Obsessive-compulsive disorder in childhood and adolescence

C. Freitas^{1,*}, M.C. Ferreira², T. Correia³, I. Portinha³, Z. Correia³
¹ Centro Hospitalar do Tâmega e Sousa, Departamento de Psiquiatria e Saúde Mental, Penafiel, Portugal

² Hospital de Braga, Serviço de Psiquiatria, Braga, Portugal

³ Centro Hospitalar do Porto, Departamento de Psiquiatria da Infância e da Adolescência, Porto, Portugal

* Corresponding author.

Obsessive-compulsive disorder (OCD) is a severe mental illness that causes significant stress in children and adolescents. It is possible to infer three distinct etiologies – neurobiology, environment and dysfunctional interpretative patterns. Certain characteristics are attributable to OCD with onset in childhood or adolescence as higher prevalence in males, increased frequency of isolated compulsions (more cleaning, repeating and checking), higher rate of aggressive obsessions and more common accumulation behaviors. There are several psychiatric comorbidities associated with OCD like anxiety disorder and major depression. The first-line treatment in OCD is the association of a selective serotonin reuptake inhibitor (SSRI) and individual psychotherapy.

The authors reviewed the clinical records of patients diagnosed with OCD observed in a child and adolescence psychiatry liaison consultation between April and September 2015, inclusive, aiming to characterize the sample, to describe the typical clinical picture

and to evaluate the existence of physical and/or psychiatric comorbidities, comparing the results with those expected in literature. The typical patient profile found was a 12-year-old male, living with relatives, with no neonatal complications, with stable home environment, without family psychiatric history, with associated medical comorbidities, with age of onset symptoms at 10.5 years-old, with only an obsession (contamination), with only a compulsion (cleaning or checking), with psychiatric comorