pathway.

Conclusions Analyses of care pathways using secondary data can contribute to identify potential for optimizing mental health care services and provide information about intersectoral interface problems, which should be considered in the quality management of mental healthcare.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Trajectories of health-related quality of life among family caregivers of individuals with dementia: A home-based caregiver-training program matters

L.M. Kuo

Taipei Medical University, School of Gerontology Health Management- College of Nursing, Taipei, Taiwan

Aim To chart distinct courses of changes in health-related quality of life (HRQoL) among family caregivers of individuals with dementia and how the probability of belonging to each course was affected by participating in a caregiver-training program.

Background No studies have explored whether these family caregivers' HRQoL follows multiple distinct trajectories, nor whether the effect of a given intervention varies across different trajectories.

Design Single-blinded randomized clinical trial.

Method Suitable family caregivers were recruited from June 2009 to March 2012. Of 116 individuals with data available for analysis, 57 were in the intervention group, and 59 were in the control group. A 4- to 6-hour training program with monthly telephone follow-ups to help family caregivers of adults with dementia detect and decrease environmental stimuli for a specific behavior problem. Caregivers' HRQoL was assessed using the Medical Outcomes Study 36-Item Short Form Survey over 18 months following completion of the training program.

Result For all dimensions of HRQoL, two distinct trajectories were identified: a well-functioning trajectory and a poor-functioning trajectory. Caregivers who received the training program had a greater chance of being in the good-functioning HRQoL group than in the poor-functioning HRQoL group. The odds ratios varied by HRQoL dimension from 2.621 for bodily pain to 9.058 for vitality.

Conclusion Participating in a brief training program improved caregivers' HRQoL over 18 months, especially in mental health-related dimensions. Caregiver training should be seriously considered as part of the protocol for managing patients with dementia and their caregivers.

³ City Unity College – MSc Health Psychology, Psychology Department, Athens, Greece

* Corresponding author.

Background Social interactions have an important effect on the subjective well-being of individuals. However, in periods of financial crisis these interactions are reduced, affecting thus the mental health of the individuals as well.

Aim To investigate the effect of the reduction in social interactions, as a result of the economic crisis, on the subjective well-being of non-insurance health care seekers in Greece.

Method Two hundred and sixty-six individuals participated in this study, 90 (35.6%) males and 163 (64.4%) females, with a mean age of 47. Analysis of data was conducted with Anova, using the SPSS software.

Results The findings showed that reductions in social interactions, caused by the financial crisis, led to significant reductions in the subjective well-being of individuals as well ($F(1,259) = 13.276$, $P < 0.001$ for social activities and $F(1,258) = 14.531$, $P < 0.001$ for peer socialization). More specifically, individuals whose social interactions were greatly affected by the financial crisis reported significantly lower subjective well-being than individuals who reported a medium effect ($M = -2.952$, $SD = .764$, $P < 0.001$). Furthermore, individuals who reported that the economic crisis had a great effect on their peer socialization reported significantly lower subjective well-being compared to both those who reported a medium ($M = -1.868$, $SD = .658$, $P < 0.015$) or low ($M = -2.77$, $SD = .809$, $P < 0.001$) effect of the crisis.

Conclusion The results of this research showed that the financial crisis reduced the well-being of affected individuals through reductions in their social interactions. Further research is needed to investigate appropriate interventions to reduce the negative impact that the financial crisis has on the well-being of affected individuals.

Factors affecting restraint practices in psychiatric inpatient units: A sample from a mental health hospital in Turkey

U. Ozer Ceri^{1,*}, U. Uzun¹, B. Sancak¹, V. Ceri², S. Ozen¹

¹ Prof Dr Mazhar Osman Mental Health and Neurological Disorders Research Hospital, Psychiatry, Istanbul, Turkey

² Dumlupinar University-Evliya Celebi Training and Research Hospital, Child and Adolescent Psychiatry, Kutahya, Turkey

* Corresponding author.

Introduction New guidelines aimed to minimize restraint in psychiatry clinics due to ethical reasons.

Objectives Further studies investigating factors affecting the decision of restraint and its potential benefits and harms are needed.

Aims We aimed to determine current rates of restraint in psychiatric clinics and sociodemographic/clinical variables which may be related with restraint practices.

Methods The study was conducted in 64-bed male and 28-bed female psychiatric inpatient units, between March 1–May 31 2015. Sociodemographic and clinical data forms were completed using case files and restraint records.

Results In a total number of 481 inpatients (351 males, 130 females), number of restrained patients was 98 (20.3%) (90 (25.7%) males, 8 (6.2%) females). There was no significant difference in sociodemographic characteristics between restrained and unrestrained patients, but duration of the illness and electroconvulsive

therapy rates were significantly different. Substance abuse (44.4%) was higher in restrained male patients. Also, restraint rates were higher in patients having a diagnosis of substance-related disorder compared to other diagnoses. Restraints occurred most commonly in the first day (48%) of hospitalization.

Conclusions The studies carried out in psychiatric hospitals suggested major differences in the rates and types of restraints among different countries and institutions. In our study, a higher restraint rate is obtained compared to other studies. Consistently with the literature, substance abuse was higher in restrained patients, and restraints occurred most commonly in the first day of hospitalization. Many factors including substance abuse should be considered to reduce restraint rates, which are still quite high in mental health hospitals in Turkey.

Assessment of functional status in oldest old: The OARS/QAFMI model for care planning

R. Rodrigues*, S. Crespo, C. Silva, I. Mendes
Escola Superior de Enfermagem de Coimbra, UICISA-E, Coimbra, Portugal

* Corresponding author.

Introduction The geriatric assessment should include the physical, cognitive, emotional and social functional status, allowing a concrete understanding of the oldest old realities for a better health planning.

Objectives To assess the functional status in main areas of the elderly's life: social resources, economic resources, mental health, physical health and activities of daily living (ADL).

Aims Provide information to health and social policy makers and improve the quality of care, adapting the training of nurses to this new social and health reality.

Methods The randomized, stratified (age and gender) sample consisted of individuals aged ≥ 75 , randomly selected and representative of Coimbra's (Portugal) elder residents ($n=11,279$; $n=1128$). The instrument for data collection was the Questionário de Avaliação Funcional Multidimensional para Idosos/Older Americans Resources and Services (QAFMI/OARS).

Results In the social resources, there are significant differences between gender ($P < 0.001$), with men presenting better scores than women. In the areas of economic resources, mental health and physical health are revealed significant differences between gender and age groups ($P < 0.001$), with the women and the age group of ≥ 85 presenting the worst results. In ADL, area is also observed significant differences between age groups ($P < 0.001$), with the oldest old individuals presenting the worst results.

Conclusions The results will play an important role in the decisions of the technicians at Health Centres to the planning of older care services and will be disseminate among the responsible entities aiming the improvement of the current policies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental health and functional status in oldest old: The use of QAFMI/OARS in Chamusca (Santarém – Portugal) Elder Residents

M. Martins^{1,*}, M. Nunes¹, P. Cunha¹, C. Brunido¹, S. Crespo², R. Rodrigues³

¹ UCC Chamusca/Golegã, ACES Lezíria, Santarém, Portugal

² Escola Superior de Enfermagem de Coimbra, UICISA-E, Coimbra, Portugal

³ Escola Superior de Enfermagem de Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction Population aging and changes in the epidemiological pattern and the social and family structure, observed in Portugal, with a particular focus at the local level, determine new needs for which it is urgent to organize appropriate and active responses. The Community Care Unit (UCC Chamusca/Golegã) and the Municipality of Chamusca decided to carry out this project in order to make the diagnosis of the situation in social and health of the elderly population.

Objectives Assess the use/need of health and social services by the elderly, related with their functional status in social resources, economic resources, mental health, physical health and activities of daily living.

Aim Assess the functional status in mental health to implement an individual monitoring plan.

Methods Quantitative methodology using the Questionário de Avaliação Funcional Multidimensional para Idosos/Older Americans Resources and Services (QAFMI/OARS). The sample consisted of individuals aged ≥ 65 , randomly selected and representative of Chamusca's elder residents ($n=2768$; $n=1868$).

Results Results showed that in mental health, there isn't a significant difference classification between genders in the different aged groups. There is only statistically significant difference between age groups, with the group of 85 and over who have worse results.

Conclusions The work developed with QAFMI/OARS lead us to consider this instrument very useful to define functional status of the elders in specific evaluation areas as mental health, becoming right to the planning of older care services.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Shiraz University of Medical Sciences, Psychiatry, Shiraz, Iran

⁴ Shiraz University of Medical Sciences, Biostatistics, Shiraz, Iran

* Corresponding author.

Background Attention deficit hyperactivity disorder is one of the most common psychiatric disorders in children.

Aim and Objective of the study The study aimed to evaluate the effectiveness of stress management program using cognitive behavior approach on mental health of the mothers of the children with attention deficit hyperactivity disorder.

Methods In this interventional study, 90 mothers of the children with attention deficit hyperactivity disorder were randomly allocated into three intervention, placebo, and control groups. The general health questionnaire was used to measure mental health. Besides, stress was assessed through the depression-anxiety-stress scale. The two instruments were completed at baseline, immediately, and one month after the intervention by the mothers.

Afterwards, within group comparisons were made using one-sample repeated measurement Anova. One-way Anova was used for inter-group comparisons. Mothers in the placebo group only participated in meetings to talk and express feelings without receiving any interventions.

Results At the baseline, no significant difference was found among the three groups regarding the means of stress, anxiety, depression, and mental health. However, a significant difference was observed in the mean score of stress immediately after the intervention ($P=0.033$) and the mean score of mental health among the three groups ($P<0.001$). One month after the intervention, the mean difference of mental health score remained significant only in the intervention group ($P<0.001$).

Conclusions The study findings confirmed the effectiveness of stress management program on mental health of the mothers of the children with attention deficit hyperactivity disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Domiciliary care service in psychiatry – Impact on hospital admissions and follow up in patients with bipolar and schizophrenia disorders

G. Sobreira^{1,*}, F. Gomes¹, I. Capeto Coelho², J. Oliveira³

¹ Centro Hospitalar Psiquiátrico de Lisboa, First Psychotic Episode Unit, Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Bipolar and Obsessive Compulsive Disorders Unit, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Neuropsychiatry and Dementia Unit, Lisboa, Portugal

* Corresponding author.

Introduction Several community psychiatry projects have been developed in Lisbon; nevertheless, there are patients whose needs are not fulfilled by the existing structures. For this reason, our institution created a domiciliary care unit (PreTrarCa).

Objectives To assess if this program has an impact in admission rates, length of stay and follow-up appointments.

Aims To improve the quality of care provided by PreTrarCA.

Methods All active patients followed by PreTrarCA in 2015 were selected ($n=90$); only those with F20 and F31 (ICD-10) diagnoses, admitted to the program after 2013, and who had information regarding duration of illness were chosen ($n=21$). A control group with similar characteristics (age, gender, ICD-10 diagnosis, disease duration) was paired to our sample. Information concerning social/demographic data, disease duration, hospital admissions and appointments, before and after the patients started the program was retrospectively collected. All data and statistical analyses were performed via SPSS program.

Results Our patients were mostly female ($n=12$); mean age 54.92; 10 and 11 had F-20 and F-31 diagnosis respectively. The test patients had fewer admissions ($P=0.027$). No statistical significance was found concerning number of appointments, missed appointments or length of stay, between the groups before or after the patients had started the program.

Conclusions Results suggest that domiciliary care may reduce costs associated with mental health care due to a decrease in admission rates. Our sample was paired to a similar group, which can account for the similar length of stay in both groups. Further studies should take into account other confounding variables.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Centro Hospitalario Benito Menni, Psychiatry, Santander, Spain

³ General University Hospital Alicante, Psychiatry, Alicante, Spain

* Corresponding author.

Introduction Intensive treatment in partial hospitalization unit may represent an efficient alternative to traditional inpatient hospitalization. However, there is evidence suggesting that this clinical resource may not be equally effective for every psychiatric disorder. **Objectives** We aimed to study possible differences in the effectiveness of treatment in a partial hospitalization regime for different psychiatric disorders.

Methods Three hundred and thirty-one patients were admitted to the Valdecilla acute psychiatric day hospital between January 2013 and January 2015. Clinical severity was assessed using BPRS-E and HoNOS scales at admission and discharge. Other relevant clinical and socio-demographic variables were recorded. For statistical comparisons, patients were clustered into 4 wide diagnostic groups (non-affective psychosis; bipolar disorder; depressive disorder; personality disorder).

Results We observed a significant difference in the status of discharge ($\chi^2=12.227$; $P=0.007$). Thus, depressive patients were more frequently discharged because of clinical improvement, while patients with a main diagnosis of personality disorder abandoned the treatment more frequently (23% vs. 4.0%).

When analysing the clinical outcome at discharge, we found that patients with a diagnosis of bipolar disorder showed greater improvement in BPRS ($F=5.305$; $P=0.001$) than those diagnosed of psychosis or depressive disorder. Interestingly, we found no significant differences between diagnoses in hospital re-admission in the following 6 months after being discharged.

Conclusions Our results suggest that acute treatment in partial hospitalization regime may be more effective for bipolar and depressive disorder, and particularly less effective for those patients with a personality disorder.

Task-shifting within health care systems – a general review of the literature and implications for mental healthcare

V. Agyapong

University of Alberta, Department of Psychiatry, Fort McMurray, Canada

Background There have been a growing interest in the effectiveness of task-shifting as a strategy for targeting expanding health

care demands in settings with shortages of qualified health personnel.

Aims To explore the reasons for task-shifting and the healthcare settings in which task-shifting are successfully applied as well as the challenges associated with task shifting.

Methods Literature searches were conducted on PubMed and Google Scholar using the search term – ‘Task shifting’ and Task-shifting’.

Results Reasons for task-shifting including: a reduction in the time needed to scale up the health workforce, improving the skill mix of teams, lowering the costs for training and remuneration, supporting the retention of existing cadres by reducing burnout from inefficient care processes and mitigating a health system's dependence on highly skilled individuals for specific services. Clinical settings in which task-shifting models of care have been successfully implemented, include: HIV/AIDS care, epilepsy and tuberculosis care, hypertension and diabetes care and mental healthcare. Finally, challenges which hinder the successful implementation of task-shifting models of care, include professional and institutional resistance, concern about the quality of care provided by lower lever health cadres and lack of regulatory and policy frameworks as well as funding to support task-shifting programmes.

Conclusion The review brings to light important health policy and research priorities which can be explored to identify the feasibility of using task-shifting models of care to address the critical shortage of health personnel in managing emerging communicable and non-communicable diseases, including opportunities for expanding mental health care in conflict and under-resourced regions globally.

At the expense of historical and social stigma of madness, people with mental disorders suffered over the centuries to acquire a decent treatment. This study aims to get an overview of public policies on mental health among the three neighbouring countries: Argentina, Brazil and Uruguay, proposing a comparison between these three realities. The methodology used was a literature review in the ISI Web of Science and PubMed databases; Articles related to the topic were selected. With the enactment of Law 10,216 of April 2001, Brazil guaranteed rights and protection to patients with mental disorders redirecting the care model, with users referred for outpatient services, Psychosocial Support Centers, Psychiatric Units in General Hospitals and others. In Argentina, Law 26,657 of December 2010 has proposals similar to the Brazilian's law. Living a period of great upheaval to suit the reality of the services with the proposals of the law dealing with limited financial resources. In contrast, Uruguay lives difficult times as the structuring of public policies on mental health, with the Pan American Health Organization required changes by 2020. The current law is the 9581 August 1936 being totally incongruous to the neighboring countries and the guidelines of World Health Organization. This study became important because it highlights the discrepancy between the realities in neighboring countries mentioned above and open new discussions on the topic proposed worldwide.

Overview of psychiatry in Poland, 2000–2015

A. Kiejna*, P. Piotrowski, T.M. Gondek
Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland

* Corresponding author.

At the beginning of the 21st century, psychiatry in Poland was functioning in the model based mostly on the network of large institutions localised outside of the main city centres. Due to Poland's accession to the European Union, it was necessary to change the mental health care system. This need was legally sanctioned when the Law on Protection of Mental Health was passed in 1994. The solutions were included in the National Programme on Mental Health Care (NPOZP). NPOZP comprised the guidelines on the mental health care system shift to community-based health services, including a roadmap for its implementation in 2011–2015. According to the evaluation of the NPOZP, including the information gathered by the Ministry of Health, the programme was implemented to a small extent. The number of large psychiatric institutions and the number of in-patient beds were reduced, the numbers of day wards as well as psychiatric wards in the multi-disciplinary hospitals were increased. The training of the staff for the new system began. A serious challenge for the continuation of the reforms being carried out is the provision of the sufficient number of mental health professionals, particularly in the face of economic migration. A short duration of the proposed NPOZP implementation period did not allow for a full application of the new mental health care solutions, however the awareness that its implementation may be at risk led to a public and media discourse which definitely will have an impact on the improvement of the execution of the programme.

Mental health policy implementation assessment: 8 years after inception

P. Mateus*, Á. Carvalho, M. Xavier
Directorate General of Health, National Programme for Mental Health, Lisbon, Portugal

* Corresponding author.

Introduction In 2007, Portugal started the implementation of a new National Mental Health Plan (NMHP). The main objectives of the plan included: assure equal access, promote and protect human rights, reduce the impact of mental health disorders, promote the decentralisation of mental health services, and the integration of mental health in primary care, general hospitals and community networks. In the last years, the fulfilment of these objectives was hindered due to economical factors.

Objectives To assess the degree of implementation of the main priorities included in the 2007–2016 NMHP, considering levels of low, medium and high implementation.

Methods A full assessment of the NMHP was conducted by the National Mental Health Programme, by means of a cross-sectional evaluation, requested by the National Health Regulatory Agency.

Results High degree of implementation: development of new services, continuing care law, workforce training, programme to fight stigma, programmes for vulnerable groups. Medium degree of implementation: reorganisation of emergency services, involvement of users and families, suicide prevention plan and grants

for innovative services. Low degree of implementation: new models for budgeting and management, new continuing care network, workforce recruitment, inpatient services for children and adolescents, collaboration with the primary care, substance use and justice sectors.

Conclusion The scarce degree of autonomy of the implementation team at the Ministry and the economical crisis hindered the fulfilment of key objectives. Dimensions including the mental health financial and management systems and the implementation of a continuing care network must be considered top priorities.

³ Escuela Universitaria de Osuna, Department of Psychology, Sevilla, Spain

⁴ Vall d'hebrón University Hospital, Department of Psychiatry and Forensic Medicine, Barcelona, Spain

* Corresponding author.

US Latinos have higher rates of substance use disorders (SUDs) than Latinas, but Latinas face substantial barriers to treatment and tend to enter care with higher SUD severity. Immigrant Latinas may face greater barriers to care than native-born despite lower overall SUD prevalence. This study aimed to identify how SUD treatment needs of Latinos are addressed depending on patient gender and immigrant status within an urban healthcare system serving a diverse population.

Methods Data from electronic health records of adult Latino/a primary care patients ($n = 29,887$ person-years) were used to identify rates of SUD treatment in primary and specialty care. Treatment characteristics and receipt of adequate care were compared by gender and immigrant status.

Results Tobacco was the most frequently treated substance followed by alcohol and other drugs. Forty-six percent of SUD patients had a comorbid psychiatric condition. Treatment rates ranged from 2.52% (female non-immigrants) to 8.38% (male immigrants). Women had lower treatment rates than men, but male and female immigrants had significantly higher treatment rates than their non-immigrant counterparts. Receipt of minimally adequate outpatient care varied significantly by gender and immigrant status (female non-immigrants 12.5%, immigrants 28.57%; male non-immigrants 13.46%, immigrants 17.09%) in unadjusted and adjusted analyses.

Discussion Results indicate overall low prevalence of SUD treatment in the healthcare system. Low rates of minimally adequate care evidence the challenge of delivering integrated behavioral healthcare for Latinos with SUD. Results also demonstrate gender and immigrant status disparities in an unexpected direction, with immigrant women receiving the highest rates of adequate care.

Correlates of depression, anxiety and stress among foreign medical students studying general medicine in Romania

A.D. Buzoianu^{1,*}, C.A. Popescu², S. Suciuc³, S.M. Armean¹

¹ UMF Cluj Napoca Iuliu Hatieganu, Pharmacology, Cluj-Napoca, Romania

² UMF Cluj Napoca Iuliu Hatieganu, Social Sciences, Cluj-Napoca, Romania

³ UMF Cluj Napoca Iuliu Hatieganu, Physiology, Cluj-Napoca, Romania

* Corresponding author.

Introduction Several studies suggest that medical students have relatively high levels of emotional disturbance, such as mental distress, anxiety, depression, suicidal thoughts, and burnout. Studying abroad is a growing trend in higher education. Culture shock is a form of psychological distress associated with migration. Given the increased mobility for study registered within the EU, there are studies investigating the processes of acculturation of the students as temporary migrants, with particular attention to the field of medicine. However, in Romania there is virtually no research addressing processes of acculturation of temporary immigrants.

Aims The aim of this study was to examine the correlates of depression, anxiety and stress in foreign medical students studying at University of Medicine "Iuliu Hatieganu" Cluj-Napoca, Romania.

Methods A total of 300 foreign students from English and French Section, completed 5 self-administered questionnaires: Culture Shock Questionnaire, Social Support Questionnaire, STAI, NEO-FFI and a questionnaire about alcohol, smoking and illicit drug use. 150 Romanian students were used as controls. Data on socio-demographic, family characteristics and living arrangement were also obtained.

Results The scores for psychological distress symptoms (stress, anxiety and depression) were significantly higher among foreign medical students. Both individual factors, such as previous problems and personality, and more contextual stress arising from medical school and negative life events, combine to determine whether medical students experience mental health problems.

Conclusions Preventive measures should be taken by medical schools to support foreign medical students, who are at risk for stress, anxiety and depression.

Traumatic pre-migration experiences: A population-based study of Russian, Somali and Kurdish origin migrants in Finland

A. Castaneda*, L. Junna, S. Rask, P. Koponen, S. Koskinen, J. Suvisaari

National Institute for Health and Welfare, The Department of Welfare, Helsinki, Finland

* Corresponding author.

Introduction Ongoing mass conflicts and the resulting flow of displaced persons have increased interest on pre-migration experiences of migrants, but population-based studies of entire migrant groups are still scarce.

Objective We aim to assess the prevalence of a variety of possibly traumatic pre-migration experiences among Russian, Somali and

Kurdish origin migrants in Finland and to determine which socio-demographic factors are associated with traumatic pre-migration experiences.

Methods We used data from the Finnish Migrant Health and Wellbeing Study (Maamu). The survey sample comprised of Russian, Somali and Kurdish origin migrants, aged 18–64 years ($n = 1000$ per group). The data specified eight different traumatic events common to those exposed to war and conflict. The age-adjusted prevalence of traumatic pre-migration experiences were calculated in the ethnic groups by gender using predicted margins.

Results Seventy-seven percent of Kurdish, 58% of Somali, and 21% of Russian origin migrants had experienced at least one traumatic event in the former host country. One third of the Kurdish men had been subject to torture. Surprisingly, migrating as a refugee or asylum seeker was not found to be associated with traumatic pre-migration experiences.

Conclusion Results indicated an alarmingly high overall trauma exposure among Kurdish and Somali migrants in Finland. This should be taken into account in the planning of mental health services in the new host country.

Psychiatric evaluation Ezidi Iraqi refugee children who settle in refugee camp in Turkey

V. Çeri^{1,*}, Ü. Özer², S. Nasıroğlu³

¹ Kütahya education and research hospital, Child and Adolescent Psychiatry, Kütahya, Turkey

² Mazhar Osman Training and Research Hospital for Psychiatry, Neurology, Neurosurgery, Psychiatry, Istanbul, Turkey

³ Sakarya university, medical faculty, Child Psychiatry, Sakarya, Turkey

* Corresponding author.

Objective We aimed to review the distribution of diagnoses in children and adolescents evaluated by a child psychiatrist, in refugee camps in Diyarbakır, Cizre and Silopi province of Turkey.

Methods Sociodemographic data, psychiatric complaints and distribution of psychiatric diagnoses of 38 children and adolescents living in refugee camps in Diyarbakır, Cizre and Silopi were evaluated. Psychiatric diagnoses were made according to DSM-5 criteria but some diagnoses as conversion disorder were also mentioned even though they were not included in DSM-5.

Results The sample consisted of 22 female and 16 male children and adolescents. The mean age was 12.1 ± 4.5 and the range was 2–18 years. The mean duration of residency in the camp was 23.2 ± 3.9 days. The most common symptom was sleep problems. The most frequently seen psychiatric disorder was depressive disorder (36.8%) and at least two comorbidities were detected in 50% of children and adolescents. This diagnosis was followed by conversion disorder (28.9%), adjustment disorder (21.8%), acute stress disorder (18.4%), enuresis nocturna (18.4%), post-traumatic stress disorder (10.5%), separation anxiety disorder (10.5%), somatization disorder (7.8%), selective mutism (2.5%) and night terror (2.5%) respectively.

Conclusion The study revealed that in refugee children and adolescents, starting from the early days of the migration period, various psychiatric symptoms and disorders might be seen. Therefore, it is essential to integrate psychosocial support units into the aid and support programs for refugees and quite important to observe and treat children in terms of psychiatric disorders, starting from the early days of the migration period.

Screening tool for Asylum-Seeker Mental Health (STAMH): A pilot study

D. Hocking^{1,*}, S. Sundram²

¹ Florey Institute of Neuroscience & Mental Health, Mental Health, Parkville, Australia

² Monash Medical Centre, Adult Psychiatry, Melbourne, Australia

* Corresponding author.

Aims and rationale The development of a brief, highly sensitive screening tool (STAMH) easily administered by non-mental health workers to screen for mental disorders in adult asylum-seekers (AS) aims to facilitate timely access to treatment.

Methods An initial version of the STAMH developed from validated scales from a previous study was refined to 10 questions through an iterative piloting process. Adult AS without a known current psychiatric diagnosis was recruited through two Melbourne-based agencies (Asylum Seeker Resource Centre & Monash Health Refugee Health Clinic), which meet AS health and psychosocial needs. All participants were administered the STAMH by non-mental health professionals and subsequently interviewed by the researcher using the MINI 6.0, to determine psychiatric morbidity. Data was analysed through CART and ROC curve analyses, and sensitivity (SN)/specificity (SP) determined the most accurate cut-off score to detect PTSD &/or major depressive disorder (MDD).

Findings Preliminary findings are based on 150 AS from 37 countries. The majority was male (71%) and required an English language interpreter (62%). 36% met criteria for at least one clinical diagnosis: 33% for MDD, 22% for PTSD. However, only 30% of these participants had received mental health treatment in Australia. A cut-off score of ≥ 2 produced .94 (SN) and .65 (SP) for PTSD &/or MDD with a ROC of .80 $P < .0001$ (95% CI = .73–.87).

Relevance to policy, research and/or practice needs The STAMH shows promise in its aim to fill a service gap of detecting mental disorders in AS, through its brevity and sensitivity.

Clinical features of neurotic disorders in internally displaced persons

V. Korostiy*, H. Kozhyna, K. Melamud, O. Platyniuk

Kharkiv National Medical University, Psychiatry, Narcology and Medical Psychology, Kharkov, Ukraine

* Corresponding author.

Introduction According to the Guiding Principles on Internal Displacement, internally displaced persons are persons who have been forced or obliged to leave their homes, in particular as a result of extreme situations, and who have not crossed a state border. As of May 21, 2015 UNHCR has information about 1,299,800 IDPs.

Aim To study clinical features of neurotic disorders in IDPs.

Methods We have a complex psychopathological and psychodiagnostic research 97 IDPs in volunteer center, located at the central train station in Kharkiv.

Results In total, 75.9% of IDPs observed have violations of adaptation: long-term depressive reaction ($F 43.21$) and predominant disturbance of other emotions ($F 43.23$). The men reactive alarm indicators (average – 37.7 ± 3.0), were higher than trait anxiety (average – 32.6 ± 2.9). On the contrary, women figures trait anxiety (average – 38.6 ± 2.9) were higher than reactive anxiety (average – 34.7 ± 3.0). Severity of depressive symptoms also slightly prevailed in women. The mean score on the Hamilton scale for men was 17.0 ± 2.3 points, women – 18.0 ± 2.3 points. Test results on a scale of quality of life showed no significant differences between men and women. We have developed a medical and psychological support system to correct the neurotic disorders in IDPs.

Conclusions The majority of people who left the ATO zone have emotional disorders of different severity and require a further correction in the specialized medical institutions.

Intra-network and inter-network shared connectivity patterns in patients with remitted late-life depression and amnesic mild cognitive impairment

J. Chen^{1,*}, H. Shu¹, Z. Wang¹, Y. Zhan², D. Liu¹, Y. Liu², Z. Zhang¹

¹ Southeast University, Department of Neurology- Affiliated ZhongDa Hospital, School of Medicine, Nanjing, China

² Chinese Academy of Sciences, Brainnetome Center, Institute of Automation, Beijing, China

* Corresponding author.

Objectives Both remitted late-life depression (rLLD) and amnesic mild cognitive impairment (aMCI) alter brain function in individual regions. They are also disconnection syndromes associated with a high-risk of developing Alzheimer's disease (AD). Resting-state functional connectivity magnetic resonance imaging (rs-fcMRI) was performed to define the shared and distinct aberrant patterns in intra-network and inter-network connectivity between rLLD and aMCI.

Methods We investigated rs-fcMRI in five functionally well-defined brain networks in 55 rLLD, 87 aMCI, and 114 healthy controls (HC).

Results Compared with HC, rLLD showed a reduced degree of functional connectivity in the bilateral inferior temporal cortex and supplemental motor area, and reduced correlations within the sensory-motor network (SMN) and in the default-mode network (DMN) – control network (CON) pair. aMCI showed only focal functional changes in regions of interest pairs, a trend toward increased correlations within the salience network and SMN, and a trend toward reduced correlation in the DMN-CON pair. Furthermore, rLLD exhibited more severely altered functional connectivity compared to aMCI. Interestingly, these altered connectivities were associated with specific multi-domain cognitive and behavioral functions in both rLLD and aMCI. Notably, altered connectivity between right middle temporal cortex and posterior cerebellum was negatively correlated with Mattis Dementia Rating Scale scores in both rLLD and aMCI.

Conclusions These results demonstrate that rLLD and aMCI may share convergent and divergent aberrant intra-network and inter-network connectivity patterns. It further suggests that dysfunction in right specific temporal-cerebellum neural circuit may contribute to the similarities observed rLLD and aMCI conversion to AD.

³ Universitat Autònoma de Barcelona UAB, Psychiatry, Barcelona, Spain

⁴ Centro de Investigación Biomédica en Red de Salud Mental CIBERSAM, G21, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction A significant cortical thinning has been repeatedly observed in adult-onset first-episode schizophrenia patients compared to healthy controls, mostly in medial and inferior prefrontal cortices. However, it is yet unclear whether all these replicated alterations are related to any particular clinical feature.

Objectives This study aimed to investigate differences of cortical thickness in a sample of first-episode, drug-naïve psychotic patients and age- and gender-matched healthy controls and explore clinical correlates of these parameters regarding negative symptoms.

Methods High-resolution T1-weighted images were acquired from 23 antipsychotic-naïve, first-episode psychotic patients and 26 age-matched healthy comparison subjects. Clinical features were measured with the negative subscale of the Positive and Negative Syndrome Scale (PANSS) at baseline and after a 2-month follow-up period.

Results No differences were found regarding age or gender when comparing patients and controls. We found a significant cortical thinning in the left medial orbitofrontal cortex and in the right lateral orbitofrontal cortex in patients compared to healthy age- and gender-matched controls. Regarding clinical performance, no correlation was found at baseline between left medial orbitofrontal nor right lateral orbitofrontal cortical thickness and scores of the negative subscale of the PANSS. However, at the 2-month evaluation clinical performances were significantly associated to the left medial orbitofrontal cortical thickness values.

Conclusions Cortical thickness alterations in prefrontal cortex appear to be present at disease onset and these alterations may relate to clinical outcome. However, our findings must be considered just as exploratory. Larger longitudinal studies may help characterize, replicate and consolidate these findings.

¹ All India Institute of Medical Sciences, Psychiatry, New Delhi, India

² All India Institute of Medical Sciences, Nuclear Magnetic Resonance, New Delhi, India

* Corresponding author.

Introduction Cognitive deficits are characteristic features of mania but their underlying pathways are not well defined.

Aims and objectives The present study was conducted to explore the various brain regions implicated in response inhibition in active mania.

Methods After obtaining ethical clearance from the Institute Review Board, we recruited 30 subjects with active mania and 15 healthy controls using purposive sampling. Computerized version of the Stroop Colour Word Test was used.

Results The two groups were similar on socio-demographic variables. No difference in performance was seen in the two groups on the total number of correct and incorrect responses and reaction times for correct responses on incongruent condition of the Stroop Test. However, subjects in the mania group were quicker in making incorrect responses. During incongruent condition of Stroop test, in the mania group (Fig. 2), only left fusiform gyrus was activated in comparison to the control group (Fig. 1), which had left cingulate gyrus, right frontal lobe, and superior temporal gyrus activation.

Discussion It is evident that mania group performed relatively poorly on response inhibition task since they took lesser time to make incorrect responses. This may be explained by the non-activation of frontal areas, responsible for the executive functioning.

Decreased interhemispheric functional coordination underlying the cognitive impairment in late-onset depression

Z. Hou^{1,*}, W. Jiang¹, Y. Yue¹, Y. Yin¹, Y. Zhang¹, Y. Sui², Y. Yuan¹

¹ Affiliated Zhongda Hospital of Southeast University, Medical School of Southeast University, Psychiatry, Nanjing, China

² Affiliated Nanjing Brain Hospital of Nanjing Medical University, Psychiatry, Nanjing, China

* Corresponding author.

Background The intuitive association between cognitive dysfunction in late onset depression (LOD) and the aberrant functional activity in the brain's default-mode network (DMN) has prompted interest in exploring the role of the DMN in LOD. The altered pattern of resting state voxel-mirrored homotopic connectivity (VMHC) in cognitive processes is not yet well understood in LOD.

Methods The study was designed to examine the implicit coupling between the alteration of interhemispheric functional coordination and cognitive impairment in LOD. Thirty-one LOD patients and 37 matched healthy controls (HC) underwent neuropsychological tests and functional magnetic resonance imaging (fMRI) in this study.

Results Compared to HC group, attenuated VMHC in superior frontal gyrus, superior temporal gyrus, posterior cerebellar lobe, postcentral and precentral gyrus was observed in LOD. Neuro-behavioral relevancy approach revealed that the imbalanced interhemispheric functional coordination in bilateral cerebellum was positively correlated with the performance of trail making test in LOD ($r = 0.367$, $P = 0.040$).

Conclusion Altered linkage pattern of intrinsic homotopic connectivity and cognition was firstly investigated in LOD, and it would provide a novel clue to reveal the neural substrates underlying the cognitive dysfunction in LOD.

Keywords Late-onset depression; Voxel-mirrored homotopic connectivity; Functional magnetic resonance imaging; Cognitive function; Cerebellum

qEEG correlates of induced anxiety in obsessive-compulsive patients – comparison of autobiographic and general anxiety

D. Kamaradova*, J. Prasko, K. Latalova, A. Grambal, J. Taborsky, M. Hajda

University Hospital Olomouc, Psychiatry, Olomouc, Czech Republic

* Corresponding author.

Introduction Obsessive-compulsive disorder (OCD) is characterized by the presence intrusive thoughts (obsessions) that cause anxiety in patients. Patients then perform various types of rituals (compulsions) to suppress symptoms of anxiety. OCD differ from other anxiety disorders. In OCD patients, the anxiety is caused by individual's specific situation. Aim of our study was to compare EEG signal during resting state, autobiographic scenario and general anxiety scenario.

Methods Resting-state eyes-closed EEG data were recorded in twenty OCD patients and fifteen healthy controls that were

involved in the study. Cortical EEG sources were estimated by standardized low-resolution electromagnetic tomography (sLORETA) in seven frequency bands: delta (1.5–6 Hz), theta (6.5–8 Hz), alpha-1 (8.5–10 Hz), alpha-2 (10.5–12 Hz), beta-1 (12.5–18 Hz), beta-2 (18.5–21 Hz) and beta-3 (21.5–30 Hz). Cognitive performance was measured by the Trail-Making Test (version A and B). Emotional states were induced by using two different scenarios. One of them was autobiographical (related to OCD symptoms of the patient) and the other aimed to induce general anxiety.

Results Our results show different activation during exposure autobiographical and generally anxiety scenario in patients with OCD. During the exhibition, generally anxious scenario the activity changed in temporo-parietal areas both in OCD patients and healthy controls. Whereas during the exposition to autobiographical scenario we found activity changes in frontal areas.

Conclusions Our results suggest differences in the activation of brain structures when exposed to specific and non-specific anxiety in OCD patients.

qEEG correlates of cognitive impairment in obsessive compulsive patients

D. Kamaradova*, J. Prasko, K. Latalova, A. Grambal, J. Taborsky, M. Hajda

University Hospital Olomouc, Psychiatry, Olomouc, Czech Republic

* Corresponding author.

Introduction Similar to patients with schizophrenia or bipolar affective disorder many studies demonstrated presence of cognitive impairment in OCD (obsessive-compulsive disorder) patients. Aim of our study was to identify correlates of cognitive impairment in OCD patients using quantitative EEG.

Methods Resting-state eyes-closed EEG data were recorded in twenty OCD patients and fifteen healthy controls that were involved in the study. Cortical EEG sources were estimated by standardized low-resolution electromagnetic tomography (sLORETA) in seven frequency bands: delta (1.5–6 Hz), theta (6.5–8 Hz), alpha-1 (8.5–10 Hz), alpha-2 (10.5–12 Hz), beta-1 (12.5–18 Hz), beta-2 (18.5–21 Hz) and beta-3 (21.5–30 Hz). Cognitive performance was measured by the Trail-Making Test (version A and B).

Results Frontal delta and theta EEG sources showed significantly higher activity in the whole group of OCD patients ($n=20$) than in control subjects ($n=15$). Subsequent analysis revealed that this excess of low-frequency activity was present only in the subgroup of 11 patients with cognitive impairment (based on the performance in the Trail Making Test-A). The subgroup of patients with normal cognitive functions ($n=9$) did not differ in cortical EEG sources from healthy controls.

Conclusion The present results suggest that frontal low-frequency cortical sources of resting state EEG rhythms can distinguish groups of cognitively impaired and cognitively intact OCD patients. Based on our results, future studies should consider whether the present methodological approach provides clinically useful information for the revelation of cognitive impairment in OCD patients.

³ University of New South Wales, School of Psychiatry, Sydney, Australia

⁴ Australian National University, John Curtin School of Medical Research, Canberra, Australia

* Corresponding author.

Introduction Neuroimaging studies of attention-deficit/hyperactivity disorder (ADHD) have revealed structural deviations of the corpus callosum in children and adolescents. However, little is known about the link between callosal morphology and symptoms of inattention or hyperactivity in adulthood, especially later in life.

Objective We aimed to further expand this understudied field by analyzing a large population-based sample of 280 adults (150 males, 130 females) in their late sixties and early seventies.

Methods We applied a well-validated approach capturing the thickness of the corpus callosum with a high regional specificity at 100 equidistant points. In addition to correlating point-wise callosal thickness with ADHD symptom measures within the whole sample, we tested for sex interactions.

Results There were significant sex interactions with respect to measures of inattention and hyperactivity, with follow-up analyses revealing significant negative correlations in males (see Fig. 1 – Top). In contrast, there were positive correlations with respect to hyperactivity only in females (see Fig. 1 – Bottom).

Conclusion A thinner corpus callosum may be associated with fewer fibers or less myelination. Thus, the negative correlations, as observed in males, suggest an impaired inter-hemispheric communication necessary to sustain motor control and attention, which may contribute to symptoms of hyperactivity, impulsivity and/or inattention. The functional relevance and underlying mechanisms of the positive correlations, as detected in females, remain to be resolved.

Gamma band dysfunction in patients with schizophrenia during a Sternberg Task: A wavelet analysis

D.D. Marasco^{1,*}, G. Di Lorenzo², A. Petito¹, M. Altamura¹, G. Francavilla¹, L. Inverso¹, A. Bellomo¹

¹ *Laboratory of Neurophysiology, Department of Clinical and Experimental Medicine, Section of Psychiatry, University of Foggia, Foggia, Italy*

² *Laboratory of Psychophysiology, Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy*

* *Corresponding author.*

Background Increasing body of evidence suggest that patients with schizophrenia (SCZ) present dysfunction of the gamma band oscillations (GBO) during cognitive tasks. The current study aimed to explore the GBO activity in SCZ during a Sternberg task.

Materials and methods Twenty-eight chronic stabilized SCZ and 18 healthy controls (HC), were recruited. Ongoing EEG was recorded during the execution of the Sternberg task. Continuous EEG data were band-pass filtered (1–100 Hz) and corrected for eye blink and muscle artefacts by ICA. For each subject, the event-related-spectral-perturbation (ERSP) and the inter-trial-coherence (ITC) were computed at the Pz channel only for those stimulus-locked segments containing correct responses. GBO wavelet analysis was performed with two different increasing cycle ranges (3 to 5.8 and 12 to 22.6; frequency range: 30–90 Hz), to obtain the best information about temporal and frequency dynamics. Student's t test (with multiple comparisons FDR correction) was used to compare the groups.

Results During the maintenance phase (4000 to 4600 ms after the stimulus onset), SCZ presented a significant increase, respect to HC, in low GBO activity (range: 30–50 Hz;). In the other phases of the Sternberg task (encoding, probe presentation and response periods), no significant difference in GBO was observed between SCZ and HC.

Conclusions These findings are in line with the evidence that GBO dysfunction in SCZ is present during selective phases of the working memory task. Future studies have to clarify the role of GBO dysfunction on the cognitive performance and the clinical utility of selective GBO modulation during cognitive rehabilitation.

Introduction Taste perception is a complex phenomenon modulated by different factors, such as taste receptors and memory brain circuits. The palatability of the food, that activates the central

reward pathways, also plays an important role in taste perception. It means that taste is able to influence the choice of food and then eating behaviour.

Objectives It is well known that people with anorexia nervosa (AN) have a lower sensitivity to reward stimuli and recent studies suggested that altered function of taste neural circuitry may contribute to restricted eating in AN.

Aims The aim of this study was to evaluate, in patients suffering from AN, the activation of brain areas involved in taste perception and in central reward mechanisms to both pleasant and aversive taste stimuli and to correlate gustatory neurocircuitry activity with eating behaviours, temperament measures and/or sensitivity to reward and to punishment.

Methods Fifteen underweight female AN patients and sixteen normal-weight healthy women underwent a functional MRI to measure brain areas activation to repeated stimuli of a pleasant taste (sucrose solution), alternated with an aversive taste (bitter solution), and water taste.

Results Compared to healthy controls, patients with AN showed a significantly reduced activation of left insula and left dorsolateral prefrontal cortex to sweet stimulus and reduced activation of right parietal cortex to bitter stimulus.

Conclusions These results, if confirmed in future studies, may improve our knowledge about the pathophysiological mechanisms of AN.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Implication of altered $\alpha 7$ nicotinic receptors and amyloid deposition in the Alzheimer's brain

K. Nakaizumi^{1,*}, T. Terada², E. Yoshikawa³, A. Kakimoto³, I. Takashi³, I. Suzuki³, B. Tomoyasu², K. Suzuki¹, Y. Magata⁴, N. Mori¹, Y. Ouchi²

⁴ *Hamamatsu University School of Medicine, Molecular Imaging-Medical Photonics Research Center, Hamamatsu, Japan*

* *Corresponding author.*

Introduction Brain amyloid- β protein (A β) deposition is a key pathology of Alzheimer's disease (AD). Cholinergic degeneration, including reductions in $\alpha 7$ nicotinic acetylcholine receptors ($\alpha 7$ -nAChR), is also known as a pathophysiology of AD. Recent imaging studies have shown cognitively normal subjects with A β depositions, indicating a missing link between A β deposition and cognitive decline.

Objectives To clarify relationships among the A β burden, $\alpha 7$ -nAChR availability, and cognitive declines in AD.

Aims To measure brain A β deposition and $\alpha 7$ -nAChR availability in the same patients with AD using positron emission tomography (PET).

Methods Twenty AD patients and age-matched 20 healthy adults were studied. The $\alpha 7$ -nAChR availability and A β deposition were evaluated using PET with [¹¹C]MeQAA and [¹¹C]PIB, respectively. Levels of specific binding were estimated by a simplified reference tissue method (BP_{ND}) for [¹¹C]MeQAA and a tissue ratio method (SUVr) for using [¹¹C]PIB. The values were compared with clinical measures of various cognitive functions using regions of interest (ROIs)-based and statistical parametric mapping (SPM) analyses.

Results [¹¹C]MeQAA BP_{ND} levels were extensively lower in the cholinergic projection regions of AD. There was a significant

negative correlation between [^{11}C]PIB SUVR and [^{11}C]MeQAA BP_{ND} in the nucleus basalis of Meynert (NBM). The NBM [^{11}C]PIB SUVR was negatively correlated with the [^{11}C]MeQAA BP_{ND} level in the anterior and posterior cingulate cortices, whereas the relation within the same region showed weak correlation. Also we found significant correlation between cognitive decline and [^{11}C]MeQAA BP_{ND} levels in the NBM.

Conclusions A β deposition-linked α 7-nAChR dysfunction may account for cognitive decline in AD.

Caudate neurochemistry in unmedicated obsessive-compulsive disorder patients: A magnetic resonance spectroscopy study

A. Parmar^{1,*}, P. Sharan¹, S. Khanalwal¹, U. Sharma², N. Jagannathan²

¹ All India Institute of Medical Sciences, Department of Psychiatry, Delhi, India

² All India Institute of Medical Sciences, Department of NMR and MRI facility, Delhi, India

* Corresponding author.

Introduction Caudate nucleus has widely regarded as having a central role in the neurobiology of obsessive-compulsive disorder (OCD). Magnetic resonance spectroscopy (MRS) provides in vivo assessment of brain neurochemistry. Previous studies suggest changes in levels of N-acetyl aspartate (NAA) and Glx levels (Glutamate + Glutamine) in patients with OCD.

Aims and objectives To measure levels of NAA, Choline (tCho), myo-inositol (ml), Glx and total creatine (tCr) in unmedicated OCD patients and compare them with healthy controls.

Methods We included 28 subjects diagnosed as OCD (DSM-IV) with total duration of illness < 5 years who were not on any specific treatment for OCD for last 8 weeks and were free from other axis-I psychiatric disorders. Twenty-six subjects without any axis-I diagnosis were included in group of healthy controls. MRS was done on a 3-Tesla MRI scanner. Absolute measures of neurochemicals were assessed using LC model software.

Results Although there were no significant differences between OCD patients and healthy controls, NAA levels were lower and Glx level were higher in patients with OCD at a trend level. Levels of ml positively correlated with disease severity (on YBOCS scale).

Discussion Our result of decreased NAA and increased Glx in caudate nucleus is in line with the previous studies although failure to reach significance can be explained by the fact that we included relatively non chronic patients as compared to most previous studies.

Conclusions Our findings suggest impaired neuronal density (decreased NAA) and hyperdopaminergic state (increased Glx) in caudate nucleus of patients with OCD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The thought of greater loss of brain tissue in Deficit Syndrome (DS) i.e. subgroup of schizophrenia with enduring primary negative symptoms defined by Carpenter et al.; this has not been verified by recent studies.

Objective Accumulated researches suggest that enlargement in Lateral Ventricles (LV) is related with current negative symptoms and poor prognosis. However, this has not been validated in DS.

Aims Our aim is to study the association between the enduring negative symptoms and LV changes schizophrenia. We included both deficit and non-deficit patients for comparison with controls.

Methods Forty-five patients (18 DS, 27 non-DS) and 37 healthy controls were recruited, evaluated for positive and negative symptoms, depression and extrapyramidal symptoms. Structural magnetic resonance imaging was performed. LV was assessed by MANCOVA (gender, age total brain volume as confounding factors) in 3-dimensional (3D) shape analyses. Correlations between clinical and imaging data were analyzed by Pearson correlation coefficient; $P > 0.05$ being significant.

Results LV of patients was found to be greater than controls, especially in regions adjacent to parietal and temporal regions but no significant difference between subgroups was detected. Enlargement in right LV by corpus callosum adjacency was found in DS. There was no correlation between negative symptoms and LV volume.

Conclusions The idea of greater amount of LV enlargement in patients with predominant negative symptoms could not be observed in 3D analyses. New pathophysiological theories are needed for the explanation of negative symptoms, loss of functioning and poor prognosis rather than only commenting about tissue decrease/loss.

Introduction Spectroscopy is a diagnostic method using MRI, to analysis tissue in vivo noninvasively. There are several studies with magnetic resonance spectroscopy (MRS) in patients with psychiatric disorders, especially schizophrenia and Alzheimer's type dementia, in their different developmental stage. Sometimes spectroscopy may allow brain metabolic changes to be observed before the onset of alterations in brain parenchyma. We do not know any documented case of spectroscopy performed on a psychiatry-targeted manner on our hospital. It is a noninvasive technique without added cost to the MRI and is available in our hospital. It seems interesting for us to combine two specialties like radiology and psychiatry in the field of a neuroimaging Project.

Objectives and aims Our goal is try to establish a radiological anatomical correlate to brain molecular levels. It's a transverse and

longitudinal prospective observational study in which subjects will be submitted to various psychiatric assessments by conducting a radiological examination that is the MRI and MRS to determine the regional metabolic pattern in the subjects explored.

Methods Informed consent to all patients, aged more than 18 years, selected according inclusion/exclusion criteria that meet ethical principles. Patients are selected within the public health network of Sacyl Health Care System, Zamora Hospital, Spain.

Expected results and conclusions Schizophrenia increased creatinine, choline and glutamate. NAA decrease in untreated patients and increased the same in patients with treatment Alzheimer: < increased NAA (N-acetyl aspartate) and increased MI (myo-inositol), their relationship has a high negative predictive value, ie if it is negative (the peaks are not increased) is discarded Alzheimer's disease. Early Dx/screening? Treatment?

Gender differences in neural activation during perceptual uncertainty in patients with major depression

T. Sobanski^{1,*}, H. Sauer², K.J. Bär², G. Wagner²

¹ Thueringen-Kliniken GmbH, Psychiatry, Psychotherapy and Psychosomatic Medicine, Saalfeld, Germany

² Friedrich Schiller University, Psychiatry and Psychotherapy, Jena, Germany

* Corresponding author.

Introduction Although male and female patients with major depression (MDD) differ in psychopathology and other illness characteristics, a potentially confounding effect of gender has not been systematically controlled or investigated in most of the previous neuroimaging studies.

Objectives We investigated activation patterns during processing of ambiguous stimuli in MDD by functional MRI.

Aims We aimed at examining potential activation differences between male and female patients.

Methods A matching task was employed in which two stimuli with varying degrees of perceptual uncertainty had to be compared with respect to their sameness. Eighteen patients meeting DSM-IV criteria of MDD and eighteen healthy control subjects participated in this study.

Results Whereas on the level of behavioral performance no significant group differences could be detected we found distinct disorder- and gender-related differences in the brain activation. Patients activated significantly stronger in superior parietal, prefrontal and cingulate regions. Gender specific analyses revealed that the hyperactivity in the patient group was mainly attributable to hyperactivity in the male patients who activated significantly stronger than the female patients in an extensive fronto-temporo- limbic network, which partly overlapped with the network we found when comparing patients and healthy controls.

Discussion Our results indicate that male patients seem to be reliant on a significantly stronger metabolism in task-relevant regions to maintain an equal level of performance.

Conclusion The present results provide evidence for gender-related differences in the functional organization of the brain in patients with MDD. Gender differences should be taken into consideration when investigating the neural correlates of MDD.

* Corresponding author.

Introduction Schizophrenia is characterized by poor social interaction contributing to poor functional outcome. Particularly nonverbal communication is disturbed. Neural correlates of impaired gesturing are currently unclear. We thus tested functional correlates of gesturing in schizophrenia patients and healthy controls.

Methods We tested 22 patients and 25 controls with an event-related fMRI (instructed delay) paradigm to dissociate brain activation during planning and execution of meaningful (e.g. use scissors) and meaningless novel gestures. Preprocessing included realignment, coregistration, normalization and spatial smoothing. We used a two stage mixed effects model for statistical analysis. Conditions were contrasted against a linguistic control within and between groups. We correlated psychopathological characteristics with beta estimates of brain areas with between group effects.

Results During planning and execution of both gesture subtypes both groups activated brain areas of the ventral and dorsal stream. However patients' activity was less prominent and more left lateralized. During planning patients showed additional activity in bilateral temporal poles, amygdala and hippocampus associated with the level of delusions. Furthermore patients had increased dorsomedial prefrontal cortex and precuneus activity when planning meaningless gestures.

Conclusion During the planning of meaningless gestures we detected aberrant activation of limbic structures in patients typically implicated in delusion formation, which also correlated with current severity of delusions. Moreover, planning of meaningless gestures relied on areas relevant for strategic control and attention. These results argue for a pathologic search for meaning in neutral gestures and increased control effort during planning of meaningless gestures in schizophrenia.

Behavioral phenotypes in patients with obsessive-compulsive disorder comorbid with schizophrenia

L. Dehelean^{1,*}, A.M. Draghici², R.S. Romosan¹, I. Papava¹

¹ "Victor Babes" University of Medicine and Pharmacy, Neuroscience/Psychiatry, Timisoara, Romania

² Timisoara Psychiatric Clinic, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction The co-occurrence between obsessive-compulsive and schizophrenic symptoms may reflect comorbidity between two different disorders, a schizo-obsessive form of schizophrenia, or a single schizo-obsessive disorder.

Objectives The purpose of the study is to identify if patients with obsessive-compulsive disorder comorbid with schizophrenia (OCD-SCZ) have different behavioral phenotypes compared with patients with obsessive-compulsive disorder (OCD).

Methods The study was carried out on patients diagnosed with OCD with or without comorbidity with schizophrenia. The following data was analyzed: socio-demographic parameters, family psychiatric history, and behavioral phenotypes such as nicotine, alcohol and illicit drug abuse, hetero-aggressivity, and suicidal attempts.

Results The OCD-SCZ sample included 30 patients, and the OCD sample 31 patients. In the OCD-SCZ sample, the mean age was 39.83 (SD = 13.6) years, and there were 13 (43.3%) men and 17 (56.7%) women. In the OCD sample, the mean age was 44.29 (SD = 13.55) years and there were 11 (35.5%) males and 20 (64.5%) females. The OCD-SCZ sample had significantly higher rates of suicidal attempts ($U = 356$, $Z = -2.83$, $P = 0.005$) and episodes of hetero-aggressivity ($U = 355.5$, $Z = -2.37$, $P = 0.01$) than the OCD sample. Moreover, the patients with OCD-SCZ presented significantly more recorded violence, substance abuse and personality disorders in their family of origin ($U = 275$, $Z = -3.19$, $P = 0.001$). We found no statistically significant differences between the two samples regarding nicotine, alcohol or illicit drug abuse.

Conclusions The patients with OCD associated with schizophrenia presented significantly more suicidal attempts, episodes of hetero-aggressivity, and have more recorded violence, substance abuse and personality disorders in their family history.

Neuroimaging correlates of insight in obsessive compulsive disorder: A fMRI study

A. Gadad*, D.Y.C.J. Reddy, D.G. Venkatasubramanian, D.J. C.N.
National Institute of Mental Health & Neurosciences, Psychiatry,
Bangalore, India

* Corresponding author.

Aim of the study To study the neural substrates of insight in OCD by comparing patients with good insight, patients with poor insight and matched healthy controls using functional MRI.

Methodology Subjects were recruited from among patients attending OCD clinic, adult psychiatry services and psychiatry ward inpatients of National Institute of Mental Health And Neurosciences (NIMHANS), Bangalore. They were further divided into 'good insight' ($n = 30$) and 'poor insight' ($n = 14$) using Brown's assessment of belief's scale. Control subjects ($n = 30$) were recruited from consenting volunteers. 3 T MRI was used, mental rotation task was paradigm used for fMRI and analysis was done by SPM 8.

Results Poor insight patients and Good insight patients comparison revealed differential activation in Left superior/Medial frontal gyrus (corresponding to the DLPFC). A negative correlation between BABS score and activation of right inferior parietal lobule. Mental Rotation task behavioural data results: OCD patients as a group had significantly lower accuracy compared to healthy controls. Poor insight group had significantly decreased accuracy ratio compared to Good insight group and healthy controls. A negative correlation was noted between BABS score and accuracy ratio, indicating that poorer the insight, greater the errors during the active task.

Conclusion Insight has been important prognostic factor in OCD. Poor insight patients had specific deficits in left medial frontal gyrus and right inferior parietal lobule as compared to good insight patients and healthy controls. Together, these indicate that insight has a strong neurobiological underpinning in OCD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Atomoxetine for hoarding disorder: A preclinical and clinical investigation

G. Grassi*, L. Micheli, L. Di Cesare Mannelli, E. Compagno,
C. Ghelardini, S. Pallanti

University of Florence, NEUROFARBA, Florence, Italy

* Corresponding author.

Aim Despite some studies suggested that childhood attention-deficit hyperactivity disorder (ADHD) and inattention symptoms may be related to hoarding, only a small case series study investigated the effectiveness of ADHD medications in hoarding disorder. The aim of the present study was to evaluate the preclinical and clinical effectiveness of atomoxetine, a noradrenaline reuptake inhibitor approved for childhood and adulthood ADHD, in an animal model of compulsive-like behaviors (marble burying test) and in patients with a primary diagnosis of hoarding disorder.

Methods We performed a preclinical investigation assessing the effects of atomoxetine on the marble burying behavior test in mice. The number of marbles buried in vehicle and atomoxetine treated groups was measured. Subsequently, we conducted a clinical investigation on five patients fulfilling the DSM-5 criteria for hoarding disorder. These patients were treated with atomoxetine 40–100 mg for 12 weeks. Full response was defined as a more of 35% decrease in UCLA Hoarding Severity Scale (UHSS) and partial response was defined as a more of 25% decrease in UHSS scale.

Results Atomoxetine significantly reduced the number of buried marbles in a dose dependent manner in comparison to control mice, without affecting the locomotor activity. Three out of five atomoxetine-treated patients were classified as full responders and two patients as partial responders after 12 weeks of treatment.

Conclusions These preclinical and clinical data suggest that atomoxetine may be considered as a potentially effective compound for hoarding disorder and therefore should be considered for future controlled trials in hoarding disorder.

Differential effects of coping strategies on autogenous and reactive obsessions

M.S. Lee^{1,*}, S.M. Kwon²

¹ Seoul National University Hospital, Department of Psychiatry,
Seoul, Korea

² Seoul National University, Department of Psychology, Seoul, Korea

* Corresponding author.

Introduction Obsessive thoughts can be categorized into two subtypes, autogenous obsessions and reactive obsessions. Although it has been investigated that each subtype associates with different maladaptive coping strategies, no studies have yet empirically compared the effectiveness of adaptive coping strategies on autogenous and reactive obsessions.

Objectives It is hypothesized that acceptance, which is a core therapeutic principle of acceptance-based cognitive therapy (ACT), is more effective on autogenous obsessions, whereas response

suppression as a principle of exposure and response prevention (ERP) has a stronger effect on reactive obsessions.

Aims To compare the effectiveness of two coping strategies (acceptance and response suppression) on autogenous and reactive obsessions.

Methods A total of 164 undergraduate students completed questionnaires for obsessional thoughts and coping strategies. According to the most distressing thought, sixty subjects ($n=30$ with autogenous obsession, $n=30$ with reactive obsession) were randomly assigned to two groups differing in treatment conditions. Individual psychoeducation and practice were performed for four different groups (2 obsessional subtypes \times 2 coping strategies).

Results Repeated measure ANOVA demonstrated that the autogenous obsessional group showed greater distress reduction after acceptance treatment than response suppression treatment, although its effect was not statistically significant. However, the reactive obsessional group did not show the interaction effect between distress reduction and the two coping strategies.

Conclusions The results suggest that coping strategies have differential effects on distress reduction of obsessional subtypes. Different therapeutic approaches may need to be offered to individuals with autogenous and reactive obsessions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Adjuvant treatment of resistant obsessive-compulsive disorder with memantine: A case report

D. Mota^{1,2,*}, A. Oliveira^{1,2}, J. Silva¹, M. Fernandes¹, J. Ribeiro¹, V. Martins¹, F. Duarte¹, M. Marques^{1,2}, A.T. Pereira^{1,2}, J. Andrade^{1,2}, A.F. Macedo^{1,2}

¹ Centro Hospitalar e Universitario de Coimbra, CRI de Psiquiatria e Saúde Mental, Coimbra, Portugal

² Faculty of Medicine, University of Coimbra, Department of Medical Psychology, Coimbra, Portugal

* Corresponding author.

Introduction OCD could be a very disabling condition, implying severe impairment of social and occupational functioning and decreased quality of life. OCD is treated with a combination of psychopharmacological treatments and cognitive-behavioural therapy. Clomipramine was the first anti-obsessive drug, and was followed by selective serotonin re-uptake inhibitors (SSRIs), both modulating serotonergic transmission. Low dose atypical antipsychotic are sometimes used to potentiate serotonergic agents. Growing evidence based on animal models and on neuroimaging shows that glutamatergic transmission could play an important role in the aetiology of OCD. Therefore, glutamate modulators such as N-methyl-D-aspartate (NMDA) receptor antagonists became the focus of the search of novel treatments for OCD. One of this drugs, memantine, already approved for Alzheimer disease treatment, was used off-label the first time ten years ago in resistant case of OCD with positive results. Besides some further successful case reports, there are a single-blind case control study and a couple of randomized, double-blind, placebo-controlled trials showing improvement of OCD symptoms with memantine adjuvant pharmacotherapy.

Objectives and aims To describe a case report of off-label treatment of a severe resistant case of OCD with memantine, after 15 weeks of treatment.

Methods Literature review and case description. Before beginning treatment with memantine, the patient made a psychological assessment (baseline) with a battery of tests (MINI Plus, Y-BOCS, QPP-15, WDO, ECPAD, OP2, OAS2, MPS-H&F, MPS-F, HEXACO-PI-R, MOCI, BDI-II). This battery will be repeated after 15 weeks of treatment, to evaluate symptom improvement.

Results and conclusions To be announced after 15 weeks of treatment course.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Increased levels of oxytocin in adult OCD patients

F. Mucci*, D. Marazziti, S. Baroni, A. Piccinni, G. Massimetti, L. Dell'osso

Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy

* Corresponding author.

Introduction The current model of the pathophysiology of obsessive-compulsive (OCD) is mainly centered on the serotonin (5-HT) system. However, other pharmacological targets have been identified, in particular the dopamine and glutamate systems, and also the neuropeptide oxytocin (OT), both per se and given its interactions with the 5-HT system.

Objectives Given the paucity of information, the present study aimed at evaluating plasma OT levels in a group on untreated OCD patients.

Aims The study aimed at evaluating plasma OT levels in a group of 44 OCD outpatients, as compared with a similar group of healthy control subjects. On the same time, the relationships between OT and clinical features and romantic attachment characteristics were examined as well.

Methods Diagnosis was assessed according to DSM-IV-TR criteria, while the OCD severity was measured by means of the Y-BOCS rating scale. All patients were drug-free and not depressed. The romantic attachment was assessed by means of the Italian version of the "Experiences in Close Relationships" questionnaire. Plasma OT levels were evaluated by means of a standard RIA kit.

Results The main findings of our study showed that OT levels were increased in OCD patients, as compared with healthy subjects, and negatively related to symptom severity. Positive relationships were detected between OT levels and the fearful-avoidant and dismissing styles of romantic attachments, but only in male OCD patients.

Conclusions Taken together, these findings suggest that OT may play a role in OCD pathophysiology and also in romantic attachment of patients with gender specificity.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Despite the potential theoretical and clinical relevance of psychopathological dimensions in Obsessive-Compulsive Disorder (OCD), few studies to date have investigated their possible association with obsession subtypes.

Objectives/Aims We aimed to examine whether, in OCD patients, anger and other psychopathological dimensions are associated with specific obsession subtypes.

Methods We consecutively recruited 57 first-visit DSM-V OCD patients (females = 66.7%; age range = 18–63 years) at the Psychiatric Outpatient Clinic of our University Hospital. These patients were affected by severe OCD, as shown by a median (1st quartile–3rd quartile) Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) score of 27.0 (23.0–32.5). We used the point-biserial coefficient (r_{pbi}) to measure the correlation between psychopathological dimensions, as assessed with the Scale for the Rapid Assessment of Psychopathology (SVARAD), and obsession subtypes, as evaluated with the Y-BOCS.

Results We found significant correlations (P -values < 0.05) between: anger/aggressiveness dimension and aggressive, contamination, and sexual obsessions; apprehension/fear dimension and contamination, religious, and somatic obsessions; sadness/demoralization dimension and contamination and somatic obsessions; obsessiveness/iterativity dimension and all obsession subtypes; impulsivity dimension and aggressive and sexual obsessions; somatic concern/somatization dimension and contamination and somatic obsessions. We also found, by using the Mann-Whitney U -test, that OCD patients with comorbid Obsessive-Compulsive Personality Disorder—but not Schizotypal or Histrionic ones—showed higher levels (P < 0.05) of obsessiveness/iterativity and anger/aggressiveness than OCD patients without the personality disorder.

Conclusions Anger and other psychopathological dimensions seem to be linked with specific obsession subtypes in OCD patients, suggesting an association between these dimensions and OCD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does cognitive flexibility moderate the relationship between disgust sensitivity and contamination fear?

E. Powell

Ferndown, United Kingdom

High disgust sensitivity and poor cognitive flexibility have been independently identified as contributing factors in the aetiology of obsessive-compulsive disorder. This study looks at the relationship between contamination fear and disgust sensitivity in a non-clinical population. In particular, at whether two moderating factors, cognitive flexibility and emotional reappraisal, have a buffering influence. One hundred participants from an undergraduate population completed a battery of questionnaires which rated their disgust and level of contamination fear. They also completed a set-shifting task to assess cognitive flexibility and an emotion regulation questionnaire. The mean age of the sample was 21.4 years with 62% of the sample population being female. SPSS 16 was used to correlate the main variables using Pearson's correlation and moderated regression, using MODPROBE, was used for analysis. Results confirmed previous findings that high disgust sensitivity is significantly associated with contamination fear (P < 0.01). In addition to this, both cognitive flexibility and emotional reappraisal reduced the influence that disgust has on an individual's contamination fear. Cognitive flexibility and emotion reappraisal were not found to be significantly correlated to each other (P = 0.511), which suggest that these variables moderate the relationship between disgust and contamination fear independently of each other. Individuals with poor cognitive flexibility and/or poor emotional reappraisal were found to have high levels of contamination fear, which suggests that these two variables may attenuate the relationship between disgust and contamination fear. Future implications of these findings have been discussed although further research is needed to confirm these conclusions in a clinical population.

The comorbidity of cluster C personality disorders in obsessive compulsive disorder as a marker of anxiety and depression severity

A. Pozza^{1,*}, S. Domenichetti², G.P. Mazzoni³, D. Dèttore⁴

¹ University of Florence, Department of Experimental and Clinica Medicine, Florence, Italy

² Florence Healthcare Services, Department of Mental Health, Florence, Italy

³ "Studi Cognitivi" Cognitive Psychotherapy and Research Center, Postgraduate Program on Cognitive Psychotherapy, Florence, Italy

⁴ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Comorbid Cluster C Personality Disorders (PDs) are the most prevalent PDs in Obsessive-Compulsive Disorder (OCD). Investigating clinical correlates associated to OCD with Cluster C PDs may allow identifying tailored treatment strategies.

Objectives The current study examined whether OCD with comorbid cluster C PDs is associated to more severe OCD symptoms, anxiety and depression relative to OCD with comorbid cluster B PDs or OCD alone.

Methods Two hundred thirty-nine patients with OCD were included (mean age = 35.64, SD = 11.08, 51% females). Seventeen percent had a comorbid Cluster C PD, 8% had a comorbid Cluster B PD, and 75% had OCD alone. The Structured Clinical Interview for Axis II Disorders, Yale-Brown Obsessive Compulsive Scale, Beck Anxiety Inventory, Beck Depression Inventory-II were administered.

Results Patients with comorbid Cluster C PDs reported more severe depression and anxiety than those with comorbid Cluster B PDs (F = 10.48, P < 0.001) or with OCD alone (F = 9.10, P < 0.001). Patients with comorbid Cluster C PDs had more severe OCD symptoms than those with OCD alone but not than those with comorbid Cluster B PDs (F = 3.12, P < 0.05).

Conclusions OCD with Cluster C PDs could be a subtype with more severe anxiety and depression. These findings could be explained with the fact that Cluster C PDs are characterized by behaviours, which can be seen as maladaptive attempts to cope with anxiety and depression. Tailored treatment strategies for OCD with comorbid Cluster C PDs are discussed to target co-occurring anxiety and depression.

Group cognitive behavioural therapy for outpatients with obsessive-compulsive disorder in a psychiatric service in Italy

A. Pozza^{1,*}, S. Domenichetti², A. Tanini², E. Ruggieri², D. Dèttore³

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² Healthcare Services of Florence, Department of Mental Health, Florence, Italy

³ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Group Cognitive Behavioural Therapy (GCBT) is a cost-effective modality of treatment alternative to individual Cognitive Behavioural Therapy (CBT). Despite several well-controlled trials demonstrated the efficacy of GCBT for Obsessive Compulsive Disorder (OCD), few studies evaluated the effectiveness of GCBT on outpatients attending routine psychiatric services, and in Italy this topic appears understudied.

Objectives The current study evaluated the effectiveness of a GCBT protocol on OCD symptoms and comorbid depression and anxiety in a group of outpatients attending a psychiatric service in Italy.

Method Twenty outpatients with a diagnosis of OCD were included in the study and received 20 sessions of GCBT, consisting of psychoeducation on anxiety and OCD, relaxation training, in vivo/imaginal exposure and response prevention, cognitive restructuring for obsessive beliefs, cognitive defusion, and assertiveness training. The Yale-Brown Obsessive Compulsive Scale (Y-BOCS), Beck Depression Inventory (BDI-II), Beck Anxiety Inventory (BAI) were administered at pre- and post-treatment.

Results Two outpatients had a comorbid bipolar disorder, eight had a concurrent personality disorder. Ten outpatients were on concurrent antidepressants, five on antipsychotics. Three outpatients prematurely dropped out from treatment. Among completers, GCBT produced significant changes on OCD symptoms, anxiety and depression from pre- to post-treatment. The GCBT protocol was feasible and the outpatients reported high satisfaction judgements.

Conclusions Future studies should investigate clinical predictors of best response after GCBT and assess maintenance of symptom changes at long-term follow-up.

Cognitive behavioral therapy in pharmacoresistant obsessive-compulsive disorder

J. Vyskocilova¹, J. Prasko^{2,*}

¹ Charles University Prague, Faculty of Humanities, Prague, Czech Republic

² University Hospital Olomouc, Faculty of Medicine and Dentistry, University Palacky Olomouc, Department of Psychiatry, Olomouc, Czech Republic

* Corresponding author.

Background The aim of the study was to determine whether patients with OCD resistant to drugs may improve using intensive, systematic CBT lasting six weeks and whether it is possible to predict the therapeutic effect using demographic, clinical and psychological characteristics at baseline.

Method There were 66 patients included in the study. Fifty-seven patients completed the program. The diagnosis was confirmed by a structured interview MINI. Patient were rated before the treatment using Y-BOCS (objective and subjective form), CGI (objective and subjective form), BAI, BDI, DES (Dissociative Experiences Scale), SDQ 20 (Somatoform Dissociation Questionnaire), and SDS (Sheehan Disability Scale), and at the end of the treatment using subjective Y-BOCS, objective and subjective CGI, BAI, and BDI. Patients were treated with antidepressants and daily intensive group cognitive behavioral therapy for the period of six weeks.

Results During the 6-week intensive cognitive behavioral therapy program in combination with pharmacotherapy, there was a significant improvement in patients suffering from OCD formerly

resistant to pharmacotherapy. There were statistically significant decreases in the scales assessing the severity of OCD symptoms, anxiety, and depressive feelings. The lower treatment effect was achieved specifically in patients who:

- showed fewer OCD themes in symptomatology;
- showed a higher level of somatoform dissociation;
- with poor insight;
- with a higher level of overall severity of the disorder in the beginning.

The remission of the disorder was achieved more probably in patients with:

- good insight;
- the lower level of initial anxiety;
- without comorbidity with the depressive disorder.

Investigation of affective temperaments and chronobiology in patients with obsessive-compulsive disorder

A. Sakalli Kani^{1,*}, C. Aksoy Poyraz², B.C. Poyraz², M.R. Bayar²

¹ Sivas Numune State Hospital, Psychiatry, Sivas, Turkey

² Istanbul University, Medical School of Cerrahpasa, Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Comorbid mood disorders affect negatively the prognosis of obsessive-compulsive disorder (OCD). Affective temperaments are assumed to be subsyndromal symptoms and precursors of mood disorders but its effects on OCD outcome remain unclear. There is a body of evidence, which supports the association between circadian rhythm disturbances and mood disorders in literature. In contrast, there is limited data concerning the effects of chronobiological preference among the patients with OCD and OCD comorbid mood disorders.

Objective The aim of this study is to assess the clinical effects of affective temperaments and chronotype differences in patients with OCD.

Methods The research was performed in patients with OCD which have been under treatment at least for 12 weeks ($n = 76$) and healthy controls ($n = 55$). Yale Brown Obsession Compulsion Scale, TEMPS-A, Morningness and Eveningness Questionnaire, Hamilton Anxiety Rating Scale and Hamilton Depression Rating Scale were used in the study.

Results There were higher scores in depressive, cyclothymic, irritable and anxious temperaments in patients with OCD compared to the healthy group. There were significant differences between patients with remission and not remission in depressive, cyclothymic, irritable and anxious temperaments. Compared to healthy group eveningness chronotype was more frequent in patients; however the difference was not statistically significant. The OCD patients did not differ from comorbid anxiety, depression and remission levels according to the chronotype.

Conclusion Understanding the effects of affective temperaments and chronotype differences on the outcome of patients with OCD, may provide developing new treatment approaches in especially treatment resistant OCD patients.

The mediating role of metacognition in the relation between intolerance of uncertainty and obsessive-compulsive disorder

S.Y. Sohn^{1,*}, I. Sohn¹, S.Y. Lee², S. Kim¹

¹ Yonsei University College of Medicine, Department of Psychiatry and Institute of Behavioral Science in Medicine, Seoul, Republic of Korea

² Dankook University College of Medicine, Cheil General Hospital & Women's healthcare center, Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction Obsessive-compulsive disorder (OCD) is a severe and incapacitating psychiatric disorder that is characterized by recurrent intrusive thoughts (obsession). Maladaptive metacognition have been found to be associated with anxiety and various psychopathology. Also, intolerance of uncertainty is considered to be related with anxiety and ambivalence. These characteristics are considered to be key characteristics of OCD.

Objectives This study conceptualized metacognition as a mediator in the relation between intolerance of uncertainty and obsessive-compulsive symptom.

Aims This study was aimed to find prerequisites for development of OCD.

Methods The recruitment includes 150 OCD subjects and 50 healthy controls. Subjects were investigated with the metacognition questionnaire (MCQ) and intolerance of uncertainty questionnaire (IOU) as self-report measures. Participants with OCD completed the Obsessive-Compulsive Inventory-Revised (OCI-R). The OCI-R taps six OCD symptom dimensions: checking, hoarding, neutralizing, obsessing, ordering and washing.

Results OCD subjects showed significantly higher metacognition score and significantly higher intolerance of uncertainty score than control group. In OCD group, the results indicated that metacognition partially mediated the relationship between intolerance of uncertainty and obsessing.

Conclusions Our findings suggest that metacognition may explain the mechanism by which intolerance of uncertainty exerts its effect on obsession.

* Corresponding author.

Introduction Primary or secondary CNS tumors are among the most difficult to manage forms of cancer. Treatment of these tumors remains a challenge in oncology and the success rates for treatment of brain tumors are much lower than in extracerebral localizations. Because most chemotherapeutic agents do not cross the

blood-brain barrier effectively and surgery is sometimes only palliative, radiotherapy remains the main method of treatment of these lesions. Both localized and generalized brain radiotherapy have numerous psychiatric complications.

Objectives The objective of the study was to assess the psychiatric comorbidities in patients with brain tumors receiving radiotherapy.

Aims This is an intermediate report of a larger study that assesses comorbidities in patients with brain tumors after radiotherapy.

Methods Twenty-five patients with different localization brain tumors were included in this observational study before receiving radiotherapy. All patients were assessed using Hospital Anxiety and Depression Scale (HADS) for anxiety and depressive symptoms, Montreal Cognitive Assessment (MOCA) for cognitive impairment and Quality of Life Enjoyment and Satisfaction Questionnaire–Short Form (Q-LES-Q-SF) at inclusion and after 3 months from finishing the radiotherapy sessions.

Results Twenty-two patients completed the study. Nine patients received antidepressant treatment (sertraline, tianeptine) during the study for depressive symptoms or anxiety. Patients receiving antidepressants showed better scores on HADS, MOCA and Q-LES-Q-SF scales.

Conclusions Antidepressant use in patients receiving radiotherapy for brain tumors could be neuroprotective and could improve quality of life.

* Corresponding author.

Introduction Oncology-related illnesses have become quite frequent in our lives. Lately, medical progress in the field of oncology has led to an increase in the survival rates of people diagnosed with cancer. The minimisation of disturbances in the lives of these people is done by each on their own, by using defence mechanisms and coping skills.

Objectives To identify the coping and defence mechanisms of subjects diagnosed with cancer compared with non-clinical subjects.

Aims To increase quality of life of subjects diagnosed with cancer through psychotherapy interventions.

Method Nineteen subjects diagnosed with cancer who were receiving chemotherapy were recruited to the study. For comparison, a control group of non-clinical participants were also recruited. Participants were included into the study according to particular inclusion/exclusion criteria. The evaluation was conducted during 2014 and consisted of the analysis of the following parameters: socio-demographic data, clinical data, defence mechanisms (DSQ-60) and coping mechanisms (COPE scale).

Results The group of subjects diagnosed with cancer demonstrated the presence of defence mechanisms of the following type: passive aggressiveness, projection and coping mechanisms that were characterised by an emphasis on social support. The control group had defence mechanisms of the following types: repression, denial and coping mechanisms that focused on emotions.

Conclusions There are differences in defence and coping mechanisms between subjects with cancer compared to the non-clinical group. It may be that defence and coping mechanisms can be optimized through psychotherapy interventions to increase quality of life.

³ NHIS Ilsan Hospital, Department of Policy Research Affairs, Goyang, Republic of Korea

* Corresponding author.

Purpose Sleep disturbance in cancer patients is common. The aim of this study is to investigate the risk of sleep disorders in cancer patients compared to patients with other diseases using the national registry data.

Method Using data from the Korean National Health Insurance Research Database between 2002 and 2013, the cancer group was composed of patients with an initial diagnosis of cancer in 2004 ($n = 3358$). The remaining people were considered as comparison group ($n = 493,577$) after excluding patients with any cancer or psychiatric disorder from 2002 to 2003 and from 2005 to 2013. Each sampled subject was tracked until 2013. Cox proportional hazard regressions were used to calculate the overall rate for sleep disorder development after adjusting for age, gender, and socio-economical confounders.

Results Cancer patients were associated with an increased risk of sleep disorder in both sexes (male hazard ratio [HR]: 1.319; 95% confidence interval [CI]: 1.232–1.413; female HR: 1.289; 95% CI: 1.198–1.386) after adjusting for potential confounders. Both results were statistically significant ($P < 0.001$). In terms of age, the effect size of the HR was largest among elder adults, aged ≥ 70 years (male HR: 1.748; female HR: 1.820). The HR tended to increase consistently.

Conclusion Initial diagnosis of cancer was significantly associated with sleep disorder development after adjusting for potential confounders. This result suggests that thorough screening and intervention for sleep disorders are required for the newly diagnosed cancer patients to improve their quality of life.

The relationship between depression and family support in breast cancer patients

J.A. Su

Chang Gung Memorial Hospital, Chiayi, Department of Psychiatry, Chiayi, Taiwan

Background Breast cancer is the most frequent cancer in women and depression is one of the common psychiatric diagnoses in survivors. Herein, we tried to explore the point prevalence of major

depressive disorder among breast cancer patients and find out the relation of family support with depression.

Methods Data of the study are from breast cancer clinic of a general hospital in central Taiwan. The patients who were diagnosed as breast cancer were recruited. We used the Family APGAR scale to assess the family support and the diagnosis of major depressive disorder was evaluated by MINI.

Results We found that the point prevalence of major depressive disorder of breast cancer patients was 8.3% and was related to pain severity, cancer duration, radiotherapy, hormone therapy and family support. Family support was a protective factor of major depressive disorder in breast cancer.

Conclusion Healthy professionals should notify the related factors of depression as well as the importance of family support when treating women with breast cancer.

Introduction Rehabilitation of concurrent psychiatric disorder and brain injury is a major challenge. E. underwent neurosurgery for right fronto-parietal astrocytoma. Before illness he was managing automatization of big companies, but was fired after the operation. E. fell into severe depression and anxiety with catastrophization of his illness, suicidal ideation. He resisted multiple prescriptions for SSRI, admitting a sect pretending to "treat" oncology by "psychological" methods. Half a year after operation he attended our center.

Objectives and aim To help E. return to paid employment.

Methods E. was evaluated by neurologists, psychiatrist, neuropsychologists. Current depressive episode appeared to be the second one with underlying schizoid and perfectionist characteristics. He had moderate text comprehension difficulties, confabulations, slight executive dysfunction. Neuropsychologist educated patient on his difficulties and developed compensatory strategies – an alternative to catastrophisation. After psychoeducational session E. agreed to receive fluvoxamine. However, he deformed the received information due to brain injury, so psychotherapy had only minor effects. Infra-low frequency neurofeedback at T4P4 and T4Fp2 sites was started to promote restoration of right brain functions. E. gradually did better, and 3 months later was able to complete CBT course along with relaxation training.

Results Improvements in emotional status along with ability to cope with cognitive difficulties allowed E. to return to a job similar to the previous. Six months after the start of treatment medications are tapered off, E. has no signs of depression and only slight anxiety.

Conclusions Interdisciplinary holistic rehabilitation may be effective in concurrent psychiatric disorder and brain injury.

* Corresponding author.

Catastrophism is a variable of great importance in the study of pain. Catastrophism refers to a negative and exaggerated compared to the experience of pain, both real and anticipated mental perception (Sullivan, Bishop and Pivick, 1995; Sullivan et al., 2001). The current study to compare the levels of catastrophism in patients with and without fibromyalgia. This study is cross-cutting and comparative. Twenty participants (M: 47.20; SD: 12.11) distributed as the following way:

- group 1: patients with fibromyalgia previously diagnosed through the American College of Rheumatology criteria ($n = 10$);
- group 2: Clinical depression, defined according to the DSM-5 ($n = 5$);
- group 3: healthy patients ($n = 5$) paired by age with the group of Fibromyalgia.

The PCS, a self-administered, was used to measure Catastrophism. Responses were summed to yield three different subscales: Rumination, Magnification and Helplessness. This instrument is validated in both experimental and clinical population (Van Damme, Crombez, Bijttebier, Gouber and Van Houdenhove, 2002; Edwards et al., 2006). A comparison among the three groups was established using one-way factor ANOVA. The results point out that patients with fibromyalgia have higher levels of magnification controls with depression and healthy group ($P < 0.05$). In contrast, although the average level of Catastrophism total presented a greater tendency in fibromyalgia patients no statistically significant differences were found. This is discussed in relation to the literature, a higher level of magnification to explain pain and maintaining the chronicity of the disease. It is important to consider the component catastrophism to have a multidimensional view of pain.

EW375

Women that present fibromyalgia have higher levels in all scales of catastrophism

K. Cabas-Hoyos
Universidad Pontificia Bolivariana, Grupo CAVIDA, Montería, Colombia

Fibromyalgia patients value their pain as modern high and they perceive it more as a threat than as a challenge (Ayan, 2011). There is a relative consensus related to catastrophic thoughts that seems to play an important role in the maintenance of chronic pain (Esteve, Ramírez and López, 2001). The objective of the present study was to explore the level of catastrophism in women with and without fibromyalgia. Adult women ($n = 39$) with an average

of 47 years old (TD: 12.14) and more than 12 years schooling, paired with healthy controls ($n = 39$) with similar characteristics. Patients with fibromyalgia were previously diagnosed according to ACR (American College of Rheumatology). This was a cross-sectional study, comparative and quantitative cut. An ANOVA was used to compare both groups. The level of catastrophism was measured through the Pain Catastrophizing Scale (Sullivan, Bishop and Pivick, 1995). Scale composed of 13 questions and three subscales: rumination, magnification and hopelessness. This instrument has been tested in both clinical and non-clinical populations (Osman et al., 2000; Sullivan et al., 1995). Rumination, magnification and hopelessness were trend significantly higher in the women group with Fibromyalgia. [Rumination: $F(1.36) = 6.22$; $P = 0.00$]; [Magnification: $F(1.36) = 17.66$; $P = 0.00$]; [Hopelessness: $F(1.36) = 6.53$; $P = 0.00$]. These results allowed that the total catastrophism level was higher in the women group with Fibromyalgia and that the statistical significance level was reached [$F(1.36) = 9.89$; $P = 0.00$]. This type of studies will allow to study the pain as a multidimensional entity comprised of physical, cognitive and affective aspects.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Chronic non-malignant pain (CNMP) and substance use disorders

L. Herrera Duran^{1,*}, I. Falgas², B. Cook³, N. Noyola¹, M. Toro¹, M. Alegria¹

¹ Massachusetts General Hospital, Disparities Research Unit, Boston, USA

² Vall d'hebrón University Hospital/Universitat Autònoma de Barcelona, Department of Psychiatry and Forensic Medicine, Barcelona, Spain

³ Cambridge Health Alliance and Harvard Medical School, Health Equity Research Lab, Boston, USA

* Corresponding author.

Introduction Chronic non-malignant pain (CNMP) is defined as pain lasting a minimum of three months. In general, chronic pain affects 20% adult worldwide population. Moreover, pain is more common in patients with depression, anxiety, and substance-use disorders and with low socioeconomic status. We aimed to better understand the influence of pain on substance use and treatment use patterns of individuals who experienced clinically recognized pain and have substance use disorder.

Methods Patients with pain disturbances were identified in Electronic Health Records (EHR) through ICD-9 code 338*, medical written diagnoses, or diagnoses of fibromyalgia. A patient was considered to have a substance use disorder if he received treatment for illicit drug or alcohol abuse or dependence. We combined 2010–2012 (EHR) data from primary care and specialty mental health setting in a Boston healthcare system ($n = 131,966$ person-years) and a specialty mental health care setting in Madrid, Spain ($n = 43,309$ person-years).

Results We identified that 35.3% of individuals with clinically recognized pain also report substance use disorder, compared to only 10.6% of individuals without clinically recognized pain ($P < 0.01$). Those with co-morbid pain and substance use disorder were significantly more likely than their specialty care counterparts without co-morbid pain and substance disorders to be seen in the emergency room (56.5% vs. 36.6%, respectively, $P < 0.01$).

Conclusion The findings suggest that CNMP is associated with an increase risk of substance abuse disorder.

³ Faculty of Medicine of the University of Coimbra, Psychological Medicine Department, Coimbra, Portugal

⁴ Coimbra Hospital and University Centre, Department of Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction The Revised-Fibromyalgia Impact Questionnaire (FIQR), composed by 21 items, is one of the most used tools to measure the impact of fibromyalgia both in clinical and research settings. Although it has demonstrated good psychometric properties (Bennet et al., 2009; Costa et al., 2015), little is known about its factorial structure.

Objective/Aims To explore FIQR's factorial structure and examine its association with several psychological constructs.

Methods Hundred and three women with fibromyalgia (mean age 47.32 ± 10.63) filled in the Portuguese validated versions of the FIQR, Perceived Stress Scale, Perseverative Thinking Questionnaire, Beck Depression Inventory-II and Profile of Mood States. A principal components analysis with varimax rotation was carried out. The number of factors to extract was based on Cattell's scree plot and eigenvalues' magnitude. The associations between FIQR dimensions and psychological constructs were examined via Pearson correlations and multiple linear regressions.

Results Three factors were extracted [F1/Function=Items 1–9, $\alpha = 0.92$; F2/Symptoms=Items 12, 16–21, $\alpha = 0.83$; F3/Impact=Items 10, 11, 13–15, $\alpha = 0.83$] explaining 58.57% of the variance. FIQR symptoms were the best and, nearly in all analyses, the only significant predictor.

Conclusions The factorial structure of the Portuguese version of FIQR partially overlaps with the proposed theoretical domains (Bennet et al., 2009). Similarly to Luciano et al.'s study (2013), factorial analysis also evidenced the multidimensionality of some items. Fibromyalgia symptoms seem to play the most deleterious effect, being associated with poor mental health indicators. Future studies are needed to confirm the factorial structure found, due to sample size, items subjectivity and study's exploratory nature.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Unraveling pathways to depression in fibromyalgia, the role of perseverative negative thinking and negative affect

A.M. Pinto^{1,2,3,*}, C. Costa², A.T. Pereira³, M. Marques^{3,4}, J.A. Pereira da Silva², A. Macedo^{3,4}

¹ Faculty of Psychology and Educational Sciences of the University of Coimbra, Cognitive and Behavioural Center for Research and Intervention, Coimbra, Portugal

² Faculty of Medicine of the University of Coimbra and Coimbra Hospital and University Centre, Rheumatology University Clinic, Coimbra, Portugal

³ Faculty of Medicine of the University of Coimbra, Psychological Medicine Department, Coimbra, Portugal

⁴ Coimbra Hospital and University Centre, Department of Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Several studies have demonstrated a strong link between fibromyalgia, negative affect (NA) and depression. However, it remains unclear why some fibromyalgia patients get depressed while others do not and, primarily, which mechanisms account for this difference. We hypothesize that, besides clinical features, the engagement in dysfunctional strategies like perseverative negative thinking (PNT) followed by an amplification of NA levels may increase the risk of fibromyalgia patients experiencing depressive symptoms.

Objective/Aims To explore the serial mediator effect of PNT and NA on the relationship between fibromyalgia symptoms and depressive symptoms.

Methods Hundred and three women with fibromyalgia (mean age 47.32 ± 10.63) completed the Portuguese version of the Revised-Fibromyalgia Impact Questionnaire, Perseverative Thinking Questionnaire, Profile of Mood States and Beck Depression Inventory-II. The association between the variables was investigated via Pearson correlations and serial multiple mediation.

Results The estimated model was significant [$F(3.86) = 57.318$, $P < .001$] explaining 66.66% of depressive symptoms variance. The total effect of fibromyalgia symptoms on depressive symptoms was of .4998 ($SE = 0.0795$, $P < 0.001$; $CI > 0.3417$ and < 0.6578), with a significant direct effect of 0.1911 ($SE = 0.0653$; $CI > 0.0614$ and < 0.3209). The total indirect effects were of 0.3086 ($SE = 0.0619$; $CI > 0.2033$ < 0.4458). Three significant specific indirect effects were found.

Conclusion The effect of fibromyalgia symptoms on depressive symptoms is partially operated through cognitive interference/unproductiveness, which in turn influences NA levels. Such findings highlight the crucial role of these constructs in the relationship between fibromyalgia symptoms and depressive symptoms and the urge to address them when treating individuals reporting greater fibromyalgia symptoms.

⁶ University of Hong Kong, School of Public Health, Hong Kong, China

* Corresponding author.

Introduction A body of evidence has accrued supporting the Fear-Avoidance Model (FAM) of chronic pain which postulated the mediating role of pain-related fear in the relationships between pain catastrophizing and pain anxiety in affecting pain-related outcomes. Yet, relatively little data points to the extent to which the FAM be extended to understand chronic pain in Chinese population and its impact on quality of life (QoL).

Objective This study explored the relationships between FAM components and their effects on QoL in a Chinese sample.

Methods A total of 401 Chinese patients with chronic musculoskeletal pain completed measures of three core FAM components (pain catastrophizing, pain-related fear, and pain anxiety) and QoL. Cross-sectional structural equation modeling (SEM) assessed the goodness of fit of the FAM for two QoL outcomes, Physical (Model 1) and Mental (Model 2). In both models, pain catastrophizing was hypothesized to underpin pain-related fear, thereby influencing pain anxiety and subsequently QoL outcomes.

Results Results of SEM evidenced adequate data-model fit (CFI³0.90) for the two models tested (Model 1: CFI = 0.93; Model 2: CFI = 0.94). Specifically, pain catastrophizing significantly predicted pain-related fear (Model 1: stdb = 0.90; Model 2: stdb = 0.91), which in turn significantly predicted pain anxiety (Model 1: stdb = 0.92; Model 2: stdb = 0.929) and QoL outcomes in a negative direction (Model 1: stdb = -0.391; Model 2: stdb = -0.651) (all *P* < 0.001) (Table 1, Fig. 1).

Conclusion Our data substantiated the existing FAM literature and offered evidence for the cross-cultural validity of the FAM in the Chinese population with chronic pain.

Table 1 Results of SEM testing the FAM for two QoL outcomes.

Model	S-B χ^2	df	P value	CFI	NNFI	RMSEA	90% CI	SRMR
Model 1: QoL-Physical	147.70	33	<0.001	0.93	0.90	0.10	0.09, 0.12	0.05
Model 2: QoL-Mental	141.50	33	<0.001	0.94	0.91	0.10	0.08, 0.18	0.05

Note: The FAM hypothesized that pain catastrophizing is the predictor of pain-related fear, which influenced pain anxiety and subsequently pain adjustment outcomes. QoL-Physical was indexed the SF-12 physical component score; QoL-Mental was indexed by the SF-12 mental component score. S-B χ^2 = Satorra & Bentler scaled chi-square statistics; df = degrees of freedom; CFI = comparative fit index; NNFI = non-normed fit index; RMSEA = root mean square error of approximation; CI = confidence interval; SRMR = standardized root mean square residual.

* Corresponding author.

Introduction While a body of research has evidenced the role of pain coping in chronic pain adjustment, the role of coping flexibility in chronic pain adjustment has received little research attention. Coping flexibility can be conceptualized with two dimensions, cognitive and behavioral. The cognitive dimension of coping flexibility (or coping appraisal flexibility) refers to one's appraisal of pain experience when changing coping strategies whereas the behavioral dimension of coping flexibility denotes the variety of coping responses individuals use in dealing with stressful demands.

Objective The aim of this paper is to present preliminary findings on the role of coping flexibility in chronic pain adjustment by assessing 3 competing models of pain coping flexibility (see Figs. 1–3).

Methods Patients with chronic pain (*n* = 300) completed a battery of questionnaire assessing pain disability, discriminative facility, need for closure, pain coping behavior, coping flexibility, and pain catastrophizing. The 3 hypothesized models were tested using structural equation modeling (SEM). In all models tested, need for closure and discriminative facility were fitted as the dispositional cognitive and motivational factors respectively underlying the coping mechanism, whereas pain catastrophizing and pain intensity were included as covariates.

Results Results of SEM showed that the hierarchical model obtained the best data-model fit (CFI = 0.96) whereas the other two models did not attain an accept fit (CFI ranging from 0.70–0.72).

Conclusion Our results lend tentative support for the hierarchical model of pain coping flexibility that coping variability mediated the effects of coping appraisal flexibility on disability.

Figure 1

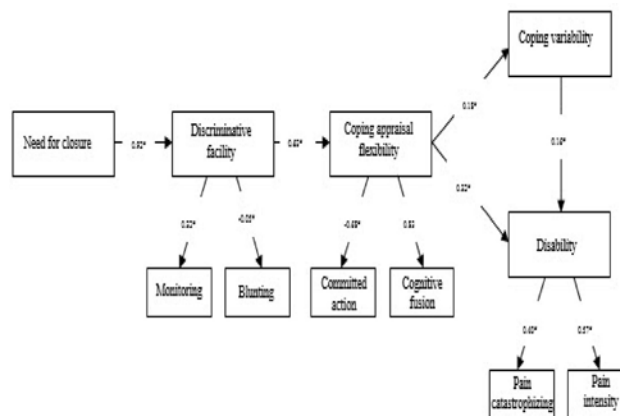

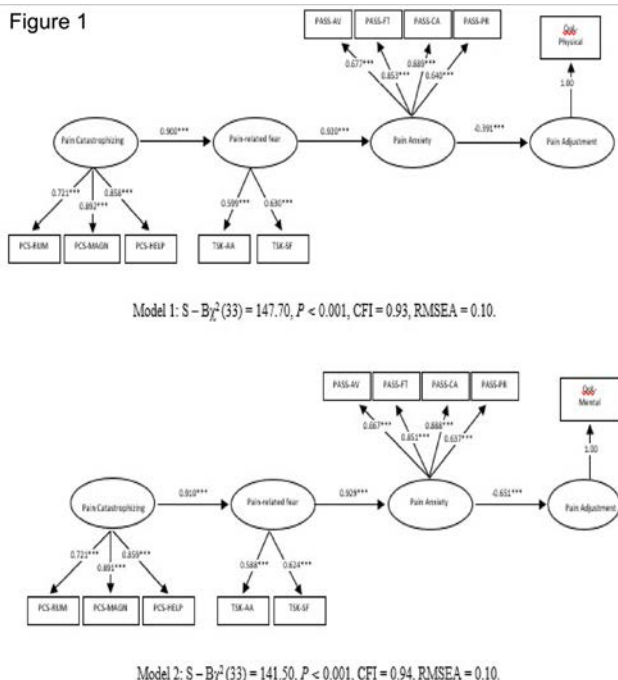

Fig. 1

Fig. 1 The hierarchical model (S-B χ^2 = 40.61, df = 24, CFI = 0.959, NNFI = 0.94, EMSEA = 0.06, 90% CI = 0.02, 0.09).

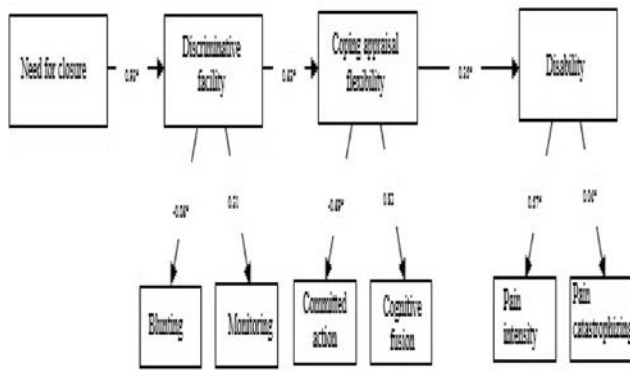

Fig. 2 The coping appraisal flexibility model (S-B $\chi^2 = 121.62$, $df = 19$, CFI = 0.723, NNFI = 0.59, RMSEA = 0.17, 90% CI = 0.14, 0.19).

Fig. 3 The parallel model (S-B $\chi^2 = 147.51$, $df = 25$, CFI = 0.695, NNFI = 0.56, EMSEA = 0.56, 90% CI = 0.13, 0.18).

The relationship between pain coping variability and committed action in chronic pain adjustment

W. Wong^{1,*}, P. Chen², Y. Chow³, H. Lim⁴, S. Wong³, L. McCracken⁵, R. Fielding⁶

¹ Hong Kong Institute of Education, Dept of Special Education & Counseling, Hong Kong, China

* Corresponding author.

Introduction Research evidenced the association of pain coping strategies with short-term and long-term adjustments to chronic pain. Yet, previous studies mainly assessed the frequency of coping strategies when pain occurs whilst no data is available on one's flexibility/rigidity in using different pain coping strategies, i.e., pain coping variability, in dealing with different situations.

Objectives This study aimed to examine the multivariate association between pain coping variability and committed action in predicting concurrent pain-related disability. Specifically, we examined the independent effects of pain coping variability and committed action in predicting concurrent pain-related disability in a sample of Chinese patients with chronic pain.

Methods Chronic pain patients ($n = 287$) completed a test battery assessing pain intensity/disability, pain coping strategies and variability, committed action, and pain catastrophizing. Multiple regression modeling compared the association of individual pain coping strategies and pain coping variability with disability (Models 1–2), and examined the independent effects of committed action and pain coping variability on disability (Model 3).

Results Of the 8 coping strategies assessed, only guarding (std $\beta = 0.17$) was emerged as significant independent predictor of disability (Model 1). Pain coping variability (std $\beta = -0.10$) was associated with disability after controlling for guarding and other covariates (Model 2) and was emerged as independent predictor of disability (Model 3: std $\beta = -0.11$) (all $P < 0.05$) (Tables 1 and 2).

Conclusions Our data offers preliminary support for the multivariate association between pain coping variability and committed action in predicting concurrent pain-related disability, which supplements the existing pain coping data that are largely based on assessing frequency of coping.

Table 1 Multiple regression models predicting concurrent pain-related disability with pain coping strategies and pain coping variability.

Predictors	Model 1		Model 2	
	Std β	95% CI	Std β	95% CI
Income	-0.01	-0.53, 0.42	-0.05	-0.55, 0.37

The Big Five Inventory (BFI): Reliability and validity of its Arabic translation in non clinical sample

B. Alansari

Kuwait University, Faculty of Social Sciences, Psychology, Kaifan, Kuwait

Introduction One of the most researched theories of personality is the Five Factor Model, frequently evaluated through the Big Five Inventory 44-item BFI. Although there is an Arabic version, its psychometrical properties in Kuwaiti population are yet unknown. **Objectives** The objective of this study was to evaluate the psychometric properties of the BFI and its factorial structure in an Arabic non-clinical sample.

Methods The participants were 685 first year undergraduate Kuwaitis: 305 males mean age = 22.77 ± 4.57 and 380 females; mean age = 19.61 ± 2.59). The Arabic version of BFI (John and Srivastava, 1999) was administered to participants. The internal consistency reliability, factor structure, and convergent validity of the BFI with PFQ-C (Barbaranelli, Caprara, Robasca, and Pastorelli, 2003) were assessed.

Results Internal consistency was satisfactory for the Neuroticism, Extraversion, and Openness to Experience, Agreeableness, and Conscientiousness subscales respectively (Cronbach's alpha = 0.83, 0.82, 0.79, 0.82, 0.90) for males and (Cronbach's alpha = 0.74, 0.83, 0.85, 0.81, 0.92) for females. The results revealed significant gender differences where the males obtained a higher score than females on extraversion and conscientiousness, while females obtained a higher score than males on neuroticism. Principal component analyses (PCA) showed that a five-component solution explains 42.27% of the total variance for males and 41.47% for females. The convergent correlations in sample between the BFI and PFQ-C (mean $r = 54$) for validity coefficients.

Conclusion These findings suggest that the BFI is a brief measure of the Big Five personality traits and it provides satisfactory reliable and valid data.

Intergenerational transmission of psychopathy and mediation via psychosocial risk factors

K. Auty

Institute of Criminology, Faculty of Law, Cambridge, United Kingdom

Introduction Intergenerational continuities in criminal behaviour have been well documented, but the familial nature of psychopathic personality is less well understood.

Objectives To establish if there is an association between the psychopathic traits of a community sample of males and their offspring and whether psychosocial risk factors mediate.

Methods Participants of the Cambridge Study in Delinquent Development ($n = 478$ dyads) were assessed for psychopathy using the PCL: SV. Multilevel regression models were used to investigate intergenerational continuity and mediation models examined indirect effects.

Results The fathers' psychopathy was transmitted to both sons and daughters. The transmission of Factor 1 scores was mediated via the father's employment problems. For males, the Factor 2 scores were mediated via the fathers' drug use, accommodation and employment problems, for females, Factor 2 scores were mediated via the father's employment problems.

Conclusions Understanding of the specific role of certain psychosocial risk factors may be useful in developing preventative measures.

EW384

Relationship between happiness and personality variables

G. Baqer

Kuwait University, Department of Psychology, Kaifan, Kuwait

Introduction The focus of interest in this study is to investigate the relationship between happiness and optimism, satisfaction with life, hope, depression, and anxiety. Many efficient instruments have been used in this study, however there is no study until this date that has used the Oxford Happiness Questionnaire (OHQ) within Arabic countries and Kuwaiti samples specifically.

Objectives The aim of the study is to investigate the correlations between happiness and optimism, satisfaction with life, hope, depression and anxiety.

Methods The sample consisted of 510 students from Kuwait University, 270 females and 240 males, with a mean age of 22.8 (SD = 4.1). The OHQ 0.90 alpha was administered to participants, in addition to the Arabic version of Life Orientation Test-Revised (LOT-R) 0.70, The Satisfaction with Life Scale (SWLS) 0.78, The Hope Scale (AHS) 0.60, Beck Depression Inventory (BDI-II) 0.87 and Beck Anxiety Inventory (BAI) 0.95. Correlations were used in this study.

Results The results revealed that all the correlations between OHQ and other scales were significant. Positive correlations have been found with LOT-R $r = 0.50$, SWLS $r = 0.44$, and AHS $r = 0.39$, while there were negative correlations with BDI-II $r = -0.38$ and BAI $r = -0.17$.

Conclusion It was concluded that happiness correlates positively with other personality variables: optimism, satisfaction with life

and hope, while it correlates negatively with Depression and Anxiety.

³ Psychiatry Service, Turkey

⁴ Biochemistry Service, Turkey

* Corresponding author.

Objective The aim of this study is to explore the presence of MTHFR mutation and its correlation with psychometric tests among subjects with antisocial personality disorder.

Methods One hundred and eight male subjects meeting DSM-IV-TR diagnostic criteria for ASPD who admitted to outpatient unit of Department of Psychiatry at GATA Haydarpara Training Hospital were included in the study. The patients and control subjects were assessed by Hare Psychopathy Checklist-Revised, Barratt Impulsiveness Scale (BIS-11), Resilience Scale for adults and Temperament and Character Inventory. Real time PCR method is used in order to identify MTHFR mutation among subjects.

Results In this study; all of the groups showed more “non-planning, lack of control impulsiveness” than other kinds. Also groups weren’t resilient in “perception of future”, “structured style” and “social competence” subgroups, groups with heterozygous and homozygous mutations were and group without mutation wasn’t resilient in “perception of self” subgroup, group with heterozygous mutation + without mutation were and group with homozygous mutation was not resilient in “family cohesion” and “social resources” subgroups. We found high novelty seeking, harm avoidance, cooperativeness, self-directedness points and low reward dependence, self-transcendence points. On the other hand, it’s identified that the impulsiveness among subjects with ASPD was non-planning type.

Conclusion In our study; there was not a significant correlation identified between the MTHFR enzyme mutation and ASPD. We thought that limitation of our study sample and not to measure MTHFR enzyme activity may play role to get these results. Additional work is needed to examine in large groups and with MTHFR enzyme activity measure.

Family skills training in dialectical behaviour therapy: The experience of the significant others

S. Ekdahl^{1,*}, E. Idvall¹, K.I. Perseus²

¹ Malmö University, Faculty of Health & Society, The Department of Care Science, Malmö, Sweden

² Red Cross University College, Department of psychiatric nursing, Stockholm, Sweden

* Corresponding author.

Introduction Borderline personality disorder (BPD) is a severe psychiatric health problem with reputation of being difficult to deal with and to treat. Significant others (SOs) of patients with BPD show higher levels of psychological distress compared with the general population. Strengthening the coping strategies of SOs plays an important role in the recovery of the patient. Support and education for SOs is important, both for SOs themselves and for the patients recovery.

Objectives Research around support and education for SOs is of great importance not only for SOs and patients, but also for psychiatric staff, in order to offer help and support, for the whole family.

Aim The aim was to describe significant others’ experiences of dialectical behaviour therapy-family skills training (DBT-FST), their life situation before and after DBT-FST, and measurement of their levels of anxiety and depressive symptoms.

Methods The study had a descriptive mixed method design. Data were collected with free text questionnaires ($n = 44$), group interviews ($n = 53$) and the HAD scale ($n = 52$) and analysed by qualitative content analysis and descriptive and inferential statistics.

Results The results show that life before DBT-FST was a struggle. DBT-FST gave hope for the future and provided strategies, helpful in daily life. For the subgroup without symptoms of anxiety and depression before DBT-FST, anxiety increased significantly. For the subgroup with symptoms of anxiety and depression the symptoms decreased significantly. This indicates, despite increased anxiety for one group, that DBT-FST is a beneficial intervention and most beneficial for those with the highest anxiety and depressive symptoms.

The purpose of this research was standardizing the questionnaire of personality disorder Cluster A

N. Farrokhi Namini

Islamic Azad University Roudehen Branch, Psychology, Tehran, Iran

Introduction As more or less stable personality traits of the person, temperament, intellect and body that makes an individual unique compatibility with the environment.

Objective The purpose of this research was standardizing the questionnaire of personality disorder Cluster A. On the basis of realizing criterion standard, DSM-5.

Method A total of 1303 people from universities of Tehran and Alborz provinces (753 females and 550 males) were examined by using the randomized sampling method. The questions of the questionnaire were conformed Dr. Shahram Vaziri on the basis of Iran’s population and culture. Then the reliability was tested and accomplished simultaneously Millon (MCMI-III) questionnaire.

Result After computing the correlation scales of Millon test with each of the questions, 20 questions that showed the highest correlation and diagnosis coefficient were chosen and scored again in next stage.

Conclusions Investigating the psychometric component of three scales (Paranoid 60%, Schizoid 66%, Schizotypal 59%) shows that they are reliable and defensibly valid. It can be said that questions related to all three measures paranoid, schizoid and schizotypal of acceptable psychometric properties and reliability are desirable.

Keywords Personality disorder; Cluster A; Paranoid; Schizoid; Schizotypal

Razo Hospital, Psychiatry C, Mannouba, Tunisia
* Corresponding author.

Introduction Several studies have explored the vulnerability to mood disorders that constitute some personality traits.

Aims To study the potential relationship between mood disorders and personality disorders.

Objective We hypothesized that personality disorders can be related to severe mood disorders.

Methods This was a retrospective study including the period from January 2000 till September 2015 and related to patients in whom the diagnosis of mood disorder and personality one were retained according to the criteria of the DSM-IV TR while the sociodemographic and clinical were collected by a pre-established railing.

Results We included 28 patients (15 ♂, 13 ♀). The average age was 38 years. Eighteen (64.3%) patients (7 ♂, 11 ♀) are unemployed. Fifteen patients (10 ♂, 5 ♀) were schooled until secondary level. Seventeen patients (60.7%) were married. The bipolar I disorder (BD I) was most frequently founded (50%), followed by the major depressive disorder in 25% ($n=7$) then by the bipolar II disorder in 21.4% ($n=6$). A case of dysthymia was also noted. Half of the personality disorders were the borderline type, followed by the histrionic type in 28.6% ($n=8$) then by the antisocial in 17.9% ($n=5$) and finally one patient presented a paranoid personality. The antisocial personality was significantly associated with the BD I ($P=0.011$) and half of the patients with a pathological personality, presented a depressive symptomatology.

Conclusion The personality disruption is a factor of severity of the thymic disorders. Consequences on the management of patients and their response to treatments remain available.

Emotional agility – a new language and paradigm for psychiatry

R. Kurz
Cubiks, IPT, Guildford, United Kingdom

Introduction Emotional Agility constitutes an alternative to the DSM-5 personality trait model.

Objective The presentation outlines how Emotional Agility is conceptualised and measured through self-report and multi-rater questionnaires.

Aims The paper highlights the development of a short Emotional Agility trait questionnaire and a corresponding behavioural measure with 18 items.

Method Data ($n=929$) from a substantial personality questionnaire with 161 questions was utilised to create a 54 question 'short form' that measures the Big 5 personality factor plus Need for Achievement through 18 facet scales of 3 items each. Data on the same subjects from a 50-item criterion measure was reduced to 18 items that are structurally aligned to the 18-predictor facets.

Results Predictor reliabilities averaged 0.752 at Factor as well as Facet level. The unit weight sum of the 54 questions achieved an uncorrected validity of 0.28 ($n=929$) against external ratings of effectiveness. Joint factor analysis showed good discrimination between the six factors. A 'positive manifold' of Emotional Agility scales emerged as expected which could be conceptualised as the opposite of the MMPI2 'Demoralisation Factor'.

Conclusion The Emotional Agility approach could ground mental health assessments firmly in positive approaches that use

every-day terminology. It seems preferable to vague scales claiming to measure obscure 'clinical' constructs through hugely overlapping items that are often not fit for purpose.

The relationships among psychopathy, empathy, and aggression

J. Lee^{1,*}, H.J. Lee²

¹ Seoul National University Hospital, Neuropsychiatry, Seoul, Korea

² Seoul National University, Psychology, Seoul, Korea

* Corresponding author.

Introduction The lack of empathy is often described as one of the core characteristics of psychopaths. However, prior studies on cognitive empathy in psychopaths have led to mixed conclusions, with some indicating that psychopaths have no impairments in cognitive empathy.

Objectives This study set out to resolve this inconsistency by distinguishing the two factors that constitute the construct of psychopathy: Factor 1 (e.g., emotional callousness, lack of guilt) and Factor 2 (e.g., irresponsible lifestyle, poor behavioral controls).

Aims The main aim of this study was to examine the differential relationship between these two factors and relevant variables including empathy, aggression, satisfaction with life.

Methods Self-report questionnaires and two online experiments (facial affect recognition task, emotional scenario task) were administered to 306 undergraduate students to collect data about psychopathy, cognitive/affective empathy, aggression, satisfaction with life.

Results Correlation analysis revealed that both Factor 1 and Factor 2 had negative correlations with self-reported measures of cognitive/affective empathy, and only Factor 1 emerged as a significant predictor of both kinds of empathy. Aggression also showed a stronger positive correlation with Factor 1 than with Factor 2, regardless of subtypes (instrumental, reactive, relational, overt aggression). On the other hand, satisfaction with life was more negatively correlated with Factor 2 than Factor 1, and regression analysis revealed that only Factor 2 was a significant predictor.

Conclusions This study showed Factor 1 is more important than Factor 2 in explaining both empathy and aggression in psychopath, while satisfaction with life is better explained by Factor 2 than by Factor 1.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Borderline personality disorder and working memory: A systematic review

S. Marini^{1,*}, C. Ranalli², C. Di Gregorio², E. Cinosi¹, M. Corbo¹, M. Lupi¹, M. Carlucci¹, V. Mancini¹, R. Santacroce¹, F. Vellante¹, T. Acciavatti¹, M. Di Giannantonio¹

¹ University G. d'Annunzio, Neurosciences and Imaging, Chieti, Italy

² Hospital G. Mazzini, Mental Health, Psychiatric Service of Diagnosis and Treatment, Teramo, Italy

* Corresponding author.

Purpose of the study The purpose of this study was to investigate cognitive functioning in Borderline Personality Disorder subjects, with particular reference to the Working Memory functioning. The Working Memory seems to be related to core features of the disorder. The final aim was to better understand the disorder and to implement a cognitive training to improve the deficits.

Methods A literature search was conducted in April 2015. Pubmed and Scopus databases were used to find studies to include

in the systematic review. The keywords used for the literature search were: “borderline personality disorder”, “borderline personality”, “working memory”, “executive functioning”. In each search, the keywords were used together with the logical operator “and”. **Summary** Three studies were included in this systematic review (Table 1). In each study, the working memory was investigated using N-back test. In two of those studies significantly differences were found between patients and healthy group in N-back task. In the third study, which used more tests to investigate working memory domain, no differences were found between the two groups. **Conclusions** Borderline personality disorder patients performed significantly worse on the N-back test compared to healthy controls and the impairment increased with increasing working memory load. In the third study the working memory domain was investigated using four different tests and single scores were not included therefore it was impossible to compare N-back data.

Executive functions (Stroop Color Word Test;ToL4; COWA; WCST; TMT; IGT). Verbal LTM (HVL T). Visual LTM (ROCF; Kimura Recurring Recognition Figures Test). General Cognitive ability (Picture arrangement; Block Design; Picture Completion; Vocabulary; Similarities. All from WAIS III)	BPD have a selective deficits in executive functioning and possibly attention as compared to healthy controls. In the other neuropsychological domains no differences were found between the two groups.
Lazzaretti et al. 2012	15 borderline personality disorder patients, 15 healthy control subjects	N-back, CPT	Borderline personality disorder patients performed significantly worse on the N-back test compared to healthy controls. The N-back deficit was more pronounced and significant in the 3-back condition.
Hagenhoff et al. 2013	28 borderline personality disorder patients, 28 healthy control subjects	Elementary cognitive processes (SRT; SDT; CRT). WM (N-back). Response inhibition (GO/NO-GO TASK). WM and response inhibition (CPT-AX)	Borderline personality disorder patients showed a lower accuracy in N-back task than HC and the impairment increased with increasing WM load. WM deficit not affect response inhibition processes. BPD patients were faster than HC in nearly all task.

Self-Concealment Scale: Validation of two Portuguese versions

M. Costa, A.T. Pereira, M.J. Soares, J. Azevedo*, A. Macedo
Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Self-Concealment Scale (SCS) is composed of ten items to measure self-concealment, defined as a tendency to conceal from others personal information that one perceives as distressing or negative (Larson and Chastain, 1990).

Objective To investigate the psychometric properties of the SCS-10 Portuguese version and of an adapted version containing two additional items specifically focused on self-concealment related to health problems (physical and psychological)–SCS-12.

Methods The Portuguese version of the SCS-12 and other validated questionnaires designed to evaluate self-reported health, perfectionism and optimism-pessimism were administered to a convenience sample of 555 adults from the community (60.5% females; mean age = 43.49 ± 10.565).

Results The SCS-10 and SCS-12 Cronbach's alphas were $\alpha < 0.80$. In both versions, all the items contribute to the internal consistency. The factor analysis, following the Kaiser and the Cattel's Scree Plot criteria, revealed that SCS-10 is unidimensional and that SCS-12 reliably and validly evaluates two dimensions: F1 Keeping secrets (Explained variance = 48.60%; $\alpha = 0.816$), F2 Personal concealment including health problems (9.65%; $\alpha = 0.797$). The pattern of correlations of the SCS dimensional and total scores was as follow: negative low correlations with physical health (@-0.20), negative moderate correlations with psychological health (@-.30), moderate correlations with self-oriented perfectionism, social-prescribed perfectionism, pessimism (@0.25) and optimism (@-0.20).

Conclusions The Portuguese versions of SCS have good reliability and validity (construct and convergent-divergent). The factorial structure partially overlaps with the original. SCS could be useful for research proposes, namely in an ongoing project on the role of the mentioned personality traits on illness and health behavior.

⁵ The Catholic University of Portugal, Braga Regional Centre, Faculty of Philosophy and Social Sciences, Coimbra, Portugal

* Corresponding author.

Introduction We have recently found that Perfectionism and Perseverative Negative are both correlates of psychological distress/PD and that PNT mediates the relationship between perfectionism and PD (Macedo et al., 2015).

Objectives To investigate if perfectionism and PNT are prospectively associated to PD and if PNT is a longitudinal mediator between perfectionism and PD, controlling for perceived stress and gender.

Methods A total of 227 university students (80.1% girls) filled in the Portuguese validated versions of Perseverative Thinking Questionnaire (PTQ), Multidimensional Perfectionism Cognitions Inventory (MPCI), Profile of Mood States and Perceived Stress Scale, with an additional item to evaluate perceived social support/PSS at T0 and after approximately one year (T1) (Mean months = 12.77 ± 1.137). Only variables significantly correlated with the outcomes (Tension/Anxiety at T1 and Depression at T1) were entered in the conditional process analysis. The moderating role of perceived support on the link between Concern over Mistakes (MPCI) and psychological distress and between PTQ total score and psychological distress (anxiety and depression separately) was examined via conditional process analyses.

Results The estimated models were significant ($F = 4.257$, $P = .002$; $F = 6.476$, $P < .001$) explaining 15.9% of tension-anxiety and 25.5% of depression variance. A significant conditional indirect effect of PTQ total score on psychological distress at average and higher levels of perceived support was found, in both models (anxiety and depression). On the contrary, the two models showed a

non-significant conditional direct effect of Concern over Mistakes on psychological distress only at any level of perceived support.

Conclusion PNT prospectively mediates the relationship between negative perfectionism and PD.

Effects of different types of instruction on the Scores of PID-5 profile

K. Riegel^{1,*}, M. Preiss², P. Harsa¹

¹ Charles University in Prague - 1st Faculty of Medicine, Department of Psychiatry, Prague, Czech Republic

² National Institute of Mental Health, Department of Clinical Psychology, Klecany, Czech Republic

* Corresponding author.

Introduction Section III of 5th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) includes a hybrid model of personality pathology, in which dimensional personality traits (PTs) are used to derive one of six categorical Personality Disorder (PD) diagnoses. The Personality Inventory for DSM-5 (PID-5) has been developed to assess PTs within this new system.

Objectives PT is a tendency to feel, perceive, behave, and think in relatively consistent ways across time and situations. PD diagnosis is generally stated if a pattern of maladaptive PTs persists at least 5 years. Nevertheless, the PID-5 instruction does not cover duration of symptoms.

Aims We have explored the effect of two different types of instructions, in which duration of symptoms is or is not explicitly mentioned, on the PID-5 scores. Moreover, we have asked whether the scores differ in psychiatric patients and healthy individuals.

Methods Differences between original and modified instructions of the Czech PID-5 version have been evaluated in a group of 62 psychiatric patients and 38 healthy controls; each respondent has been administered both instruction types in random sequence. ANOVA mixed design has been used to test the relation between groups and different sequence of administration.

Results We have found no consistent differences in PID-5 scores using the different types of instruction described above.

Conclusions In our sample, PID-5 seems to reflect strong beliefs of a subject regardless of symptoms' duration and could be reliably used with both types of instruction. The PID-5 represents an appropriate instrument for the assessment of maladaptive PTs.

Perfectionism, cognitive emotion regulation and perceived distress/coping

C. Juliana, M.J. Soares*, A.T. Pereira, A. Macedo

Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Perfectionism and cognitive emotion regulation (CER) mechanisms have been associated with perceived stress/coping, negative affect (NA) and mental problems. Comparatively, the correlates of Positive Affect (PA) have been less studied.

Aim To compare Perfectionism, CER and Perceived distress/coping by groups with different levels of NA/PA.

Methods A total of 344 medical students (68.4% girls) completed the Hewitt & Flett and the Frost Multidimensional Perfectionism Scales (H&F-MPS/F-MPS), the Profile of Mood States, the Perceived Stress Scale, and the Cognitive Emotion Regulation Questionnaire.

Results The subjects with high NA, when compared to those with low NA, showed significant higher levels of Evaluative Concerns (EC), Positive Striving (PStr), of H&F-MPS/F-MPS total and dimensions scores (excluding Organization) of Rumination, Blaming others, Self-blaming, Catastrophizing and Perceived distress (all $P < 0.01$). They also revealed lower levels of Positive reevaluation and planning; Positive refocusing, Putting into perspective and Perceived coping (all $P < 0.01$). The subjects with high and medium levels of PA, when compared to the subjects with low PA, showed significant lower levels of Perceived distress, EC, Socially-Prescribed Perfectionism, Doubts about action, Concerns over Mistakes, (all $P < 0.01$), Self-Oriented Perfectionism, PStr ($P < 0.01$, $P < 0.05$, respectively) and higher levels of Perceived coping, Positive reevaluation and planning, Positive refocusing, Putting into perspective (all $P < 0.01$) and Acceptance ($P < 0.01$, $P < 0.05$, respectively).

Conclusions NA is associated with perfectionism, high maladaptive and low adaptive CER, and also with high Perceived distress/low coping, which might increase the subject's vulnerability to psychopathology. Low perfectionism, high adaptive CER and perceived coping are associated with PA and might be protective factors.

Post-traumatic stress disorder

EW396

The psychological impact of trauma in plastic surgery

N. Bansal

Lancashire, United Kingdom

Introduction Post-traumatic stress disorder (PTSD) is triggered by an extremely threatening or catastrophic event. Untreated PTSD can lead to depression, panic disorder, phobias and substance abuse. Early intervention and referral to a clinical psychologist has a role in preventing chronic problems subsequently. Trauma patients in our plastic surgery department are not routinely screened however due to the nature and severity of their injuries, they are at considerable risk of developing PTSD and/or depression.

Aim To identify and treat trauma patients at risk of PTSD and depression in plastic surgery.

Methods We used a validated 10-point questionnaire, the post-traumatic adjustment scale (PAS), to assess risk of depression and PTSD in plastic surgery trauma patients. Patients scoring total > 16 were at risk of PTSD and scores > 4 (PAS sum of scores from questions 1 + 2 + 4 + 7 + 8) were at risk of depression.

Results Twenty-one cases collected from inpatients on the plastic surgery ward. Nature of injuries included crush, stabbing/knife lacerations, dog bites and road traffic accidents. Of these, 19% were at risk of PTSD and 19% at risk of depression. The study was repeated in plastics trauma clinic where patients first present. A further 20 cases were collected and of these, 40% were at risk of depression and 5% at risk of PTSD.

Conclusion In both samples, 1/3 patients were at risk of depression. Numbers at risk of PTSD were greater in the sample collected from plastics inpatient ward. Based on this, we propose trauma

patients in plastic surgery should be routinely screened and considered for further psychological intervention.

Negative emotions and threat perception in narratives from battered women

M. Crespo*, V. Fernández-Lansac, M. Gómez-Gutiérrez, C. Soberón

Complutense University–Psychology School, Clinical Psychology, Madrid, Spain

* Corresponding author.

Introduction Trauma narratives contain a lot of emotion words, in comparison with narratives about other autobiographical memories. Negative emotion's words, as well as words about death (as an indicator of threat perception), have been associated to a worse adjustment after trauma. However, the different kind of negative emotions reported have been rarely explored. Also, in violence victims, the use of words about abuse might indicate threat perception.

Objectives Analyzing the use of negative words and threat perception (death and abuse words) in trauma narratives from 50 battered women, compared with stressful narratives from 50 non-traumatized women, and positive narratives. The relationship between narratives aspects and symptomatology is explored.

Aims Exploring differences in emotions and threat perception related to psychological functioning after trauma.

Methods Battered women were asked to remember the worst violence episode, whereas non-traumatized women narrated their most stressful experience. Both groups remembered also a neutral and a positive episode. LIWC software was used to calculate the percentage of different words used.

Results Anger was the most used negative emotion. Anger and sadness words were more reported in stressful and trauma narratives than in positive ones. There were differences between groups in the use of death and abuse words. Anger and abuse words were associated to anxiety and depression, but not PTSD symptoms. Death words were related to a better functioning.

Conclusions This study evidences the need to explore the role of different negative emotions in the posttraumatic adaptation. Also contextual aspects involved on threat perception must be considered.

³ Vall d'Hebron University Hospital, Department of Psychiatry and Forensic Medicine, Barcelona, Spain

* Corresponding author.

Introduction PTSD is associated with medical and psychiatric comorbidities. Less is known regarding differences in PTSD comorbidities and service use by gender.

Objectives To examine variations in comorbidities for PTSD by gender and implications for quality of care.

Aims We identify the prevalence of PTSD, medical and psychiatric comorbidities diagnosed by gender within outpatient, inpatient and emergency services.

Methods We conducted a retrospective analysis using existing medical records from all outpatient, inpatient and emergency department (ED) encounters in 2010–2012 in a safety net health care system in the US. We identified the rates of PTSD diagnosis by gender, co-occurring diagnoses in ED and inpatient care, and rate of different comorbid diagnoses following initial PTSD diagnosis.

Results Women in the sample had twice the likelihood of having a diagnosis of PTSD as compared to men (1.9% vs. 3.6%, $P > 0.001$), the most common comorbid diagnoses for ED visits were substance use disorder (SUD), depression, anxiety and pain. Men were more likely to have pain as a diagnosis in the ED as compared to women ($P > 0.001$). In inpatient services, men with PTSD were more likely to be diagnosed with a SUD (35% vs. 26%, $P > 0.001$) and women more likely diagnosed with comorbid depression (32% vs. 43%, $P > 0.001$). Men were more likely to have combined medical and substance use disorders and women more likely to have combined medical and psychiatric disorders.

Conclusions Given the different patterns of comorbidity by gender, services should focus on tailoring services early to contend with these differences.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Every day on the world, so many lost their dears because of events and became grieving. In this regard, Iran country is encountered to so many natural events (especially earthquake and flood) or manmade events (like war and driving events).

Objectives The present study examined the prevalence of post traumatic stress disorder and symptoms associated with impaired quality of life in survivors of the gas explosion victims' wives ferns was conducted in Mashhad.

Methods Accordingly, in the form of a descriptive and correlation study of all surviving personnel of the gas transmission pipeline project Fern-Mashhad who were present on 8.9.2010 at work, including contractors, engineers, professionals and workers ($n = 55$) the research sample, the modes were selected.

Results Accident victims of deceased victims of Post-Traumatic Stress Disorder Inventory Scale (M-PTSD), a questionnaire for quality of life (QOL) questionnaire and the researcher-made questionnaire. Statistical analysis showed that the 14/3% of survivors with posttraumatic stress disorder.

Conclusions The relationship between quality of life and post traumatic stress disorder in survivors of the victims showed that elevated post traumatic stress disorder symptoms, quality of life, in all aspects of the victims of physical, psychological, and social environment was significantly reduced. The Managing Director of Chaharmahal and Bakhtiari Province Gas Company to support the program, and also respectful of all employees participated in the survey and thank the gas company and I appreciate.

Keywords Post-traumatic stress disorder; Quality of life; Gas pipeline explosion Fern-Mashhad

Russian–Georgian war crimes and its outcomes

M. Jishkariani

The International Psycho, Rehabilitation Centre for Victims of torture “Empathy”, Treatment and Rehabilitation Department, Tbilisi, Georgia

Introduction Georgia is the Country located in Caucasian Region with two occupied territories: Abkhazia and South Ossetia. Since 1993 as a result of military actions 500,000 civilians became victims of ethnic cleansing. In October 13, 2015 the Prosecutor of the International Criminal Court, requests judges for authorization to open an investigation into the Situation in Georgia that clearly shows importance of the problem addressed by this study.

Objectives of the study includes Observation of outcomes of traumatic stress among three categories of victims: IDPs, population living in the military conflict zone and civilians living in the so called “Buffer Zone”. Aim of the study was to provide comparative analysis between trauma affected different groups.

Methods The clinical and paraclinical methods using the semi-structured clinical interview, psychological test battery and paraclinical diagnostic tests were used, analysis were provided by using the SPSS.

Results Based on observation in 2014–2015 $n = 150$ victims of war crimes were observed. Also additional stressors for all target groups were identified. Differences and similarities of psychological and somatic after effects of trauma revealed.

Conclusions We can conclude that prolonged stress situation with unsecured environment and daily life under unexpected circumstances caused prolongation of PTSD alongside of behavioral changes and with damages in social adaptation. On the other hand completed trauma with leaving of native living areas and significant changes in social life in most of cases caused emotional disturbances with prolonged chronic depression and persistent fillings of grief.

⁴ University of Zagreb School of Medicine, Department of Chemistry and Biochemistry, Zagreb, Croatia

* Corresponding author.

Introduction Association of pro-inflammatory cytokines with severity of various psychiatric disorders is shown. Evidence suggests omega-3 fatty acids reduce psychiatric symptoms due to anti-inflammatory properties.

Objectives To evaluate if serum levels of pro-inflammatory cytokines correlate with the intensity of PTSD symptoms, and the observed change in symptoms' severity induced by omega-3 supplementation.

Methods We included 26 Croatian Homeland war veterans (aged 39–60) with chronic PTSD and no major comorbidity, who were on stable therapeutic sertraline dose at least three months before recruitment. Levels of pro-inflammatory cytokines (TNF- α , IL-6, and IL-1 β) were determined by the enzyme-linked immunosorbent assay method. Intensity of PTSD symptomatology was assessed by Clinician-Administered PTSD Scale (CAPS), Hamilton Anxiety Scale (HAM-A) and 17-item Hamilton Depression Scale (17-HAM-D). During 12 weeks, participants took omega-3 capsules (600 mg/day) while continuing sertraline therapy.

Results Most participants presented with moderate PTSD evaluated by CAPS. At baseline, cytokine levels were not associated with the severity of PTSD symptoms, as measured by all three scales ($P \geq 0.209$). After 12 weeks of omega-3 supplementation the severity of PTSD symptoms significantly decreased, on average by 8 to 13% on the psychometric scales per person ($P < 0.001$ for all). However, no association was found between the change in cytokine levels and the change in scores, induced by omega-3, on the assessed scales ($P \geq 0.730$).

Summary Cytokine levels are not associated with PTSD severity or with improvement in PTSD symptomatology. At the same time, sertraline therapy supplemented with omega-3 seemed to reduce the severity of PTSD symptoms.

The “building block” effect of prior trauma for psychological outcome in victims of a natural disaster

B. Kraemer^{1,*}, S. Schumacher², B. Winkel², C. Imboden¹, L. Wittmann³

¹ Psychiatric Services Solothurn, Department of Psychiatry, Solothurn, Switzerland

² University Hospital, Department of Psychiatry, Zurich, Switzerland

³ International Psychoanalytic University, Psychoanalysis, Berlin, Germany

* Corresponding author.

Background With increasing numbers of previous traumatic experiences, a rising risk of psychiatric morbidity and in particular post-traumatic stress disorder following an acute trauma has been reported. This dose-effect relationship was called the building block effect. Most results are derived from studies on riot and prosecution victims. We investigated victims of a natural disaster with respect to the building block effect due to prior traumatization.

Methods We assessed tourists who had been affected by the Indian Ocean Tsunami 2004 using the Post-traumatic Diagnostic Scale, the Hospital Anxiety and Depression Scale, and the Post-traumatic Growth Inventory. Outcome variables were related to the numbers or prior civil trauma according to the trauma history scale of the PDS.

Results We found a building block effect for the development of anxiety ($P = 0.018$) and by trend with PTSD symptoms ($P = 0.06$), but not with depressive symptoms ($P = 0.436$). Prior traumatization and the actual Tsunami exposure significantly explained variance of personal posttraumatic growth ($P = 0.013$). Prior interpersonal traumata emerged as a strong risk factor for the development of posttraumatic psychiatric morbidity.

Conclusions We suggest that an increasing number of trauma is closely associated with anxiety but not with depressive disorders in the aftermath of natural disasters. For clinical practice, it is

necessary to ask victims of natural disasters about prior traumatization, in particular about prior interpersonal trauma.

Glucocorticoid-based therapeutic options for PTSD

S. Ouanes

Valais Hospital, Department of Psychiatry and Psychotherapy, Sion, Switzerland

Introduction PTSD has been associated with HPA axis alterations, mainly consisting of reduced cortisol levels, elevated CRH and enhanced glucocorticoid receptor responsiveness. These findings led to the emergence of glucocorticoid-based therapeutic options for PTSD.

Objective To outline the different glucocorticoid-based interventions for PTSD either for prophylactic or for curative treatment.

Methods A systematic review was performed. The Medline database was searched using the following keywords: 'PTSD', 'treatment', 'Glucocorticoids', 'hydrocortisone'.

Results Glucocorticoid-based therapeutic for PTSD comprise preventive and curative interventions. Preventive interventions mainly consist of administering one single bolus of hydrocortisone shortly following the exposure to a traumatic event. Evidence comes from six published trials, all positive. Curative interventions include: prescribing hydrocortisone over short periods of time to treat PTSD symptoms, using Glucocorticoids to augment psychotherapy (in particular exposure therapy) for PTSD and using Mifepristone, a glucocorticoid receptor antagonist. Moreover, novel glucocorticoid receptor modulators are currently being developed and tested on animal models as a potential curative treatment for PTSD.

Conclusions Use of hydrocortisone in preventing PTSD might be tempting, as is the use of hydrocortisone or Glucocorticoid receptors antagonists/modulators in treating PTSD. Yet, it should be emphasized that these interventions are not mainstream yet. They rather reflect a revolutionary new direction.

Risk factors for post-traumatic stress disorder – an epidemiological study

B. Pejuskovic^{1,*}, D. Lecic-Tosevski²

¹ Institute of Mental Health, Department for education, Belgrade, Serbia

² Institute of Mental Health, Director, Belgrade, Serbia

* Corresponding author.

Introduction Exposure to a traumatic event is necessary but not sufficient condition for development of posttraumatic stress disorder (PTSD). This is evident from the fact that many people who experience traumatic stressors do not develop this disorder. PTSD is a multicausal phenomenon and a final end point of the combination of a number of potential causes.

Objectives To examine the different factors as potential risk factors for developing PTSD in general adult population.

Methods The sample consisted of 640 subjects, randomly chosen in five regions of the country. The assessment has been carried out by MINI-5, Life Stressor Checklist-Revised, Brief Symptom Inventory, and Manchester Short Assessment of Quality of Life scale.

Results Older age, low education and lower monthly income can predict current PTSD, as well as decreased quality of life, psychiatric comorbidity and higher personal distress.

Conclusions The risk and resilience factors contribute to the development/protection of developing PTSD, which is important for prevention and treatment of this disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Importance of C-PTSD symptoms and suicide attempt

M. Pinheiro^{1,*}, D. Mendes², T. Mendes³, J. Pais², T. Cabral², J.C. Rocha³

¹ Souto, S.M. Feira, Portugal

² CHTS, DPSM, Penafiel, Portugal

³ CESPU, Psicologia, Paredes, Portugal

* Corresponding author.

Introduction Traumatizing experiences have been shown to be important in suicide ideation and attempt. A prolonged and continuous exposure to stressing interpersonal events can have more complex consequences. Therefore, the concept of Complex Post-Traumatic Stress Disorder (C-PTSD) has been emerging.

Objectives Our goal is to relate the symptoms of C-PTSD with suicide attempt and to evaluate the differences between C-PTSD and PTSD on those patients. Moreover, we compared our findings with a control population without prior suicide attempts.

Methods Fifty patients that had been hospitalised in the Psychiatry ward following a suicide attempt were evaluated one week after the event with the ICD-11 Trauma Questionnaire (PTSD and C-PTSD). The same evaluation was performed on a control population without known suicide attempts.

Results There is a statistically significant relationship ($P < 0.001$) between the symptoms of C-PTSD and PTSD and suicide attempt, which effect is higher for C-PTSD. These symptoms are almost absent in the control group.

Conclusion C-PTSD seems to be a more relevant risk factor for suicidal attempts. This aspect is important to define preventive and treatment programs and for suicidal attempts follow-up. The importance of traumatic events and of traumatic stress symptoms as moderator factors should be considered in future research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effect of psychoeducation on anger management and problem solving skills of the patients with post-traumatic stress disorder

M. Senyurt^{1,*}, M. Demiralp², N. Ozmenler¹, C. Acikel³

¹ Gulhane Military Medical Academy, Mental Health and Illness, Ankara, Turkey

² Gulhane Military Medical Academy, School of Nursing, Ankara, Turkey

³ Gulhane Military Medical Academy, Biostatistics, Ankara, Turkey

* Corresponding author.

This study was conducted as pre-test and post-test experimental design with the control group in order to identify the effect of psychoeducation on anger management and problem solving skills of the patients with post-traumatic stress disorder. This study was carried out in Gülhane Military Medical Academy, the department

of Military Psychology and Battle Psychiatry between May 2012 and May 2013. The study sample included 22 control and 22 intervention group patients with PTSD who admitted to participate in the study and who were asked to receive the drug treatment by staying in the clinic. Psychoeducation was only performed on the intervention group. In the collection of research data, “Sociodemographical Information Form”, “Trait-Trait Anger Expression Inventory”, “Problem Solving Inventory” and “The Impact of Event Scale” were used. Data were assessed by Repeated Measures Variance Analysis via SPSS (15.0). Problem solving skills of the patients who had high-school and up to the level of high-school education were identified to be more insufficient than the ones having undergraduate and graduate educations. Before receiving psychoeducation, it was identified that the levels of trait anger of the patients were high, and that they perceived themselves as mild insufficient individuals in problem solving skills. It was identified that trait anger increased the anger control and problem-solving skills while it decreased inward and outward anger levels in the intervention group of psychoeducation. As a consequence, it has been recommended that the continuity of psychoeducations the psychiatry nurses applied have been provide in psychiatry clinic.

Post-traumatic stress disorder: Women – Ecuador

V. Valdez*, J. Veloz, D. Rueda, C. Santana
Universidad Catolica de Guayaquil, Ecuador
 * Corresponding author.

Objectives To determine the incidence of traumatic events in Ecuadorian women exposed to domestic violence and other complex social situations and their relationship with PTSD.

Methods We applied a transversal descriptive study accomplished by the INEC (National Institute of Statistics and Census). The INEC recruited Ecuadorian women from 15 years old and more, the surveys were focused on this population. In total, 18,800 rural and urban housings were selected all over the country, 24 provinces. Date of the survey: November 16–December 15 of 2011. A, D and G were taken as references for guidelines following the criteria diagnosis of DSM V (Diagnostic and Statistical Manual of Mental Disorders) to determine a Traumatic Event.

Results The average age of the sample was 28 years old. The standard deviation was 21, ages: 15–25 years old: 14.265 (21.6%), 25–35 years old: 9.324 (14.1%), 35–45 years old: 8.132 (12.3%), 45–55 years old: 6.283 (9.5%), 55–65 years old: 4.302 (6.5%), > 65 years old: 23.745 (35.9%). Prevalence of the traumatic event (DSM-V) 4.6%. Women experienced any kind of violence 60.6%: 61.4% urban, 58.8% rural. Types of abuse: psychological: 53.9%, physical: 38.0; sexual, patrimonial: 35.3%. Domestic violence 76.0% y other types of violence 24.0%.

Conclusion Domestic violence rate is high, also, in this study, we determined that women face an important index of violence during their daily activities. Psychological abuse is the highest abuse, higher in the urban areas. These results based on acute traumatic events may predispose women to develop PTSD. The prevalence of traumatic events must be an alert to the Mental Health Organizations, not only in Ecuador but also in Latin American.

* Corresponding author.

Introduction Both clinical and subclinical psychosis is probably a consequence of underlying genetic and environmental interactions.

Objectives Defining differential impact of environmental/familial risk factors and psychotic experiences across the onset of clinical psychosis.

Aims To assess mental health outcomes in a 6-year follow-up of a representative general population sample with a special focus on extended psychosis phenotype.

Methods Addresses were contacted in multistage clustered area probability sampling frame covering 9 districts and 302 neighbourhoods (n : 4011) at baseline (T_1) and 6 years after (n : 2142) (T_2). Psychotic experiences were screened with Composite International Diagnostic Interview and probable cases were re-interviewed with SCID-I. Relations were tested using logistic regression models.

Results Of subclinical psychotic symptoms at baseline, 6.4% transitioned to clinical psychosis; 44.4% persisted, 90.2% transitioned to any DSM disorder. Of newly onset clinical psychosis at T_2 , 62.8% had subclinical psychotic expressions at baseline. The risk of developing clinical psychosis was greater in those with baseline subclinical psychotic experiences, alcohol–cannabis abuse, stressful-forensic event history and family history of mental disorders. Most of risk factors associated with psychosis proneness at T_1 were also associated with clinical psychotic outcome at T_2 (Table 1).

Conclusions Psychotic experiences takes attention for the risk to develop psychosis due to underlying genetic and environmental interactions; also may be an important risk factor to develop any mental disorder.

Table 1 Associations between independent variables and newly onset clinical psychosis at T_2 .

	OR	%95 CI	p	OR*	%95 CI	p
No subclinical psychotic expression at T_1	ref			ref

* Corresponding author.

Introduction The World Health Organization (WHO) considers stigma of mental illness as a crucial problem (WHO, 2001). Stigma contributes to the onset (Morgan et al., 2010) and the outcome of people affected by schizophrenia (Himan, 2015).

Objectives To evaluate the perception of patients affected by psychotic disorders of being stigmatized by the community.

Aims To compare the perception of stigma among subgroups of patients at different stage of their disorder.

Methods Thirty-five patients affected by a first-episode of psychosis (FEP) and 96 patients affected by chronic psychosis were recruited. The Devaluation of Consumers Scale (DCS) and the Devaluation of Consumer Families Scale (DCFS) were administered to assess the perceived public stigma (Struening et al., 2001). The Positive And Negative Schizophrenic Symptoms Scale (PANSS) (Kay et al., 1987) and the Global Assessment of Functioning (GAF) (Goldman et al., 1992) were administered to assess psychotic symptoms and global level of functioning.

Results Patients affected by chronic psychosis perceived higher devaluation against mental disorders than patients with a recent onset of psychosis (Mann–Whitney's $U = 910.500$, $P = 0.017$). DCS and DCFS correlated with increased voluntary admissions ($Rho = 0.355$, $P = 0.002$; $Rho = 0.257$, $P = 0.029$) and DCS with increased compulsory admissions ($Rho = 0.349$, $P = 0.003$). Only among chronic patients, DCS factor 2 was related to global level of functioning ($Rho = 0.217$, $P = 0.041$).

Conclusions Patients affected by chronic psychotic disorders perceived a more pessimistic attitude of the community towards their participation in social and community life and this is related to increased admissions and disability.

* Corresponding author.

Introduction Conditions of depression and anxiety among employees' leads to increased absenteeism and decreased social and professional function.

Objectives To test a collaborative model for contributing to mental health at work at the lowest interference and highest possible availability among Danish workers.

Aims To investigate the effect of early detection and treatment in order to interrupt and improve conditions of clinical and sub-clinical levels of mental illness.

Methods Self-reporting questionnaires were used for identification of clinical and sub-clinical cases of mental illness and for follow-up. Four questionnaires were distributed to all employees in six medium-large companies in Denmark ($n = 1292$) during a period of 16 months. Employees meeting the screening criteria were assessed diagnostically. Outpatient psychiatric treatment was offered to employees diagnosed with mental illness and preventive CBT-session to those assessed with sub-clinical conditions. Follow-up questionnaires were filled out after 6 and 12 months. Data were analysed using repeated measure mixed effects linear regression.

Results Of the 587 (55%) employees that returned the questionnaires, 58 were referred to either outpatient psychiatric treatment ($n = 38$) or preventive treatment ($n = 20$). Levels of psychopathology decreased significantly in both treated groups. Comparing with the pre-treatment period, a significant positive difference in change in psychopathology was detected for employees in psychiatric treatment. Measured up to healthy controls, the self-perceived level of stress also decreased significantly among employees in psychiatric treatment.

Conclusions An integrated collaborative model for early detection and treatment was beneficial in order to interrupt and improve the course of mental health problems among Danish employees.

* Corresponding author.

Introduction Concern for medical doctors' health has been widely recognized over the past ten years. EFPT is aware of the heterogeneity of support set up for doctors in distress, recognizing the need for further cross-Europe research.

Aims The EFPT "HELP Project" was designed to investigate psychiatry trainees' perceptions of and attitudes towards health seeking at a Europe-wide scale. Furthermore, it aims to determine what services are available in Europe specifically to support physicians' health.

Methods Multinational, cross-sectional survey conducted in 14 European countries between 2013 and 2014. Data collection was accomplished by an anonymous online or hard copy questionnaire. Completion implied consent to participate. Data was analysed using SPSS v20.0.

Results Of the respondent trainees, 57.7% were from developed economies; 46.2% under 30 years; 26.9% males. Ninety-eight per cent said they would have surgery in the public sector, versus 42.3% who agree to get treatment there for an eating disorder, depression (28.8%) or addiction (17.3%). Trainees from developing economies were significantly less confident in using public sector help for mental health difficulties. When asked for advice regarding the same problems in their fellow trainees, they said they would recommend public sector help. Specific services for doctors exist in the UK, Spain, The Netherlands and Switzerland, but most trainees said there were no services locally.

Conclusion The EFPT believes specialised physician health services are needed to ensure doctors seek help when necessary, while avoiding feeling stigmatised or punished in doing so. The authors plan to create a 'survival guide' for European trainees in distress, with collated information about local services for doctors.

The temporal evolution of life satisfaction in institutionalized elderly: A longitudinal study

H. Espírito-Santo, S. Guadalupe, L. Lemos*, S. Simões, F. Daniel
Miguel Torga Institute, Psychology, Coimbra, Portugal

* Corresponding author.

Introduction Research shows that variables, such as depression, less functionality and health, less contact with family and others, may have a negative impact on life satisfaction.

Objectives To verify which variables correlate with satisfaction with life (SWL) and analyse which of them predict the evolution of SWL.

Aims To examine correlates and predictors of SWL in institutionalized elderly.

Methods This study involved a subsidiary longitudinal analysis of cross-sectional data gathered at Phase I (2010–2012; $n=493$ elderly) and after 36 months at Phase II (2013–2014; $n=85$) of Aging Trajectories Project from Miguel Torga University College.

Results At Phase I, higher scores in SWL scale correlated with having visits ($r=0.17$; $P<0.01$), specially from family ($r=0.20$; $P<0.01$), less depressive ($r=-0.42$; $P<0.001$) and anxiety symptoms ($r=-0.25$; $P<0.001$), less loneliness feelings ($r=-0.37$; $P<0.001$), less functionality ($r=0.15$; $P<0.01$), and better general physical health ($r=0.25$; $P<0.001$). Age, sex, civil status, cognitive, and executive status did not correlate with SWL. SWL, depressive and anxiety symptoms, and loneliness feelings were stable through time, between assessment stages ($P<0.01$). The worsening of depression and loneliness through time predicted the negative evolution of SWL (respectively, $\beta=1.16$; $P<0.01$; $\beta=-0.69$; $P<0.05$).

Conclusions These findings highlight the relevance of early detecting depressed mood and loneliness feelings in institutionalized elderly, and the importance of the treatment and the development of preventive interventions for this vulnerable population.

³ Catholic University of the Sacred Heart, Institute of Hygiene & Public Health, Rome, Italy

* Corresponding author.

Introduction Stigma towards psychiatry and mental illness significantly worsens the quality of life of psychiatric patients. Negative prejudices in medical students make it difficult for future doctors to send patients to mental health services and promote an increased risk of premature death.

Aims Our aim is to assess stigma towards mental illness and psychiatry in medical students, and to study the influence of real-world experiences, such as having visited a psychiatric ward, having personally met a psychiatric patient or having friends and/or family members who suffer from a mental illness.

Methods One hundred and thirteen Italian medical students completed the following tests:

- Attitudes Towards Psychiatry (ATP-30);
- Community Attitudes Towards Mental Ill (CAMI);
- Perceived Discrimination Devaluation Scale (PDD);
- Baron-Cohen's Empathy Quotient (EQ).

Results Having visited a psychiatric ward correlates with a better attitude towards psychiatry ($P=0.008$), rather than towards the mentally ill. Having personally known someone with mental disorders correlates with less stigmatizing scores in CAMI: total score ($P=0.002$), authoritarianism ($P<0.001$), benevolence ($P=0.047$) and social restriction ($P=0.001$). Similar results emerged in those who have close relationships with a psychiatric patient. There is no statistical significance as to empathy.

Conclusions The students who have visited a psychiatric ward have a less stigmatizing vision of psychiatry, while having

personally known psychiatric patients favors a less stigmatizing attitude towards them. Those who have not had this experience, have a more hostile and intolerant vision of mental illness, and consider psychiatric patients as inferior subjects that require coercive attitudes and that would be better to avoid because socially dangerous.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differences in attitudes towards mental illness and psychiatry among medical students, before and after the academic course of psychiatry

M. Pascucci^{1,*}, M. La Montagna¹, E. Stella¹, A. De Angelis², P. Parente³, V. Di Nunzio¹, A. Ventriglio¹, L. Janiri², G. Pozzi², A. Bellomo¹

¹ University of Foggia, Institute of Psychiatry, Foggia, Italy

² Catholic University of the Sacred Heart, Department of Psychiatry, Rome, Italy

³ Catholic University of the Sacred Heart, Institute of Hygiene and Public Health, Rome, Italy

* Corresponding author.

Background Stigma towards mental illness and psychiatry have a major impact on psychiatric patients' quality of life; in particular, prejudicial beliefs make it more difficult for future doctors to send patients to mental health services, leading to a delay of necessary care.

Aims Our aim is to evaluate the stigma towards mental illness and psychiatry, in a sample of Italian medical students. We studied the differences between the first-year students who have not attended the academic course in psychiatry, compared to the senior students who have attended the psychiatric lectures.

Methods We tested 113 medical students, using the following questionnaires:

- Attitudes Towards Psychiatry (ATP 30);
- Community Attitudes Towards Mental Ill (CAMI);
- Perceived Discrimination Devaluation Scale (PDD), to assess the discrimination towards mental illness perceived in society;
- Baron-Cohen's Empathy Quotient (EQ), to measure empathy.

Results Among the 113 students, 46 have already attended the academic course of psychiatry and CAMI scores were less stigmatizing as total score ($P=0.014$) and in authoritarianism subscale ($P=0.049$), social restriction ($P=0.022$) and ideology of mental health in the community ($P=0.017$). However, there were no statistically significant differences in empathy, perceived discrimination in the society and stigmatization of psychiatry.

Conclusions The 67 students who have not attended the academic course of psychiatry are more stigmatizing, considering psychiatric patients as inferior people that require coercive attitudes, socially dangerous and that should be treated faraway from the community. Studying psychiatry is therefore useful to reduce, in the future doctors, these prejudices toward mentally ill patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Karamandaneion Hospitak, Pediatrics, Patras, Greece

* Corresponding author.

Introduction Studies have shown that sport participation is connected with a more positive self-image and higher self-esteem in adolescents (Bowkers, 2006, Kirkcaldy et al., 2002), whereas sedentary behavior is associated with negative mental health characteristics (Primack et al., 2009).

Purpose The aim of this study was to investigate whether physical activity influences adolescents and young people's emotions, self-esteem and generally mental health.

Material Questionnaires were redacted by the research team investigating participants' habits, emotions and health benefits concerning physical activities.

Method Questionnaires were administered to 150 adolescents, aged 18–20 years old in Technological Educational Institutes, colleges and fitness centers in Patras, Southern Greece during 2015's spring.

Results Eighty-seven percent of the respondents worked out in fitness centers or in natural environment. Most of them answered that exercise contributed to revitalization and euphoria feelings (63%), stress relief (78%), better self-image, and better health (49%). According to 63% of the adolescents, exercise improved their school performance and 61% of them felt that exercise affected positively mental health.

Conclusions Present study's results underline physical activities' benefits in students' mental health, self-esteem, feelings and school performance being in line with other studies' results [Biddle et al. (2011), Ekeland et al. (2005), Brown et al. (2013)]. Restrictions refer mainly to small size sample.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effects of implicit affect on emotional coping and school adjustment: A short-term longitudinal study with a school-based universal prevention program for enhancing emotional abilities

K. Uchida^{1,*}, T. Yokoshima², K. Yamasaki¹

¹ Naruto University of Education, Department of Human Development, Naruto, Japan

² Naruto University of Education, Center for the Science of Prevention Education, Naruto, Japan

* Corresponding author.

In recent years, affect and emotions are hot research topics in the domains of psychology and brain science. Moreover, an increasing number of studies have started to investigate the effects of implicit affect on health and adjustment. The purpose of this study was to examine the effects of implicit affect on explicit emotional coping with others' emotions and school adjustment in children.

Methods Participants were 5th- and 6th-grade children in two public elementary schools in Japan. The final samples were fifty-six children (25 boys and 31 girls). Participants completed a battery of three questionnaires just before (T1) and after (T2) an

school-based universal prevention program for enhancing emotional coping abilities with others' emotions, which was implemented in eight classes during one month. The questionnaires were utilized for assessing implicit positive and negative affect (IPA and INA), explicit emotional coping abilities to identify, understand, and regulate others' emotions, and the adaptive status of children at school.

Results Hierarchical regression analyses showed that higher IPA at T1 was associated with higher explicit emotional coping and motivation for learning at T2. Also, higher INA at T1 was related to better peer relationship at T2. Moreover, higher IPA and INA at T1 were concerned with higher scores of classroom climate and approval at T2.

Conclusion This study suggested that higher IPA leads to higher explicit emotional coping with others' emotions. Also, it suggested that higher implicit affectivity (i.e., both higher IPA and INA) causes more adaptive status of children at school.

Oxidative DNA damage is associated with antidepressant use, not depression or anxiety disorders

C. Black^{1,*}, M. Bot¹, P. Scheffer², B. Penninx¹

¹ VU University Medical Center, Psychiatry/GGZ inGeest, Amsterdam, Netherlands

² VU University Medical Center, Clinical Chemistry, Amsterdam, Netherlands

* Corresponding author.

Introduction Oxidative stress has been implicated in the pathophysiology of depression and anxiety disorders and may be influenced by antidepressant use.

Objectives This study investigated the association of oxidative stress, measured by plasma levels of F2-isoprostanes and 8-hydroxy-2'-deoxyguanosine (8-OHdG), reflecting oxidative lipid and DNA damage respectively, with major depressive disorder (MDD), generalized anxiety disorder, social phobia, panic disorder, agoraphobia and antidepressant use in a large cohort.

Methods Data was derived from the Netherlands Study of Depression and Anxiety including patients with current ($n = 1641$) or remitted ($n = 610$) MDD and/or anxiety disorder(s) (of which $n = 709$ antidepressant users) and 633 controls. Diagnoses were established with the Composite Interview Diagnostic Instrument. Plasma 8-OHdG and F2-isoprostanes were measured using UHPLC-MS/MS. ANCOVA was performed adjusting for sampling, sociodemographic, health and lifestyle variables.

Results F2-isoprostanes did not differ between controls and patients, or by antidepressant use. Patients (current or remitted) using antidepressants had lower 8-OHdG (adjusted mean 38.3 pmol/L) compared to patients (current or remitted) without antidepressants (44.7 pmol/L) and controls (44.9 pmol/L, $P < 0.001$; Cohen's d 0.26). Findings for 8-OHdG were similar over all disorders and all antidepressant types (SSRIs, TCAs, SNRIs; $P < 0.001$).

Conclusion Contrary to previous findings this large-scale study did not find increased oxidative stress measured by F2-isoprostanes or 8-OHdG in MDD or anxiety disorders. 8-OHdG levels were lower in antidepressant users, which suggests antidepressants may have antioxidant properties.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antioxidant uric acid is lower in current major depression and anxiety disorders

C. Black^{1,*}, M. Bot¹, P. Scheffer², B. Penninx¹

¹ VU University Medical Center, Psychiatry/GGZ inGeest, Amsterdam, Netherlands

² VU University Medical Center, Clinical Chemistry, Amsterdam, Netherlands

* Corresponding author.

Introduction It has been hypothesized that lowered antioxidant capacity, which leads to increased oxidative stress, may be involved in the pathophysiology of major depressive disorder (MDD) and anxiety disorders and might be altered by antidepressant treatment.

Objectives This study investigated the association of plasma uric acid, the greatest contributor to blood antioxidant capacity, with MDD, generalized anxiety disorder, social phobia, panic disorder, agoraphobia and antidepressants in a large cohort.

Methods Data was derived from the Netherlands Study of Depression and Anxiety including patients with current ($n = 1648$) or remitted ($n = 609$) MDD and/or anxiety disorder(s) (of which $n = 710$ antidepressant users) and 618 controls. Diagnoses were established with the Composite Interview Diagnostic Instrument. Symptom severity was ascertained in all participants with the Inventory of Depressive Symptoms and the Beck Anxiety Inventory. ANCOVA and regression analyses were adjusted for sociodemographic, health and lifestyle variables.

Results Plasma uric acid was lower in those with current MDD and/or anxiety disorder(s) (adjusted mean 270 $\mu\text{mol/L}$) compared to those with remitted disorders (280 $\mu\text{mol/L}$, $P < 0.001$) or to controls (281 $\mu\text{mol/L}$, $P < 0.001$; Cohen's d 0.14). Within patients antidepressants were not associated with uric acid levels. Increasing symptom severity was associated with lower uric acid levels for both depression ($\beta = -0.05$, $P = 0.001$) and anxiety symptoms ($\beta = -0.05$, $P = 0.004$).

Conclusion This large scale study finds that the antioxidant uric acid is lower in current, but not remitted, MDD or anxiety disorders and in persons with higher symptom severity, suggesting disturbances in redox homeostasis play a role in the pathophysiology of depression and anxiety disorders.

³ Wrocław Medical University, Department and Clinic of Gynaecology and Obstetrics, Wrocław, Poland

⁴ Institute of Immunology and Experimental Therapy, Polish Academy of Science, Department of Experimental Therapy, Wrocław, Poland

* Corresponding author.

Introduction The influence of the immune deregulation on the risk and psychopathology of schizophrenia is increasingly recognized in the literature.

Aim To assess the association between serum IL-1RA on schizophrenia psychopathology.

Methods We recruited 88 schizophrenia patients (38 males and 49 females, mean age 38.12 ± 12.67 years) and 88 healthy adult control subjects (68 males, 20 females, mean age 40.63 ± 7.99 years). Lifetime psychopathology was evaluated using Operational Criteria for Psychotic Illness (OPCRIT) checklist, while current psychopathology was assessed using Positive and Negative Syndrome Scale (PANSS). Serum samples were stored in aliquots at -80°C . Serum levels of IL1-RA were measured using Immunoassay (ELISA).

Results There were statistically significant differences between schizophrenia patients and healthy controls (median \pm interquartile range: 350.81 ± 227.04 and 888.74 ± 762.63 , respectively [pg/ml]) (*U* Mann–Whitney test, $Z = -7.99$, $P < 0.0001$). There were no differences in serum IL1-RA levels between male and female among patients with schizophrenia (*U* Mann–Whitney test, $Z = -0.22$, $P = 0.82$) nor among healthy control subjects (*U* Mann–Whitney test, $Z = -0.17$, $P = 0.86$). Among schizophrenia patients, there was a trend-level association between IL-1RA serum level with negative symptoms (Spearman correlation coefficient, $r = -0.23$, $P = 0.056$), positive symptoms (Spearman correlation coefficient $r = -0.22$, $P = 0.066$), and on a statistically significant level with general symptoms (Spearman correlation coefficient $r = -0.28$, $P = 0.018$).

Conclusion Serum IL1-RA level is higher in schizophrenia patients in comparison to healthy controls and it is associated with schizophrenia psychopathology.

⁵ Institute of Psychiatry, Psychology and Neuroscience, Psychosis Studies, London, United Kingdom

* Corresponding author.

Introduction Antibodies to the voltage-gated potassium channel (VGKC) complex and glutamic acid decarboxylase (GAD) have been reported in some cases of psychosis. We conducted the first systematic review on VGKC and GAD, and meta-analysis on GAD, to investigate their prevalence in people with psychosis.

Objectives The objective was to examine the available evidence to determine the prevalence of serum VGKC and GAD antibody positivity in psychosis.

Aims To search the available literature for data indicating the prevalence of these antibodies in psychosis. If data were sufficient, we anticipated conducting a meta-analysis.

Methods Two authors searched major electronic databases for studies reporting the prevalence of VGKC and GAD65 antibody seropositivity in psychotic disorders. We then conducted a random effects analysis with Comprehensive Meta-Analysis software (CMA, Version 3).

Results Only three studies presenting prevalence rates of VGKC sero-positivity in psychosis could be identified, with an overall prevalence of 0.5% (1/196) with 0% in healthy controls (0/50). Meta-analysis established the pooled prevalence of GAD65 autoantibodies was 8.67% (95% CI 3.9–17.80%, $I^2 = 75\%$, 8 studies) in psychotic disorders. People with psychosis were more likely to have GAD65 antibodies than controls (OR 3.14 95% CI 1.55–6.37%, $P = 0.001$, 7 studies, $I^2 = 0\%$).

Conclusions Rates of VGKC antibody positivity appear to be low in psychosis, although there is a lack of published evidence. The prevalence of GAD65 antibodies is higher but available studies did not control for the presence of T1 diabetes, a condition in which GAD65 antibodies are also found.

EW421

Adverse childhood experiences and later in life depression as risk factors for cancer incidence and mortality. A nationally representative, prospective longitudinal study

M.V. Hansen

Aarhus, Denmark

Introduction Adverse childhood experiences (ACEs) have shown to influence the risk of various chronic diseases alone, and in combination with depression later in life. To date, only little research has examined the relationship, and findings have been inconsistent.

Objective To conduct a nationwide prospective study on ACEs and the risk of cancer.

Aims – Examine the relationship between ACE and a range of cancer types;

- to test for a linear dose-response relationship;
- to investigate differences in the effects of the specific ACE on the risk of cancer;
- to determine if there are any sex differences as well as windows of vulnerability;
- to examine if later in life occurrence of depression influence the risk of cancer in combination with ACE.

Methods A prospective population-based study including approximately 1.1 mio individuals was conducted using linked Danish registries that hold data on objective measures of ACEs and cancer incidences. Survival analyses were used to estimate relative risk of cancer among those with ACE and depression, compared to those without, while adjusting for relevant confounders.

Results This study will provide results on the relative risk of cancer after exposure to ACE compared to those without, as well as information on the combination of ACE and depression, sex differences, effect of timing and dose-response analyses.

Conclusion This preliminary study will help to further advance our understanding on how ACEs influence the risk of serious chronic diseases later in life, and the findings may contribute to understanding the etiology of cancer.

Inflammatory markers in depressed pregnant womenS. Hergüner^{1,*}, H. Toy², E. Türen², H. Dülger³¹ Necmettin Erbakan University, Meram Faculty of Medicine, Department of Child and Adolescent Psychiatry, Konya, Turkey² Necmettin Erbakan University Meram Faculty of Medicine, Department of Gynecology, Konya, Turkey³ Necmettin Erbakan University, Meram Faculty of Medicine, Department of Biochemistry, Konya, Turkey

* Corresponding author.

Objectives In the literature, there are limited number of studies investigating the relation between depression and inflammatory markers, including cytokines TNF alfa, and IL-6. In this study, we aimed to examine the association between TNF alfa, and IL-6 levels and depression, and anxiety levels in pregnant women.

Methods The study group consisted of 145 pregnant women who were their first and singleton pregnancies during their 28–36 weeks of gestation without any chronic physical conditions. They fulfilled Edinburgh Postpartum Depression Scale (EPDS) and State Trait Anxiety Inventory (STAI). Their blood was taken after they completed the questionnaires and levels of TNF alfa, and IL-6 were examined.

Results The mean age of the participants were 23.2 ± 4.5 years and mean gestation week was 32.9 ± 2.7 . According to the EPDS score, we divided the group into 2, as probable depressive (≥ 12) and non-depressive (< 12). There were no difference between the two groups in terms of age, education, and gestational age. Women with depression had significantly higher TNF alfa, and IL-6 levels than non-depressive group.

Conclusion Our findings support that depression in pregnant women may be related with inflammatory process.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Immunomodulatory role of paliperidone in the poly(I:C) model of schizophreniaK. MacDowell^{1,2,*}, E. Munarriz-Cueva^{2,3},D. Martín-Hernández^{1,2}, A. Sayd^{1,2}, B. García-Bueno^{1,2}, J. Meana^{2,3}¹ University Complutense of Madrid-School of Medicine, Pharmacology, Madrid, Spain² Centro de Investigación Biomédica en Red en el Área de Salud Mental, CIBERSAM, Madrid, Spain³ University of Basque Country UPV/EHU, Bizkaia, Department of Pharmacology, Bilbao, Spain

* Corresponding author.

Introduction Alterations on the innate inflammatory response may underlie the pathophysiology of psychiatric diseases, but the mechanisms implicated remain elusive. Current antipsychotics modulate pro/anti-inflammatory pathways, but the specific mechanisms involved remain elusive. One attractive possibility is the regulation of the intracellular signalling pathways of the innate immune receptors Toll-like 3 (TLR3), which triggers antiviral and inflammatory responses.

Aims To elucidate the regulatory role of paliperidone on maternal immune activation (MIA) induced alterations on TLR3 pathway and on the two emerging endogenous antiinflammatory/antioxidant mechanisms NRF2/antioxidant enzymes pathway and the cytokine milieu regulating M1/M2 polarization in microglia.

Methods Pregnant mice were treated with the synthetic Toll-like Receptor 3 (TLR3) agonist Poly(I:C) in gestational day 9 and chronically treated with paliperidone (0,05 mg/kg i.p.) in adult offspring.

Animals were sacrificed one day after treatment and behavioral test. Inflammation oxidative stress-related mediators were analysed at mRNA and protein level in prefrontal cortex samples. In addition, behavioral test t-maze was conducted.

Results Paliperidone prevented TLR3 pathway activation and the subsequent MIA-induced neuroinflammatory response. Also, paliperidone induced an increment in the activity and protein expression of nuclear NRF2, as well as increased mRNA levels of the antioxidant enzymes HO1, SOD and catalase in the MIA model. Otherwise, paliperidone increases the antiinflammatory cytokines levels TGF β and IL-10 in favour of a M2 microglia profile and increased the levels of the M2 cellular markers Arg1 and FOLR2.

Conclusions The modulation of neuroinflammation and enhancement of endogenous antioxidant/anti-inflammatory pathways by current and new antipsychotics could represent an interesting therapeutic strategy for the future.

Psychosis among HIV-infected patients – a serious and complex associationM. Marinho^{1,*}, J. Marques^{2,3}, M. Bragança^{1,3}¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Porto, Portugal³ Faculty of Medicine of Porto University, Department of Clinical Neurosciences and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Psychosis represents an uncommon but serious complication in the course of HIV infection, and always requires a careful differential diagnosis.

Objectives To provide an overview of psychosis in HIV-infected patients.

Methods Literature review based on PubMed/MEDLINE, using the keywords “HIV” and “psychosis”.

Results Psychosis in HIV-positive individuals can be divided into psychotic disorders predating HIV infection and new-onset psychotic disorders in HIV-seropositive patients. The pathophysiology of psychosis in this population is complex and a multifactorial etiology is likely in most instances. The authors will analyze them and describe the differences of psychopathological pattern in first-episode psychosis between HIV-positive and HIV-negative patients. Antipsychotic agents are the treatments of choice regardless of the underlying diagnosis. However, they should always be used at the lowest possible dose for the shortest possible duration. Increased sensitivity to extrapyramidal reactions, high risk for dyslipidemia and hyperglycemia, potential interactions between HAART and some antipsychotic agents are also important considerations. Importantly, psychosis may be a harbinger of dementia. Cross-sectional studies have also suggested that psychosis may adversely impact the morbidity and mortality associated with HIV-infection.

Conclusions Psychosis disorders may arise before or at any time during the course of HIV infection. A solid understanding of the complex relationship between psychosis and HIV allows for better evaluation and more effective treatment for psychotic individuals at risk for or infected with HIV. Thus, both HIV care programs and psychiatric care clinics should be made familiar with this important subject.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Existence of integration, mutual relations of nervous and immune systems, which cellular elements are characterized by expressed phenotype and functional similarity, means the possibility of immune cells participation in the regulation of higher nervous activity.

Objectives Previously, we demonstrated the possibility of targeted regulation of animal's behavior by the transplantation of immune cells with definite functional characteristics. Based on the our previous research results in the present study, we investigated the modulating effect of the immune cells, treated in vitro with chlorpromazine on the nervous and immune systems functional activity in aggressive mice.

Methods (CBA × C57Bl/6) F1 aggressive mice, exposed to 10-days chronic social stress, were undergoing the transplantation of immune cells in vitro treated with chlorpromazine. Animal's behavioral parameters, cytokines synthesis in the brain and immune cells before and after transplantation were estimated.

Results It was shown that aggression is associated with the increased production of spleen T-helper 1 cell-derived cytokines IL-2 and IFN γ , as well as decreased TNF α production by the spleen mononuclear phagocyte cells. These alterations were more pronounced following mitogen stimulation. Spleen cells, obtaining from aggressive mice, were treated in vitro with chlorpromazine and then injected intravenously into syngeneic aggressive recipients. The cell's transplantation led to the reduction of the recipient's motor activity in the "open field" and Porsolt swimming tests and normalized cytokines synthesis in the brain and immune cells.

Conclusion Research results demonstrated the neuroleptic effect in aggressive mice, obtained by the transplantation of immune cells treated in vitro with chlorpromazine.

Impact of anti-inflammatory drugs on the risk of anxiety disorders after critical illness

C.R. Medici^{1,2,*}, S.D. Østergaard^{3,4}, H.T. Sørensen¹, C.F. Christiansen¹

¹ Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark

² Aarhus University Hospital, Psychiatric Research Academy, Department of Affective Disorders, Aarhus, Denmark

³ Aarhus University Hospital, Department of Clinical Medicine, Aarhus, Denmark

⁴ Aarhus University Hospital, Research Department P, Aarhus, Denmark

* Corresponding author.

Introduction Critical illness increases the risk of mental illness, including anxiety disorders. As critically ill patients exhibit high levels of inflammation and inflammation plays a role in mental illness, critical and mental illnesses may be linked by systemic inflammation.

Objective To investigate whether anti-inflammatory drugs reduce the risk of subsequent anxiety disorders among intensive care patients requiring mechanical ventilation.

Aims To assess the risk of anxiety disorders after intensive care requiring mechanical ventilation according to pre-admission use of non-steroidal anti-inflammatory drugs (NSAID), glucocorticoids, statins or combination. To compare risk in users with non-users.

Methods This nationwide, registry-based, cohort study includes all patients receiving mechanical ventilation in Danish intensive care units during 2005–2013. Preadmission use of NSAIDs, glucocorticoids, statins or combinations will be identified from filled prescriptions. Risk of anxiety disorders in users and non-users of these anti-inflammatory drugs will be estimated using the cumulative incidence method, accounting for death as a competing risk. After propensity-score matching, risk in users and non-users will be compared using hazard ratios from a Cox regression.

Results N/A. The estimated number of patients is 100,000. Expected preadmission use is 14% for statins, 15% for NSAIDs, and 10% for glucocorticoids. The study will have 95% power to detect a 10% decrease in risk between users and non-users.

Conclusions N/A. The study potentially will contribute knowledge about the pathogenesis of anxiety disorders and a mechanism linking critical illness and mental illnesses. If anti-inflammatory drugs reduce risk of anxiety disorders, this may guide trials.

Family functioning and individual psychopathology in a non-clinical general population

D. Adamis^{1,*}, I. Petmeza², G. McCarthy³, A. Tsampanli⁴

¹ Sligo Mental Health Services, Psychiatry, Sligo, Ireland

² National and Kapodistrian University of Athens, Early Childhood Education, Athens, Greece

³ Sligo Mental Health Services, Sligo Medical Academy, NUI Galway, Psychiatry, Sligo, Ireland

⁴ University of the Aegean, Clinical Psychology, Rhodes, Greece

* Corresponding author.

Introduction A family "constructs" an identity of its own derived from their assumptions about relationships and the social environment they live in. This identity transcends the individual while at the same time encourages individual differentiation. Family functioning is influenced from different factors like social context, qualitative characteristics, and from individual's medical or psychiatric condition.

Aims and objectives To examine the effects of sociodemographic factors and individual psychopathology on the function of family in a non-clinical sample.

Methods Cross-sectional study of participants and their families. The follow data collected:

- demographics (age, gender, occupation, education);
- description of the family (number of members, single parents family, adoption);
- history of mental or physical illnesses;
- Family Assessment Device (FAD);
- Symptom Checklist-90 (SCL-90).

Results The sample constituted of 151 families, (453 individuals), in 48 families, 2 family members participated, in 56 families, 3 members participated, in 46 families 4 members participated and

1 family had 5 members participating. One hundred ninety-four (42.8%) were children and 259 (57.2%) were parents. The mean age of the children was 23.62 (SD: 6.35) and 68 (35%) were males. Mean age of the parents was 51.4 (SD: 8.2) and 117 (45.2%) were males. SCL-90 identified 183 participants as caseness. Multilevel analysis showed that individual psychopathology (caseness) was the only statistical significant factor for family dysfunctioning.

Conclusion There is strong association between family dysfunction and psychopathology of a member. Dysfunctional families need further psychiatric evaluation of the members. Cause-effect cannot be concluded from this cross-sectional study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Subthreshold depression as a predictor of emergence and persistence of psychotic experiences: A six-year longitudinal population-based cohort

H. Elbi^{1,*}, T. Binbay², U. Kırılı¹, B. Kayahan¹, H. Onay³, F. Özkinay³, K. Alptekin²

¹ Ege University Faculty of Medicine, Department of Psychiatry, Izmir, Turkey

² Dokuz Eylül University Faculty of Medicine, Department of Psychiatry, Izmir, Turkey

³ Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey

* Corresponding author.

Introduction Subthreshold depression is prevalent in general population and is associated with poorer quality of life, higher health care use and increased risk of mental disorders mainly depression.

Objectives Testing predictive impact of subthreshold depression on emergence and persistence of subclinical psychotic experiences. **Aims** To assess association between subthreshold depression and persistence of subclinical psychotic experiences in a 6-year follow-up of a representative general population sample.

Methods A longitudinal prospective cohort study (the TürkSch The Izmir Mental Health Survey for Gene-Environment in Psychoses) was conducted with a general population sample ($n = 4011$) from Izmir, Turkey, who were 15–64 years of age at baseline. Sociodemographic factors, subthreshold depression (based on responses to systematic screening questions of the relevant questions with having less than five symptoms or having symptoms less than two weeks or having non-interfering impairment due to symptoms), and measures of psychopathology (subclinical psychotic experiences) were assessed across two waves (T₁-2008 and T₂-2014; $n = 2192$) using the Composite International Diagnostic Interview.

Results Prevalence estimates of subthreshold depression at T₁ and persisted psychotic experiences were 4.2% and 8.3%, respectively. Subthreshold depression at T₁ was associated with persistence (OR = 1.6; 95% CI = 0.6–2.9) of psychotic experiences at T₂.

Conclusions Psychosis may be a poor outcome of subthreshold extended phenotypes in the general population with early expression of sets of symptoms blending from depressive, anxious and psychotic states. Assessing the early dynamics of symptoms that affect each other over time may facilitate the understanding of the dynamic circuit of early psychopathology.

Thought overactivation as a marker of bipolar disorder

M. Ferrari^{1,*}, P. Ossola¹, V. Lucarini¹, V. Accardi¹, C. De Panfilis¹, M. Tonna², C. Marchesi¹

¹ University of Parma, Department of Neuroscience, Parma, Italy

² Local Health Agency, Mental Health Department, Parma, Italy

* Corresponding author.

Introduction Recent studies have underlined the importance of considering the form of thoughts, beyond their content, in order to achieve a better phenomenological comprehension of mental states in mood disorders. The subjective experience of thought overactivation is an important feature of mood disorders that could help in identifying, among patients with a depressive episode, those who belong to the bipolar spectrum.

Objectives Patients with a diagnosis of bipolar disorder (BD) were compared with matched healthy controls (HC) on a scale that evaluates thought overactivation.

Aims Validate the Italian version of a scale for thought overactivation (i.e. STOQ) in a sample of bipolar patients.

Methods Thirty euthymic BD and 30 HC completed the Subjective Thought Overactivation Questionnaire (STOQ), the Ruminative Responses Scale (RRS), the Beck Depression Inventory-II (BDI-II) and global functioning (VGF).

Results The 9-items version of the STOQ has been back translated and its internal consistency in this sample was satisfactory ($\alpha = .91$). Both the brooding subscore of RRS (b-RRS) ($r = .706$; $P < .001$) and STOQ ($r = .664$; $P < .001$) correlate significantly with depressive symptoms whereas only the first correlate with VGF ($r = -.801$; $P < .001$). The two groups did not differ in the b-RRS (HC = 8.41 vs BD = 9.72; $P = .21$), whereas BD were significantly higher in the STOQ total score (HC = 6.62 vs. BD = 14.9; $P = .007$).

Conclusion Our results, although limited by the small sample size, confirm the validity of the STOQ and suggest that this scale could grasp a feature characteristic of BD, independently from their tendency to ruminate. The latter seems to impact more on global functioning.

³ University of Gothenburg, Centre of Ethics, Law and Mental Health CELAM, Gothenburg, Sweden

* Corresponding author.

Introduction The MOODS-SR is a self-report instrument consisting of 161 dichotomous items. It is designed to assess lifetime presence of mood spectrum psychopathology. Recently, it has been proposed that a subset of 33 items can be used to distinguishing bipolar disorder.

Aim To evaluate psychometric properties of a 33-item subset and to propose a clinically relevant cut-off for screening for bipolar disorder.

Methods Patients with mood disorders were recruited from outpatient services at Sahlgrenska University Hospital. Patients and a convenience sample of healthy controls were offered to fill in the

MOODS-SR. A post-hoc analysis was conducted for the 33-items subset of the MOODS-SR.

Results The subset showed high internal consistency (Cronbach $\alpha = 0.95$). The mean scores of patients with bipolar disorder (22.7 ± 6.4) were significantly higher than those of the unipolar (11.3 ± 4.9) and control group (7.0 ± 7.0 , $P < 0.005$). A significant correlation was found between YMRS ($r = 0.50$, $P < 0.005$) and the 33-item subset, but not with MADRS ($r = -0.22$, $P = 0.223$).

Conclusion The 33-item subset of MOODS-SR showed promising psychometric properties, including good known-group validity. It discriminated bipolar patients from unipolar patients and healthy subjects. The clinical usefulness of these findings needs further investigation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The frequency, type and impact of appearance comparisons on body dissatisfaction and disordered eating behaviours in women's daily lives

K. Drutschinin¹, M. Fuller-Tyszkiewicz², T. De Paoli¹, V. Lewis³, I. Krug^{4,*}

¹ University of Melbourne, Psychological Sciences, Melbourne, Australia

² Deakin University, Psychology, Melbourne, Australia

³ Canberra University, Psychology, Canberra, Australia

⁴ University of Melbourne, Psychology, Melbourne, Australia

* Corresponding author.

Objective To examine the impact of appearance comparison behaviours, trait body dissatisfaction and eating pathology on women's state body dissatisfaction and engagement in disordered eating behaviours in daily life.

Method Using ecological sampling method (ESM), 116 women residing in Australia, completed a baseline questionnaire containing the trait-based measures, before being signalled by an iPhone app six times daily, for seven days, to self-report on their recent appearance comparison behaviours, current state body dissatisfaction and recent disordered eating behaviours.

Results Multi-level modelling revealed that upward comparisons (comparisons against more attractive individuals) elicited increases in state body dissatisfaction ($\beta = 0.89$, $P < .001$) and disordered eating behaviours ($\beta = 0.29$, $P = .002$). Contrastingly, downward comparisons (comparisons against less attractive individuals) elicited decreases in state body dissatisfaction ($\beta = -0.31$, $P = .048$) and, unexpectedly, increases in disordered eating behaviours ($\beta = 0.46$, $P < .01$). The frequency of appearance comparison engagement, regardless of whether it was upward or downward comparisons, was also predictive of increased disordered eating behaviours ($\beta = 0.12$, $P < .001$). In addition, eating pathology and trait body dissatisfaction were directly associated with higher state body dissatisfaction, and increased in disordered eating behaviours (all $P < .001$).

Conclusion These findings highlight the general negative impact that appearance comparisons have on fluctuating states of body dissatisfaction and eating pathology, as well as illustrating how trait characteristics partially account for this volatility. These findings provide further information that may be used to inform eating disorder prevention and intervention efforts.

⁴ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

⁵ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Disgust propensity (DP) and disgust sensitivity (DS) contribute to individual differences in the experience of disgust. Studies have shown that DP and DS are predictive of some anxiety (e.g., spider phobia and blood-injection-injury phobia) and obsessive-compulsive and related disorders.

Aim The aim of this study was to develop and validate a Portuguese version of the Disgust Propensity and Sensitivity Scale-Revised (DPSS-R; van Overveld et al., 2006) for use in Portuguese-speaking populations.

Method Two hundred and six participants (162 females), with ages between 18 and 47 ($M = 25.92$; $SD = 8.75$), filled in the DPSS-R, which was first translated and adapted into Portuguese language by individuals highly proficient in English and then back-translated by a bilingual with no prior knowledge of the scale. Finally, the DPSS-R was subjected to a think-aloud procedure.

Results The results showed good internal consistency (Cronbach's $\alpha = .833$) for a DPSS-R. The two subscales displayed an adequate internal consistency ($DP_{Cronbach's\ \alpha} = .776$; $DS_{Cronbach's\ \alpha} = .790$). Test-retest analysis documented good intraclass correlation coefficient for the two subscales ($ICC_{Propensity} = .889$; $ICC_{Sensitivity} = .900$). We also confirmed the bifactorial structure using a confirmatory factor analysis, since we obtained appropriate values in all goodness of fit indices ($\chi^2/df = 1.906$; $CFI = .94$; $PCFI = .736$; $GFI = .93$; $PGFI = .607$; $RMSEA = .067$).

Conclusion DPSS-R obtained good psychometric properties and may therefore be proposed as a valid instrument to assess DS and DP in the Portuguese population. This instrument may provide an important contribute to study the development and maintenance of psychopathology associated with disgust.

³ South London and Maudsley NHS Foundation Trust, Biomedical Research Centre Nucleus, London, United Kingdom

⁴ University of Oxford, Department of Psychiatry, Oxford, United Kingdom

* Corresponding author.

Introduction Mood instability is an important problem but has received relatively little research attention. Natural language processing (NLP) is a novel method, which can be used to automatically extract clinical data from electronic health records (EHRs).

Aims To extract mood instability data from EHRs and investigate its impact on people with mental health disorders.

Methods Data on mood instability were extracted using NLP from 27,704 adults receiving care from the South London and Maudsley NHS Foundation Trust (SLaM) for affective, personality or psychotic disorders. These data were used to investigate the association of mood instability with different mental disorders and with hospitalisation and treatment outcomes.

Results Mood instability was documented in 12.1% of people included in the study. It was most frequently documented in people with bipolar disorder (22.6%), but was also common in personality disorder (17.8%) and schizophrenia (15.5%). It was associated with a greater number of days spent in hospital (B coefficient 18.5, 95% CI 12.1–24.8), greater frequency of hospitalisation (incidence rate ratio 1.95, 1.75–2.17), and an increased likelihood of prescription of antipsychotics (2.03, 1.75–2.35).

Conclusions Using NLP, it was possible to identify mood instability in a large number of people, which would otherwise not have been possible by manually reading clinical records. Mood instability occurs in a wide range of mental disorders. It is generally associated with poor clinical outcomes. These findings suggest that clinicians should screen for mood instability across all common mental health disorders. The data also highlight the utility of NLP for clinical research.

⁴ University of Coimbra, Psychological Medicine, Coimbra, Portugal

⁵ Faculty of Medicine, University of Coimbra, Institute for Biomedical Imaging and Life Sciences IBILI, Coimbra, Portugal

* Corresponding author.

Introduction Stimuli that are relevant to our survival, especially those that signal the presence of a threat in the environment (e.g., threatening faces), automatically attract our attention.

Objective The same may be true for faces displaying subtle disease cues as they may signal danger of potential contamination and, hence, disease-avoidance behaviour, which was the focus of the present research.

Aim The present study investigated, for the first time to our knowledge, whether faces with disease cues (DF), compared to control stimuli (faces without such cues) (CF), interfered with the participants' performance in a letter discrimination task.

Method Eighty-six (44 women) university students volunteered to participate in a letter discrimination task where 240 DF and 240 CF were presented.

Results The results confirmed our hypothesis by showing that for DF, compared to CF, participants took longer to discriminate

the target letters. Moreover, the results from a further rating task showed that DF, compared to CF, were rated as significantly more disgusting and associated with disease, thus confirming our experimental manipulation and suggesting that disgust may be driving automatic attention to DF.

Conclusions Our findings provide important insights on the possible influence of exogenous attention to disease cues in social avoidance behaviour, which may have relevant implications in clinical disorders with disgust at its core.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Longer duration of untreated illness, longer duration of current episode, and severity of medication side effects may negatively influence the psychosocial functioning in major affective and anxiety disorders. Studies also suggested the involvement of sensory perception in emotional and psychopathological processes.

Objective The objective of this study is to investigate the nature of the association between duration of untreated illness, duration of current episode, and severity of medication side effects.

Aims The study is aimed to examine the relationship between sensory processing disorders (SPD), duration of untreated illness, duration of current illness episode, and the severity of side effects related to psychoactive medications.

Methods The sample included 178 participants with an age ranging from 17 to 85 years (mean = 53.84 ± 15.55); psychiatric diagnoses were as follows: unipolar major depressive disorder (MDD) (50%), bipolar disorder (BD) (33.7%), and anxiety disorders (16.3%). Subjects completed a socio-demographic questionnaire, the Udvalg for Kliniske Undersøgelser (UKU), and Adolescent/Adult Sensory Profile (AASP) questionnaire.

Results Longer duration of current episode correlated with greater registration of sensory input and lower avoidance from sensory input among unipolar patients, lower registration of sensory input, and higher tendency for sensory sensitivity/sensation avoidance among bipolar participants. In addition? longer duration of current episode correlated with lower sensory sensitivity/avoidance among anxiety participants, respectively. Mean UKU total scores were associated with lower sensory sensitivity among bipolar individuals as well.

Conclusions SPD expressed in either hypo-/hypersensitivity may be used to clinically characterize subjects with major affective and anxiety disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dysfunctional meta-cognitive beliefs across psychopathology: A meta-analytic review

X. Sun*, S.H.W. So, C. Zhu, P.W.L. Leung

The Chinese University of Hong Kong, Department of Psychology, Hong Kong, China

* Corresponding author.

Introduction It is assumed that dysfunctional meta-cognitive beliefs about one's thoughts increase problematic appraisals and coping behaviors, which further contribute to the development of mental disorders (Wells and Matthews, 1994; Wells, 2000). Although this research interest originated around generalized anxiety disorder (GAD), recent studies have begun to examine similar meta-cognitive processes in other disorders. The majority of studies using Meta-cognitions Questionnaire (MCQ; Cartwright-Hatton & Wells, 1997) and its variants to assess meta-cognitive beliefs.

Objectives We conducted a meta-analysis to integrate empirical findings on group differences in meta-cognitive beliefs between healthy individuals and patients with various psychiatric disorders.

Methods We followed the PRISMA guideline (Liberati et al., 2009). A systematic literature search was conducted. We included studies that involved a diagnosed psychiatric group and healthy controls (aged 18 or above), reported group comparisons of metacognition, and were published during the period of 1990–27 August 2015. Effect sizes were computed.

Results A final set of 43 studies was included. Large combined effect sizes were found on each subdomain of the MCQ, indicating increased levels of dysfunctional meta-cognitive beliefs in patients. Subgroup analyses were carried out based on psychiatric diagnosis (i.e. psychosis, $n = 10$; GAD, $n = 7$; obsessive-compulsive disorder, OCD, $n = 15$; anorexia nervosa, $n = 5$). All patient groups were more dysfunctional on each subtype of meta-cognitive beliefs than controls. Effect size of U/D was particularly large for GAD, and that of CSC was particularly large for OCD.

Conclusions Dysfunctional meta-cognitive beliefs are evident across several psychiatric disorders, with specific types of beliefs being more marked in certain diagnoses.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Catatonia in acute psychiatric patients

R. Takacs^{1,*}, M. Asztalos², G. Gazdag¹¹ Szent Istvan and Szent Laszlo Hospitals, Centre for Psychiatry and Addiction Medicine, Budapest, Hungary² Semmelweis University, School of Doctoral Studies, Budapest, Hungary

* Corresponding author.

Introduction Over the past years, catatonia received increasing attention. The concept of catatonia has been decoupled from schizophrenia and broadened.

Aim The aim of our prospective study was to determine the prevalence of catatonia in patients admitted to an acute psychiatric ward.

Material and methods We examined all patients acutely admitted to the Centre for Psychiatry and Addiction Medicine (CPAM) of Szent István and Szent László Hospitals, from 01/04/2015 to 31/07/2015. We used Bush Francis Catatonia Screening Instrument (BFCIS) for the assessment of catatonic signs. In case of presence of 2 or more symptoms on BFCIS, the severity of catatonia was rated with Bush Francis Catatonia Rating Scale (BFCRS). After detailed

clinical examination, we used Structured Clinical Interview for DSM-IV, Mini Mental State Examination and Clock Drawing Test in setting up a diagnose.

Results In the study period, altogether 338 patients were admitted to CPAM. Catatonia could be diagnosed in 8.55% of them, according to BFCRS and in case of 5.02% the diagnosis of catatonia could be set up according to DSM-5 diagnostic criteria. Female patients were present in 58.62%. The mean age was 57.62 years. Schizophrenia spectrum disorder was diagnose in 41.3%, dementia in 27.5%, affective disorder in 6.89%, alcohol, drug withdrawal syndrome, Down syndrome and mental retardation in 3.44% each, other organic disease in 10.34% of all catatonia cases.

Conclusion Catatonia can be present in a variety of psychiatric conditions. Its specific therapy gives a special importance to the recognition of this syndrome.

Hematological safety of olanzapine

A. Alageel^{1,*}, E. Gaffas²¹ Imam University, Psychiatry Dep., Riyadh, Kingdom of Saudi Arabia² Alamal Complex for Mental Health, Psychiatry Department, Riyadh, Kingdom of Saudi Arabia

* Corresponding author.

Introduction Olanzapine is an atypical antipsychotic medication, previously expected to be safe in terms of hematological side effects and an alternative choice to clozapine in patients who develop hematotoxicities. However, since olanzapine was introduced to the market, a lot of cases reports have been published revealing it could cause hematotoxicity. Some of them indicate that olanzapine induces agranulocytosis. Because of that, it raises the concerns about hematological safety of olanzapine.

Objective To date, no review discusses this topic specifically, so we conducted a systemic review to explore and address this issue.

Methods We searched Pubmed, Google Scholar, Ovid and Medline databases for articles between 1998 and 2015 that include keywords olanzapine, leukopenia, neutropenia, and agranulocytosis.

Results A total of 38 publications were identified. The case reports included patients aged 16 to 83 years. Doses ranged from 2.5 to 30 mg. After starting treatment, onset of hematotoxicity varied from the first day to 2–3 years, but most commonly within the first month. Also, olanzapine could induce leukopenia in patients who have never developed drug-related leukopenia.

Conclusion Among antipsychotic medications, olanzapine is the third leading cause of neutropenia and the second leading cause of atypical antipsychotic medication. Because of the small body of literature regarding the hematotoxic side effects of olanzapine, we encourage further research to understand the mechanism by which olanzapine causes granulocytopenia. The identification of risk factors could facilitate the development of new surveillance guidelines in patients taking olanzapine. We recommend that the guidelines of using and monitoring olanzapine need to be reconsidered.

Utilization of psychotropic drugs in Europe: Why is Portugal such a particular case?

T. Alves-dos-Reis^{1,2,*}, M.A. Matias³

¹ Hospital do Espírito Santo de Évora, Psiquiatria e Saúde Mental, Évora, Portugal

² NOVA Medical School Faculdade Ciências Médicas, Mental Health, Lisbon, Portugal

³ Nova School of Business and Economics, Universidade Nova de Lisboa, Business and Economics, Lisbon, Portugal

* Corresponding author.

Introduction Psychotropic drugs are among the most utilized medications in Europe.

Objectives To perform an international comparison of the utilization trends of antidepressants, anxiolytics, hypnotics and sedatives (AHS).

Methods We used data from the Organization for Economic Cooperation and Development (OECD). We used the World Health Organization's Defined Daily Dosage (DDD) per 1000 inhabitants per day (DHD) methodology. We performed a general comparison between 14 European countries and a more detailed comparative analysis between Portugal, Italy, Spain and Germany. These countries were selected according to the following criteria: similar 12-month prevalence of mental health disorders, similar results for negative mental health (SF-36 questionnaire) and similar standardized death rates for suicide.

Results Portugal had the highest overall utilization of antidepressants and AHS in 2011, amounting to 110.7 DHD, and the highest increase in utilization of AHS (1.8%) from 2003 and 2011. Concerning antidepressants, Portugal had the third highest utilization of these drugs in 2011 (78.3 DHD). Regarding the more detailed comparative analysis, utilization of AHS was still significantly higher in Portugal. Considering antidepressants, Portugal experienced an increasing utilization, which grew by approximately 11.4% from 2003 and 2008. From 2009 onward the utilization increased but at a slower pace.

Conclusion The very high utilization of these drugs, especially of AHS, is a worrying fact since this might indicate an inadequate treatment choice for anxiety and depressive disorders. Further research is needed to better understand the relationship of these findings with regulations concerning utilization of psychotropic drugs and compliance with best medical practices between distinct European countries.

⁷ St. Vincent's Hospital, psychiatry, Suwon, Republic of Korea

⁸ Naju National Hospital, psychiatry, Naju, Republic of Korea

* Corresponding author.

Introduction Evidences for antipsychotics augmentation for schizophrenic patients with suboptimal efficacy have been lacking although it has been widespread therapeutic strategy in clinical practice.

Objectives The purpose of this study was to investigate the efficacy and tolerability of blonanserin augmentation with an atypical antipsychotics (AAPs) in schizophrenic patients.

Methods A total of 100 patients with schizophrenia partially or completely unresponsive to treatment with an AAP recruited in this 12-week, open-label, non-comparative, multicenter study. Blonanserin was added to existing AAPs which were maintained during the study period. Efficacy was primarily evaluated using Positive and Negative Syndrome Scale (PANSS) at baseline, week 2, 4, 8, and 12. Predictors for PANSS response ($\geq 20\%$ reduction) was investigated.

Results The PANSS total score was significantly decreased at 12 weeks after blonanserin augmentation (-21.0 ± 18.1 , $F = 105.849$, $P < 0.001$). Response rate on PANSS at week 12 was 51.0%. Premature discontinuation was occurred in 17 patients (17.0%) and 4 patients among them discontinued the study due to adverse events. Nine patients experienced significant weight gain during the study. Response to blonanserin augmentation was associated with severe (PANSS > 85) baseline symptom (OR = 10.298, $P = 0.007$) and higher dose (> 600 mg/day of chlorpromazine equivalent dose) of existing AAPs (OR = 4.594, $P = 0.014$).

Conclusions Blonanserin augmentation improved psychiatric symptoms of schizophrenic patients in cases of partial or non-responsive to an AAP treatment with favorable tolerability. Patients with severe symptom despite treatment with higher dose of AAP were benefited from this augmentation. These results suggested that blonanserin augmentation could be an effective strategy for specific patients with schizophrenia.

⁴ Soonchunghang University, psychiatry, Cheonan, Republic of Korea

⁵ Dongguk University, psychiatry, Gyeongju, Republic of Korea

⁶ Chung-Ang University, psychiatry, Seoul, Republic of Korea

⁷ Wonkwang University, psychiatry, Iksan, Republic of Korea

* Corresponding author.

Objective Emerging preclinical and clinical evidence suggests a potential role of nicotinic acetylcholine receptors in the pathophysiology of depression. Several clinical trials have investigated the efficacy of nicotinic acetylcholine receptor antagonists in treatment-resistant depression. We performed this meta-analysis to investigate whether nicotinic acetylcholine receptor antagonists significantly improve symptoms in patients with major depressive disorder who have an inadequate response to standard antidepressant therapy.

Methods A comprehensive literature search identified 6 randomized controlled trials. These 6 trials, which included 2067 participants, were pooled for this meta-analysis using a random-effects model.

Results Nicotinic acetylcholine receptor antagonists failed to show superior efficacy compared to placebo in terms of the mean change in the Montgomery-Asberg Depression Rating Scale (MADRS) score [mean difference = -0.12 (95% CI = -0.96 to 0.71); response rate (risk ratio [RR]) = 0.92 (95% CI = 0.83 to 1.02)]; and remission rate [RR] = 1.01 (95% CI = 0.83 to 1.23)].

Conclusion This meta-analysis failed to confirm preliminary positive evidence for the efficacy of nicotinic acetylcholine receptor antagonists in treatment-resistant depression. Further studies investigating the efficacy of various alternative treatment strategies for treatment-resistant depression will help clinicians to better understand and choose better treatment options for these populations.

Efficacy and safety of generic escitalopram (Lexacure) in patients with major depressive disorder: A 6-week, multi-center, randomized, rater-blinded, escitalopram-comparative, non-inferiority study

J.H. Jeong¹, W.M. Bahk^{2,*}, Y.S. Woo², K.U. Lee³, M.D. Kim⁴, W. Kim⁵, J.C. Yang⁶, K.H. Lee⁷, S.Y. Lee⁸

¹ St. Vincent's Hospital, psychiatry, Suwon, Republic of Korea

⁶ Chonbuk National University Medical School, psychiatry, Jeonju, Republic of Korea

⁷ College of Medicine, Dongguk University, psychiatry, Seoul, Republic of Korea

⁸ Wonkwang University School of Medicine, psychiatry, Iksan, Republic of Korea

* Corresponding author.

Objectives The primary aim of this non-inferiority study was to investigate the clinical effectiveness and safety of generic escitalopram (Lexacure) versus branded escitalopram (Lexapro) for patients with major depressive disorder (MDD).

Methods The present study included 158 patients who were randomized (1:1) to receive a flexible dose of generic escitalopram ($n=78$) or branded escitalopram ($n=80$) over a 6-week single-blind treatment period. The clinical benefits in the two groups were evaluated using the Montgomery-Asberg Depression Rating Scale (MADRS), the 17-item Hamilton Depression Rating Scale (HDRS), the Clinical Global Impressions-Severity Scale (CGI-S), and the Clinical Global Impressions-Improvement Scale (CGI-I) at baseline, week 1, week 2, week 4, and week 6. The frequency of adverse events (AEs) was also assessed to determine safety at each follow-up visit.

Results At week 6, 28 patients (57.1%) in the generic escitalopram group and 35 patients (67.3%) in the branded escitalopram group had responded to treatment ($P=0.126$), and the remission rates (MADRS score: ≤ 10) were 42.9% ($n=21$) in generic escitalopram group and 53.8% ($n=28$) in the branded escitalopram group ($P=0.135$). The most frequently reported AEs were nausea (17.9%) in the generic escitalopram group and nausea (20.0%) in the branded escitalopram group.

Conclusions The present non-inferiority study demonstrated that generic escitalopram is a safe and effective initial treatment for patients with MDD and may also be considered as an additional therapeutic option for this population.

⁶ Shire, Global HEOR and Epidemiology, Wayne, USA

⁷ Central Institute of Mental Health, Department of Child and Adolescent Psychiatry and Psychotherapy, Mannheim, Germany

* Corresponding author.

Objective To document patient characteristics and treatment patterns in a real-world population diagnosed with attention-deficit/hyperactivity disorder (ADHD).

Methods This was a retrospective chart review of children/adolescents (6–17 years) diagnosed with ADHD in the UK, Germany and Netherlands who initiated stimulant monotherapy (SM), non-stimulant (atomoxetine) monotherapy (NSM) or polypharmacy (SM/NSM \pm SM/NSM or other psychotropics) on/after 1-1-2012. To facilitate descriptive comparisons, cohort quotas were imposed: $\sim 50\%$ SM; $\sim 25\%$ NSM; $\sim 25\%$ polypharmacy. Index date was first SM, NSM or polypharmacy treatment on/after 1-1-2012. Patients were required to have ≥ 6 months' pre-index (baseline) history and ≥ 12 months' post-index follow-up. Analyses were descriptive.

Results In total, 497 patients were included (mean [SD] age: 10.8 [2.9] years; 77% male); 65% (SM), 63% (NSM) and 83% (polypharmacy) had at least marked baseline ADHD severity based on Clinical Global Impressions scale ($P < 0.05$ SM/NSM vs polypharmacy). Ninety percent (SM), 75% (NSM) and 73% (polypharmacy) were pharmacotherapy naive at index (all $P < 0.10$); 61% (SM), 65% (NSM) and 72% (polypharmacy) received previous behavioural therapy. In SM patients, methylphenidate was predominant (most frequent brands: Concerta® [29%], Medikinet® [28%]); in polypharmacy patients, methylphenidate plus atomoxetine (22%) or other psychotropic (19%) was most common. Index therapy switch was common, particularly in polypharmacy patients (25%) ($P < 0.05$ vs SM [14%] and NSM [13%]). Switches were precipitated by poor response in 75% of cases overall.

Conclusions Polypharmacy patients generally presented a more complicated history (including higher ADHD severity) and treatment pathway versus monotherapy patients. Index therapy switches were commonplace and more frequent in polypharmacy patients, often due to poor response.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexual side effects in patients treated with desvenlafaxine: An observational study in daily practice

B. Navarro^{1,*}, L. Perez¹, L. Erkoreka¹, A. Arroita², I. Perez³

¹ Red de Salud Mental de Bizkaia, CSM Barakaldo, Bilbao, Spain

² Re de Salud Mental de Bizkaia, CSM Barakaldo, Bilbao, Spain

³ Hospital Universitario Cruces, psiquiatría, Barakaldo, Spain

* Corresponding author.

Introduction Sexual function is important for patients' well-being but it is a common side effect of SSRI and SNRI, included desvenlafaxine.

Objectives and aims Evaluate incidence and characteristics of sexual dysfunction caused by desvenlafaxine in the clinical practice.

Methods One hundred and thirty-three patients with recently introduced desvenlafaxine treatment are recruited from Barakaldo and Uribe-Kosta Mental Health Centres in Biscay, Spain. UKU scale is administered to measure sexual side effects. Statistical analysis is performed using SPSS v.22.

Results Sexual dysfunction is observed in 5 patients (3.7%) at 50 and 100 mg/d (2 and 3 patients, respectively) desvenlafaxine doses. Two patients (1.5%) have experienced more than one sexual side effect. Regarding gender differences, the most frequent sexual dysfunctions are diminished sexual desire (5.5%) and erectile dysfunction (5.5%) in men and orgasmic dysfunction (1.2%) in women (*P*-values are 0.034; 0.034 and 0.408, respectively). Discontinuation is decided in 60% of patients.

Conclusions Desvenlafaxine has a well-tolerated sexual side effect profile in general population. There are some gender-related differences both in presentation and perception, as it has been described with other drugs, and this should be taken into account by prescribers.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁷ University of "G. D'Annunzio", Department of Neuroscience, Imaging and Clinical Science, Chieti, Italy

⁸ Laboratory of Molecular Psychiatry and Psychopharmacotherapeutics, Section of Psychiatry, Department of Neuroscience, University School of Medicine "Federico II", Naples, Italy

* Corresponding author.

Introduction Cariprazine (RGH-188) is a novel antipsychotic drug that exerts partial agonism of dopamine D₂/D₃ receptors with preferential binding to D₃ receptor, antagonism of 5HT_{2B} receptors and partial agonism of 5HT_{1A}. Currently, cariprazine is in late-stage clinical development (phase III clinical trials) in patients with schizophrenia (S) and in patients with bipolar disorder (BD), as

well as an adjunctive treatment in patients with Major Depressive Disorder (MDD) and drug-resistant MDD.

Objectives Cariprazine has completed phase III trials for the acute treatment of schizophrenia and bipolar mania, phase II trials for the bipolar depression and MDD whilst it is undergoing phase III trials as an adjunct to antidepressants.

Aims The present review aims at proving a comprehensive summary of the current evidence on the safety, tolerability and efficacy of cariprazine in the treatment of schizophrenia, BD (manic/mixed/depressive episode) and MDD.

Methods A systematic search was conducted on PubMed/Medline/Scopus and the database on Clinical Trials from inception until April 2015 by typing a set of specified keywords.

Results Available evidence seems to support cariprazine efficacy in the treatment of cognitive and negative symptoms of schizophrenia. Preliminary findings suggest its antimanic activity whilst it is still under investigation its efficacy in the treatment of bipolar depression and MDD. Furthermore, the available data seems not to allow judgements about its antipsychotic potential in comparison with currently prescribed antipsychotics.

Conclusions Further studies should be carried out to better investigate its pharmacodynamic and clinical potential, particularly as alternative to current antipsychotic drugs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of inhaled loxapine in acute psychiatric agitation

S. Ovejero^{1,*}, M. Iza¹, S. Vallejo¹, C. Vera¹, A. Sedano¹, R. Álvarez², L. Mata¹, S. Sánchez-Alonso¹

¹ Hospital Universitario Fundación Jiménez Díaz, Psychiatry, Madrid, Spain

² Hospital Universitario Rey Juan Carlos, Psychiatry, Móstoles, Spain

* Corresponding author.

Objectives The aim of this work is to study the efficacy of loxapine inhalation powder on agitated patients in a psychiatric inpatient unit.

Methods Nineteen patients sample, with an average age of 39.4 years old, diagnosed with schizophrenia, bipolar disorder or schizoaffective disorder. Patients inhaled loxapine 10 mg, using the staccato system, when they suffered a psychomotor agitation. The clinical efficacy was measured as a change from baseline in the Positive and Negative Syndrome Scale-Excited Component (PANSS-EC) and in the Young Mania Rating Scale (YMRS) one hour after the administration of loxapine.

Results A mean of 9.8 points reduction (22.6 at baseline and 12.7 one hour after the administration) was found on the PANSS-EC (*t*-test, *P* < .001) and 68.4% of the patients were considered responders as they obtained a reduction of at least 40% of the basal score. On 10 of the total of the agitated patients showed an improvement of the psychomotor excitement, and this allowed the clinicians to remove the physical restraint; on 6 of the agitated patients the physical restraint could be avoided during the whole treatment; and 3 of the patients experienced a reduction of the excitement. The reduction on PANSS-EC on the latest group was not statistically significant (*t*-test, *P* = .121).

Conclusions Inhaled loxapine was a non-invasive, rapid and effective alternative treatment for acute agitation in a psychiatric inpatient unit. It resulted more effective on mild and moderate cases; not been significantly effective on the severe cases of agitation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Which antidepressants are associated with increased risk of developing mania? A retrospective electronic case register cohort study

R. Patel^{1,*}, P. Reiss¹, H. Shetty², M. Broadbent², R. Stewart³, P. McGuire¹, M. Taylor¹

¹ Institute of Psychiatry, Psychology and Neuroscience, Department of Psychosis Studies, London, United Kingdom

² South London and Maudsley NHS Foundation Trust, Biomedical Research Centre Nucleus, London, United Kingdom

³ Institute of Psychiatry, Psychology and Neuroscience, Department of Psychological Medicine, London, United Kingdom

* Corresponding author.

Introduction The symptoms of bipolar disorder are sometimes misrecognised for unipolar depression and inappropriately treated with antidepressants. This may be associated with increased risk of developing mania. However, the extent to which this depends on what type of antidepressant is prescribed remains unclear.

Aims To investigate the association between different classes of antidepressants and subsequent onset of mania/bipolar disorder in a real-world clinical setting.

Methods Data on prior antidepressant therapy were extracted from 21,012 adults with unipolar depression receiving care from the South London and Maudsley NHS Foundation Trust (SLaM). Multivariable Cox regression analysis (with age and gender as covariates) was used to investigate the association of antidepressant therapy with risk of developing mania/bipolar disorder.

Results In total, 91,110 person-years of follow-up data were analysed (mean follow-up: 4.3 years). The overall incidence rate of mania/bipolar disorder was 10.9 per 1000 person-years. The peak incidence of mania/bipolar disorder was seen in patients aged between 26 and 35 years (12.3 per 1000 person-years). The most frequently prescribed antidepressants were SSRIs (35.5%), mirtazapine (9.4%), venlafaxine (5.6%) and TCAs (4.7%). Prior antidepressant treatment was associated with an increased incidence of mania/bipolar disorder ranging from 13.1 to 19.1 per 1000 person-years. Multivariable analysis indicated a significant association with SSRIs (hazard ratio 1.34, 95% CI 1.18–1.52) and venlafaxine (1.35, 1.07–1.70).

Conclusions In people with unipolar depression, antidepressant treatment is associated with an increased risk of subsequent mania/bipolar disorder. These findings highlight the importance of considering risk factors for mania when treating people with depression.

⁶ Royal Free Campus, University College London, UCL Institute of Liver and Digestive Health, London, United Kingdom

* Corresponding author.

Introduction/objective The hepatic safety of agomelatine was assessed in 49 phase II and III studies. The aim was to analyze the characteristics of patients who developed an increase in transaminases whilst taking agomelatine.

Method A retrospective pooled analysis of changes in serum transaminase in 7605 patients treated with agomelatine (25 mg or 50 mg/day) from 49 completed studies was undertaken. A significant increase in serum transaminase was defined as >3-fold the upper limit of normal (>3 ULN). Final causality was determined in a case-by-case review by five academic experts.

Results Transaminase increased to >3 ULN in 1.3% and 2.5% of patients treated with 25 mg and 50 mg of agomelatine respectively, compared to 0.5% for placebo. The onset of increased transaminases occurred at <12 weeks in 64% of patients. The median time to recovery (to ≤2 ULN) was 14 days following treatment withdrawal. Liver function tests recovered in 36.1% patients despite the continuation of agomelatine, suggesting the presence of a liver adaptive mechanism. Patients with elevated transaminases at baseline, secondary to obesity and fatty liver disease (NAFLD), had an equally increased risk of developing further elevations of transaminases with agomelatine and placebo. This reflects the widespread fluctuations of serum transaminases in patients with NAFLD.

Conclusions The overall incidence of abnormal transaminases was low and dose dependent. No specific population was identified regarding potential risk factors. Withdrawal of agomelatine led to rapid recovery, and some patients exhibited an adaptive phenomenon. The liver profile of agomelatine seems safe when serum transaminases are monitored.

Hospital admissions and direct costs: A comparative study between paliperidone palmitate and oral antipsychotics

A. Soler Iborte^{1,*}, S. Galiano Rus², J.A. Ruíz Sánchez³

¹ Servicio Andaluz de Salud, UGC Jaén Norte, Unidad de Salud Mental Comunitaria de Linares, Linares, Jaén, Spain

² Servicio Andaluz de Salud, UGC Jaén Norte, Hospital San Juan de la Cruz, Úbeda, Jaén, Spain

³ Servicio Andaluz de Salud, UGC Jaén Norte, Unidad de Salud Mental Comunitaria Úbeda, Úbeda, Jaén, Spain

* Corresponding author.

Introduction The total costs of schizophrenia increased to 2576 million Euros in 2013 in Spain, or 2.7% of the annual cost of health services. The hospitalizations, along with other intermediate resources, such as Day Hospital, etc., significantly contribute to the increase of economic burden. In Spain, the average hospital stay of schizophrenic patients is 18.24 days, totalling to an average cost of 6,753 Euros/patient (370.23 Euros/patient/day).

Material and methods The sample selected included patients from both sexes, aged between 18 and 65 years old, with diagnostic criteria of schizophrenia (according to DSM-IV and ICD-10), admitted in the Mental Health Hospital Unit (MHHU), Úbeda between 2012 and 2013, with registered visits of at least 2 outpatient visits or 1 hospitalization related to the schizophrenia diagnosis ($n = 48$).

Results After the start of treatment with the injectable antipsychotic drug of prolonged duration, the number of patients that required hospitalization for any psychiatric motive went from 24 patients (49.7%) to 11 patients (22.4%; $P < 0.001$). The patients who started treatment with PAP during hospitalization had an average

stay of 15.7 days, as compared to 18.24 days of average hospital stay due to schizophrenia in Spain. The direct costs of hospitalization stays due to psychiatric reasons decreased from 162,071.88 Euros to 74,282.95 Euros ($P < 0.001$).

Conclusions This observational study shows us that the treatment with PAP reduced the average length of the hospital stay, and resulted in a decreased percentage of re-admissions as compared to oral treatments for schizophrenia. These data led to savings of more than 50% of the direct costs of hospitalization.

Hyperuricemia in children and adolescents with autism spectrum disorders treated with risperidone: The risk factors for metabolic adverse effect

C. Sukasem*, N. Vanwong

Faculty of Medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

* Corresponding author.

Introduction The prevalence of hyperuricemia in ASDs pediatric patients including the association of serum uric acid and metabolic adverse effect in ASDs pediatric patients treated with risperidone have never been examined.

Objective To determine the prevalence of hyperuricemia in ASD pediatric patients treated with risperidone and the relationships between serum uric acid level and risk factor components of metabolic syndrome.

Methods This cross-sectional study recruited 127 Thai ASDs children and adolescents, which age 3–20 years and had received risperidone for more than 4 weeks. The condition of hyperuricemia was defined as a high level of uric acid in the blood > 5.5 mg/dL.

Results Hyperuricemia was observed in 73 of 127 (57.48%) subjects. Serum uric acid level were statistically significant positively associated with age, risperidone dose, duration of treatment, BMI, waist circumference, triglycerides (TG), TG/HDL cholesterol ratio, insulin, homeostatic model assessment index (HOMA-IR), leptin, and high-sensitivity CRP (hs-CRP). Furthermore, serum uric acid was statistically significant negatively associated with HDL cholesterol and adiponectin level. In multiple regression, only age, BMI, TG/HDL-C, and adiponectin level remained significant associated with serum uric acid level ($P < 0.0001$).

Conclusions High level of serum uric acid related with adolescence. Serum uric acid level correlated with most of the risk factors of metabolic syndrome, except blood glucose and LDL-C levels. The information might encourage the clinicians for aware to the possible consequences of hyperuricemia, in order to verify possible complications of early metabolic syndrome in ASDs pediatric treated with risperidone.

Development and validation of liquid chromatography/tandem mass spectrometry analysis for therapeutic drug monitoring of risperidone and 9-hydroxyrisperidone in pediatric patients with autism spectrum disorders

C. Sukasem*, S. Prommas

Faculty of medicine Ramathibodi hospital, pathology, Bangkok, Thailand

* Corresponding author.

Objectives The sensitive, accurate and specific LC-MS/MS method, which a small-volume injection has been developed and validated for simultaneous quantification of RIS and 9-OH-RIS plasma concentrations in ASD pediatric patients.

Methods Plasma samples were extracted by using the protein precipitation extraction technique and were separated on an Agilent, USA C18 column (4.6 cm \times 50 mm; 1.8 μ m particle size). Detection was by MS-MS with an analytical run time of 6 minutes.

Results The recoveries were in the range of 95.01–112.62% for RIS and 90.27–114.00% for 9-OH-RIS. The method was applied in the therapeutic drug monitoring (TDM) of ASD pediatric patients treated with oral RIS. This study was to investigate the relationship between RIS dosages with RIS plasma levels including to investigate the correlations between RIS plasma levels and serum prolactin levels in ASD pediatric patients. Risperidone doses were significantly positively related with the concentration of RIS, 9-OH-RIS and active moiety. Moreover, the result indicates that the higher concentrations of RIS and its metabolite have a tendency to produce prolactin elevations than the lower RIS concentrations.

Conclusion The determination of RIS and its metabolites in individual patient could be clinically useful for prediction and monitoring of treatment response to RIS. Therefore, we recommend the determination of RIS and its metabolites as part of an ongoing study in which routinely monitored for compliance and to adjust the RIS dose to achieve the optimum clinical outcome as well as to aware of the adverse drug reaction.

9-hydroxyrisperidone induced hyperprolactinemia in Thai children and adolescents with autism spectrum disorder

C. Sukasem*, M. Chamnanphon

Faculty of medicine Ramathibodi hospital, pathology, Bangkok, Thailand

* Corresponding author.

Introduction Although our previous study has revealed association between prolactin level and risperidone dosage, data on plasma drug concentration of risperidone therapy was lacking.

Objectives Therefore, the aim of this study was to investigate the association between plasma drug concentrations of risperidone and serum prolactin level in Thai children and adolescent with autism spectrum disorders (ASD).

Methods The subjects were 103 children and adolescent with ASD (90 males and 13 females). Blood sample were collected 12 hours after the last drug administration. Serum prolactin levels, plasma risperidone and 9-hydroxyrisperidone level were measured. The clinical data of patients collected from medical records—age, weight, height, body mass index, dose of risperidone, and duration of treatment—were recorded.

Results Serum prolactin level was significantly positively correlated with plasma 9-hydroxyrisperidone levels ($r_s = 0.355$, $P < 0.001$). The median of 9-hydroxyrisperidone level in group of hyperprolactinemia (7.59 ng/mL IQR; 4.86–15.55) significantly higher than non-hyperprolactinemia (5.18 ng/mL; IQR 2.10–8.99) after risperidone treatment ($P = 0.006$).

Conclusion The results of this study showed that serum prolactin levels, especially autism with hyperprolactinemia during risperidone treatment, were significantly correlated with level of the

9-hydroxyrisperidone. These results propose that hyperprolactinemia may develop during risperidone treatment.

Efficacy and safety of long-term cabergoline treatment of antipsychotic-induced hyperprolactinemia (naturalistic study)

O. Yunilaynen^{1,*}, E. Starostina², L. Dzeranova¹, P. Baranov³, I. Dedov⁴

¹ National research center for endocrinology, neuroendocrinology, Moscow, Russia

² Moscow regional clinical & research institute MONIKI, endocrinology, Moscow, Russia

³ Russian medical academy of post-graduate training, psychiatry, Moscow, Russia

⁴ National research center for endocrinology, diabetes center, Moscow, Russia

* Corresponding author.

Introduction Antipsychotic-induced hyperprolactinemia (AIH) is associated with disturbing clinical symptoms, such as sexual dysfunctions, menstrual disorders and galactorrhea. Long-term studies of dopamine agonists in AIH are scarce.

Objectives To assess efficacy and safety of cabergoline use in psychiatric patients with AIH, including impact on sexual function and quality of life (QoL).

Methods It was an open-labeled non-randomized naturalistic prospective comparison of cabergoline vs no treatment in 84 chronic psychiatric patients (F/M=77/7) with AIH. Cabergoline treatment was started in 44 patients, the control group included 40 patients who rejected the treatment with cabergoline. For assessment of QoL, sexual dysfunction and other hyperprolactinemia symptoms, UKU side effects rating scale (UKU) and SF-36 were used.

Results The main and control groups were comparable on all main clinical and psychiatric characteristics. The effective cabergoline dose was 0,25-3 (median-0,5) mg weekly; total cabergoline exposure-534 patient-weeks. Normal prolactin levels were achieved after 4-44 (median-14) weeks in 95% of patients. At 3 months after cabergoline discontinuation, prolactin remained normal in 71%, and AIH recurred in 29% of patients. Prolactin normalization was associated with significant reduction of menstrual disorders, galactorrhea, improvement of UKU scores on sexual desire, orgasmic dysfunction, total UKU score and SF-36 scores on subscales of social functioning ($P=0,006$), role-emotional ($P=0,042$), and mental health ($P=0,049$). The rate of psychosis exacerbation in control group was higher than in the treatment group (37,5% vs 0%; $P<0,001$).

Conclusions Cabergoline is effective and safe in majority of AIH patients. Long-term cabergoline treatment is not associated with psychosis exacerbation. Beyond reversal of typical AIH symptoms, treatment with cabergolin improves sexual function and QoL.

Electroconvulsive therapy in elderly - a preliminary study

C. Agostinho*, M. Duarte, R. Alves, I. Cunha, A.M. Batista
Centro hospitalar psiquiátrico de Lisboa, Lisboa, Portugal

* Corresponding author.

Introduction Studies with electroconvulsive therapy (ECT) in elderly focus mainly on the assessment of possible side effects on the cognitive functioning; there are few studies that evaluate the effectiveness.

Objective Evaluate the effectiveness of this treatment in the population over 65 years.

Aims Perform a preliminary study to evaluate the response to ECT of ≥ 65 years patients with depression.

Methods We carry out a descriptive study based on patients treated in the last 10 years in the ECT Unit of Centro Hospitalar Psiquiátrico de Lisboa.

Results Our initial sample consisted of 457 patients. We select patients aged ≥ 65 years with depression, and with complete data, including electroconvulsive parameters, and initial and final Hamilton Rating Scale for Depression (HRSD) scores ($n=59$). Of this, 81.36% ($n=48$) had unipolar depression, and 18.64% ($n=11$) had bipolar depression. In the first group, the mean variation between the initial and final scores in HRSD was 13.88 points, and 27.10% ($n=13$) of the patients ended the treatment in the normal range of HRSD score. In the second group, the mean variation was 12.82, and 63.60% ($n=7$) ended the treatment in the normal range of HRSD. Considering the initial and final HRSD scores, it appears that unipolar depression group presents higher values (severe depression) ($P<0.05$). When we compare the mean variation between the initial and final HRSD scores, we didn't observe a statistically significant difference between the two groups. There was a clinical improvement in both.

Conclusions The acute treatment with ECT appears to improve depressive symptoms in bipolar and unipolar depression, when considering an elderly population.

Knowledge and attitude toward repetitive transcranial magnetic stimulation (rTMS) among psychiatrists in Saudi Arabia

A. Alhadi^{1,2,*}, A. AlShiban³, M. Alomar³, O. Aljadoa³,
A. AlSayegh³, M. Jameel³

¹ King Saud university, department of psychiatry, Riyadh, Kingdom of Saudi Arabia

² King Saud university, SABIC psychological health research & applications chair SPHRAC, Riyadh, Kingdom of Saudi Arabia

³ King Saud university, college of medicine, Riyadh, Kingdom of Saudi Arabia

* Corresponding author.

Introduction Repetitive transcranial magnetic stimulation (rTMS) is a new treatment, used for different psychotic disorders mainly depression.

Objectives Assessing knowledge and attitude toward rTMS among psychiatrists in Saudi Arabia, and determining factors affecting that.

Aims To ensure that psychiatrists have sufficient knowledge regarding rTMS. A good knowledge will most likely have a positive impact on their attitude.

Methods Cross-sectional study was conducted through an online survey. The study population is all psychiatrists in Saudi Arabia. A new valid and reliable questionnaire was developed.

Results Sample of 96 psychiatrists enrolled in the study, 81% were males. Participant's mean age was 37 years. Half of participants were consultants. The sample mainly consists of general psychiatrists (65%). The study showed that 80% of psychiatrists have an efficient knowledge about rTMS. Consultants have higher knowledge than residents do. Abroad training has no association with the level of knowledge or attitude. Seventy-nine percent of psychiatrists have a positive attitude toward rTMS. Only 53% of psychiatrists agreed to receive (rTMS) in case they were in a psychotic depressive condition. Minority (7%) of psychiatrists would not refer their patients for rTMS.

Conclusion Most of psychiatrists have a good knowledge and a positive attitude toward rTMS. Those who have high level of training and experience show higher level of knowledge. Articles are found to be a better source for updating knowledge. Having an rTMS treated person in the family or relatives will positively affect the psychiatrist's attitude.

Changes in symptom severity and biochemical markers of brain injury in patients with treatment-resistant schizophrenia

N. Petrova^{1,*}, M. Dorofeikova¹, V. Dorofeykov², M. Ivanov³, D. Zubov³

¹ Saint Petersburg State university, medical faculty, Saint-Petersburg, Russia

² D.O. Ott research institute of obstetrics - gynecology and reproductive technology, laboratory of biochemistry, Saint-Petersburg, Russia

³ Saint-Petersburg V.M. Bekhterev psychoneurological research institute, department of biological therapy, Saint-Petersburg, Russia

* Corresponding author.

One of the major problems of the methodology of translational research is to find biomarkers that serve as indicators of treatment response.

The aim was to study the dynamics of biochemical markers in the process of combined antipsychotics and electroconvulsive therapy. **Material and methods** Present study was conducted in 34 patients with treatment-resistant schizophrenia (31.6 ± 9.4 years old) that underwent combined ECT (10 ECTs on average) and pharmacological treatment. The assessment included PANSS and determination of NSE and S100B protein concentrations using automated immunochemical analyzer "Elecsys 2010". Blood samples were obtained before the beginning of ECT, 24 hours after the third and sixth ECTs.

Results Average reduction of PANSS score was 29,1%, >20% for 85% of patients. There were no significant differences in NSE and S100B concentrations at different stages of treatment. This result is consistent with data on the safety of ECT from the point of view of the integrity of cells. There were found statistically significant differences between S100B concentration in women and men (60 ± 18 and 43 ± 23 ng/L, respectively, $P = 0.029$) and a trend of increase in S100 levels with the increase of disease duration ($r = 0.372$, $P = 0.062$). Serum S100B concentrations at baseline negatively correlated with positive and negative symptoms severity and with PANSS composite score. No correlation between treatment efficiency and biochemical markers' levels was found.

Conclusion Combined antipsychotic and electroconvulsive therapy was effective for treatment-resistant schizophrenic patients and did not induce nerve cells damage. Initial symptom severity was correlated with S100B levels.

ECT-treatment in Western Norway; first data from the Regional register of neurostimulation treatment

U. Kessler^{1,*}, H. Schoeyen²

¹ Haukeland university hospital, clinic for psychosomatic medicine, Bergen, Norway

² Stavanger university hospital, department of psychiatry, Stavangerno, Norway

* Corresponding author.

Introduction Electroconvulsive therapy (ECT) is one of the most polarizing treatments in medicine. Although the treatment effect is well documented in clinical studies, there is a lack of data regarding patients treated in an ordinary clinical setting. In 2013, we established a regional register of neurostimulation treatment in Western Norway.

Objectives To describe the use of ECT at the Haukeland university hospital in Bergen.

Methods Patients treated with ECT between June 2013 and June 2015 were included in the register.

Results One hundred and forty-seven patients received ECT during the 2 years period. The mean age was 58.4 years (22–91 years), 67% were female. Half of the patients (49.7%) had been treated with ECT previously. Indication for treatment was depression in 137 patients (93.2%), of which 29 (19.7%) were moderately, and 69 patients (46.9%) severely depressed, and additional 37 patients (25.2%) presented with severe depression with psychotic features. All but two patients were treated with right unilateral electrode placement, with a mean of 9.7 (3–22) treatments.

The mean MADRS before treatment was 34.2 (4–56) and after treatment 11.9 (0–39). One hundred and ten patients (74.8%) responded to treatment; of which 89 (60.5%) remitted (response defined as a 50% or greater decrease from MADRS baseline score, remission defined as MADRS ≤ 12). Twenty patients (13%) continued with continuation or maintenance ECT after the index series.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Repetitive transcranial magnetic stimulation (rTMS) for the management of treatment-resistant depression in schizophrenia

S. Mosolov*, N. Maslenikov, E. Tsukarzi

Moscow research institute of psychiatry, therapy of mental disorders, Moscow, Russia

* Corresponding author.

Introduction Depression is the most common co-occurring syndrome in schizophrenia, which affects up to 60% of patients. Depression aggravates negative symptoms and cognitive deficit and can deteriorate social functioning, quality of life and outcome of the disease. Insufficient clinical response to adequate pharmacotherapy determines rising interest to brain stimulation techniques such as rTMS.

Objectives The primary goal was to evaluate safety and efficacy of rTMS in treatment-resistant schizophrenia patients with dominant depressive and negative symptoms in open non-controlled trial.

Aims and patients Thirty-one schizophrenia (ICD-10) patients with evident depression (CDSS ≥ 6) and negative symptoms and with stable low rate positive symptoms on combined adequate pharmacotherapy (antipsychotic + antidepressant), which have not been changed for at least 6 weeks, were included to the study.

Methods All patients received 15-Hz rTMS on the left dorsolateral prefrontal cortex (100% intensity, 1800 pulses per session, 5 sessions per week, 15 sessions per course) with 8-shaped coil of Neuro-MS/D stimulator (Neurosoft). The primary efficacy measure was 50% CDSS score reduction after the 3rd week of treatment. The secondary measures were weekly reduction rates for CDSS and for PANSS negative syndrome scale.

Results Twenty (64,5%) patients respond to rTMS. Final mean CDSS score reduction was 55,2% ($P=0,000004$), and mean PANSS negative scale score reduction was 21,3% ($P=0,000012$). Two patients (6,5%) were excluded due to persistent headaches, no serious adverse events were observed.

Conclusions rTMS is safe and effective strategy for the management of treatment-resistant depression in schizophrenia and can alleviate negative symptoms. Further sham-controlled studies are needed.

² University psychiatric centre of KU Leuven, psychiatry, Leuven, Belgium

³ University psychiatric centre of KU Leuven, psychiatry, Leuven, Belgium

⁴ Catholic university of Leuven, centre for psychology of learning and experimental psychopathology, Leuven, Belgium

* Corresponding author.

Introduction We previously reported that deep brain stimulation (DBS) in the anterior limb of the internal capsule/bed nucleus of the stria terminalis (IC/BST) is effective in reducing symptoms in severe treatment-resistant obsessive-compulsive disorder patients.

Objective To examine the long-term evolution of obsessive compulsive disorder (OCD) symptoms in 24 patients treated with chronic electrical stimulation in IC/BST.

Aims We aimed to examine the evolution of the Yale-Brown Obsessive Compulsive Scale (Y-BOCS) and to determine if a number of predictors assessed before surgery are significantly related to this evolution.

Methods We used a linear mixed model to investigate the evolution of the Y-BOCS in 24 patients. Data was collected in a naturalistic manner. Seven hundred measurements, taken during a total of 1836 follow-up months, are included in this analysis.

Results Our analysis showed a long-term, sustained effect of electrical stimulation in the IC/BST. After a fast initial decline of OCD symptoms, these symptoms stay relatively stable. In addition, results show a strong ON/OFF effect of stimulation (e.g., due to battery depletion). Beside the ON/OFF effect of stimulation, the surgery itself has no additional effect on OCD symptoms. The Beck Depression Inventory (BDI) at baseline was the only predictor significantly related to the evolution of the Y-BOCS. A higher BDI at baseline seemed to be related to a smaller decrease of the Y-BOCS over time.

Conclusion Electrical stimulation in the IC/BST has a fast and sustained effect on OCD symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Superficial neurostimulation application, alpha rhythm and clinical effects

P. Rico^{1,*}, P. Aranguren²

¹ Universidad Alcala de Henares, medical specialties, Madrid, Spain

² Universidad complutense, psychology, Madrid, Spain

* Corresponding author.

Introduction The alpha rhythm (EEG) in prefrontal regions has been related with the emotional equilibrium, predisposition for a positive mood (Urry et al., 2004) and the activation of the approximation system (Davidson and Irwin, 1999). Superficial neurostimulation application (SNSA) provokes an increase of such rhythm in prefrontal and temporal areas (Bardasano et al., 2010).

Aims To demonstrate that the increase of alpha synchronization is a common factor in the satisfactory evolution of patients with different pathologies.

Methods Thirty patients with different symptoms (hostility, anxiety, bruxism and obsessive symptoms) received 20 weekly sessions of 45 minutes long using the SNSA.

Materials -SNSA topology system: it is a machine for superficial stimulation that uses electricity through superficial electrodes which are placed on feet and hands and an electrode over the 7th cervical vertebra;

-digital encephalogram;

-Faraday cage.

Results The alpha rhythm was incremented in 85% of the cases in anterior regions of the brain, related with the improvement of scale's punctuation.

Conclusion The alpha rhythm has been showed to be presented in all individuals that improved their symptoms after the application of SNSA (Fig. 1).

Fig. 1 Distribution of cranial α calotte activity post-SNSA. 20th session. Distribution of cranial α calotte activity pre-SNSA. 1st session.

Digging out insights and behavioral correlates of false and true femininity in borderline personality disorder patients attending four-step integrative model group psychotherapy

M. Abdelhameed*, R. Mahfouz, A. Kamal, M. Taha
Minia university, psychiatry and neurology, Minia, Egypt

* Corresponding author.

Introduction The four-step integrative model of psychotherapy is concerned with individual's needs, wants, rights and decisions in that order. It may carry a promise for deep and changing vision for patients with borderline personality disorder (BPD).

Objectives The study of the illuminating and changing effect of dealing with BPD patients in view of their needs, wants, rights and decisions.

Aims To evaluate the effect of group work through the hierarchy of the four-step integrative model with BPD patients and to help them explore false and true elements of their femininity.

Methods Forty-three female patients (age range: 19-37) diagnosed according to DSM-IV diagnostic criteria for BPD were enrolled in a dynamic psychotherapy group. Their progress was evaluated using Borderline evaluation of severity over time (BEST) and they wrote down detailed comments about their experience quarterly.

Results Results of regular attendants for 2 years were included (35 = 81.4%). The results of BEST showed a significant reduction of BPD severity at the end of 1 and 2 years. During psychotherapy sessions and within their quarterly comments, patients expressed their change in terms of moving from a state of cunning, manipulation, aggression, arrogance, envy and rejection (as stemming from their false femininity) into wisdom, confrontation, patience, pride, healthy competition and containment respectively (as stemming from their true femininity).

Conclusions Patients with BPD may gain a better insight and genuine change as they realize what is false and what is true about their femininity in the context of attending four-step integrative model group psychotherapy.

What makes for good outcomes in solution-focused brief therapy? A follow-up study

B. Cortes^{1,*}, A. Ballesteros², J. Collantes³, M.L. Aguilar⁴

¹ Dr. Cortes Clinic, psychiatry and psychotherapy, Salamanca, Spain

² Estella health centre, psychiatry, Estella, Spain

³ Private practice, psychology, Madrid, Spain

⁴ Hospital of Salamanca, psychiatry, Salamanca, Spain

* Corresponding author.

Introduction Solution-focused brief therapy (SFBT) is a strength-based and a social constructivist approach that assumes that

individuals have the ability to develop creative solutions that enhance their lives to develop a new self, modify worldviews, and implement behaviour changes.

Objectives To develop a quantitative research to determine which clinical variables and process variables are measured using the technique of judges and determine its statistical association with the outcome at termination of therapy and follow-up, using the videos of SFBT psychotherapy sessions, and a follow-up call.

Aims To identify variables associated with outcome at termination and follow-up and to evaluate the success applying SFBT.

Methods Sample was composed by 74 cases.

Criteria of inclusion A telephone number available to make the follow follow-up call and at least 6 months since termination (6 months to 39 months, mean 15.6 months). Three questionnaire were used, The First-Session Rating Questionnaire, The Last-Session Rating Questionnaire and The Follow-up Questionnaire.

Results Goals were reached 88% of the cases, patients said that complaint was totally resolved were 17% and 26% when the dropouts were excluded, and that complaint was partially resolved were 76% and 65% when the dropouts were excluded. According to the judges, the successful at termination was the 86%, and the successful at follow-up was 67% according to the Follow-Up Questionnaire. No variables were statistically associated to the successful at termination or the follow-up.

Conclusions SFBT reaches the "minimum efficacy permitted" according to the general consensus of experts. Clinical of process variables was not associated to success.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive analytic therapy: A bibliometric review

E. Gimeno^{1,*}, C. Chiclana²

¹ University CEU San Pablo, department of psychology, Valladolid, Spain

² University CEU San Pablo, department of psychology, Madrid, Spain

* Corresponding author.

Introduction Cognitive Analytic Therapy (CAT) has emerged as an integrative new approach with promising results in the treatment of personality-disordered patients, particularly in borderline personality disorder. Although this approach has already demonstrated its effectiveness in adults, increasingly studies try to validate it in young population, which has meant a turning point in research.

Aim and objectives The goal of this study is to know the whole production about CAT in a double way:

–articles that describes the main theoretical concepts underlying CAT theory;

–articles with evidence supporting its effectiveness in different mental disorders.

Methods A bibliometric review of 397 scientific articles extracted from research databases including Dialnet, EBSCO, PUBMED, Unika and Scholar Google was conducted.

Results The results indicate an exponential growth in published studies on CAT, from first publications in the late 1960s, particularly strong in the last two decades and reaching its peak in 2008. Total research includes 247 literature reviews, 109 clinical studies, 47 case studies, 17 letters and comments from authors, 4 studies on diagnostic tests and 1 meta-analysis. Most research has focused on borderline personality disorder or other personality disorders (35% and 12% respectively) and eating disorders (11%). Studies have been conducted with adults (49%) the same as children and adolescents (46%) whereas only the 4% has been developed for elderly population.

Conclusions Cognitive analytic therapy represents a well-documented psychotherapy with a proven efficacy in a wide range of clinical contexts.

EMDR trainings for Bosnia-Herzegovina mental health workers resulted with child training in Sarajevo for 75 EMDR psychotherapists aftermath the 1992–1995 war

M. Hasanovic^{1,*}, J. Morris-Smith², S. Morgan², S. Oakley², Š. Šabanović³

¹ Tuzla, Bosnia and Herzegovina

² Humanitarian Assistance Programmes, UK & Ireland, Hove, United Kingdom

³ EMDR Europe, EMDR Association of Bosnia-Herzegovina, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

Objectives Bosnia-Herzegovina affected by war 1992–1995, children survived severe war traumatization together with adult war victims. The Humanitarian Assistance Programmes UK & Ireland (HAP) work in partnership with mental health professionals in Bosnia-Herzegovina (BH) from 2009, providing knowledge and expertise in the treatment of trauma, and specifically in the use of EMDR (eye movement desensitisation and reprocessing).

Aim In this way, we aim to build a body of qualified and experienced professionals who can help children and adolescents, not only for adults.

Method Authors described educational process for healing childhood trauma with EMDR considering the history of idea and its realization through training levels.

Results Joanne Morris-Smith was invited by the EMDR Association of Bosnia & Herzegovina to provide Child Training in Sarajevo for 75 participants drawn from the 3 cohorts who HAP UK & Ireland has already fully EMDR trained. Many of our trainees work with both children and adolescents as well as adults so they were delighted to get this specialist training. Trainees were instructed to learn about the ways of modifying the standard protocol for children according to their developmental age, and other teaching points. The possibility of using narrative presentation of the traumatic event while applying tactile stimulation was an important discovery.

Conclusion EMDR for children and adolescents training of Bosnia-Herzegovina mental health workers to effectively use EMDR with traumatized children and adolescents, with enthusiastic help of EMDR trainer Joanne Morris-Smith from HAP UK & Ireland resulted with increased psychotherapy capacities of EMDR therapists in postwar BH.

Effect of an acceptance and commitment group therapy in the treatment of panic disorder and agoraphobia. A preliminary study

L. Leon-quismondo^{1,*}, F. Lopez-rios², E. Rodriguez-pedraza¹, A. Fernandez-liria¹, G. Lahera³

¹ “Principe de Asturias” university hospital, Psychiatry, Alcala de Henares, Spain

² University of Almeria, psychology, Almeria, Spain

³ University of Alcala, Irycis- Cibersam, psychiatry, Alcala de Henares, Spain

* Corresponding author.

Introduction Acceptance and commitment therapy for the treatment of panic disorder and agoraphobia has been a big boost in last years, and there are preliminary studies about its efficacy. However, most studies have used individual interventions.

Objectives Evaluate the effect of an acceptance and commitment group therapy in patients with panic disorder and agoraphobia.

Methods The sample consisted of 24 patients, aged between 18 and 55 years old, who were referred to groups by psychologists and psychiatrists of Mental Health Center. The intervention in each group consisted of 12 treatment sessions of 1 h 30 m duration, weekly. One pretest and posttest evaluation was conducted. The variables studied were: severity of panic disorder (Panic Disorder Severity Scale [PDSS]), fear of physical sensations (Body Sensations Questionnaire [BSQ]), frequency of catastrophic thoughts (Agoraphobic Cognitions Questionnaire [ACQ]) and level of experiential avoidance (Acceptance and Action Questionnaire-II [AAQ-II]).

Results The mean scores for all variables studied decreased in the post-evaluation. Means in post-evaluation were significantly lower (*t* Student, *a*=0.10) in three of the four variables studied: severity of the condition (*P*=0.001), frequency of catastrophic thoughts (*P*=0.038) and level experiential avoidance (*P*=0.073). In other words, patients had fewer panic attacks after treatment, and those who had were less intense, they had less catastrophic thoughts about consequences of anxiety, and they were better to accept their feelings and thoughts.

Conclusions Although it is necessary to continue the study with a larger sample, these preliminary results support the use of ACT in group format in the treatment of panic disorder and agoraphobia.

Shifting focus approach: An alternative to classical CBT therapy for relapse prevention among opioid detoxified patients

A. Rady^{1,*}, T. Moukookheya¹, E. Shawky²

¹ Alexandria university school of medicine, psychiatry, Alexandria, Egypt

² Mamoura psychiatric hospital, psychiatry, Alexandria, Egypt

* Corresponding author.

Aim Most current psychotherapeutic approaches are self-focused in terms of focusing attention on how one thinks, feels, behaves or maintains, in one way or another, a pathological chain reactions. The aim of current is to challenge such focus by shifting the focus of attention to serving others rather than analyzing one's self.

Method Sixty patients were recruited after heroin detoxification, all have been subject to psycho-education about addictive behavior, craving process and risks of relapse. Half of them (group A; *n*=30) were subject to weekly basis classical CBT group sessions while the other half (group B; *n*=30) were subject to shifting focus approach where they were encouraged to serve on voluntary nonprofit basis at Alexandria university hospitals with weekly group support sessions to share experiences and encourage action. Patients in both arms were followed for 3 months and evaluated in terms of abstinence rate and quality of life.

Results Both groups were balanced in terms of age, marital status, age of onset of abuse, number of previous detoxification, criminal

record and score of the Quality of Life Scale QLS at base line before psychotherapy. After 3 months, no difference as regards abstinence rate between both arms ($X^2 = 1.763$; $P = 0.288$), also no difference between both groups as regards change in QLS score after 3 months ($t = 0.039$; $P = 0.969$).

Conclusion Shifting focus approach shows no difference in terms of abstinence or quality of life improvement compared to classical CBT in non inferiority study.

Student's strategies to cope with stressful situations

M. Theodoratou*, M. Ntavarinou, E. Stratoudaki-chondrou, M.P. Xiga, I. Nikolopoulou, P. Kloni, A. Psychogiou
Technological institute of Western Greece, social work, Patras, Greece
 * Corresponding author.

Introduction It is well known that students have several stressful situations to cope with and their coping strategies are of a wide range (Brougham et al., 2009, Zi et al., 2011, Pierceall and Cane, 2009).

Objective The purpose of the study was to investigate how students coped with various stressful situations they faced.

Aims One hundred participants, 60 men and 40 women, studying at TEI of Patras, Greece, were randomly selected and asked to describe their stressful situations and the ways they dealt with them.

Method The questionnaire used was based on "Échelle Toulousaine de Coping" (Tap et al., 1993) adjusted by Theodoratou et al. (2006).

Results Forty-five percent of the students could not control their feelings, while facing a difficult situation and might feel panic, but the majority of the students (63%) did not use medication to cope with a difficult situation. When facing a problem, the 45% of the students did not amuse themselves and 35% of the participants avoided communication with other people when they faced a problem. Moreover, 29% of the students chose to pray to face a difficult situation. Finally, 58% of the participants estimated that a counseling center in TEI of Western Greece would be necessary.

Conclusions In conclusion, many students were overwhelmed by a negative emotion and most of them chose social withdrawal. Thus, they might feel helpless and suggested that a counseling center in their College and university might help them to overcome difficulties during their studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction The number of psychiatrists continues to grow in Canada. Patient psychiatry utilization statistics, including reasons for termination of such services, are important factors that have the potential to impact future Canadian and international psychiatry service policies and practices. In addition, understanding the reasons for psychiatry service termination is necessary to improve service quality and effectiveness.

Aims This study focused on utilization trends, perceived effectiveness of psychiatry services, and reasons for termination of psychiatry services in Canada.

Method Prevalence of psychiatry service use, perceived effectiveness, and reasons for termination of such services were investigated in a Canadian sample ($n = 25,113$). Prevalence rates were investigated by geography, sex, and age. Data were self-reported and collected through a national Canadian phone survey focused on mental and physical health.

Results Results highlight that a small percentage of participants reported utilizing psychiatry services. The majority of participants using such services perceived them as useful. Across geographical regions, reasons for discontinuing services were most often related to completing treatment, feeling better, or not seeing the treatment as helpful.

Conclusions This study explored psychiatry utilization trends, perceived psychiatry effectiveness, and reasons for patient termination of such services. Results are explored through a geographical region breakdown, sex differences, and age stratification. Implications for policy, practice, and training are discussed from a Canadian and international perspective.

How we can enhance treatment adherence? Perspective of patients and clinicians

A. Cardoso^{1,*}, P. Aguiar², M. Byrne³, M. Xavier⁴

¹ Faculty of medical sciences, mental health, Lisbon, Portugal

² National school of public health, public health, Lisbon, Portugal

³ University of Wollongong, psychology, Wollongong, Australia

⁴ Nova medical school, mental health, Lisbon, Portugal

* Corresponding author.

Introduction Non-adherence to antipsychotic medication is commonly found in mental health disorders (MHD), thus forming a major obstacle to long-term maintenance treatment and contributing to high relapse rates and also can influence the attitudes and beliefs of mental health professionals (MHP).

Objectives –assess the beliefs of MHP;

–assess perception of illness in patients with MHD.

Aims Contribute to treatment adherence of patients with MHD, through developing adequate strategies to their needs.

Methods In this cross-sectional study, we use a convenience sample of patients with MHD attending in the mental health departments of three general hospitals in Lisbon great area. Data is being collected through individual interviews. We have applied clinical and socio-demographic questionnaire and additional measures to assess symptom severity, treatment adherence and attitudes towards medication. For MHP, we used a optimism

scale (ETOS), Difficulty Implementing Adherence Strategies (DIAS); Medication Alliance Beliefs Questionnaire (MABQ).

Results Two convenience samples were composed by 150 patients with MHD (mean age: 39.7; SD \pm 9.8) and 65 MHP (mean age: 37.0; sd 8.3) working in a variety of settings is being collected. From the perspective of patients, the most important reason for adherence is to accept the illness (54.7%, $n=82$). 50.8% ($n=33$) of MHP believes that if patients are unmotivated for treatment, adherence strategies are unlikely to be effective. 43.1 ($n=28$) of MHP agrees that if patients do not accept their illness, any adherence strategies that result.

Conclusion With this study, we expect to gain further knowledge on the factors related patients and MHP that might influence compliance and, therefore, contribute to the development of effective strategies to promote treatment adherence in MHD.

A neuropsychological group rehabilitation program with institutionalized elderly

L. Lemos*, H. Espírito-Santo, S. Simões, F. Silva, J. Galhardo, M. Oliveira, M. Costa, S. Martins, F. Daniel
Miguel Torga institute, psychology, Coimbra, Portugal

* Corresponding author.

Introduction Elderly institutionalization involves an emotional adaptation and the research shows that the risk of depression increases.

Objectives Evaluate the impact of a neuropsychological group rehabilitation program (NGRP) on depressive symptomatology of institutionalized elderly.

Aims NGRP influences the decrease of depressive symptoms.

Methods Elderly were assessed pre- and post-intervention with the Geriatric Depression Scale (GDS) and divided into a Rehabilitated Group (RG), a Waiting List Group (WLG), and a Neutral Task Group (NTG).

Results In this randomized study, before rehabilitation, 60 elderly people (RG; 80.31 \pm 8.98 years of age; 74.2% women) had a mean GDS score of 13.33 (SD=9.21). Five elderly included in the NTG (80.13 \pm 10.84 years; 75.0% women) had a mean GDS score of 10.60 (SD=4.72). Finally, 29 elderly in the WLG (81.32 \pm 6.68 years; 69.0% women) had a mean GDS score of 14.93 (SD=6.02). The groups were not different in GDS baseline scores ($F=0.74$; $P=0.478$). ANCOVA has shown significant differences ($P<0.05$) in GDS scores between the three groups after 10 weeks. Sidak adjustment for multiple comparisons revealed that elderly in the WLG got worse scores in GDS, comparing with elderly in RG ($P<0.01$), and with elderly in NTG ($P<0.05$).

Conclusions Elderly that are not involved in a task get worse in depressive symptomatology. Being involved in a structured group task means lower depressive symptoms and being in a NGRP means even greater results.

Cognitive training using a web-based tailor-made program for first-episode psychosis patients: An exploratory trial

B. Moura^{1,*}, T. Mendes¹, F. Antunes¹, R. Barandas¹, M. Croca¹, P. Frade¹, L. Linhares¹, J. Vian¹, P. Levy¹, M.L. Figueira²

¹ Santa Maria hospital, psychiatry department, Lisboa, Portugal

² Faculty of medicine- university of Lisbon, department of psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Cognitive deficits are a core feature of the first psychotic episode patients and could be an obstacle to functional ability. Cognitive stimulation could be a promising method to surpass neuropsychological deficits.

Objectives –to implement an online training protocol to stable first psychotic episode outpatients;

–to assess adherence to the intervention;

–to measure neurocognitive, psychopathological and functional outcomes pre- and post-training.

Aims To investigate the feasibility of an online-based resource for cognitive stimulation (COGWEB®) and explore possible benefits in different domains.

Methods Fifteen patients were enrolled from the Early Psychosis Intervention Program (PROFIP) at the Department of Psychiatry of Santa Maria Hospital, Lisbon. The training consisted on 30-40-minute online sessions performed every weekday during 6 months at home. Assessments were performed at baseline and after program completion and included: psychopathological scores; personal and social functioning scores; Clinical Global Impression and a neuropsychological battery.

Results Every participant had some kind of impairment on baseline. Mean training time was 36 h. Six patients left the program before completion (half of them because they got employed). The program showed overall good feasibility and safety with no reported significant psychiatric occurrences or hospitalizations. Results regarding final neuropsychological, psychopathological and functioning showed a tendency for stability or improvement on an individual case analysis.

Conclusions Our results show that cognitive training using an online-based stimulation software is a feasible intervention for first-episode psychosis patients with possible benefits for this population. However, results should be analyzed very carefully because of different participant trajectories and of study limitations.

Effectiveness and factors predicting success of therapeutic patient education in obese patients candidates for bariatric surgery

D. Piacentino^{1,*}, E. Proserpi², G. Guidi², R. Asprino², A. Pinto², L. Gnassi², A. Lenzi²

¹ Sapienza - university of Rome, NESMOS neuroscience- mental health- and sensory organs department, Rome, Italy

² Sapienza - university of Rome, C.A.S.C.O.–center of high specialization for the cure of obesity EASO collaborating centres for obesity management COMS- experimental medicine department- food science and human nutrition research unit, Rome, Italy

* Corresponding author.

Introduction Obesity is an increasingly common chronic disease. Its biopsychosocial basis provides the rationale of multidisciplinary interventions, such as Therapeutic Patient Education (TPE, WHO 1998), which is effective for lifestyle change and awareness improvement, thus reducing the disease's prevalence and its health care-related financial burden. However, patients' socio-demographic and psychopathological factors may influence TPE's effectiveness.

Objectives/Aims We aimed to assess the effectiveness of an 8-week TPE program in obese patients candidates for bariatric surgery and identify factors predicting its success.

Methods We enrolled 159 patients with a BMI > 35 Kg/m² and obesity-related comorbidities (females = 71.3%; age range = 18–35 years) at the C.A.S.C.O. (EASO COMs) of our University Hospital. They filled out the Binge Eating Scale (BES), the Symptom Checklist-90-R (SCL-90-R), and the Short Form-36 Health Survey (SF-36). We used Tukey's multiple comparison test to assess Quality of Life (QoL) improvement after TPE and multivariate logistic regression to estimate the size of the association between TPE and the aforementioned factors.

Results The SF-36 showed a significant improvement ($P < 0.05$) of physical and mental QoL post-TPE, especially in obese patients without binge eating disorder. The same applied to BES and SCL-90-R scores. The factors predicting TPE success were a short duration of obesity, a limited number of past diets, and low levels of anxiety/depression pre-TPE.

Conclusions In obese patients candidates for bariatric surgery, TPE is useful to improve physical and mental QoL, eating behavior, and psychological status. Several factors are predictive of TPE success, allowing a personalization of the intervention to render it more effective.

* Corresponding author.

Introduction The Family Assessment Device (FAD) is a self-report questionnaire, developed to assess the six dimensions of the McMaster Model of family functioning. It has been translated to the Greek language but never validated.

Aims and objectives To evaluate the psychometric properties of the Greek version of FAD in a non-clinical sample.

Methods In a sample of Greek families, FAD was administered together with the already validated Family Adaptability and Cohesion Evaluation Scale (FACES-III). In a subsample of 96 participants, the scales were administered again after 1 month.

Results A sample of 453 participants (194 children and 259 parents) had completed both questionnaires (151 families). Mean age of children was 23.62 (SD: 6.35), 68 (35%) were males. Mean age of parents was 51.4 (SD: 8.2), 117 (45.2%) males. All subscales of FAD had significant correlation (concurrent validity) with FACES-III ($n = 453$, $P < 0.001$). Test-retest reliability range from 0.58 to 0.82 ($n = 96$, $P < 0.001$). Internal consistency (Cronbach's alpha) range from 0.47 to 0.94. A model with the 6 factors had a good statistical fit but not all the items were loading in the same components as from the theory assumed.

Conclusions The Greek FAD has good psychometric properties, although its factor structure might differ from the original version.

Further evaluation of the Greek version of FAD in other settings and in different samples especially clinical remains a task for future research.

¹⁰ Naju National Hospital, psychiatry, Naju, Republic of Korea

* Corresponding author.

Objectives The Bipolar Depression Rating Scale (BDRS) is a scale for assessment of the clinical characteristics of bipolar depression. The primary aims of this study were to describe the development of the Korean version of the BDRS (K-BDRS) and to establish more firmly its psychometric properties in terms of reliability and validity.

Methods The study included 141 patients (62 male and 79 female) who had been diagnosed with bipolar disorder, were currently experiencing symptoms of depression, and were interviewed using the K-BDRS. Other measures included the Montgomery and Asberg Depression Scale (MADRS), the 17-item Hamilton Depression Scale (HAMD), and the Young Mania Rating Scale (YMRS). Additionally, the internal consistency, concurrent validity, inter-rater reliability, and test-retest reliability of the K-BDRS were evaluated.

Results The Cronbach's α -coefficient for the K-BDRS was 0.866, the K-BDRS exhibited strong correlations with the HAMD ($r = 0.788$) and MADRS ($r = 0.877$), and the mixed symptoms score of the K-BDRS was significantly correlated with the YMRS ($r = 0.611$). An exploratory factor analysis revealed three factors that corresponded to psychological depressive symptoms, somatic depressive symptoms, and mixed symptoms.

Conclusions The present findings suggest that the K-BDRS has good psychometric properties and is a valid and reliable tool for assessing depressive symptoms in patients with bipolar disorder.

* Corresponding author.

Introduction Both genetic and environmental factors play a role in the extended psychosis phenotype which covers psychotic experiences, symptoms and disorders.

Objectives The respective contributions of genetic and environmental factors over time remain largely unknown.

Aims To describe the objectives and design of a multistage study.

Methods The TürkSch (Izmir mental health survey for gene-environment interaction in psychoses) is a prospective-longitudinal study consisted of several data collection stages to screen extended psychosis phenotype in a general population sample, and to assess individual, familial, genetic and neighbourhood level variables.

Results The study aimed to assess the prevalence of psychotic experiences and symptoms in Izmir-Turkey (stage I, cross-sectional; n : 4011), the socioeconomic deprivation and the social capital of neighbourhoods in a separate sample (stage II, cross-sectional; n : 5124) in 2008. A nested case-control study (stage III) recruited individuals with psychotic outcomes and healthy controls from stage I, and included blood sampling for gene-environment interaction and clinical reappraisal as well. After 6 years, follow-up study (stage IV) was set to assess the mental health outcomes with a focus on extended psychosis phenotype, environmental exposures of the eligible sample (n : 2192) from the stage I, and to collect blood samples for further genetic analysis. On both stages, Composite International Diagnostic Interview was used by clinically trained interviewers, and was able to provide broad assessment of psychotic experiences, experience-related disabilities, help-seeking and health care utilization.

Conclusions The TürkSch has a unique study design and yields data of high quality in the Turkish population, with a specific focus on psychosis.

Google trends-enabled digital pharmacovigilance: Monitoring interest towards antidepressants and their usage patterns in Italy

N. Bragazzi^{1,*}, A. Siri²

¹ University of Genoa, school of public health- department of health sciences DISSAL, Genoa, Italy

² University of Genoa, UNESCO CHAIR "Anthropology of Health-Biosphere and Healing system", Genoa, Italy

* Corresponding author.

Introduction The Internet is playing a major role in nowadays life and more often psychiatric patients are using it as a valuable source of information. Furthermore, the new media can be exploited for providing them with personalized psycho-educational interventions and counseling. On the other hand, a misuse of the new technologies can lead to cyber-addiction behaviors and to others psychopathologies.

Objectives and aims In this contribution, we want to explore the Internet pattern of searching online for antidepressants in the Italian population. The prescriptions and usage of these drugs have been increasing in the last years, and therefore constitute an important economic burden for the National Health System (NHS).

Methods We analyzed the hit-search volumes with Google Trends, an online tracking system of Internet hit-search volumes, and the wavelet power spectrum analysis (WPSA), a mathematical technique that decomposes a time series into time versus frequency space. The hit-search volume data were compared with the data provided by the Italian National Drug Agency. Pearson correlation was used and P -values less than 0.05 were considered to be statistically significant.

Results We found a seasonality and cyclical pattern in searching online for antidepressants, as confirmed by the WPSA. Moreover, the pattern was increasing throughout the years, reflecting the usage pattern as recorded and monitored by the Italian Drug Agency. Pearson correlation yielded a value of 0.98 with a P -value of $1.42 \cdot 10^{-5}$.

Conclusion Digital pharmacovigilance can be employed as a complementary approach together with the classical traditional methodology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Agreement between clinical judgments and subjective perceptions of clinical change

M. Müller*, V. Stefan, W. Godehard, S. Prinz, S. Egger
University hospital for psychiatry Zurich, ZIP- Rheinau, Zurich, Switzerland

* Corresponding author.

Introduction Research into the relationship between the subjective perception of clinical change and the objective evidence of the same is very limited. Less is known about the relationship between clinical judgments by mental health experts and the patient's perception of symptom change, in particular across different diagnostic groups.

Aims and objectives This study aims to determine the level of concordance between the HONOS as a tool for clinical outcome monitoring and the self-reported change in psychopathology in a total sample of psychiatric patients as well as stratified by their primary diagnosis at admission.

Methods A consecutive sample of patients admitted to a Swiss psychiatric hospital for either alcohol use disorders, schizophrenic psychoses, mood disorders, anxiety and somatoform disorders, or personality disorders, was assessed using the Brief Symptom Inventory (BSI) at admission and at discharge. The HoNOS were rated by the responsible clinicians. Complete data of admission and discharge were available from approximately 600 cases. Reliable change index (RCI) will be calculated to determine a clinically meaningful change based on the HoNOS scores. Concordance of RCI and change in BSI scores will be explored and compared between different diagnostic groups.

Results and conclusions According to our preliminary results from this ongoing evaluation program, we hope to provide a step towards a deeper understanding of the interrelationship between clinical

judgments and the course of subjectively experienced mental health problems.

Properties of a coding system for traumatic memories

V. Fernández-Lansac*, C. Soberón, M. Crespo, M. Gómez-Gutiérrez

Complutense university-psychology school, clinical psychology, Madrid, Spain

* Corresponding author.

Introduction Narrative studies have focused on the language used by the individuals to describe stressful or traumatic experiences. Hence, linguistic procedures have been applied aiming to obtain information about autobiographical memories and trauma processing. However, there is a general lack of agreement about how to measure narrative aspects. Software programs for this purpose are limited, since they don't capture the language context, and systems based on judge's rates are not free of subjective biases.

Objectives This study presents a coding system developed to analyze several language categories related to traumatic memories and psychological processes. Structural aspects (e.g., coherence) and content dimensions of traumatic narratives (e.g., emotional or cognitive processes) are measured. Each narrative aspect is coded by raters using both dichotomous (presence/absence) and numerical values (Likert scale).

Aims To propose a structured coding system for traumatic narratives that considers the language context and maximizes consensus among different raters.

Methods Traumatic narratives from 50 traumatized women and stressful narratives from 50 non-traumatized women have been evaluated according to the system developed. Three blind raters coded each narrative.

Results Inter-rater reliability data are provided for the different narrative categories. The agreement between raters is discussed for both structural and content language domains.

Conclusions The analysis of the inter-rater reliability allows exploring subjective biases in assessing different structural and content language dimensions. This study advances in the development of a procedure to analyze autobiographical narratives in a valid and reliable way, with a special focus on traumatic and other unpleasant memories.

* Corresponding author.

Introduction Agitation is a psychiatric emergency that requires immediate assistance. Inhaled loxapine is a new option for achieving rapid tranquillisation avoiding coercive measures and over-sedation, which fits with patient's preferences and increases their satisfaction with treatment.

Objective Review the experience of use of inhaled loxapine in clinical practice.

Methods We included data from all reports of case series with 10 or more patients published by European prescribers.

Results Ten posters were included that reported data on 116 patients, mostly diagnosed with psychotic or bipolar diseases. Among the 60 patients that were evaluated using PANSS-EC, baseline agitation intensity was above 20 in 45 of them (75%) and between 15 and 32 in 15 (25%). Regarding patients evaluated with the CGI-S scale, 17 patients had a score between 6 and 7 points and 4 had scores between 4 and 5. All patients were able to properly inhale the drug. In some patients agitation receded as early as 2 minutes, and almost all of them were controlled within 10 minutes. Only 6 patients required the 2nd dose of loxapine within 24 hours. When patients were asked for, they showed a preference for inhaled administration instead of intramuscular one, manifested high levels of satisfaction with inhaled treatment, and in one report inhaled loxapine was stated to contribute to avoid mechanical restraint. Inhaled loxapine was well tolerated and no over-sedation was reported or any EPS, just a case of mild orthostatic hypotension.

Conclusion This pool-data review of inhaled loxapine in real world clinical practice shows that it is an effective treatment, with a very rapid response, easy to administer and well tolerated, with a good acceptance from patients.

⁴ University of Coimbra, faculty of psychology and educational sciences, Coimbra, Portugal

* Corresponding author.

Introduction In recent years, researchers and clinicians have shown an increasing interest in self-compassion. Indeed, several studies have suggested that self-compassion is a positive factor for mental and physical health. The Self-Compassion Scale (SCS; Neff, 2003) has been widely used to assess six dimensions of self-compassion (self-kindness, self-judgment, common humanity, isolation, mindfulness and over-identification) among diverse populations. Recently, it has also been used in perinatal samples but its psychometric properties in pregnant women is still unexplored.

Objective This study aims was to investigate the reliability and the validity of the SCS using Confirmatory Factor Analysis in a sample of Portuguese pregnant women.

Methods Participants were 417 pregnant women with a mean age of 33 years old (SD=4.74) in their second trimester of pregnancy (M=17.26, SD=4.78, weeks of gestation). Participants completed the Portuguese version of the SCS while waiting for the routine prenatal consultation in Maternity Hospital, Portugal.

Results A was tested and results showed that the six-factor model had a good fit to the data (TLI=0.93, CFI=0.94, RMSEA=0.06). The total SCS presented a good internal reliability ($\alpha=0.91$) and their subscales showed Cronbach's alphas ranging between adequate ($\alpha=0.77$) and good ($\alpha=0.87$).

Conclusions Overall, these findings suggest that the Portuguese version of the SCS is a valid and reliable measure to assess

self-compassion among pregnant women. Thus, SCS could be useful in diverse settings in the perinatal period.

⁵ Faculty of psychology and educational sciences -university of Coimbra, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Failures in regret anticipation undermine regret avoidance, increasing regret frequency and ultimately the risk of regret-related problems. The Regret Anticipation Failures Scale (RAFS; Schmidt and Linden, 2011) was developed to evaluate interindividual differences in regret anticipation.

Objective To investigate the psychometric properties of the RAFS Portuguese version.

Methods A community sample composed of 108 university students and 79 employees (78.1% females; mean age = 33.16 ± 13.175; range: 17–62) answered the Portuguese preliminary version of the RAFS. To study the temporal stability, 31 participants (83.9% females; mean age = 26.54 ± 18.761) answered the RAFS again after approximately 6 weeks.

Results The RAFS Cronbach alpha was “very good” ($\alpha = 0.81$). All the items presented significant correlations with the total (excluding the item; >0.20); only item 2 (Even when I’m stressed, I can foresee the regrets that certain behaviors could evoke in me) had the effect of lowering the internal consistency if deleted. The test-retest correlation coefficient was high, positive and significant (0.61 ; $P < 0.001$); there was not significant difference between test and re-test scores [14.26 ± 5.170 vs. 13.06 ± 4.761 , $t(30) = 1.532$, $P = 0.136$]. Following Kaiser and Cattell Scree Plot criteria, only one factor was extracted, meaning that the scale is unidimensional.

Conclusions The Portuguese version of RAFS has good reliability and construct validity. It could be very useful both in clinical and research contexts, namely in an ongoing project on the relationship between regret, personality and psychological distress.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Validation of the Depression, Anxiety and Stress Scale–DASS-21 in a community sample of Portuguese pregnant women

S. Xavier^{1,*}, E. Bento¹, J. Azevedo¹, M. Marques¹, M.J. Soares¹, V. Freitas¹, D. Mota², A. Macedo¹, A.T. Pereira¹

¹ Faculty of medicine - university of Coimbra, psychological medicine, Coimbra, Portugal

² Coimbra hospital and university centre- Portugal, psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction The Depressive Anxiety and Stress Scale (DASS-21; Antony et al., 1998) had been widely used to measure psychological

distress among clinical and non-clinical populations, including in Portugal (Pais-Ribeiro et al., 2004). Although DASS-21 has been considered useful to evaluate psychological distress in the perinatal period, studies reporting on its psychometrics are scarce (Brunton et al., 2015).

Objective To investigate the psychometric properties of the DASS-21 in a Portuguese sample of pregnant women.

Methods Four hundred and twenty-seven pregnant women (mean age: 32.56 ± 4.785 years) in their second trimester of pregnancy (17.34 ± 4.790 weeks of gestation) completed the Portuguese versions of DASS-21 and of Postpartum Depression Screening Scale (PDSS-24; Pereira et al., 2013).

Results The DASS-21 Cronbach’s alpha was “very good” ($\alpha = 0.92$). Following the Kaiser and the Cattell Scree Plot criteria, two factorial structures were explored. Three factors structure (explained variance/EV = 57.18%): F1-stress (included 8 items; $\alpha = 0.89$); F2-Anxiety (7 items; $\alpha = 0.79$); F3-Depression (6 items; $\alpha = 0.82$). In the two factors structure (EV = 50.96), the Stress and Anxiety items load in the same factor (F1: 15 items; $\alpha = 0.91$) and the F2 is composed of the Depression items (F2: 6 items; $\alpha = 0.82$). Pearson correlations between DASS-21 total and dimensional scores and the PDSS-24 scores were all significant, positive and moderate to high (@.50).

Conclusions The Portuguese version of DASS-21 has good reliability, construct and concurrent validity when used with pregnant women. Its factorial structure significantly overlaps with the original, with only one item loading in another factor. DASS-21 could be very useful in diverse settings in the perinatal period.

* Corresponding author.

Introduction Regret is defined as an aversive negative emotion associated to specific cognitive contents, felt when we consider that our current situation could be better, if we had taken a different decision (Zeelenberg and Pieters 1997). Regret Scale/RS corresponds to the regret-trait dimension of Regret and Maximization Scale developed by Schwartz et al. (2002).

Objective To investigate the psychometric properties of the RS Portuguese version.

Methods A community sample composed of 108 university students and 79 employees (78.1% females; mean age = 33.16 ± 13.175; range: 17–62) answered the Portuguese preliminary versions of the RS and Bedtime Counterfactual Processing Questionnaire (BCPQ) and also the Profile of Mood States to evaluate Negative Affect/NA. To study the temporal stability, 31 participants (83.9% females; mean age = 26.54 ± 18.761) answered the RAFS again after 6 weeks.

Results The EA Cronbach alpha was “very good” ($\alpha = 0.72$). All the items contributed to the internal consistency. The test-retest correlation coefficient was high, positive and significant (0.72 ; $P < 0.001$). Following Kaiser and Cattell Scree Plot criteria, only one factor was extracted, meaning that the scale is unidimensional. Pearson correlations of EA and BCPQ2 and NA were significant and high ($r @ .50$).

Conclusions The Portuguese version of RS has good reliability and validity. It could be very useful both in clinical and research contexts, namely in an ongoing project on the relationship between regret, personality and psychological distress.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW484

Bedtime Counterfactual Processing Questionnaire (BCPQ): Validation of the Portuguese version

J. Borges¹, D. Borges¹, A.T. Pereira^{2,*}, A.S. Cabral³, J. Azevedo², A. Macedo²

¹ University of Coimbra, faculty of medicine, Coimbra, Portugal

² Faculty of medicine - university of Coimbra, psychological medicine, Coimbra, Portugal

³ Coimbra hospital and university centre, Coimbra, Portugal

* Corresponding author.

Introduction Counterfactual thinking is a set of mental representations of alternatives to the past actions. When it focuses on personal decisions, the emotion that results is regret, which has important implications for psychological distress (Borges et al., 2015). The Bedtime Counterfactual Processing Questionnaire (BCPQ; Schmidt and Linden, 2009) was developed to assess the frequency of regret-related counterfactual thoughts during the pre-sleep period.

Objective To investigate the psychometric properties of the BCPQ (extended version) Portuguese version.

Methods A community sample composed of 108 university students and 79 employees (78.1% females; mean age = 33.16 ± 13.175; range: 17-62) answered the Portuguese preliminary versions of the BCPQ and Regret Scale (Schwartz et al., 2002). To study the temporal stability, 31 participants (83.9% females; mean age = 26.54 ± 18.761) answered the BCPQ again after 6 weeks.

Results The BCPQ2 Cronbach alpha was “very good” ($\alpha = 0.81$). All the items contributed to the internal consistency. The test-retest correlation coefficient was high, positive and significant (0.78; $P = 0.05$); there was not significant difference between test and re-test scores [29.87 ± 5.309 vs. 30.13 ± 5.353 , $t(30) = -0.204$, $P = 0.840$]. Following the Kaiser and the Cattell’s Scree Plot criteria, two meaningful factors were extracted which explained variance (EV) was of 65.06%: F1 Regret (EV 43.17%; $\alpha = 0.88$), F2 low pride (21.88%; $\alpha = 0.88$). Pearson correlations of EA total score with BCPQ2 and F1 were significant and moderate ($r @ .50$) and with F2 was non-significant.

Conclusions Although the Portuguese version of the extended version of BCPQ has good reliability and validity, the low pride-related dimension seems to be relatively independent of regret.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Frequency of subtypes of irritable bowel syndrome in positive and negative subtypes of schizophrenia

S. Ahmed^{1,*}, G. Rasool²

¹ Quetta, Pakistan

² Bolan medical college and complex hospital, psychiatry, Quetta, Pakistan

* Corresponding author.

Objective The aim of the study was to determine the frequency of subtypes of irritable bowel syndrome in positive and negative subtypes of schizophrenia.

Methods Sixty-two drug naïve hospitalized patients between 18 and 65 years (mean age: 33.6) with first episode of schizophrenia based on DSM IV-TR and 69 control subjects matched for age and sex completed this study. A semi-structured clinical interview was used to assess both groups. Clinical data were obtained and basic lab investigations and ultrasonography of abdomen were done in all subjects to exclude any related abdominal pathology. Axis-I disorders of DSM IV-TR were excluded in control subjects. Positive and Negative Syndrome Scale (PANSS) and Rome III Urdu language version scale (cross-validation obtained) for irritable bowel syndrome (IBS) were administered to assess the severity of positive and negative symptoms of schizophrenia and subtypes of irritable bowel syndrome, IBS constipation (IBS-C), IBS Diarrhoea (IBS-D) and IBS Mix (IBS-M) in case and control groups respectively.

Results Forty-seven patients (75.8%) and 15 patients (24.2%) had positive and negative schizophrenia respectively. Patients with positive and negative schizophrenia had higher rate of IBS-C 6.5% ($n = 4$), IBS-D 8.1% ($n = 5$), IBS-M 12.9% ($n = 8$), non-IBS 72.6% ($n = 45$) versus healthy subjects IBS-C 1.4% ($n = 1$), IBS-D 2.9% ($n = 2$), IBS-M 2.9% ($n = 2$), and non-IBS 92.8% ($n = 64$), OR = 4.8; 95% CI.

Conclusion Irritable bowel syndrome is more frequent in patients with schizophrenia than in general population. This functional gastrointestinal disorder associated with psychotic symptoms requires attention and management while managing patients with subtypes of schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Dokuz Eylul university, psychiatry, Izmir, Turkey

* Corresponding author.

Cognitive dysfunctions are one of the main domains of symptom clusters in schizophrenia that are strongly related to poor prognosis and psychosocial impairment. We conducted a study to investigate the level of cognitive functions in patients with first episode psychosis (FEP) and effect of psychosocial factors related to psychosis and cognitive dysfunctions in this population. We included 60 FEP patients and 60 healthy control subjects. Cognitive functions of the study population were evaluated by using neuropsychological test battery including Stroop, Rey Verbal Learning and Memory, Digit Span, Trail Making, Digit Symbols, Controlled Word Association etc. Psychosocial risk factors were assessed using Childhood Trauma Questionnaire, Social Environment Measurement Tool, Life Events Scale, Tobacco Alcohol Use Scale and Substance/Marijuana Use Scale. Cognitive functions were significantly impaired in FEP patients compared to normal controls. Patients had poor performance in verbal memory, attention, processing speed, working memory and executive functions that is similar to the previous literature findings. Stressful life events in the last year and familial liability of schizophrenia and psychosis in 1st degree relatives were strong predictors to develop psychosis in patients with FEP. Both factors also seemed to be related to cognitive dysfunctions. In this study, patients with stressful life events in the last year

were likely to have memory and executive dysfunctions. It has been shown that psychosocial risk factors had played an important role in developing psychosis. However, these factors also may negatively affect cognitive functions that may make the patient predispose to develop psychosis in FEP patients.

Pharmacokinetics, safety, and tolerability of four 28-day cycle intramuscular injections for risperidone-ISM 75 mg in patients with schizophrenia: A phase-2 randomized study (PRISMA-2)

L. Anta*, J. Llaudó, I. Ayani, B. Gorostidi, M. Monreal, J. Martínez-González, L. Ochoa, I. Gutierrez Rovi S.A., Medical Dpt, Madrid, Spain

* Corresponding author.

Introduction Risperidone-ISM is a new long acting intramuscular formulation of risperidone, for monthly administration without oral supplementation.

Objective To characterize the pharmacokinetic of risperidone over multiple intramuscular injections in patients with schizophrenia.

Method A multicenter, open label, two-arm, parallel design clinical trial was performed. Each patient received 4 intramuscular injections of 75 mg of risperidone-ISM in either, gluteal or deltoid muscle at 28-day intervals.

Results A total of 70 patients were randomized, 67 received at least one dose of study medication. Preliminary data show that mean C_{max} of the active moiety was achieved 24–48 hours (T_{max}) after each administration and ranged over four consecutive doses from 39.6–53.2 ng/mL and 54.1–61 ng/mL, when given in gluteal or deltoid, respectively. All subjects achieved therapeutic levels (>7.5 ng/mL for the active moiety) between 2–8 hours after drug administration. The mean concentrations were maintained above therapeutic levels throughout the 4-week dosing period. No significance changes across the study were observed, either on Positive and Negative Syndrome Scale or Extrapyramidal Symptoms Scale. Overall, 63 subjects (94%) experienced at least 1 Treatment Emergent Adverse Event (TEAE) during the study. One serious TEAE (dystonia) was related to study treatment. One death not related to study medication was informed. The most frequently reported TEAEs were hyperprolactinaemia (57.7%) and injection site pain (32.8%).

Conclusions Risperidone-ISM achieved therapeutic levels from the first hours after drug administration and provided a sustained release throughout the 4-weeks dosing period over multiple intramuscular injections independently of the injection site. Risperidone-ISM was found to be safe and well tolerated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The association between childhood trauma and empathy in patients with stable schizophrenia

A. Arous*, R. Trabelsi, J. Mrizak, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi hospital, department psychiatry F, Tunis, Tunisia

* Corresponding author.

Introduction Empathy, which refers to the ability to understand and share the thoughts and feelings of others, has emerged as an important topic in the field of social neuroscience. It is one of the most understudied dimensions of social cognition in schizophrenia (SCZ).

Objectives To investigate the relationship between cognitive and affective empathy and CT in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the Childhood Trauma Questionnaire retrospectively assessing five types of childhood trauma (emotional, physical and sexual abuse, and emotional and physical neglect). They also completed the Questionnaire of Cognitive and Affective Empathy (QCAE) comprising five subscales intended to assess cognitive and affective components of empathy.

Results Patients with a history of sexual abuse better emotion contagion scores ($P=0.048$) which means that develop more easily self-oriented emotional state matching the affective states of others. Patients with a history of emotional neglect or/and in denial of CT had higher scores in perspective taking score ($P=0.017$). Perspective taking assesses the extent to which respondents can take another's perspective or see things from another's point-of-view.

Conclusions Investigating psychosocial mechanisms, specifically the role of CT, underlying the development of empathic capacities is important since empathy can represent a treatment-target.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How do social cognition dimensions relate to DSM-5 dimensions of psychosis?

A. Arous*, J. Mrizak, R. Trabelsi, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi hospital, department psychiatry F, Tunis, Tunisia

* Corresponding author.

Introduction Existing research shows that individuals with schizophrenia (SCZ) show substantial deficits in social cognitive domains, including facial emotion recognition (FER), empathy, and Theory of Mind (ToM). Their exact relationship with the different dimensions included in the “Clinician- Rated Dimensions of Psychosis Symptom Severity” of the 5th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) remains unexplored.

Objectives To investigate the relationship between different social cognition dimensions and the dimensions of psychosis included in the DSM-5.

Methods Fifty-eight outpatients with stable SCZ completed the Intention-Inferencing Task (IIT), a non-verbal ToM task and the Questionnaire of Cognitive and Affective Empathy (QCAE). They also completed a newly developed and validated FER task constructed from photographs of the face of a famous Tunisian actress and evaluating the ability to correctly identify Ekman's six basic facial emotions. The clinician-rated dimensions of psychosis symptom severity was used to evaluate 8 dimensions of psychosis.

Results The patients presenting higher cognitive empathy capacities had less present abnormal psychomotor behaviour scores ($P=0.05$). Higher levels of affective empathy were correlated to lower present delusions score ($P=0.037$). Better scores in the IIT were correlated to less present negative scores ($P=0.013$) and less impaired cognition scores ($P=0.009$). FER task score didn't correlated with any clinical dimension.

Conclusions Our results suggest the existence of specific relationships between social cognition dimensions and psychosis dimensions. Further studies are needed to confirm these relationships.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evaluation of reproductive hormones relations with response to treatment in male patients with first episode psychosis

A. Ates^{1,*}, I. Oner¹, C. Basoglu¹, A. Algul², R. Tutuncu², H. Balibey², O. Ipcioglu³

¹ GATA Haydarpaşa training hospital, Istanbul, Turkey

² Istanbul, Turkey

³ Biochemistry service, Istanbul, Turkey

* Corresponding author.

Objectives Data regarding schizophrenia treatment has been increasing whereas the information about predictors of treatment response is limited. In this study, our aim is to investigate the serum levels of reproductive hormones as a biological predictor in terms. **Methods** Thirty-three hospitalized male patients in GATA Haydarpaşa Training Hospital with the diagnosis of first episode psychosis were included into the study. The study was prospective and naturalistic in design. The clinical course was recorded by means of Positive and Negative Symptom Scale (PANSS) in pretreatment period, 2nd and 6th weeks of the study. Prolactin, FSH, LH, estrogen, testosterone and oxytocin serum levels were also measured at the same dates.

Results Treatment response was assessed as unresponsive when PANSS total scores were lower than 25%, partial response when PANSS total scores were between 25%–40% changes, and response when PANSS total scores were higher than 40%. Patients were grouped according to those cut-off points. There was a significant positive correlation between oxytocin, FSH serum levels and positive symptoms ($\rho = 0.437$, $P = 0.011$; $r = 0.385$, $P = 0.027$). There was also significant negative correlation between testosterone serum levels and negative and total psychopathology scores ($r = -0.352$, $P = 0.044$; $r = -0.429$, $P = 0.013$). It was seen that pretreatment testosterone levels had a significant biological marker on predicting remission when the serum levels were lower than 460,91 ng/dL.

Conclusions This study shows that hypothalamo-hypophysial-gonadal axis hormones and reproductive hormones, especially testosterone, may be an important biological marker of treatment response prediction in first episode psychosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Universidad de Jaén, Psychology, Jaén, Spain

⁴ Servicio Andaluz de Salud, Mental Health, Linares, Spain

* Corresponding author.

Background Antipsychotic drugs are effective in schizophrenic disorders, but they are also used to treat other psychiatric conditions. Typical antipsychotics cause important extrapyramidal symptoms (EPS), which frequently result in non-compliance with antipsychotic medication. It has been stated that the second-generation antipsychotics (atypical) provoke EPS side effects less

frequently than typical antipsychotics. However, there is some controversy around this statement, especially because of inefficient measures of EPS. Clinical assess of EPS normally relies upon observer-based ratings, but their reliability and validity has not been consistently established.

Objective In the present work, we have explored the convergent and discriminant validity of the Abnormal Involuntary Movement Scale (AIMS) and the Simpson-Angus Scale (SEE), in a Spanish sample of patients with severe mental disorders. Patients could be under typical or atypical antipsychotics, antidepressants, benzodiazepines, or a combination of these.

Method Sixty-one patients with severe mental disorders from the Mental Health Day Hospital of St. Agustín (Linares, Spain) participated in the study. Inclusion criteria were DSM-V diagnosis of schizophrenia or schizophrenic disorder, bipolar, or borderline personality disorders, and age between 18–61. In order to explore the discrimination capacity of each rating scale, Receiver Operator Characteristic (ROC) analyses were conducted.

Results ROC curves indicated a suitable construct validity of the scales in the measurement of drug-induced motor symptoms. However, the scales were not sensitive to the number of years under treatment.

Conclusions In line with previous research, our results question the use of rating scales as the only measure in the evaluation of EPS symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Metacognitive training vs psycho-educational group, results from a clinical trial in patients with psychosis of recent onset

M.L. Barrigon^{1,*}, S.M.S.G.²

¹ Fundación Jiménez Díaz, Psychiatry Department, Madrid, Spain

² Spain

* Corresponding author.

Aim To assess the efficacy of Metacognitive Training (MCT) in symptoms and metacognitive variables in people with a recent onset of psychosis.

Method A multicenter, randomized and controlled clinical trial was performed. One hundred and twenty-six patients were randomized to MCT or a psycho-educational intervention. Patients with a recent onset of psychosis were recruited from 9 centers of Spain. The treatment consisted in 8 weekly sessions in both groups. Patients were assessed at baseline, post-treatment, and 6 months of follow-up. Symptoms were assessed by the PANSS. Metacognition was assessed by a battery of questionnaires of cognitive biases and social cognition: BCIS, IPSAQ, TCI, Hinting task and Emotional Recognition Test.

Results PANSS positive symptoms significant declined between baseline and post-treatment in psycho-educational ($P = 0.04$) and MCT group ($P = 0.01$), while general PANSS and total PANSS were significant between baseline and post-treatment in the MCT group only ($P = 0.008$; $P = 0.005$). Across time, the MCT group was superior to psycho-educational on the BCIS total and self-certainty subscale ($P = 0.042$). Regarding irrational beliefs, the intolerance to frustration subscale declined more strongly in the MCT in relation to psycho-educational group ($P = 0.016$). ToM, Personalizing Bias and JTC improved more strongly in the MCT group compared to psycho-educational group ($P < 0.001$ – 0.032). Most results remained significant at the follow-up.

Conclusions MCT could be an effective psychological intervention for people with a recent onset of psychosis in order to improve symptoms, insight, tolerance to frustration and personalizing bias.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Hôpitaux universitaires de Strasbourg- Inserm U1114- FMST- Fondation FondaMental, psychiatry, Strasbourg cedex, France

* Corresponding author.

Introduction The primary objective of this study was to determine if second generation antipsychotic (SGA) administration was associated with lower aggressiveness scores compared to first generation (FGA) in schizophrenia (SZ). The secondary objective was to determine if antidepressants, mood stabilizers and benzodiazepines administration were respectively associated with lower aggressiveness scores compared to patients who were not administered these medications.

Methods Three hundred and thirty-one patients with schizophrenia ($n=255$) or schizoaffective disorder ($n=76$) (mean age = 32.5 years, 75.5% male gender) were systematically included in the network of FondaMental Expert Center for Schizophrenia and assessed with the Structured Clinical Interview for DSM-IV Axis I Disorders and validated scales for psychotic symptomatology, insight and compliance. Aggressiveness was measured by the Buss-Perry Aggression Questionnaire (BPAQ) score. Ongoing psychotropic treatment was recorded.

Results Patients who received SGA had lower BPAQ scores than patients who did not ($P=0.01$). On the contrary, patients who received benzodiazepines had higher BPAQ scores than patients who did not ($P=0.04$). These results were found independently of socio-demographical variables, psychotic symptomatology, insight, compliance into treatment, daily-administered antipsychotic dose, the way of antipsychotic administration (oral vs long acting), current alcohol disorder and daily cannabis consumption.

Conclusion The results of the present study are in favor of the choice of SGA in SZ patients with aggressiveness, but these results need further investigation in longitudinal studies. Given the potent side effects of benzodiazepines (especially dependency and cognitive impairment) and the results of the present study, their long-term prescription is not recommended in patients with schizophrenia and aggressive behavior.

* Corresponding author.

Introduction Adequate emotion identification ability facilitates forming emotional relationships and effective communication. Patients suffering from schizophrenia have deficits in emotional recognition (ER), which leads to impaired social and occupational functioning.

Objectives To compare the differences in ER between the healthy control group (HC) and two patient groups at different phases of illness: first episode psychosis (FEP) and chronic, multi-episode schizophrenia (MEP).

Aims To investigate the pattern of emotional recognition deficit during the course of schizophrenia.

Methods We compared three groups of participants: MEP, FEP and HC, each containing 50 participants, based on their emotional recognition abilities using the Penn Emotion Recognition Task and The I FEEL Pictures. Patients were diagnosed using Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria for schizophrenia (schizophreniform disorder) with their psychopathology rated with the Positive and Negative Syndrome Scale (PANSS) scale. Besides ER tasks, patients were administered self-evaluation scales for the assessment of quality of life, depression, suicidality, impulsivity, aggression, and relationship with their parents.

Results Our findings showed deficits in emotional recognition ability of both patient groups in comparison with HC, especially in the identification of negative emotions: sadness, fear and anger. There was no statistically significant difference between groups in the identification of happiness. First episode patients showed better results than the MEP group.

Conclusions Although the FEP group was more successful than the ME group, our results showed that the emotional recognition impairment exists at a significant level even at the beginning of the illness.

* Corresponding author.

Introduction Substance use is usually associated with poorer psychiatric medication adherence among schizophrenic patients. Previous findings remain unclear about the relationship between cannabis use and poor medication adherence. Identifying predictor factors of medication adherence among these patients is very important because it's associated with relapse and re-hospitalization.

Objective Determining whether cannabis use is a risk factor for compliance to medication in a population of schizophrenic patients. **Method** Schizophrenic inpatients were assessed by Medication Adherence Rating Scale (MARS). Socio-demographic, clinical data, and urine drug screens were collected just after their admission.

Results A sample of 403 inpatients with schizophrenia diagnosed with Diagnostic and Statistical Manual of Mental Disorders, 4th Edition (DSM-IV) criteria (mean age = 33, 35 ± 9, 16), predominantly man (90%), paranoid (62%) and 89% of them received classical antipsychotics. A total of ($n=25$; 6, 2%) inpatients were adherent, among this group, 19 patients (76%) were tested negative for

cannabis use, and the rest of them ($n=6$; 24%) were tested positive. These results show a high significant correlation between cannabis use and medication adherence ($P=0.009$). Besides, medication adherence is strongly associated with a high socioeconomic status ($P=0.005$).

Conclusion Cannabis use has a major effect on the non-adherence to medication treatment for schizophrenia. These results could be more effective if it addresses issues of cannabis use with patients throughout the early years of treatment.

With regards to the neurocognitive deficits and cognitive bias of schizophrenic disorders, it may be hypothesized that these patients suffer a deficit in recognizing helping intentions in others. To investigate help recognition, new technologies allowing to control an interaction with virtual affective agents were used with an adaptation of a previously described card-guessing paradigm (project COMPARSE ANR-11-EMCO-0007). We investigated whether the same game proposed successively by two virtual agents asking either empathetic (i.e. on the subject's feelings) or non-empathetic (i.e. on technical aspects of the game) questions to the participant would elicit different interpretations on their intentions. Dependent variables consisted of monetary allocation to the virtual agent, of questionnaires assessing the agent's help, interest, attention, etc. A group of 20 individuals with schizophrenia and one of 20 healthy controls, matched on gender, with comparable age, estimated verbal-IQ and educational level were recruited. The healthy subjects' ratings of the virtual agent's behavior demonstrated that they interpreted empathetic questioning as helping and rewarded it positively with an increased monetary allocation. Schizophrenic patients had a qualitatively reduced perception of the differences between the two agents. Only the rating concerning the "interest/attention" of the agent toward them exhibited medium effect size when contrasting conditions. Hypothetically, schizophrenic patients take into account the fact they are the object of another's attention, but may fail to infer the intentional meaning and to provide an increased monetary allocation.

Introduction Aripiprazole long-acting injection is the latest long-acting injectable (LAI) antipsychotic medication released in the market which requires a monthly injection.

Objectives The aim of our study is to present our experience in the use of Aripiprazole long-acting injection as maintenance therapy in patients with schizophrenia and other psychotic disorders.

Methodology Our sample consists of 20 patients who started treatment with long acting aripiprazole during the last 6 months of its release. Validated scales for collecting information on sociodemographic, clinical evaluation (CGI scale), quality of life (health questionnaire SF-36) and function (Sheehan Disability Inventory and social relationship scale SBS) were used.

Results The health condition of the patients was generally good and 68% reported feeling better than during the last year. Social functioning was adequate (level 1 or 2) in about 70% of the patients. Social, employment and family's disability was mild in 57% of cases, the average stress' perception was 23% and the average social support perception was 72%. Regarding the clinical evaluation, in comparison to the initiation of the treatment 18% of the patients were slightly better, 45% moderately better and 36% much better.

Conclusion A remarkable clinical improvement was observed, maintaining good health, with an acceptable level of functionality. This study shows that the incorporation of long-acting Aripiprazole to the treatment of our sample has been a significant improvement in overall functioning of the patient.

Assessing theory of mind in schizophrenia during a collaborative game

M. Champagne-Lavau^{1,*}, A. Michelas¹, C. Faget², C. Portes¹, M. Klein¹, L. Boyer³, C. Lançon²

¹ Aix-Marseille université, CNRS- LPL- UMR 7309, Aix-en-Provence, France

² La Conception university hospital, department of psychiatry, Marseille, France

³ Aix-Marseille université, EA 3279- public health- chronic diseases and quality of life research unit, Marseille, France

* Corresponding author.

Introduction While Theory of mind (ToM) impairments have been well established in schizophrenia (SZ), very few studies have investigated these impairments during social interactions. However, in daily life the attribution of mental states to others (ToM) is most often implicit and spontaneous whereas classical ToM tasks rely on explicit, deliberate and cognitively-demanding reasoning.

Objective The aim of the present study was to fully characterize ToM ability in schizophrenia by investigating this ability during a collaborative game.

Methods Ten individuals with schizophrenia (SZ) and ten healthy control (HC) participants were recruited. Patients' severity of symptoms was measured using the PANSS. All participants were asked to play a collaborative game with an experimenter. During this game, the aim of the participant was to transfer a given route from his/her map to his/her interlocutor. The prosodic focus marking was used as a linguistic marker of ToM. Participants were also submitted to a classical ToM task requiring explicit attribution of mental states and to a neuropsychological evaluation.

Results The results showed that, by contrast to HC participants, SZ patients did not produce prosodic focus marking revealing difficulties to attribute knowledge to their interlocutor during the collaborative game. SZ patients were impaired on both explicit and implicit ToM assessment. No correlation was found between the

ToM abilities and the symptoms or the neuropsychological evaluation.

Conclusions Thus, the interactive task we used appears to be an original option for studying ToM ability in schizophrenia since it is close to what happens in real-life interactions.

² University of L'Aquila, department of biotechnological and applied clinical sciences - section of psychiatry, L'Aquila, Italy

³ University of Turin, department of neuroscience - section of psychiatry, Turin, Italy

⁴ University of Bari, department of neurological and psychiatric sciences, Bari, Italy

* Corresponding author.

Introduction Neurocognition may represent an indicator of genetic risk and poor outcome in schizophrenia patients (SCZ) predicting real life functioning.

Objectives As cognitive performance of unaffected first-degree relatives (UR) is intermediate between SCZ and healthy controls (HC), neurocognitive impairment may represent a marker of vulnerability to schizophrenia.

Aims To investigate social and neurocognition in all subjects and their impact on functional capacity of patients as markers of vulnerability.

Methods Sample: 922 SCZ, 379 UR and 780 HC. Assessment: MATRICS Consensus Cognitive Battery (neurocognition), Facial Emotion Identification Test and Awareness of Social Inference Test (social cognition) and Specific Level of Functioning Scale (social functioning). Analyses: Structural Equation Model (SEM) analyses to model the impact of all variables on functional outcome.

Results SCZ scored worse in all domains than UR and HC. UR had significant impairments in all cognitive domains with respect to HC. Cognitive functioning had direct and indirect impacts on functional outcome mainly through social cognition and functional capacity. Social cognition had a direct impact on outcome, independent of neurocognition.

Conclusion SCZ and UR display similar patterns of social and neurocognition deficits. Our results confirm a strong impact of neurocognition on functional outcome. Social cognition has become an interesting object of study and its conceptualization as trait variable and the existence of a continuum between SCZ and UR are hypotheses for further research.

Validation of the remission criteria in a Chinese population with chronic schizophrenia

Y.H. Chou

Taipei Veterans general hospital, psychiatry, Taipei, Taiwan

Background A consensus definition of symptomatic remission in schizophrenia was recently established based on a fixed threshold for symptom severity and a time component. The objective of this study was to determine the clinical relevance of this definition in a Chinese population and find the predictors of symptomatic remission, functional outcome and cognition.

Methods Seventy-five schizophrenic patients were recruited within a period of 2 years. All patients need to prospectively be followed up in an outpatient clinic for at least 6 months. During this period, it was not allowed to adjust their medications. Three different definitions of symptomatic remission included the Remission in Schizophrenia Working Group (RSWG), clinical global impression (CGI) and brief psychiatric rating scale (BPRS) was evaluated. In addition, the function and cognition was assessed as the measured outcomes. The prediction model of outcomes measurement was used for statistic analysis.

Results The cumulative percentage of achieving remission criteria among three different definitions of symptomatic remission was 52% in RSWG criteria, 63% in CGI and 65% in BPRS, respectively. In comparison of remitted and non-remitted groups, there were significant differences in sex, education, function and cognition in terms of RSWG definition but not in CGI and BPRS. Female gender and education were two factors for predicting symptomatic remission and function, whereas body mass index and education were two factors for prediction of better cognition.

Conclusions Our study indicates that the definition of RSWG was more clinical relevant compared with CGI and BPRS in Chinese schizophrenia.

Introduction Schizophrenia (SZ) patients present subtle motor deficits known as Neurological Soft Signs (NSS). Those deficits encompass impairments of motor coordination, sequencing of complex motor acts and sensory integration. It has been shown that SZ patients present also deficits of higher motor functions as implicit motor learning. Growing number of studies indicate that both NSS and implicit motor learning deficits are associated with impairments of common cortico-cerebellar pathways, however relationship between these two deficits has not been evaluated yet.

Objectives To assess NSS and implicit motor learning in SZ patients.

Aims To evaluate associations between NSS and implicit motor learning scores in SZ patients.

Methods Twenty schizophrenia patients and 20 healthy controls were examined. Patients were under olanzapine, clozapine or quetiapine treatment. NSS were assessed with Neurological Evaluation Scale (NES). Implicit motor learning were assessed with a use of Serial Reaction Time Task.

Results SZ patients presented statistically higher NSS scores than healthy controls ($P < 0.001$) and presented no signs of implicit motor learning. There was statistically significant negative correlation between implicit motor learning score and total score of

neurological soft signs ($r = -0.44$), sequence of motor acts subscore ($r = -0.54$) and sensory integration subscore ($r = -0.47$) in SZ patients group ($P < 0.05$).

Conclusions There is association between implicit motor learning deficits and neurological soft signs in SZ patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction A certain degree of depressive symptoms is common in schizophrenic patients. The assessment and treatment of depressive symptoms in schizophrenia is clinically challenging.

Objectives We conducted a cross-sectional study to investigate the depressive dimension of schizophrenic patients.

Aims The aim was to evaluate the effect of pharmacotherapy on depressive symptomatology.

Methods Thirty-four outpatients (18–65 years old) with stable schizophrenia in monotherapy with FGAs or SGAs. We evaluated: depressive symptoms with Calgary Depression Scale for Schizophrenia; positive and negative symptoms (with Positive and Negative Symptom Scale); neurocognition (with Matrics Cognitive Consensus Battery); social cognition (with Facial Emotional Identification Test); social functioning (with Personal and Social Performance Scale and with UCSD Performance-based Skills Assessment). Collected data underwent statistical analyses.

Results A SGAs therapy was associated with: lower depressive symptoms (mean SGAs group = 4.0; mean FGAs group = 7.86, $P < 0.05$); lower mean positive symptoms (mean SGAs group = 12.65; mean FGAs group = 17.43, $P < 0.05$); lower negative symptoms (mean SGAs group = 21.35; mean FGAs group = 29.07, $P < 0.05$); lower scores on the PANSS-total (mean SGAs group = 71.05; mean FGAs group = 91.86, $P < 0.01$). After correction for multiple variables, the SGAs group still had significantly lower values towards the FGAs group ($P < 0.05$).

Conclusions Our study support the notion that switch from a FGA to a SGA could be a relatively simple first-step for the treatment of this condition. Atypical antipsychotics might exercise antidepressant effects with different potential mechanism including: remission of a FGA-induced depression and action on of 5-hydroxytryptamine, dopamine [other than postsynaptic D2], and $\alpha 1$ -noradrenergic receptor sites.

* Corresponding author.

Introduction Second-generation long-acting injectable antipsychotics (LAI) constitute a valuable alternative for the treatment of schizophrenia and combine advantages of both long-acting injectable drugs and atypical antipsychotics. Realistic, naturalistic studies are necessary to evaluate the impact of LAIs on specific cluster of symptoms.

Objectives To collect clinical and functioning outcomes in outpatients with schizophrenia treated with LAIs during a follow-up period of 6 months.

Aims To determine the impact on symptoms and functioning of second-generation LAIs.

Methods It is a 6-month naturalistic, observational, prospective, non-interventional study of patients diagnosed with DSM-V schizophrenia disorder. Clinical data were assessed by the Positive and Negative Syndrome Scale (PANSS) and the Global Assessment of Functioning (GAF). For statistical analysis, we used the Wall-work's five-factor model of the PANSS.

Results A total of 50 schizophrenia patients (70% male; mean age: 36.2 ± 10.4) referred to the Depot Clinic at Sant'Andrea Hospital in Rome was included. Eight patients received treatment with risperidone LAI (RLAI), 20 with paliperidone-palmitate LAI (PLAI), 10 with olanzapine-pamoate LAI (OLAI) and 12 with aripiprazole LAI (ALAI). LAIs were overall associated with improved functioning and positive symptoms; OLAI, ALAI e PLAI correlated with improved negative symptoms, RLAI, OLAI e PLAI with improved disorganised/concrete symptoms, OLAI e PLAI with improved excited symptoms; ALAI improved depressive symptoms.

Conclusion Over the 6-month period, LAIs were associated with improved functioning and illness severity in schizophrenia patients with different symptoms profile. Treatment with PLAI and OLAI showed the major clinical advantages, whereas only ALAI correlated with improved depressive symptoms.

Reduction of negative social attributions towards people with mental illness through a combination of treatments

C. Vaquero^{1,*}, M. Cebollero¹, M.Á. Escudero¹, J. Saiz^{1,2}

¹ Grupo 5, psychosocial rehabilitation, Aranjuez, Spain

² Universidad Complutense de Madrid, Facultad de Psicología, Madrid, Spain

* Corresponding author.

Introduction Stigma towards people with mental illness can have very negative consequences for the persons that experience it. So, it becomes strongly necessary to combat this problem.

Objectives/Aims Evaluate the effectiveness of multiple interventions to reduce stigma against mental illness in a group of high school students.

Methods Quasi-experimental study. Seventy-six students between 16 to 19 years old from 3 schools of southern Madrid State participated. No significant differences in age and gender between groups were found. The quasi-control group was obtained from 3 different classrooms (1 in each school). This group did not go through any treatment. The experimental group

had 2 treatments. Treatment “A” consisted in 1 psychoeducation session. Treatment “B” was 1 visit (real or virtual) to the Thyssen-Bornemisza museum. Persons exercising as museum guides had been diagnosed with mental illness. They already were participants in the PCEA program of the CRPS Latina. The instrument to assess stigma was the AQ-27, validated in Spanish.

Results We found significant reductions of stigma in all dimensions explored: Anger (A vs BC; $P < 0.001$), Threat (A vs BC; $P < 0.001$), Fear (A vs BC; $P < 0.001$), Coercion (A vs BC; $P < 0.001$) Segregation (A vs BC; $P < 0.001$) and Avoidance (A vs BC; $P < 0.001$).

Conclusions The combination of treatments for intervention on stigma in samples of school students seems to be a very effective option to reduce stigma.

Avolition in schizophrenia: associations with trait and state anhedonia

S. De Simone*, A. Mucci, P. Bucci, E. Merlotti, M. Chieffi, G. Piegari, T. Campana, S. Patriarca, M. Rocco, D. Palumbo, S. Galderisi

University of Naples SUN, department of psychiatry, Naples, Italy
* Corresponding author.

Introduction Current research suggested that avolition in patients with schizophrenia (SCZ) is not due to a deficit of hedonic experience, but to a poor ability to translate pleasurable experiences into motivational states. In line with this hypothesis, several evidences showed a preserved hedonic experience, even in the presence of severe trait anhedonia and avolition in SCZ.

Objectives To test the hypothesis that memory dysfunction, generally found in SCZ, could lead to inaccurate representations of emotional experiences and interfere with translation of pleasurable experience in motivation.

Aims The present study was aimed to investigate the relationships between state and trait anhedonia, avolition and cognitive functioning in 35 SCZ.

Methods In SCZ and matched healthy controls (HC) the Temporal experience of Pleasure (TEPS) and Chapman's scales were used to assess trait anhedonia. The MID task was used to assess in-the-moment hedonic experience. Avolition was measured by the Schedule for the Deficit Syndrome. MATRICS Consensus Cognitive Battery was used to assess cognition.

Results SCZ did not differ from HC on TEPS or on MID task performance but reported higher scores for trait social anhedonia. Trait social anhedonia was associated with memory dysfunction and showed a correlation with avolition.

Conclusions Our results confirm the disjunction between state and trait anhedonia and demonstrate a relationship of the latter with memory impairment and avolition, suggesting that inaccurate representations of emotional experiences might impede their translation in motivation to act.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relation between EEG source functional connectivity and the negative symptom severity in schizophrenia: a preliminary report from a multicentre study

G. Di Lorenzo^{1,*}, A. Mucci², A. Daverio¹, F. Ferrentino¹, A. Vignapiano², D. Marasco³, C. Niolu¹, M. Altamura³, S. Galderisi²

¹ University of Rome “Tor Vergata”, department of systems medicine, Rome, Italy

² University of Naples SUN, department of psychiatry, Naples, Italy

³ University of Foggia, department of clinical and experimental medicine, Foggia, Italy

* Corresponding author.

Introduction Neural dysconnectivity is hypothesized to be a key element in pathophysiology of schizophrenia. However, the relation of disordered connectivity with the different clinical characteristics of the syndrome is not fully elucidated.

Objectives The current research investigated the relations between resting-state EEG Source Functional Connectivity (EEG-SFC) and the two main clusters of negative symptoms derived from the Brief Negative Symptom Scale, the Expressive Deficit (ED) and the Avolition (AV), in subjects with schizophrenia (SCZ) enrolled to the multicentre study of the Italian Network for Research on Psychoses.

Methods Out of 97 chronic, stabilized SCZ included, we selected subjects according the lower and the upper quartile of the ED and AV value distribution: 25 were in upper and 24 in the lower quartile of ED (respectively, HIGH-ED and LOW-ED); 27 were in upper and 24 in the lower quartile of AV (respectively, HIGH-AV and LOW-AV). Fifty-five healthy controls (HC) were included, comparable to SCZ for gender, age and educational level. EEG-SFC analysis was based on the lagged phase synchronization (LPS) computed by eLORETA from 5 minutes resting-state EEG recordings in eyes closed condition. LPS indices were determined for each spectrum band and between all 28 regions of interest (ROI) pairs. Group differences were significant for corrected P -value < 0.05 .

Results SCZ had higher theta band LPS than HC. Respect to LOW-ED, HIGH-ED showed significant increased alpha LPS in fronto-cingulate, para-hippocampal and insular inter-hemispheric ROI pairs. No significant difference emerged between HIGH-AV and LOW-AV.

Conclusions Subgrouping SCZ according to negative symptom severity reveals heterogeneous patterns of resting-state LPS connectivity.

Low erythrocyte glutathione peroxidase activity in schizophrenic patients is mediated by gender, the number of episodes, disease duration and drug treatment

V. Djordjevic^{1,*}, M. Knezevic²

¹ Clinical center Nis, Daily hospital, Nis, Serbia

² Faculty of medical sciences, institute for psychiatry, Kragujevac, Serbia

* Corresponding author.

Introduction Inconsistent data showed that erythrocyte glutathione peroxidase (GPx) activity in schizophrenics is altered.

Aim The aim of this study was to evaluate whether some of the demographic, clinical and therapeutic factors had any significant impact on erythrocyte GPx activity in patients with schizophrenia.

Methods This study included 68 schizophrenic patients and 59 healthy individuals. GPx activity was tested related to patient age, gender, heredity, the onset of the disease, the duration of the disease, the number of episodes, PANSS scores and drug treatment. GPx activity was determined in erythrocyte hemolysates by Ransel commercially available test.

Results Erythrocyte GPx activity was significantly lower in patients with schizophrenia than in controls. Male patients had significantly lower GPx activity in comparison with those in female ones. Heredity negative patients showed significantly lower enzyme activity compared to control values. Significantly lower GPx activity was obtained independently of the onset of the disease. The patient group having more than one psychotic episode also showed significantly lower GPx activity compared to the control group. The disease duration of more than 1 year caused a significant decrease in enzyme activity. There was a significant difference in GPx activity between patients with different PANSS scores. In patients treated with second generation antipsychotics and in those treated with both first and second generation antipsychotics, GPx activity was significantly lower than in controls.

Conclusion This study shows that the low erythrocyte GPx activity in schizophrenics depends on patient gender, the number of episodes, disease duration and drug treatment.

Exploration of the link between clinical judgments and subjective perceptions of clinical change in patients treated for schizophrenia

S. Egger*, S. Vetter, S. Prinz, G. Weniger, M. Müller

University hospital for psychiatry, ZIP- Rheinau, Zurich, Switzerland

* Corresponding author.

Introduction Subjective perceptions of clinical change in patients with schizophrenia are often not congruent to the objective evidence of the same, especially since a lack of insight is part of the symptomatology. However, the exploration of the relationship between clinical judgments from mental health experts and the patients' perception of symptom change is fairly understudied.

Aims and objectives This study aimed to investigate the performance of the Positive and Negative Syndrome Scale (PANSS) as a tool for clinical outcome monitoring in schizophrenia in concordance with the change of self-reported psychopathology assessed with the Frankfurt Complaint Questionnaire (FCQ) in patients with a schizophrenia.

Methods A consecutive sample of patients admitted to a Swiss psychiatric hospital for schizophrenia was assessed with the FCQ at admission and discharge. The PANSS was rated by the responsible clinicians at admission and discharge. Complete data of admission and discharge were available from approximately 60 cases. Reliable change index (RCI) was calculated to determine a clinically meaningful change based on the PANSS scores. Logistic regression models were conducted to explore the link between RCI levels and the change of self-reported perceptions of psychopathology.

Results and conclusions Our study found no relationship between the change of PANSS and FCQ from admission to discharge in a sample of patients treated for schizophrenia. Therefore, our findings provide evidence for a large discrepancy between the observed clinical severity and the subjective perception of symptoms in individuals with schizophrenia.

Introduction Studies shown ethnic difference in illness-awareness, medication acceptance, difference in types and doses of medication prescribed in certain ethnic groups in treatment of psychosis.

Objectives To study antipsychotic adherence patterns in ethnic groups and to study factors influencing.

Aims To analyse any difference in the adherence patterns between ethnic groups and identify factors mediating any effects.

Methods One hundred and twenty-seven consecutive patients presenting to early-intervention service in South-London included in naturalistic study. Sample binarised into Caucasian (white British, other white background, $n=36$, 28%) and combined Black and Minority Ethnic (BME, $n=91$, 72%) groups. Medication adherence studied using self and carer reports, looking for percentage of times taking medications, any gaps in treatment (at least 1 month). Range of demographic and clinical parameters collected including use of substances and medications side-effects.

Results Patients with treatment gap (at least 1 month) had similar demographic and clinical characteristics with the rest, except the former were more likely to have reported extra-pyramidal (EPSE) (Pearson $\chi^2=5.6$, $df=1$, $P=0.02$), and to be BME rather than Caucasian (BME $n=57$, 64%, Caucasian $n=16$, 44%, Pearson $\chi^2=4.5$, $df=1$, $P=0.05$). These variables were further entered in stepped multivariate regression, only the effect of EPSE remained significant, with odds ratio 8, $P=0.05$. There was no difference in Chlorpromazine equivalent dose between ethnic groups (Caucasian mean-dose 156 mg, BME 138 mg, $t=1.2$, $P=0.2$). Also there was no significant difference in types of antipsychotics prescribed ($\chi^2=4$, $P=0.1$, $df=2$) between the ethnic groups.

Conclusions Ethnic difference in antipsychotic adherence may also be influenced by sensitivity to certain side effects.

Introduction Autoantibodies (Abs) to different neuronal receptors and DNA were detected in the blood of patients with

schizophrenia. Abs hydrolyzing DNA were detected in pool of polyclonal autoantibodies in autoimmune and infectious diseases, such catalytic Abs were named abzymes.

Objectives To investigate the level of anti-DNA antibodies and DNA-hydrolyzing activity of IgG from the serum of patients with schizophrenia depending on leading clinical symptoms.

Aims – To measure the concentration of anti-DNA Abs in serum of patients with leading positive and negative symptoms;
– to determine DNA-hydrolyzing activity of IgG.

Methods In our study, 51 patients were included. The levels of antiDNA Abs were determined using ELISA. DNA-hydrolyzing activity was detected as the level(%) of supercoiled pBluescript DNA transition in circular and linear forms. Statistical analysis was performed in “Statistica 9.0”.

Results Anti-DNA Abs of patients with schizophrenia not only bind DNA, but quite efficiently hydrolyze the substrate. IgG of patient with schizophrenia were shown to possess DNA hydrolyzing activity. It should be noted that DNAase activity of IgG in patients with schizophrenia with a negative symptoms was significantly higher, than in patients with positive symptoms (Table 1).

Conclusions The data show a correlation with the level of DNase activity and leading symptoms of patients with schizophrenia.

Table 1 Concentration of anti-DNA Abs and relative hydrolysis of DNA in different groups of patients with schizophrenia.

Groups of patients	Concentration of anti-DNA Abs U/mL (M ± SD)		Relative hydrolysis of DNA(%)
	Anti-ssDNA	Anti-dsDNA	
Healthy donors (n = 24)	7.4 ± 2.7	6.9 ± 0.9	9,1 ± 6,5
Total group of patients with schizophrenia (n = 51)	6.9 ± 3.7	7.4 ± 3.7	55.4 ± 32.6*
Positive symptoms (n = 25)	7.2 ± 4.1	5.3 ± 3.05	43.3 ± 33.1
Negative symptoms (n = 26)	5.4 ± 2.4*	7.9 ± 4.5	73.3 ± 23.8**

Clinical and functional outcomes of patients with severe schizophrenia undergoing comprehensive treatment: A 6-year follow-up

J.J. Fernandez-Miranda*, S. Diaz-Fernandez
SESPA, AGCSM-V, Gijon, Spain

* Corresponding author.

Introduction To increase treatment compliance and consequently to reach clinical and rehabilitation goals in people with schizophrenia is a main challenge in their treatment.

Objectives and aims To know the retention in treatment (and reasons for discharge) of people with severe schizophrenia enrolled in a specific, intensive, comprehensive and community programme for them; and also to know treatment (clinical and functional) outcomes.

Methods A 6-year prospective, observational study of patients with severe schizophrenia (ICD 10: F 20; CGI-S ≥ 5) undergoing specific severe mental illness programme (n = 200). Assessment

included the Clinical Global Impression-Severity scale (CGI-S), the Camberwell Assessment of Needs (CAN) and the WHO Disability Assessment Schedule (WHO-DAS). Time in treatment and reasons of discharge were measured. Laboratory tests, weight and medications were reported. Hospital admissions were measured.

Results CGI at baseline was 5.86 ± 0.7. After 6 years 48% of patients continued under treatment (CGI = 4.31 ± 0.8; P < 0.01); 31% were medical discharged (CGI = 3.62 ± 1.6; P < 0.001); DAS decreased in the four areas (P < 0.01) and also CAN (P < 0.01); 7% had moved to other places; 8% were voluntary discharges. Eight patients dead; three of them committed suicide. Forty-five percent of all of them were treated with atypical long-acting antipsychotics, with good tolerability. There were significantly less hospital admissions than during the previous 6 years (P < 0.001).

Conclusions Retention of severe mentally ill patients with schizophrenia in a specific and intensive care programme was really high; and seemed to help getting in remarkable clinical and functional improvement. Long-acting medication also seemed to be useful on improving treatment adherence, mainly due to their good tolerability.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depressive symptoms in a sample of patients diagnosed with schizophrenia

A. Fernandez-Quintana*, M.D.C. García-Mahía

Clinical university hospital of La Coruña, psychiatry, La Coruña, Spain

* Corresponding author.

Introduction Previous studies highlight the difficulty of correctly diagnosing depressive symptoms in schizophrenic patients, as well as the impact on clinical progression among patients who present with both syndromes, worsening treatment adherence and overall prognosis.

Aims To determine the prevalence of depressive symptoms in patients diagnosed with schizophrenia. To analyze the relationship of depressive symptoms with other demographic and clinical variables.

Material and methods Eighty-four patients diagnosed with schizophrenia according to ICD-10 criteria and treated in an Outpatient Mental Health Clinic were recruited for this study. Symptom severity was assessed using The Positive and Negative Syndrome Scale (PANSS; Kay et al., 1987); classifying patients as positive, negative or mixed schizophrenia subtypes. Data from clinical and sociodemographic variables was obtained from clinical records.

Results The mean age was 43.2 years (SD: 10.2). Depression is objectively detected in 10.3% of the sample, and presented as subjective depression in 29.5%. The prevalence of depressive symptoms is higher among women, unmarried patients, lower social classes and patients who met criteria for predominantly positive Schizophrenia subtype. Higher prevalence of depressive symptoms was found in patients with a shorter course of disease.

Conclusions Depressive symptoms present with a high prevalence among patients diagnosed with schizophrenia, especially during the early years of the disease. Given the severe impact of depression on both the evolution and prognosis of patients with severe mental illness, screening and early treatment must be carried out.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Schizophrenia and other psychotic disorders are associated with high rates of morbidity and mortality, caused by the use of specific treatments as well as health factors directly related to those processes. One of the high-frequency side effects in patients treated with classic and atypical antipsychotics is hyperprolactinemia. It causes alterations in neuroendocrine sphere (amenorrhea, galactorrhea, gynecomastia...), and other mid- and long-term effects (osteoporosis, cardiovascular risk increase and increased risk of developing cancers - specifically in breasts and endometrium).

Objectives Check hyperprolactinemia induction by maintained treatment with atypical antipsychotics.

Methodology A naturalistic prospective study was conducted following 75 patients on maintenance treatment with a single atypical antipsychotic during 24 months. Anthropometric and laboratory data were collected, along with the presence of different endocrine-metabolic during the 2-year study alterations.

Results Changes in prolactin levels were found in a large number of patients, with statistically significant differences between 0 (basal) and 24 months (Basal [M=26.27; SD=21], 2 years [M=38.08, SD=34.65]; $t=-2.758$; $P=0.013$), with hyperprolactinemia increasing from 46.6% of patients at baseline to 65.5% at 2 years, mainly with paliperidone and risperidone long acting injection (statistically significant increase in both cases) (Fig. 1).

Conclusions Paliperidone and risperidone long acting injectable induce increased prolactin levels in patients in long-term antipsychotic treatment.

Fig. 1 Prolactin variation at 24 months.

Objective Explore the basis of cortical morphometry in patients with schizophrenia and non-affected siblings by Magnetic Resonance Structural analyzing cortical thickness.

Methods Twenty-nine patients with schizophrenia treated with atypical antipsychotics and clinically stable in the last 6 months were recruited. Twenty-three not affected siblings of patients with schizophrenia and 37 healthy volunteers were recruited. Magnetic Resonance Structural was performed. FreeSurfer the brain imaging software package for analysis of Cortical Thickness is used. In the analysis of group differences in cortical thickness (CT) with the general linear model (GLM), the P -value was established in 0003 following the Bonferroni correction to control for multiple comparisons (seven regions of interest a priori in each hemisphere).

Results Significant differences in cortical thickness between patients and healthy controls. Differences between groups were calculated by general linear model (GLM) with age and sex as covariables (Table 1).

Conclusions In applying the correction for multiple comparisons, differences in bilateral-lateral orbitofrontal, medial orbitofrontal-right and left temporal transverse frontal cortex are significant. Our study replicates previous findings and provides further evidence of abnormalities in the cerebral cortex, particularly in the frontal and temporal regions, being characteristic of schizophrenia.

Table 1 Significant differences in cortical thickness in healthy controls, not affected siblings and patients with schizophrenia.

Introduction Patients with schizophrenia and bipolar disorder have higher rates of medical comorbidities and mortality than general population [1,2].

Aims To find severe mental illness biomarkers. Here, we present the peripheral biological parameters of patients with schizophrenia (SCH), bipolar disorder (BD) and healthy subjects (HS).

Methods Cross-sectional, naturalistic study. Inclusion criteria: DSM-IV diagnosis of schizophrenia or bipolar disorder; age > 17 years; and written informed consent given.

Results One hundred and twenty-three SCH, 102 BD and 80 HS. Laboratory tests: red cells, haemoglobin, leukocyte, platelets, glucose, urea, creatinine, uric acid, cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, GPT, AP, CA, P, FE, insulin, HbA1c and TSH. Age and gender were used as covariates. There were differences in: HDL-cholesterol ($P < 0.0001$), triglycerides ($P < 0.0001$), insulin ($P < 0.0001$), AP ($P = 0.006$) and TSH ($P = 0.013$). The differences were between SCH and HS (HDL-cholesterol, triglycerides, insulin, AP and TSH), and, between BD and HS (HDL-cholesterol, triglycerides, insulin and TSH), but not between SCH and BD.

Conclusion There are differences in peripheral biological parameters between patients with SCH or BD and HS. Biological biomarkers may play a role in severe mental disorders pathogenesis [1,2].

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

The aim is to describe the experience of treatment with Paliperidone Palmitate long acting injection (PP) in patients with psychotic active clinic, whether diagnoses with schizophrenia or in patients with the first episode psychosis, as well as to reflect the improvement in the control of the symptoms that the patients can improve increasing the dose.

Methods We have done a descriptive study of 34 patients hospitalized in psychiatry between January and July 2015 for psychotic active clinic who started treatment with PP or the previous dose was increased.

Results 91.2% of patients admitted for acute exacerbation of their usual pathology and 8.8% for a first episode psychosis. In the CGI scale, all the patients admitted scored as severe or markedly ill; going mostly mildly ill at discharge. For 55.9% of patients, the treatment was changed to PP, 29.4% of the dose was increased PP and 14.7% antipsychotic treatment was started with PP. Among patients change treatment, the main reason was non-adherence (47.4%). 70.6% of our patients were discharged with PP as only antipsychotic and 29.4% which was discharged with another antipsychotic, the most frequent association was of PP with Quetiapine (80%).

Conclusions PP is a highly effective medicament in the treatment of the schizophrenia that improves the adherence to the treatment, so in our experience and we consider it a medicament to be considered in the early stages of the disease. According to our experience and there are patients who can benefit from better control of symptoms adjusting the dose individually.

⁵ Universidad de Oviedo, Morfología y Biología Celular, Oviedo, Spain

* Corresponding author.

Introduction The concept of schizophrenia as a systemic disease includes, not only psychosis, but an increase in somatic comorbidity and cardiovascular risk [1]. Furthermore, it is known the implication of inflammation in the pathogenesis of schizophrenia [2].

Objectives To determinate potential inflammatory/metabolic biomarkers of schizophrenia's dimensions.

Methods Sample: 36 outpatients with schizophrenia for less than 11 years, under stable maintenance treatment (mean age [32.25], males [63.9%]) and their 36 matched controls (age [32.53 ± 6.63]; males [72.2%]).

Evaluation PANSS, Clinical Assessment Interview for Negative Symptoms(CAINS), Calgary Scale(CDS), CGI, Personal and Social Performance Scale(PSP). Biomarkers: C-reactive protein (CRP), homocysteine, glucose, insulin, HOMA-IR (insulin resistance), cholesterol, HDL, LDL, triglycerides.

Results Biomarkers differences between groups are shown in Table 1. Table 2 shows the correlations found after controlling for Body Mass Index [patients(28.61 ± 5.69);controls(24.64 ± 3.80); p=0.001] and Smoking [patients(52.8%-yes);controls(5.6%-yes);p=0.000].

Conclusions 1. CRP, a potential inflammatory biomarker in schizophrenia, is related to depression severity. Homocysteine, representing an oxidative stress, is related to positive, negative, cognitive and depressive symptoms severity, and worse functioning. 2. Patients with schizophrenia have lower HDL-related to negative and cognitive symptoms severity and worse functioning—and insulin resistance – related to worse cognition –.

Table 1

	Patients(Mean±SD)	Controls(Mean±SD)	t
CRP(mg/dl)	0.42±0.73	0.11±0.09	2.50*
Homocysteine(mg/dl)	12.97±3.35	12.05±3.78	0.98
Glucose(mg/dl)	85.2±11.34	80.88±9.76	1.80

Introduction Data on clinical outcomes with long-acting antipsychotic treatment in young, newly diagnosed patients with schizophrenia is sparse.

Objectives To explore hospitalization, drug utilization and clinical outcomes from medical records of newly diagnosed schizophrenia patients during first 12 months of treatment with once-monthly paliperidone palmitate (PP).

Methods International, multicenter, retrospective, observational study. Outcomes presented: baseline (BL) characteristics and demographics, clinically relevant improvements in disease severity (ie $\geq 20\%$ decrease in PANSS or BPRS total score or CGI-S Change ≥ -2 or CGI-C ≥ 3 , with no score showing worsening) and clinically relevant functional improvement (i.e. change in PSP total score $\geq +7$ points or change in GAF total score $\geq +20$ points, with no score showing worsening) from BL to last-observation-carried-forward endpoint (LOCF-EP) within 12-month documentation period, mean mode PP dose and adverse drug reactions.

Results Eighty-four patients analyzed: 69% male, mean age at initiation of PP was 24.1 (SD2.7) years, mean BL weight was 78.7 (SD16.0) kg and 80.0 (SD14.7) kg at LOCF-EP, with a mean change of 1.2 (SD3.9) kg; mean time from first psychotic episode to initiation of PP was 5.5 (SD3.3) months. At LOCF-EP 86.6% achieved a clinically relevant improvement (71/84, Kaplan-Meier median time from initiation of PP: 52.4 days). 63.4% achieved a clinically relevant functional improvement (52/84, Kaplan-Meier median time from initiation of PP: 53.1 days). PP mean mode maintenance dose was 96.4 (SD19.8) mg. ADRs reported in $\geq 5\%$ of patients were weight increase 9.1% and hyperprolactinemia 5.7%.

Conclusions Treatment with once-monthly PP was well tolerated and associated with clinically relevant improvements in disease severity and functioning in young, newly diagnosed schizophrenia patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Early schizophrenia patients treated with once-monthly paliperidone palmitate over a 12-month period - a retrospective observational study

L. Hargarter^{1,*}, P. Bergmans², P. Cherubin³, A. Schreiner¹

¹ Janssen Cilag Germany, Medical Affairs EMEA, Neuss, Germany

² Janssen Cilag Netherlands, Biostatistics, Tilburg, Netherlands

³ Janssen Cilag France, Medical Affairs EMEA, Issy-Lès-Moulineaux, France

* Corresponding author.

Introduction Little is known about patient characteristics and rehospitalization in newly diagnosed patients with schizophrenia treated with long-acting antipsychotics.

Objectives To retrospectively explore hospitalizations, drug utilization and clinical outcomes from medical records of young, newly diagnosed schizophrenia patients during the first 12 months of treatment with once-monthly paliperidone palmitate (PP).

Methods International, multicenter, retrospective, observational study. Outcomes presented are patient characteristics, reason for PP initiation and hospitalization data.

Results Eighty-four patients were analyzed: mean age (years) at first psychotic episode was 23.8 (SD2.6), 23.9 (SD2.6) at first antipsychotic treatment and 24.1 (SD2.7, range 19-29) at PP initiation. Time between first antipsychotic treatment and PP initiation was 4.8 (SD: 3.4, range: 0-12) months. At PP initiation, 42.9% of patients were in hospital, primarily for the management of the first episode/relapse (97.2%). Reason for PP initiation was: LAT favored over oral treatment for relapse prevention (56%), partial/non adherence with previous oral medication (20.0%), convenience (15.5%) or limited access to health care systems (2.4%). Mean time (days) between admission and initiation of PP, and between initiation of PP and discharge from hospital was 28.8 (SD23.0) and 23.2 (SD24.5), respectively. 96.4% of patients were not hospitalized during the 12-month PP treatment period. 3/84 patients (3.6%) had a single hospitalization of 15.7 (SD: 8.1) days for management of episode/relapse.

Conclusions In this young, newly diagnosed schizophrenia population, the number of hospitalizations following PP initiation was low. Main reason to initiate PP was clinicians favoring LAT over oral antipsychotic treatment for relapse prevention or due to partial/non adherence with previous oral treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Real-world paliperidone palmitate data from acute units: The SHADOW study

E. Parellada^{1,*}, M. Bioque¹, B. Herrera², M. García-Dorado²

¹ Hospital Clínic de Barcelona, Unitat d'Esquizofrènia Clínic, Barcelona, Spain

² Janssen-Cilag S.A., Medical Department, Spain

* Corresponding author.

Introduction There is an increasing interest in understanding how antipsychotic treatments work in a real-world-setting. This is especially important with long-acting-antipsychotics, where explanatory trials may not always represent the real-world-population. Observational studies and pragmatic-clinical trials could provide additional information about new therapies, which could inform decision-making processes.

Objectives To assess the effectiveness of Paliperidone-Palmitate(PP) in an acute setting within real-world-conditions. Functionality, satisfaction with treatment and pattern of use were also evaluated.

Methods An observational, prospective 6-week follow-up study was performed in acute units including adult patients with acute exacerbation of schizophrenia that started treatment with PP. Data were collected from initiation of PP until week-6 (or patient's discharge if earlier). Clinical-Global Inventory-Severity (CGI-S) was used to assess effectiveness as well as changes in illness severity. Other outcomes included total score on the Personal and Social Performance scale (PSP), patient-satisfaction with medication (MSQ) and tolerability. Student's-*t* tests were used to assess changes from baseline in CGI-S and PSP.

Results Two hundred and eighty patients were included in the analysis (mean age: 40.5 ± 12.2 [SD] years). A significant decrease in mean (SD) CGI-S score between baseline (4.7 [0.9]) and endpoint (3.3 [0.9]) ($P < 0.0001$) was observed. (Note that 21% of patients were discharged on PP-monotherapy). Patient-functioning also significantly improved from baseline to endpoint ($P < 0.0001$). Seventy-four percent of patients were satisfied (measured by MSQ) at the end of follow-up. Anticholinergic-treatment was less frequent for PP discharged on monotherapy vs. not monotherapy (12.5% vs 21.2% respectively). Overall, PP was well-tolerated. Twenty-five AEs were reported in 20 patients (incidence 7.1%). No serious AEs occurred.

Conclusions These results support the effectiveness and tolerability of PP in an acute setting under daily-clinical-practice with good acceptance by patients.

Reducing cardiovascular risk in non-selected outpatients with schizophrenia: A 2.5-year programme conducted in a real-life setting

P. Hjorth^{1,*}, P.M. Jørgensen², A. Kynde³

¹ Aarhus university hospital, mental health center- psychiatric hospital, Randers, Denmark

² Odense university hospital, department of psychiatry, Odense, Denmark

³ Aarhus university hospital- Risskov, department of organic mental disorder and emergency Ward, Aarhus, Denmark

* Corresponding author.

Introduction Patients with schizophrenia have increased somatic morbidity and increased mortality. Knowledge of how to integrate prevention and care of somatic illnesses into the treatment of psychiatric patients is required.

Objectives Forty-seven patients diagnosed with schizophrenia participated in the programme (mean age: 33.3 years, SD: 11.9).

Aims To investigate whether a 2.5-year interventional programme to improve physical health is effective.

Method The intervention consisted of health promotion activities focusing on the patients' health, not their diseases. The patients' physical health parameters were intensely monitored and each patient received individual guidance on healthy food and on how to live a physically active life.

Results Extensive problems with obesity, especially among the women, were observed, and low level of physical activity among the patients was demonstrated. The included patients were in a high risk of developing cardio vascular diseases and diabetes type 2. The main outcomes were reduction in waist circumferences and in consumption of soft drinks and an increase in coffee drinking. Furthermore, an increase in time spent on moderate and light physical activities was observed. The patients showed great interest in the programme, and it was unproblematic getting the patients to participate in the entire programme. Moreover, they willingly followed the health guidance and achieved a healthier life.

Conclusions The intervention seems relevant and manageable in an outpatient setting. The results are promising in the ongoing process of improving physical health among patients with schizophrenia. We recommend implementation of the programme in daily practice.

A mirror image study of the utility of long acting aripiprazole

R. Hodgson*, C. Aladakatti, N. Kataria, T. Saravanappa, D. Brittainy

Lyme Brook Centre, Psychiatry, Stoke-on-Trent, United Kingdom

* Corresponding author.

Aims and background Ablify Maintena (AM) is a long acting injection of aripiprazole that received marketing authorisation in the UK in January 2014. It is costly compared to first generation antipsychotics (FGAs) LAIs and there are no robust trials comparing AM with FGAs. We examined the effectiveness and use of AM in a mental health trust.

Methods We identified all patients prescribed AM in North Staffordshire (population: 470,000) since launch and examined records for demography, diagnosis, bed and medication use. We examined the effectiveness of AM using a mirror image design.

Results Thirty patients received AM in a time frame allowing a 1-year follow-up. Sixty-nine percent were male and the mean age was 39 years. Over half were detained under the 1983 Mental Health Act and 30% were inpatients on a psychiatric intensive care unit when AM was started. Twenty-eight patients had a psychotic diagnosis. There was a significant reduction in bed occupancy (63 v 6 days, $P = 0.0001$) and admissions (1.6 v 0.5, $P = 0.0001$). The median dose was 400 mg. Lack of effectiveness/poor adherence with prior treatments were the main reason for starting AM in 84%. Eighty-six

percent of patients clinically improved on AM. Blood parameters were in the normal range.

Discussion Within the limitations of the methodology, our results show a reduction in psychiatric bed use in the year following AM initiation on an intention to treat basis. The reduction in bed use equates to a minimum annual saving of £14,250 per patient. AM at the median study dose costs £2645 per year.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Coping strategies and quality of life in schizophrenia outpatients treated by Psychopharmacs - cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹, R. Hruby³, D. Kamaradova¹, M. Ociskova¹, K. Latalova¹, A. Grambal¹

¹ Faculty of medicine and dentistry- Palacky university Olomouc- university hospital Olomouc, department of psychiatry, Olomouc, Czech Republic

² Regional hospital Liberec, department of psychiatry, Liberec, Czech Republic

³ Psychiatric outpatient department, Martin, Slovakia

* Corresponding author.

Introduction The modern psychiatric view of schizophrenia spectrum disorders and their treatment has led to an increasing focus on coping strategies and quality of life of these patients.

Objectives Understanding the relationship between quality of life and coping strategies can help in finding those coping strategies that enhance the quality of life. It is important to study the inner experience and striving of patients because of connection with well-being and treatment adherence.

Aims : In the present study, the authors examined the relationship between demographic data, the severity of symptoms, coping strategies, and quality of life in psychotic outpatients.

Methods Psychiatric outpatients who met ICD-10 criteria for a psychotic disorder (schizophrenia, schizoaffective disorder, or delusional disorder) were recruited in the study. Questionnaires measuring the coping strategies (SVF-78), the quality of life (Q-LES-Q), and symptoms severity (objective and subjective clinical global impression–objCGI; subjCGI) were assessed. Data were analysed using one-way ANOVA, Mann-Whitney U-test, Pearson and Spearman correlation coefficients, and multiple regression analysis.

Results One hundred and nine psychotic outpatients were included in the study. The QoL was significantly related to the Positive and Negative coping strategies. The severity of disorder highly negatively correlated with the QoL score. Stepwise regression analysis showed that symptoms severity (subjCGI), Positive coping strategies (especially Positive Self-instruction), Difference between the objCGI and subjCGI and Negative coping strategies explain totally 53.8% of variance of the QoL (Tables 1–3).

Conclusions Our study suggests the importance of utilizing the Positive coping strategies in improving the quality of life in patients with psychotic disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-stigma and quality of life in Psychopharmacs treated outpatients with schizophrenia and related disorders - A cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹, K. Latalova¹, M. Ociskova¹, A. Grambal¹, D. Kamaradova¹, K. Vrbova¹, R. Hruby³

¹ Faculty of medicine and dentistry- Palacky university Olomouc-university hospital Olomouc, department of psychiatry, Olomouc, Czech Republic

² Regional hospital Liberec, department of psychiatry, Liberec, Czech Republic

³ Psychiatric outpatient department, Martin, Slovakia

* Corresponding author.

Introduction Self-stigma is a maladaptive psychosocial phenomenon that can disturb self-image and quality of life in psychiatric outpatients and may lead to dysphoria, social isolation and reduced adherence to treatment.

Objectives Self-stigma and QoL could be reflected as important factors for patients, who suffer from schizophrenia spectrum disorders, their caregivers and mental health specialists. Focus on reducing the self-stigma in supportive and educational therapy could be an important factor in promoting a higher QoL.

Aims Current research moved attention to the relationship between demographic data, the severity of symptoms, self-stigma and quality of life in schizophrenic outpatients compared to the QoL in healthy controls.

Methods Patients who met ICD-10 criteria for schizophrenia spectrum disorder were recruited in the study. The Quality of Life Satisfaction and Enjoyment questionnaire (Q-LES-Q), Internalized Stigma of Mental Illness (ISMI) and severity of the disorder measured by objective and subjective Clinical Global Impression severity scales (CGI) were assessed.

Results One hundred and nine psychotic patients and 91 healthy controls participated in the study. Compared to the control group,

there was a lower QoL and a higher score of self-stigma in psychotic patients. We found the correlation between the self-stigma, duration of disorder and QoL. The level of self-stigma correlated positively with total symptom severity score and negatively with the QoL. Stepwise regression analysis revealed that the objective severity and self-stigma score were significantly associated with the quality of life (Tables 1 and 2, Fig. 1).

Conclusions Our study suggests a negative impact of self-stigma level on the quality of life in patients suffering from schizophrenia spectrum disorders.

Cognitive function in early psychosis patients from a low-income country

M.O. Husain^{1,*}, I.B. Chaudhry², T. Kiran², R. Thomasson³, N. Mehmood⁴, N. Husain²

¹ Manchester mental health and social care Trust, general adult psychiatry, Manchester, United Kingdom

² University of Manchester, psychiatry, Manchester, United Kingdom

³ Penine acute care NHS Trust, psychiatry, Manchester, United Kingdom

⁴ Pakistan institute of learning and living, research and development, Karachi, Pakistan

* Corresponding author.

Background Cognitive impairments are well established findings in schizophrenia and are associated with significant impairment of social functioning. Episodic memory, working memory and executive function test scores are typically 1 standard deviation below healthy controls. There are reports suggesting the presence of neurocognitive deficits prior to illness onset, opening the possibility of using cognitive profiles as disease markers. Interest in exploring cognitive functioning in early stages schizophrenia has continued to grow, as earlier treatments could possibly lead to improved outcomes.

Methods This is a cross-sectional assessment of cognitive profiles in patients with early psychosis. A total of 51 patients suffering from psychosis in the age group of 18–65 years were recruited and matched with 51 healthy controls. A wide range of neurocognitive domains were assessed using standardised neuropsychological tests.

Results There was evidence of statistically significant impairments in cognitive functioning across a broad range of cognitive domains in early-psychosis patients, as compared to healthy controls. More pronounced deficits were seen in executive function tests.

Conclusions To our knowledge, this is the first study to report cognitive deficits across a range of domains in patients with first episode psychosis from a low-income country. This study found deficits across multiple domains, including language, memory, attention, executive function, and visuospatial function in patients with early psychosis. Evidence of neuropsychological deficits in

the early course of the disease may highlight crucial therapeutic windows for both pharmacological treatments and cognitive rehabilitation. This may improve functional outcomes in this patient group in the longer term.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Short-term compliance in first-episode psychosis

N. Iriarte Yoller^{1,*}, J. Vicente García¹, F. Rico Villademoros²

¹ Hospital universitario de Burgos, psiquiatría, Burgos, Spain

² Instituto de neurociencias, universidad de Granada, Granada, Spain

* Corresponding author.

Introduction Non-compliance is a significant problem in patients with first-episode psychosis (FEP), representing a challenge for mental health professionals due to the heterogeneous course and functional outcomes.

Objectives The aim was to describe the short-term compliance in FEP and analyze the demographics, clinical features, and management issues potentially associated with non-compliance.

Methods This observational and retrospective study included all consecutive FEP admitted to our psychiatry unit from January to June 2015, belonging to our catchment area. To be categorized as compliant, patients had to attend month-1 and month-3 follow-up visits. Characteristics of compliant and non-compliant were compared using a bivariate analysis.

Results We included 18 patients whose characteristics are shown in the table. Overall, 8 (44.4%) were non-compliant. Patients who were non-compliant had a significantly shorter length of stay (10.3 [6.3] vs. 18.5 [8.9] days). Most patients (66.7%) had cannabis abuse, being slightly more frequent among non-compliant (75% vs. 60%, $P = NS$); in addition, the diagnosis of substance-induced psychotic disorder was also more common among non-compliant (50% vs 20%, $P = NS$). There were 2 patients who were readmitted, both in the non-compliant group (Table 1).

Conclusions Short-term non-compliance is high among patients with FEP. Despite the limitations of our study, our results suggest that, beside other factors (e.g. substance abuse), non-compliance could be associated with management-related factors.

Quality of care for medical comorbidities among patients with and without schizophrenia

M. Jørgensen^{1,*}, J. Mainz¹, S. Paaske Johnsen²

¹ Aalborg university hospital, psychiatry, Aalborg, Denmark

² Aarhus university hospital, department of clinical epidemiology, Aarhus N, Denmark

* Corresponding author.

Introduction The association between schizophrenia and quality of care for medical comorbidities in universal health care systems remains unclear.

Objectives To elucidate whether equal access also implies equivalent and sufficient care.

Aims To compare the quality of care for heart failure, diabetes and chronic obstructive pulmonary disease (COPD) among patients with and without schizophrenia in Denmark.

Methods In a nationwide population-based cohort study, we used Danish national registries to estimate the risk of receiving guideline recommended disease-specific processes of care between 2004 and 2013.

Results Compared to patients without schizophrenia, patients with schizophrenia had lower chance of receiving high overall quality of care ($\geq 80\%$ of recommended processes of care) for heart failure (Relative risk [RR] 0.67, 95% CI: 0.48–0.92), diabetes (RR 0.84, 95% CI: 0.79–0.89) and COPD (RR 0.82, 95% CI: 0.72–0.93) as well as lower chance of receiving individual disease-specific processes of care including treatment with beta-blockers (RR 0.87, 95% CI: 0.79–0.96) in heart failure care and measurement for albuminuria (RR 0.96, 95% CI: 0.93–0.99), eye examination at least every second year (RR 0.97, 95% CI: 0.94–0.99) and feet examination (RR 0.96, 95% CI: 0.93–0.99) in diabetes care. Diabetic patients with schizophrenia also had lower chance of receiving antihypertensive (RR 0.84, 95% CI: 0.73–0.96) and ACE/ATII inhibitors (RR 0.72, 95% CI: 0.55–0.94). In COPD care, patients with schizophrenia had lower chance of receiving LAMA/LABA medication (RR 0.92, 95% CI: 0.87–0.98), however, higher chance of treatment with non-invasive inhalation (RR 1.85, 95% CI: 1.61–2.12).

Conclusions Quality of care for three medical comorbidities was suboptimal for patients with schizophrenia.

Efficacy and tolerability of switching to long-acting injectable (LAI) aripiprazole in outpatients with schizophrenia

B. Fernández-Abascal Puente, M. Juncal Ruiz*,

R. Landera Rodríguez

Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction Switching antipsychotics is a therapeutic alternative for managing side-effects, or efficacy and compliance issues.

Aim To evaluate the efficacy and tolerability of switching to LAI-aripiprazole in patients who had insufficient response or were intolerant to the previous antipsychotic, or required a more convenient treatment regimen.

Methods This was a prospective, observational, 6-months study carried out in 45 outpatients with schizophrenia who were clinically stabilized but a switching to another antipsychotic was clinically indicated. Patients who required hospitalization, treatment discontinuation or adding another antipsychotic (including supplementation with oral-aripiprazole) were considered treatment failures. Switching was considered successful if the side-effect/symptom/adherence/convenience improved or, if applicable, disappeared.

Results Patients aged 38 years, 51% women, and previous antipsychotics comprised: LAI-paliperidone (42%), oral-aripiprazole (22%), oral-olanzapine (11%), oral-risperidone (7%), LAI-risperidone (4%) and others (14%). The efficacy results of the switching are presented in the table. Of the 45 patients, 7 (15%) were considered treatment failures: 3 patients were hospitalized due to recurrence of psychotic symptoms, 2 discontinued LAI-aripiprazole, and 2 required supplementation with oral-aripiprazole (Table 1).

Conclusions Our results suggest that switching to LAI-aripiprazole is an efficacious strategy for managing some antipsychotic-induced side-effects, persistence of negative symptoms and/or lack of treatment adherence.

Table 1

Reason for switching	Baseline, n(%)	Outcome (month 6), n(%)		
		Resolution	Improvement	Overall success
Hyperprolactinemia	10(21%)	8(80%)	2(20%)	10(100%)
Persistent negative symptoms	10(21%)	NA	8(80%)	8(80%)
Metabolic syndrome	9(20%)	1(11%)	7(80%)	8(91%)
Sexual dysfunction	5(12%)	1(20%)	4(80%)	5(100%)
Extrapyramidal symptoms	4(9%)	0(0%)	2(50%)	2(50%)
Lack of adherence	4(9%)	NA	3(67%)	3(67%)
Convenient regimen	3(8%)	NA	2(75%)	2(75%)

Disclosure of interest The authors have not supplied their declaration of competing interest.

Visual memory deficits and symptoms in schizophrenia

D. Kontis^{1,2,*}, E. Theochari^{1,2}, V. Grigoriou¹, K. Goulas¹, M. Kafritsa¹, D. Vassos¹, A. Andreopoulou¹, S. Vassilouli¹, D. Giannakopoulou¹, E. Tsaltas²

¹ Psychiatric Hospital of Attica, Unit for the Study of Cognition in Psychosis, Athens, Greece

² Athens University Medical School, 1st Department of Psychiatry, Athens, Greece

* Corresponding author.

Introduction Cognitive deficits have been associated with negative, but not positive, symptoms in schizophrenia.

Aim The investigation of the relationship of visual memory performance with schizophrenia symptoms.

Patients and methods Forty individuals with schizophrenia who were referred to our Unit were assessed using the Benton Visual Retention Test (BVRT) (visual memory), the Positive and

Negative Syndrome Scale (PANSS) (symptoms) and the Global Assessment of Functioning Scale (GAF) (functioning). The dose of antipsychotic medications was calculated in chlorpromazine equivalents (ChlorpromEqs). Antipsychotic polypharmacy versus monotherapy receipt and the total duration of pharmacotherapy were also recorded. Multiple linear regression models were employed to investigate the relationship of BVRT total errors with PANSS total and subscales' scores, controlling for antipsychotic dose, receipt of antipsychotic polypharmacy and duration of pharmacotherapy.

Results The mean age of participants (32 males, 8 females) was 43.07 years (standard deviation [SD]=12), mean duration of pharmacotherapy = 15.94 years (SD=9.65), mean GAF score = 55.16 (SD=9.76) and the mean antipsychotic dose = 937.26 (SD=630.39) ChlorpromEqs. Twenty-four individuals were receiving polypharmacy and 16 monotherapy. The PANSS total score was positively associated with the number of total errors in BVRT ($B=0.152$, 95% CI=0.048, 0.256, $t=3.06$, $P=0.006$). This association was driven by the relationship of visual memory errors with PANSS negative ($B=0.310$, 95% CI=0.053, 0.568, $t=2.53$, $P=0.021$) and general psychopathology ($B=0.237$, 95% CI=0.1, 0.374, $t=3.63$, $P=0.02$) scores. The relationship of visual memory performance with positive symptoms was not significant.

Conclusions Visual memory deficits are associated with negative and general psychopathology symptoms in schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

COMT polymorphisms and Mini-Mental State Examination performance in schizophrenia

D. Kontis^{1,2,*}, E. Theochari^{1,2}, V. Grigoriou¹, K. Goulas¹, M. Kafritsa¹, D. Vassos¹, A. Andreopoulou¹, S. Vassiloulis¹, D. Giannakopoulou¹, A. Prokopiou¹, V. Avgikou¹, M. Kouloumpi¹, E. Tsaltas²

¹ Psychiatric Hospital of Attica, Unit for the Study of Cognition in Psychosis, Athens, Greece

² Athens University Medical School, 1st Department of Psychiatry, Athens, Greece

* Corresponding author.

Introduction Individuals with schizophrenia have cognitive deficits which have been associated with genetic polymorphisms such as those of the gene coding for the catechol-O-methyltransferase enzyme (COMT-[rs4680]).

Aim To examine the relationship of schizophrenia diagnosis and COMT-[rs4680] polymorphisms with the performance on the Mini-Mental State examination (MMSE).

Patients and methods Ninety-two individuals with schizophrenia and 29 healthy controls were tested on the MMSE. COMT polymorphisms were characterized using the Restriction Fragment Length Polymorphisms method from DNA isolated from peripheral blood sample lymphocytes. Hierarchical linear regression analysis was used to examine the COMT polymorphisms X diagnosis interaction and the effects on MMSE scores, controlling for age and education.

Results Individuals with schizophrenia versus healthy controls had a mean age of 43.69 (standard deviation [SD]=9.71) versus 43.79 (SD=7.80) years and mean education of 10.92 (SD=3.42) versus 12.82 (2.91) years. The two groups significantly differed in education (Mann-Whitney $z=2.55$, $P=0.011$). We found no evidence that COMT polymorphisms moderated any effect of diagnosis on MMSE or that they are associated with MMSE performance. Individuals with schizophrenia had lower MMSE scores than controls (mean difference = 1.676; 95% Confidence Interval = 0.499, 2.85; $t=2.822$, $df=115$; $P=0.006$).

Conclusion Schizophrenia patients have lower MMSE scores controlling for the effect of age and education. COMT polymorphisms are not associated with MMSE scores.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is clinical global impression associated with intelligence in schizophrenia?

D. Kontis^{1,2,*}, E. Theochari^{1,2}, A. Andreopoulou¹, V. Grigoriou¹, K. Goulas¹, M. Kafritsa¹, S. Vasiloulis¹, D. Giannakopoulou¹, D. Vassos¹, A. Melachrinou¹, A. Tsihlikis¹, E. Tsaltas²

¹ Psychiatric hospital of Attica, unit for the study of cognition in psychosis, Athens, Greece

² Athens University Medical School, 1st Department of Psychiatry, Athens, Greece

* Corresponding author.

Introduction The findings of studies examining the association of cognition with symptoms or functioning in schizophrenia are contradictory.

Aim To investigate the clinical and functional correlates of general intelligence in schizophrenia.

Method Forty-nine stabilized individuals with schizophrenia were recruited in a cross-sectional study. Intelligence was assessed using the Wechsler Adult Intelligence Scale III (WAIS). Clinical symptoms were measured with the Positive and Negative Syndrome Scale (PANSS) and the Clinical Global Impression Scale (CGI). Functioning was assessed with the Global Assessment of Functioning Scale (GAF) and the Strauss-Carpenter Scale (SCS). Separate linear regression analyses were conducted using WAIS full scale as the dependent variable and the following predictors: PANSS total or PANSS positive or PANSS negative scores or CGI or GAF or SCS scores. Significant predictors were entered in one final overall model. Age and gender were entered as covariates in all analyses.

Results ANOVA models for PANSS total, positive and negative psychopathology scores and SCS scores were not significant. However, negative symptoms were inversely associated with intelligence ($B=-0.61$, 95% CI=-1.012, -0.209, $t=-3.06$, $df=45$, $P=0.004$). CGI scores inversely correlated with WAIS total scores ($B=-6.078$, 95% CI=-9.029, -3.128, $t=-4.151$, $df=44$, $P<0.001$). GAF was positively associated with intelligence ($B=0.336$, 95% CI=0.084, 0.589, $t=2.679$, $df=45$, $P=0.01$). In the final (overall) model, only CGI remained significant. One unit increase in CGI (e.g. mildly versus moderately ill) was associated with 5.2 units decrease in full IQ scores ($B=-5.168$, 95% CI=-9.257, -1.078, $t=-2.550$, $df=0.002$, $P=0.015$).

Conclusions Clinical global impression of stabilized individuals with schizophrenia predicts their level of general intelligence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Serum hormone levels and cognitive functioning in male schizophrenia patients

K. Krysta*, A. Bratek, A. Koźmin-Burzyńska, I. Krupka-Matuszczyk

Medical university of Silesia, department of psychiatry and psychotherapy, Katowice, Poland

* Corresponding author.

Background Hormones deregulation is a common feature in schizophrenia. Among the hormones that gained increased interest

are sex hormones, thyroid hormones and prolactin. However, the question whether there is an impact of the hormonal disturbances on cognitive functioning of schizophrenia patients is rarely addressed.

Objective To assess the relationship between serum levels of hormones and cognitive abilities in male schizophrenic patients.

Subjects and methods In the index group, there were 15 schizophrenia male patients, mean age 36. The control group was formed by 15 healthy volunteers, mean age 36. In the two groups, serum hormones levels were measured and neuropsychological tests were performed. Analysed hormones included thyroid-stimulating hormone (TSH), luteinizing hormone (LH), follicle-stimulating hormone (FSH), estradiol, testosterone, progesterone and prolactin. Cognitive abilities were measured with the following tests: Trail Making Test (TMT) Part A and B, Semantic Category Fluency (SCF), Initial Letter Fluency (ILF) and Stroop Task Part 1 and 2.

Results The levels of FSH, LH and testosterone were lower in the index group than in the control group (3.01 mIU/mL vs 5.90 mIU/mL; 3.83 mIU/mL vs 5.28 mIU/mL; 2.76 ng/mL vs 4.69 ng/mL; accordingly) while the level of prolactin was higher in the index group (620 uIU/mL vs 118 uIU/mL). Patients performed worse than controls in all neuropsychological tests. The differences in scores of TMT Part B, ILF and Stroop Task Part 2 were found to be statistically significant.

Conclusions There was no significant relationship between serum level of analysed hormones and performance on cognitive tasks.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Reaction time, processing speed and sustained attention in patients with schizophrenia: Impact on functioning

A. Orozco¹, M. Vicens¹, A. Ruiz¹, A. Brañas¹, G. Lahera^{2,*}

¹ Príncipe de Asturias university hospital, psychiatry, Alcalá-Madrid, Spain

² University of Alcalá- IRyCIS- CIBERSAM, medicine and medical specialties, Madrid, Spain

* Corresponding author.

Introduction Some studies have related processing speed with functionality. A more discriminative analysis of different components of this neuropsychological construct is needed.

Objectives/Aims To measure the performance of a group of patients with schizophrenia in reaction time, processing velocity and sustained attention. To compare the impact on functioning of these three measures.

Methods Ninety-eight outpatients between 18 and 65 years diagnosed with schizophrenia, based on the DSM-V, with a 3-month period of clinical stability, were recruited. Sociodemographic and clinical data were collected: PANSS scale, Akathisia Simpson-Angus Brief Scale, State-Trait Anxiety Inventory (STAI) and Global Functioning Scale (GAF). The following variables were measured: reaction time (SUPERLAB PRO), processing speed (TMT-A, subtest of symbol coding BACS, verbal fluency) and sustained attention (Continuous Performance Test).

Results Functionality of patients was correlated to Elective Reaction Time (the subject must react to different types of stimuli and to choose between several possible answers) [$P = -0.205$; $P = 0.047$], but NOT with Simple Reaction Time [$P = 0.109$; $P = 0.293$]. Functionality was significantly correlated to Symbols Coding ($P = 0.328$; $P = 0.001$), and a trend was observed regarding semantic fluency ($P = 0.190$; $P = 0.06$) and the TMT-A ($P = -0.179$; $P = 0.08$). In CPT, Correct Detection was correlated with GAF score ($P = 0.380$; $P = 0.000$) but not omission errors. The model of lineal regression shows a differential impact of every measure in global functioning.

Conclusions Reaction time, processing speed and sustained attention are different variables and each of them have impact on functioning in schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Objective To examine the effect of cariprazine, a dopamine D₃/D₂ receptor partial agonist with preferential binding to D₃ receptors, on predominant negative symptoms of schizophrenia.

Methods Subjects with schizophrenia and PANSS factor score for negative symptoms (PANSS-FSNS) ≥ 24 and no pseudospecific factors (e.g. extrapyramidal symptoms, depression) were randomized to cariprazine 4.5 mg/d (dose range: 3–6 mg/d) or risperidone 4 mg/d (dose range: 3–6 mg/d) for 6 months.

Results Four hundred and sixty-one patients were randomized 1:1 to double-blind risperidone ($n = 231$) or cariprazine ($n = 230$) treatment. Change from Baseline (CbB) at week 26 in the primary parameter, PANSS-FSNS, was larger in the cariprazine group than in the risperidone group (LSMD = -1.47 ; 95% CI: $[-2.39, -0.53]$; $P = 0.002$) significant from week 14 onwards. CbB at week 26 in the functional parameter, Personal and Social Performance (PSP) total score, showed similarly greater improvement with cariprazine than risperidone (LSMD = 4.63 ; 95% CI: $[2.71, 6.56]$; $P < 0.001$) significant from week 10 onward. Statistically significant differences in favor of cariprazine at week 26 were shown in the PSP areas of self-care, socially useful activities and personal and social relationships. Most patients tolerated the study treatment well, as reflected by low discontinuation rates due to adverse events (AEs). Adverse event profiles of cariprazine and risperidone were similar. The most common AEs during study treatment were insomnia (10.0%), and headache (10.4%), both in the risperidone group.

Conclusion 26-week cariprazine treatment, given as antipsychotic monotherapy, was significantly more effective on negative symptoms and on functioning than risperidone in patients with predominant negative symptoms of schizophrenia.

Identification of subtypes of Chinese schizophrenia patients before discharge: A cluster analysis

S. Liu*, Z. Li

Peking Union Medical College, School of Nursing, Beijing, China

* Corresponding author.

Introduction People with schizophrenia is a highly heterogeneous group. Identifying subtypes of people with schizophrenia before discharge may help develop targeted discharge plans.

Objectives To explore possible subtypes among people with schizophrenia before discharge by their self-management ability, self-efficacy and cognitive function status.

Aims To identify possible subtypes among people with schizophrenia before discharge.

Methods Totally, 150 Chinese people with schizophrenia before discharged from a tertiary psychiatric hospital in Beijing were assessed by Self-management Instrument for People with Schizophrenia and Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). Cluster analysis using SPSS 20.0 package was performed to categorize subjects based on their scores.

Results Four different types of subjects were revealed. Type I low cognition with no participation ($n = 25$), patients' self-management ability, self-efficacy and cognitive function were very poor; type II medium cognition with blind confidence ($n = 42$), patients' self-efficacy was good, while self-management ability was poor and cognitive function is medium; type III high cognition with high level skill ($n = 46$), patients' cognitive function, self-management ability and self-efficacy were good; type IV low cognition with medium level skill ($n = 37$), patients' cognition was very poor, while self-management ability and self-efficacy were medium. These four types of subjects had significant differences in long-term use of antipsychotics and primary caregivers' education level ($P < 0.05$).

Conclusions The finding of different subtypes of people with schizophrenia presenting in this sample may help health professionals give effective screening and targeted discharge measures which can further promote patients' recovery and reduce readmission rates.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Perceived and anticipated stigma are relevant issues in patients with schizophrenia. Stigma has negative consequences both in quality of life and in the course of illness.

Objectives To analyze differences in perceived and anticipated discrimination in two groups of patients with schizophrenia: one with a recent diagnosis of illness and another with a long course of disease.

Methods A cross-sectional study was carried out in a sample of 100 patients with diagnosis of schizophrenia, 18 or more years old, clinically stabilized, without axis I DSM-IV comorbidity. Patients received treatment in the outpatient services of a catchment area in Madrid. Perceived and anticipated discrimination was evaluated through the DISC-12 (Discrimination and Stigma scale). Other study variables were: socio-demographic status, length of disease, symptoms of depression (Calgary Scale) and functionality degree measured by Global Assessment of Function (GAF). Two sub-groups of patients were compared: one with a length of illness below 5 years and a second one with a length of illness over 5 years.

Results Patients with a length of illness longer than 5 years showed elevated degree of perceived and anticipated discrimination compared with patients with less than 5 years of illness course. In the same way, patients with a recent diagnosis of illness showed increased scores in the measure of face the stigma.

Conclusions Preventive strategies to avoid the stigma in schizophrenia should consider some differences in patients in relationship with the length of evolution of illness in order to be more accurate. Early intervention programs about stigma are necessary.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Perceived and anticipated stigma in schizophrenia in relationship with depressive symptoms and functionality degree

C. López-Micó*, B. Reneses, L. Gallego, G. Maria Sagrario,
R. Fernandez, Á. Huidobro, L. Reyes, P. Gómez
Hospital Clínico San Carlos, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Perceived and anticipated stigma is relevant issues in patients with schizophrenia. Stigma has negative consequences both in quality of life and in the course of illness.

Objectives To analyze the degree of perceived and anticipated stigma and discrimination in patients with schizophrenia and their relationship with clinical and socio-demographic variables.

Methods A cross-sectional study was carried out in a sample of 100 patients with diagnosis of schizophrenia, 18 or more years old, clinically stabilized, without axis I DSM-IV comorbidity. Patients received treatment in the outpatient services of a catchment area in Madrid. Perceived and anticipated discrimination was evaluated through the DISC-12 (Discrimination and Stigma scale). Other study variables were: socio-demographic characteristics, symptoms of depression (Calgary Scale) and functionality degree measured by Global Assessment of Function (GAF).

Results The presence of symptoms of depression evaluated by the Calgary Scale and low degree of functionality measured by GAF are associated with greater feelings of discrimination and stigma, especially in the sub-scales of experienced and anticipated discrimination of the DISC 12. Anticipated stigma is higher in men than in women while the rest sub scales of the DISC-12 do not correlate with gender or other sociodemographic variables.

Conclusions Preventive strategies to avoid the stigma in schizophrenia should consider some characteristics associated with disease, especially the degree of functionality and presence of depressive symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

First-episode psychosis: What does it mean?

S. Marques*, F. Godinho, A.L. Melo, D. Barrocas
Hospital do Espírito Santo de Évora, Department of Psychiatry and
Mental Health, Évora, Portugal

* Corresponding author.

Introduction First-Episode Psychosis (FEP) is a variable condition, characterized by the emergence of new psychotic features for a period of at least 1 week. The majority of existing studies about FEP only address schizophrenia spectrum psychosis (SSP), which may limit the capacity to fully characterize this entity.

Objectives/Aims Report the clinical and socio-demographic characteristics of patients with FEP in real-world setting, and compare the differences among SSP and affective FEP.

Methods Retrospective analysis of clinical files of patients admitted to our hospital unit with FEP diagnosis from January/2012 to April/2015. Clinician-rated dimensions of psychosis symptom severity scales (DSM-5) were applied.

Results Annual incidence of FEP was 11,3/100,000. From a total of 755 patients, 57 (7,5%) corresponded to FEP; 38 (66,7%) were diagnosed with SSP, 11 (19,3%) affective psychosis, 3 (5,2%) toxic psychosis and 5 (8,8%) organic psychosis. Most were female (61,4%), with a mean age of 49 years. The majority were unemployed (66,7%), lived with family (57,9%), and presented with moderate-severe delusions (80,1%), but without hallucinations (57,8%), disorganized speech (59,6%) or negative symptoms (85,9%). Affective FEP patients were older (61 vs 45 years), presented with less severe psychotic symptoms (7,2 vs 8,3 points), but with higher hospital admission (26,1 vs 21,1 days).

Conclusions Regardless the growing interest concerning FEP, its conceptualization and characterization remains controversial. Our results differ from pre-existing literature data, especially concerning gender and age. By including all the possible etiologies of FEP, we aimed to obtain a more realistic characterization of this entity in a real-world setting.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Pro/antiinflammatory imbalance has been found in first-episode psychotic (FEP) patients, even 12 months later. Current research is every time more focused in the need to find biomarkers to understand the underlying pathophysiological mechanisms of this severe illness.

Objectives To assess peripheral levels of neurotrophins and their receptors and their correlation with inflammation, clinical symptomatology and response to antipsychotic treatment, over the time.

Methodology Ninety-four FEP patients and 80 matched healthy controls were included. Blood samples were taken at baseline to measure BDNF and NGF and their receptor levels (TrkB-full, TrkB-truncated and TrkA) and pro/antiinflammatory parameters (NFκB, COX-2, iNOS, PPARgamma, 15d-PG12). Patients were followed-up during 12 months.

Results BDNF TrkB-full receptor and NFG TrkA receptor levels increased during the follow-up whereas BDNF TrkB-truncated form receptor decreased. After adjusting for confounding vari-

ables, baseline levels of proinflammatory variables were significantly related to TrkB-full/TrkB-truncated ratio (FL/T), suggesting that a higher proinflammatory status is related to a higher FL/T ratio expression. Furthermore, baseline FL/T ratio could have a predictor role of patient's functionality 1 year after the illness onset, depending on whether patient is treated or not with antipsychotic drugs.

Conclusion Inflammatory processes, neurotrophic pathways and functional status of FEP patients seem to be related which is of great translational relevance. Specific, the expression of the 2 isoforms of BDNF receptor should be taken into account before starting an antipsychotic drug treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Although being highly consensual that antipsychotic adherence is an important outcome predictor in psychosis, existing reviews have found mean rates of adherence around 40–60%. Several aspects, such as patient-related, medication-related, environmental-related variables have been described as important predictors.

Aims This study aim is to develop, administer and present preliminary psychometric properties of a new scale for antipsychotic medication adherence that includes different types of predictors (clinical, psychosocial, and practical among others).

Methods The “AMAS” was developed by a multidisciplinary team and was based on recent research on factors influencing antipsychotic adherence. The scale evolved from multiple drafts and experts were contacted in order to improve the final version. Over 50 patients with a diagnosis of a psychotic-spectrum disorder taking antipsychotic medication will be assessed with the “AMAS” and the Medication Adherence Rating Scale. Additionally, each patient's psychiatrist will fill in a form with demographic and clinical variables (such as type of symptoms, previous adherence problems, current adherence, insight and other relevant variables).

Results This is an ongoing study and the sample is still being collected (scheduled finish date: February/2016). Our statistical analysis' plan includes: reliability analysis (Chronbach's alpha, alpha if item deleted, inter item correlations and covariances and item-total correlations); validity (convergent validity); factorial analysis.

Conclusions It is hypothesized that the “AMAS” will be a practical, reliable and valid unidimensional instrument with clinical utility assessing adherence to antipsychotics. The “AMAS” can be also useful in assessing intervention targets (e.g. psychotherapeutic, psychoeducational) to enhance adherence.

Quality of Life Assessment in schizophrenia - development of a short version of the QLIS

M. Franz^{1,*}, T. Senin², T. Meyer²

¹ Vitos Klinik Kurhessen, Vitos Klinik Kurhessen, Bad Emstal, Germany

² Institute of epidemiology- social medicine and health services research, Integrative rehabilitation research unit, Hannover, Germany

* Corresponding author.

The QLIS (Quality of Life in Schizophrenia) is a disease-specific questionnaire with high content validity and sound psychometric properties. It comprises 54 items related to 12 subscales. However, its use in surveys or clinical studies is limited due to its length. Our aim was to develop and validate a short form of the QLIS.

Four steps were taken to develop the short form (QLIS-SF) using samples from the Clinical Analysis of the Treatment of Schizophrenia study. 1. A model with second order scales was developed using exploratory factor analysis. 2. The resulting model was tested in an independent sample using confirmative factor analysis (CFA). 3. Based on this model, items were selected on grounds of distributional properties, content reviews, and item loadings. 4. The resulting short form was validated independently through CFA.

Results Three second order scales were constructed: illness-related quality of life, social life, and global subjective well-being. CFA of the new theoretical model resulted in a CFI of 0.67 and absolute fit indices of CMIN/df=2.55, RMSEA=0.08, SRMR=0.09. We selected 13 items that showed good statistical properties and good fit of content to subscale. Fit of the underlying theoretical model with the 13 items was satisfactory (CFI=0.95, CMIN/df=2.23, RMSEA=0.06, SRMR=0.04). Composite reliability scores for the three subscales were above 0.70.

The QLIS-SF showed adequate model fit and reliability. It offers a novel, well-founded opportunity to assess quality of life in persons with schizophrenia in situations in which the application of the long version is not considered possible.

The relationship between childhood trauma and theory of mind in schizophrenia

J. Mrizak*, R. Trabelsi, A. Arous, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction A history of childhood trauma is reportedly more prevalent in people suffering from psychosis than in the general population. Previous studies linked childhood trauma (CT) to neurocognitive impairments in schizophrenia (SCZ), but rarely to theory of mind (TOM) deficits.

Objectives To investigate the relationship between TOM deficits and CT in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the Childhood Trauma Questionnaire retrospectively assessing five types of childhood trauma (emotional, physical and sexual abuse, and emotional and physical neglect). They also completed an intention-inferencing task, in which the ability to infer a character's intentions from information in a short story is assessed.

Results Our results suggest a relationship between specific kinds of CT and TOM deficits. A history of childhood physical neglect was significantly correlated to a worse performance in the intention-inferencing task ($P=0,001$). Patients with higher scores of CT denial also had less correct answers ($P=0,035$) and more false answers ($P=0,013$).

Conclusions Our results need replication but underline the necessity of investigating psychosocial mechanisms underlying the development of social cognition deficits, including deficits in TOM.

⁴ Specialized Psychiatric Hospital "Gornja Toponica", Forensic Ward, Gornja Toponica- Niš, Serbia

* Corresponding author.

Objective We performed a case-control clinical study, which included 285 long term hospitalized schizophrenic patients, both gender, treated with monotherapy clozapine, olanzapine or risperidone for at least 6 months. Patients with diagnosed metabolic syndrome according to International Diabetes Federation (IDF) criteria were classified as cases, while the "controls" were patients treated with the same antipsychotic drug without the metabolic syndrome presence. The aim of this research was to determine the correlation of the studied variables as a potentially risk factors for the metabolic syndrome presence.

Materials and methods The following variables were collected: basic physical parameters (height, weight, waist circumference, blood pressure), clinical status (BPRS scale and PANSS scale for schizophrenia), laboratory data (fasting glucose level, serum lipid levels, C-reactive protein, microalbuminuria), and medical-record data.

Results General prevalence of metabolic syndrome was 31,2%, in patients treated with clozapine 41,3%, olanzapine 34,4% and risperidone 19%, statistically significant clozapine vs. risperidone ($P<0.05$). Predictors of the metabolic syndrome computed by multivariate logistic regression: - patients treated with olanzapine: case-history data about diabetes mellitus in close family member (OR 14.134, 95% CI 2.724–73.348, $P=0.002$); hyperlipidemia in close family member- (OR 53.134, 95% CI 2.768–1019.916, $P=0.008$; BMI [kg/m²] - (OR 1.328, 95% CI 1.105–1.597, $P=0.002$); C-reactive protein over the cutoff point of 5 mg/L (OR 4.555, 95% CI 1.057–19.627, $P=0.042$), and mankind (OR 4.653, 95% CI 1.008–21.479, $P=0.049$); patients treated with clozapine: diabetes mellitus in close family member (OR 14.127, 95% CI 2.407–82892, $P=0.003$); patients treated with risperidone - there were no significant predictors.

Effectiveness of Brief Individual Cognitive Behavioral Therapy for auditory hallucinations in a sample of Egyptian patients with schizophrenia

D. Nagui Rizk^{1,*}, H. Salama¹, T. Molokhiya¹, L. Kassem²¹ Alexandria university, neuropsychiatry department, Alexandria, Egypt² National Institute of Health, Department of health and human services, Maryland, USA

* Corresponding author.

E-mail address: dalianagui82@hotmail.com (D. Nagui Rizk)

Background Auditory hallucination is one of the most common symptoms in schizophrenia. The frequency of the auditory hallucinations and ensuing distress make the individual believe that these voices are not able to be controlled and to be coped with.

Aim Testing the effectiveness of brief cognitive behavioral therapy for psychosis (CBTp) for auditory hallucinations, using it in modifying the beliefs about the voices and improving symptom severity and overall functioning.

Methods Forty participants with schizophrenia were randomized into intervention and control groups. Intervention group were 20 patients who received 8 individual sessions of CBTp plus Treatment As Usual (TAU) over 8 weeks and the control group were the other 20 patients who received TAU only. The Positive and Negative Syndrome Scale (PANSS), the Arabic version of Beliefs About Voices Questionnaire (BAVQ) and the General Assessment of Functioning scale (GAF) were assessed at baseline and at the end of the study.

Results Intervention group showed a statistically significant increase in GAF ($P=0.012$), a statistically significant reduction regarding the Positive ($P<0.001$), Negative ($P=0.008$), General ($P<0.0001$) and total ($P\leq 0.0001$) sub-scales of PANSS. Regarding BAVQ, Intervention group showed a statistically significant reduction in Malevolence ($P=0.008$), Engagement ($P=0.001$); and showed a statistically significant increase in Resistance ($P=0.049$) compared to control.

Conclusions Brief cognitive behavioral therapy for auditory hallucinations can improve severity of schizophrenia, increase the level of functioning and improve the beliefs about the voices.

The effect of a 16-week walking program on biomarkers, physical fitness, health related quality of life and self-perceptions of adults with schizophrenia

E. Oliveira^{1,*}, M. Uba-Chupel², D. Sousa³, C. Rocha⁴, A. Teixeira², P. Ferreira²¹ Sisters Hospitallers of the Sacred Heart of Jesus, Occupational Therapy - Casa Saúde Rainha Santa Isabel, Coimbra, Portugal² Faculty of Sport Sciences and Physical Education- University of Coimbra, Research Unit for Sport and Physical Activity, Coimbra, Portugal³ Sisters Hospitallers of the Sacred Heart of Jesus, Nurse - Casa Saúde Rainha Santa Isabel, Coimbra, Portugal⁴ Polytechnic Institute of Coimbra- ESTESC - Coimbra Health School, Department Complementary Sciences- INESCC, Coimbra, Portugal

* Corresponding author.

Introduction People with schizophrenia exhibit low levels of physical activity, which have impact on physical and mental health

as well as overall quality of life (QOL). Mental and physical benefits of exercise are known, although the mechanisms through which physical exercise improves schizophrenia symptoms are not fully understood.

Objectives To assess the effect of a 16-week exercise program (EP) on the expression of BDNF and S100B biomarkers, physical fitness, health related quality of life and self-perceptions of adults with schizophrenia.

Methods Thirty-five patients with schizophrenia (PwSZ) were divided in three groups Institutionalized Patients ($n=11$); Psychosocial Rehabilitation ($n=13$); and Control Group ($n=11$). The EP consisted of one-hour walking session three times a week during 16 weeks. All participants were assessed before and after EP using the six minutes walking test, a psychological tests battery including MOS Short Form 36, Rosenberg Self-Esteem Scale, Physical Self-Perception Profile, Satisfaction with Life Scale as well as the BDNF and S100B measurements using serum analysis.

Results No significant statistical differences were found both for BDNF and S100B levels as a result of exercise. Additionally, no significant statistical differences were found for Physical Self-concept and Global Self-esteem changes as a result of the walking program (WP). However, PwSZ showed significant statistical differences on the satisfaction with life ($P<0.05$) and on the perceived health related QOL ($P<0.05$) in all groups participating in the EP.

Conclusion In spite of the limited impact of the WP in PwSZ, this group may obtain positive outcomes of the exercise participation based on a more positive attitude towards life.

Social cognition across stages and forms of schizophrenia

O. Papsuev*, M. Minyaycheva, L. Movina, I. Gurovich
Moscow Research Institute of Psychiatry, Outpatient Psychiatry and Organization of Psychiatric Care, Moscow, Russia

* Corresponding author.

Introduction Social cognition is considered as a main predictor of functional outcomes and a candidate for endophenotype of schizophrenia. We hypothesize that social cognition capacities follow the course of schizophrenia as a prodromal disorder.

Objective To investigate social cognition across different groups of patients with schizophrenia and schizophrenia spectrum disorders.

Aims To evaluate social cognitive impairments in patients with first episode psychoses (FEP), chronic schizophrenia (CS) and schizophrenia-spectrum disorders (SSD).

Methods In a cross-sectional study, 71 patients with FEP, CS and SSD were assessed with a battery of clinical and social cognitive tests. Three key social cognitive domains were assessed: emotion perception, Theory of Mind and attributional style.

Results Patients with schizoaffective disorder and schizotypal disorder showed better scores in Hinting task (mean ranks: 47.0 and 39.9 respectively) than patients with less favourable forms of schizophrenia (mean ranks: 24.7 and 30.2 respectively) ($P=0.003$). Patients with FEP showed better results in Hinting task (18.1 ± 2.4) versus CS patients (17.4 ± 2.0) ($P<0.05$). No differences in emotion perception (Ekman-60 task) among FEP and CS patients were detected. Patients with schizoaffective disorder showed better scores in emotional processing comparing to all forms of schizophrenia patients (mean ranks 49.1 vs. 30.1, 34.5, 28.0, $P<0.05$). No significant differences in attributional style were registered.

Conclusions Emotion perception and Theory of Mind domains show different level of impairment across FEP and CS patients and across forms of schizophrenia. Further longitudinal studies

to establish how social cognition domains mirror the course and severity of schizophrenia and SSD are needed.

Monosodium glutamate (MSG) threshold of taste perception in deficit and nondeficit schizophrenia

J. Pelka-Wysiecka^{1,*}, M. Wronski¹, P. Bienkowski², J. Samochowiec¹

¹ Pomeranian Medical University, Psychiatry, Szczecin, Poland

² Institute of Psychiatry and Neurology, Pharmacology, Warsaw, Poland

* Corresponding author.

Introduction Deficit schizophrenia (DS) with persistent, primary negative symptoms has a confirmed neuroanatomical background, similarly to structures involved in the process of taste. DS may be regarded as a subtype of schizophrenia caused by neurodevelopmental disorders, with probable link to specific genetic traits which are responsible for the formation of synapses and neuroplasticity. The process eventually leads to symptoms of the illness and physiologic disorders affecting the perception of taste.

Objective The study of threshold of taste perception (TTP) was part of the search for the helpful marker to identify DS patients.

Aims Taste evaluation was supposed to determine differences in TTP-MSG between DS and NDS.

Methods Eighty-two patients with DS and 72 patients with NDS (nondeficit schizophrenia), somatically healthy and without acute psychotic symptoms were subjected to TTP-MSG: seven triplets (water, water, 0,0001%-1% MSG) were applied. Demographic and psychometric data were analyzed.

Results An analysis of TTP-MSG did not disclose differences between DS and NDS. Most patients in both groups correctly detected the taste starting from 0,1% MSG. No differences in other collected data were found between DS and NDS.

Conclusions Physiologic studies of TTP-MSG should not be the base for differentiation between DS and NDS groups of patients. This work was supported by grant MNiSW no N N402 456738.

* Corresponding author.

Introduction Long-acting injectable aripiprazole is the most recently introduced depot treatment in schizophrenia.

Objectives The objective of this study is to determine the tolerability and safety of this new treatment.

Aims The aim is to provide useful information regarding the use of this new drug.

Methods Our sample consists on 20 patients treated with a monthly dose of long-acting aripiprazole. They were previously stabilized on oral aripiprazole before the first injection. The data on tolerability and safety were obtained by face-to-face interviews, using the Hogan Drug Attitude Inventory, the Patient Satisfaction with Medication Questionnaire and the UKU Side Effects Scale.

Results Our sample consists of 20 patients, with a 50/50 gender distribution and a mean age of 39 years. The average score in the satisfaction scale Hogan was positive (an average of 7.25). In the Patient Satisfaction With Medication Questionnaire, 85% said they were satisfied with the new treatment, compared with 15% who showed some degree of dissatisfaction with the change. Overall, 90% of patients showed a preference for the current treatment compared to the previous. The patients showed good tolerance to medication, with a low score in the UKU scale (total score = 13.5). Side effects did not interfere with daily activity of the patient.

Conclusions Long acting injectable aripiprazole proved to be a safe treatment, with a good degree of acceptance among patients. These advantages makes of this new drug a useful addition to our kit tool.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comparative study of the side-effect profile between clozapine and non-clozapine patients

S. Ramos Perdigues^{1,*}, A. Mane Santacana², P. Salgado Serrano², E. Jove Badia³, X. Valiente Torrelles³, L. Ortiz Sanz³, F. Dinamarca³, J.R. Fortuny Olive³, V. Perez Sola²

¹ Hospital Can Misses, Psychiatry, Ibiza, Spain

² Hospital Del Mar, Psychiatry, Barcelona, Spain

³ Centre Dr. Emili Mira, Psychiatry, Santa Coloma De Gramanet, Spain

* Corresponding author.

Introduction For resistant schizophrenia, the only approved treatment is clozapine. However, clozapine is underused, mainly due to its wide range of side-effects. Secondary effects differ amongst antipsychotics (Leucht et al., 2009). Despite that there is no good evidence that combined antipsychotics offer any advantage over the use of a single antipsychotic, combination increases the frequency of adverse events (Maudsley guidelines).

Objectives To compare the side-effect profile between clozapine and non-clozapine patients.

Aims To provide evidence that clozapine patients do not show a worse side-effects profile.

Methods We cross-sectionally analysed all patients from a Spanish long-term mental care facility ($n=139$). Schizophrenic/schizoaffective patients were selected ($n=118$) and their treatment was assessed, 31 patients used clozapine. We paired clozapine and non-clozapine patients by sex and age and assessed antipsychotic side effects and possible confounder variables.

Results Our sample was 27 clozapine patients and 29 non-clozapine patients. 67,9% were male with a mean age of 51.3 (SD 9.6) years. For continuous variables: age, BMI, waist/hip, cholesterol, TG, glucose, prolactin, heart-rate, blood pressure, sleeping hours, the only statistical differences found were lower heart-rate ($P=0.001$) in clozapine group and higher salivation subscale of SAS ($P=0.002$) in clozapine group. For discrete variables: monotherapy, obesity, overweight, metabolic syndrome or possible confounders as propranolol, laxative, diet, antiglycemic or insulin, fibrates or statins, antihypertensive or anticholinergic, no statistical differences were found.

Conclusions We did not find differences in cardiometabolic parameters, which are the main barrier to prescribing clozapine, probably due to the concomitant use of other drugs in both groups.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Poor adherence to treatment is one of the main problems in health care to psychiatric patients. The second-generation antipsychotics, and the subsequent emergence of the depot forms (long acting formulations) have facilitated this aspect, increasing the time to clinical relapse in patients with schizophrenia.

Goals Determine the time to relapse in a clinical sample of patients diagnosed with schizophrenia treated with paliperidone palmitate over 3 years. Other objectives include the possible reduction in hospital admissions, as well as the possible reduction of psychiatric emergency visits, concomitant medication (benzodiazepines and Biperiden) and the possible increase in drug monotherapy.

Methodology This is a study with a sample of 101 patients with schizophrenia who had started treatment with PP (consecutive sampling). Quantified variables in the 12 months prior to the change of PP treatment with variables at 6, 12, 24 and 36 months after initiation of treatment with PP were compared.

Results and conclusions At the end of the tracking, 72.22% (73 patients) remained clinically stable, with adequate adherence to treatment and there have been no clinical relapses. It has obtained a statistically significant reduction in the use of concomitant medication, emergency room visits and the average duration of revenues, with no clinical relapse should occur in patients of the sample in the second and third year.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Tobacco use has been associated with more excitement and agitation symptoms, greater severity of global psychopathology as measured by the Clinical General Impression (CGI) Scale, and psychotic symptoms in patients with schizophrenia.

Aim To assess the effects of nicotine abstinence versus nicotine maintenance on the clinical symptoms of a sample of outpatients smokers diagnosed with schizophrenia.

Methods Sample: 81 outpatients with schizophrenia [72.8% males; mean age (SD)=43.35 (8.82)] currently smoking tobacco [no. of cigarettes (SD)=27.96 (12.29)]. Design: non-randomized, open-label, 6-month follow-up and multi-center study conducted at 3 sites in Spain (Oviedo, Santiago de Compostela and Orense). Instruments: Positive and Negative Syndrome Scale (PANSS), Clinical Global Impression for Schizophrenia (CGI-SCH), Hamilton Depression Rating Scale (HDRS). Anthropometric measures: Body mass index (BMI) and waist circumference. Vital signs: heart rate. Procedure: Patients were assigned to 2 conditions:

- control group = patients continuing their tobacco use;
- experimental group = patients participated in varenicline or nicotine patches treatment for smoking cessation.

Patients were evaluated at baseline (all patients smoking) and after 3 and 6 months.

Results No significant differences ($P>.05$) were found between groups at baseline evaluation. Likewise, there were no significant differences between smokers and non-smokers after treatment (3 and 6 months follow-up) in their clinical symptomatology (according to PANSS, HDRS and CGI-SCH), anthropometric measures and heart rate.

Conclusions No significant differences were found in the clinical symptoms after a period of nicotine abstinence. Therefore, clinicians should motivate and help their patients to quit smoking (CIBERSAM - FIS PI11/01891).

³ IdiSNA, Navarra Institute for Health Research, Pamplona, Spain

* Corresponding author.

Introduction Cognitive impairment is considered the best predictor of functional outcome in psychosis. However, the nature of this relationship still remains to be determined.

Objective To ascertain the relationship of negative symptoms and cognitive impairment with functional outcome in psychosis.

Methods Ninety patients with a DSM-IV psychotic disorder diagnosis and 65 healthy controls were included in the study. We assessed the predominant negative symptoms over the course of illness with the Comprehensive Assessment of Symptoms and History (CASH). Functional outcome was assessed with the Specific Levels of Functioning (SLOF). Cognition was assessed with a set of neuropsychological tests, which were normalised to z-scores (regarding controls' performance). Then, a Global Cognition Index (GCI) was obtained as a mean of the cognitive domains assessed: processing speed, attention, verbal and visual memory, executive functions, working memory and social cognition. We divided the sample in four groups, considering the presence/absence of negative symptoms (cut-off point of 2 in the CASH), and the

presence/absence of cognitive impairment (considering a GCI z-score of -1 as cut-off point). We performed a MANOVA to compare the 4 groups' functional outcome scores.

Results Fig. 1 shows the significant differences between groups regarding functional outcome.

Conclusions The combination of negative symptoms and cognitive impairment has deleterious effects over functionality, but negative symptoms alone are related to functional outcome, independently of cognitive impairment.

Electroconvulsive therapy in schizophrenia – where do we stand?

J. Silva^{1,*}, J. Mota², P. Azevedo³

¹ Custoias, Portugal

² Hospital de Magalhães Lemos, ECT Unit- C Service, Oporto, Portugal

³ Hospital de Magalhães Lemos, C Service, Oporto, Portugal

* Corresponding author.

Introduction Electroconvulsive therapy is currently used in the management of severe depression, long-term mania and catatonia. Regarding schizophrenia-related psychosis ECT is also an option, but the indication is restrictive to severe cases, drug intolerance or resistant ones. Lack of evidence of cost-effectiveness compared to clozapine, and side effects of ECT techniques before 2003, influenced NICE guidance to not recommend ECT in schizophrenia, but modern ECT machines and procedures are subsequent to 2003. ECT is often performed when clozapine fails to respond in monotherapy or if there is intolerance to antipsychotic side effects. ECT in combination with clozapine seems to have significant results allowing the patients to achieve rapid control of psychotic symptoms with fewer side effects, comparing with antipsychotics-association strategies.

Objectives To summarize the latest literature about this field and to present recent data from the Electroconvulsive therapy Unit, in Hospital de Magalhães Lemos, Portugal.

Aim To explore and critically review the controversies of electroconvulsive therapy in the management of drug-resistant schizophrenia.

Methods Retrospective data of an Electroconvulsive Therapy Unit during 2006–2015 was reviewed.

Results 198 ECT treatments in schizophrenic patients were performed in our unit, during 2006–2007, in a total of 647 ECT (30,6%). In 2014–2015, 945 schizophrenic patients received ECT treatment, in a total of 2149 performed ECT (43,9%).

Conclusions Although guidelines are crucial for the uniform practice of medicine, sometimes is important to be critical about

them. The use of ECT in schizophrenia is safe and effective and further research is needed to continue to support this treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Symptoms of schizophrenia and suicidal behaviour

M. Sisek-Šprem*, M. Herceg, V. Jukić

University Psychiatric Hospital Vrapče, Integral Ward, Zagreb, Croatia

* Corresponding author.

Introduction Risk prediction for suicide in schizophrenia is known to be complex. Illness-related risk factors are important predictors, with number of prior suicide attempts, depressive symptoms, active hallucinations and delusions.

Aims To analyze the impact of clinical features of schizophrenia on suicidal behaviour and analyze relationship between violence and suicidality.

Methods We compared a group of 28 suicidal, 32 hetero-aggressive and 60 non-aggressive male patients with schizophrenia. The severity of the psychopathology was assessed using PANSS, hetero-aggressiveness using OAS and suicidality using C-SSRS and InterSePT scales.

Results Suicidality is in positive correlation with the presence of depression ($r=0.485$, $P<0.001$) and imperative hallucinations ($r=0.391$, $P<0.001$) but in negative correlation with total PANSS score ($r=-0.297$, $P<0.001$), impulsiveness ($r=-0.237$, $P<0.001$) and hetero-aggressive behaviour ($r=-0.551$, $P<0.001$). Previous attempt was found in 53% suicidal patients ($P=0.047$). Heteroaggressiveness is in positive correlation with total PANSS ($r=0.43$, $P<0.001$) and impulsive behaviour ($r=0.57$, $P<0.001$). This study supports the contention that high impulsivity in schizophrenia patients is significant in the etiology of violent but not suicidal behaviour.

Conclusion In the order to diminish the level of suicide among patients with schizophrenia we must be aware of the importance of depressive symptoms, imperative hallucinations and previous attempts. This study supports the contention that high impulsivity in schizophrenia patients is significant in the etiology of violence but not suicidal behaviour.

Second-generation antipsychotics and the metabolic syndrome in drug-naïve adolescents

C. Sjo*, N. Bilenberg

Research Unit for Child- and Adolescent Psychiatry Odense-Psychiatric Hospital and University of Southern Denmark, Psychiatric Hospital and University of Southern Denmark, Odense, Denmark

* Corresponding author.

Introduction Poor physical health and shorter life expectancy often follows from mental illness. If the disorder starts in childhood/adolescence, the risk of this outcome is even higher. Second generation antipsychotics (SGAs) are suspected to increase cardiovascular risk factors through the development of the metabolic syndrome.

Objective We investigated all the aspects of the metabolic syndrome in drug-naïve youth, over a period of 12 months of treatment with SGAs.

Aims This study examines drug-naïve youth in their first year of treatment with SGAs, and the possible development of markers of the metabolic syndrome, in a naturalistic setting. We also look at aspects of the patient's disease and environment that may predict which patients are the most at risk for these metabolic derangements.

Methods Thirty-five drug-naïve adolescents were recruited after their contact with the Psychosis Team at Department of Child and Adolescent Psychiatry in Odense, Denmark. Measurements were taken at different times over the course of their first year of treatment. The markers included, among others: body mass index, waist circumference, blood pressure, fasting blood glucose, as well as high density, low density and total cholesterol. Factors of the patients' lifestyle and development were recorded as well.

Results The results will be presented at the EPA March 2016 in Madrid.

Conclusions This is, to our knowledge, the first study to include all of the aforementioned aspects in drug-naïve adolescents over a 12-month period. Because of this, it may provide us with a unique insight into how, and in which patients, these metabolic changes develop.

Depression in the active phase of paranoid schizophrenia in relation to age of onset and sex

M. Skokou*, P. Gourzis

University Hospital of Patras, Psychiatry, Patras, Greece

* Corresponding author.

Introduction Depression is often observed in schizophrenia, in all phases of the disorder. Age of illness onset and sex have been found to correlate with depressive symptomatology in many but not all studies.

Aims In the present work the relation between depressive symptoms and age of onset and sex was investigated, in a sample of patients with paranoid schizophrenia.

Methods Eighty-eight (88) patients with paranoid schizophrenia according to DSM-IV-TR criteria were examined, 21 of which became ill at ≥ 35 years of age (late onset), whereas 60 had age of onset < 30 years (young onset). During the active phase the Calgary Depression Scale for Schizophrenia (CDSS) was applied. Comparisons were performed by using the two-tailed Wilcoxon rank-sum and Chi-squared tests.

Results The percentage of patients with depression (CDSS > 6) in the whole sample was 27.2%. There was a trend for higher scores in early awakening in late onset patients ($P=0.060$). In men, there was a trend for heavier depression in late onset patients, and higher scores in early awakening ($P=0.082$, 0.019 , respectively). In young onset patients, there was a trend for heavier symptomatology in women compared with men, and heavier pathological guilt ($P=0.073$, 0.007 , respectively), whereas in late onset patients, there was a trend for heavier self depreciation in men ($P=0.072$).

Conclusions Although the frequency of depression does not seem to be influenced by age of onset or sex, more subtle differences are found in the severity of certain depressive symptoms, in relation to these factors, possibly warranting further investigation.

A growing body of evidence suggests that experiences of social disadvantage are associated with an increased risk of psychosis. However, only a few studies have specifically looked at cumulative effects and long-term associations. We compared the prevalence of specific markers of social disadvantage at, and prior to, first contact with psychiatric services in patients suffering their first episode of psychosis and in a control sample and explored long-term associations, cumulative effects, and directions of associations. We collected information from 332 patients and from 301 controls recruited from the local population in South-East London. Three indicators of social disadvantage in childhood and six indicators of social disadvantage in adulthood were analysed. Compared with controls, cases were approximately two times more likely to have had a parent die before the age of 17 (OR 1.95, 95% CI 0.9–3.8) and approximately three times more likely to have experienced a long-term separation from one or both parents before the age of 17 (OR 3.04, 95% CI 2.1–4.3). Cases were also more likely than controls to report two or more markers of adult social disadvantage, not only at first contact with psychiatric services (OR 9.5, 95% CI 5.4–16.7), but also at onset (OR 8.5, 95% CI 4.8–15), one year pre-onset (OR 4.5, 95% CI 2.8–7), and five years pre-onset (OR 2.9, 95% CI 1.8–4.6). Greater numbers of indicators present and long-term exposure were associated with progressively greater odds of psychosis. There is some evidence that social disadvantage tends to cluster and accumulate.

Introduction Sarcosine - glycine transporter inhibitor - increases glycine concentration around NMDA (N-methyl-D-aspartate) receptors. Function of the glutamatergic system in the prefrontal cortex and hippocampus is impaired in schizophrenia, which may lead to negative and cognitive symptomatology.

Aims We evaluated the influence of sarcosine therapy on the concentration of metabolites (NAA, N-acetylaspartate; Glx, complex of glutamate, glutamine and γ -aminobutyric acid (GABA); ml, myo-inositol; Cr, creatine; Cho, choline) in the left dorso-lateral prefrontal cortex (DLPFC) and left hippocampus in patients with stable schizophrenia.

Methods Fifty patients with schizophrenia, treated with constant antipsychotics doses, in stable clinical condition were randomly assigned (25 patients in each group) to administration of sarcosine (2 g) or placebo for six months. $^1\text{H-NMR}$ spectroscopy (1.5 T) in both localisations and clinical evaluation (PANSS) was performed before and after sarcosine addition.

Results Initially we noted no differences in metabolite concentrations between groups. In the left DLPFC, NAA/Cho, ml/Cr and ml/Cho ratios were significantly higher in the sarcosine than the placebo group after six months. In the sarcosine group, NAA/Cr, NAA/Cho, ml/Cr, ml/Cho ratios also increased compared to baseline values. In the placebo group, only the NAA/Cr ratio increased. In the left hippocampus Glx/Cr and Glx/Cho decreased in sarcosine group at the end of our study.

Conclusions The addition of sarcosine to antipsychotic therapy for six months caused increase of neurons viability (NAA) and neurogical activity (ml) markers in the left DLPFC and decrease of hyperglutamatergic overstimulation parameters in the left hippocampus with simultaneous improvement of clinical parameters including negative symptoms.

Introduction Deficit of glutamatergic transmission and aberrant function of kynurenine pathway, with disturbed synthesis of glutamate receptors antagonist, kynurenic acid (KYNA) and neurotoxic metabolite of kynurenine, 3-hydroxykynurenine (3-OH-KYN) have been implicated in the pathogenesis of schizophrenia.

Objectives Demonstrated by others higher level of KYNA in the brain may cause relative deficiency of glutamate-mediate transmission with resulting behavioural and cognitive changes.

Aims Search for predictors of satisfactory response to antipsychotic treatment based on the analysis of KYNA and 3-OH-KYN serum levels.

Methods Fifty-three patients with chronic schizophrenia and 46 healthy individuals were enrolled in the study. Quantitative analyses of KYNA and 3-OH-KYN were performed using high-pressure liquid chromatography (HPLC) and electrochemical detection, respectively. Clinical assessments (PANSS, SANS, SAPS) and blood analyses were conducted at 3 time-points: during the active phase of disease, after 4 weeks of modified pharmacotherapy, and after reaching remission.

Results In schizophrenia group, lower levels of KYNA ($P=0.002$) and non-altered levels of 3-OH-KYN ($p=0.195$), as compared to control, were detected during active phase of disease. Despite clinical improvement, no significant changes in the level of studied metabolites were observed later on. The initial level of 3-OH-KYN correlated negatively ($r=-0.368$; Spearman's rank) with clinical improvement (negative symptoms) ($P<0.05$).

Conclusions 1. The peripheral dysregulation of kynurenine pathway metabolites in chronic schizophrenia manifests as relative increase in the ratio between neurotoxic 3-OH-KYN and neuroprotective KYNA. 2. The higher serum level of 3-OH-KYN during relapse of schizophrenia seems to predict poor response to antipsychotic treatment.

Obsessive-compulsive symptoms interact with disorganization in influencing social functioning in schizophrenia

M. Tonna*, R. Ottoni, F. Paglia, P. Ossola, C. De Panfilis, C. Marchesi

University of Parma, Neuroscience, Parma, Italy

* Corresponding author.

Objective Recent research has suggested a dual impact of obsessive-compulsive dimension on functioning in schizophrenia with a gradual transition from an improving to a worsening effect depending on obsessive-compulsive symptoms (OCS) severity (from mild to moderate-severe). Aim of the present study was to investigate whether this varying effect of OCS on functioning might be mediated or moderated by schizophrenia symptom dimensions or occur independently.

Method Seventy-five patients affected by schizophrenia were administered the Structured Clinical Interview for DSM-IV Disorders, the Positive and Negative Syndrome Scale, the Yale-Brown Obsessive-Compulsive Scale and the Social and Occupational Functioning Assessment. The sample was divided into two groups according to the severity of OCS (absent/mild and moderate/high OCS group).

Results In both groups, the effect of OCS on functioning was not mediated by their effect on positive, negative or disorganization symptoms. Conversely, a significant interaction between OCS and disorganization dimension was found: the dual effect of OCS on functioning occurred only among patients with low disorganization symptoms while it was no more apparent at high levels of disorganization.

Conclusion Data suggest that in patients with schizophrenia, functioning at least in part depends on the interaction between disorganization and OCS. Particularly, since mild OCS contribute to lesser functional decline in patients with low disorganized psychosis, they may favor the constitution of a subtype of schizophrenia with a better functioning. In keeping with the historical concept of "pseudoneurotic schizophrenia", we speculate that

obsessive dimension might have a pathoplastic influence, balancing the effect of low disorganization symptoms.

Analysis of the attitudes towards the medication in ambulatory patients with diagnosis of schizophrenia

E. Torío*, L. González Blanco, I. Abad Acebedo, S. Bestene Medina, J. Rodríguez Revuleta

Hospital Universitario Central de Asturias, Psiquiatría, Oviedo, Spain

* Corresponding author.

Introduction The scale autoapplied Drug Attitude Inventory (DAI) [1] is an instrument to evaluate the subjective response to the neuroleptics in patients diagnosed of schizophrenia. We have used the brief version [2].

Objectives To study the possible relation between DAI and sociodemographic factors [3] as well as medical treatment [4] (references 3 and 4 are not available for this abstract).

Methods A descriptive and comparative study. Sample of 30 patients with ambulatory follow-up from Oviedo. Sociodemographic data and drug prescription were collected.

Results Comparative analysis: DAI and sociodemographic, drug prescription (Table 1). Correlation between DAI/age/I number of antipsychotics (Table 2). The comparative analysis only shows positive significant correlation between DAI and antidepressant treatment.

Conclusions There is no correlation of DAI depending on the age and the number of antipsychotics. The antidepressant treatment in schizophrenic patients could be a predictor variable of better punctuation in DAI.

Table 1

	DAI mean ± SD	Statistics
Sex: man/woman	16.21 ± 2.07/16.54 ± 0.93	$t = 0.505^a$
Age: <45/≥45	16.77 ± 1.56/16.10 ± 1.83	$t = -0.961^a$
Polytherapy	16.38 ± 1.83	$t = 0.408^a$
Antipsychotic: typical/atypical	14.50 ± 0.70/16.46 ± 1.71	$t = -1.593^a$
Depot + oral	16.12 ± 1.96	$t = -0.699^a$
Antipsychotic depot	16.25 ± 1.88	$t = -0.368^a$
BZD	16.46 ± 1.59	$t = 0.416^a$
Antidepressants yes/antidepressants no	17.37 ± 1.06/15.95 ± 1.78	$t = 2.105^b$
Anticovulsants/anticholinergics	16.37 ± 1.40/15.83 ± 2.13	$t = 0.078^a / t = -0.787^a$

SD = Standard deviation.

^a $P \geq 0.05$, not significant.

^b $P < 0.05$, significant.

Table 2

	DAI (Correlation Pearson)	DAI (significant)
Age	-0.05	0.797 ^a
No. of antipsychotics	-0.07	0.700 ^a

^a $P \geq 0.05$, not significant.

Affective psychopathology and recognition of facial expressions in schizophrenia and in affective disorders

S. Trifu^{1,*}, L. Radoi²

¹ UMF Carol Davila, Psychiatry, Bucharest, Romania

² University of Bucharest, Psychology, Bucharest, Romania

* Corresponding author.

Introduction We noticed some differences between the patients diagnosed with schizophrenia, those diagnosed with affective disorders and the normal persons, as regards the empathy level, the recognition degree of facial expressions, depression level of positive/negative affectivity.

Objectives The exploration of its affectivity and pathology, as well as the changes emerging in the forming of interpersonal relationships with others in schizophrenia and in affective disorders, and the comparison of these changes with the values recorded within the group of normal persons.

Aims Highlighting some differences as regards aspects of affective life and forming of interpersonal relationships in patients diagnosed with schizophrenia/affective disorder.

Methods The instruments used: Beck's Depression Inventory (BDI), Toronto Empathy Questionnaire (TEQ), The Positive and Negative Affect Schedule (PANAS) and a test of identification of facial expressions.
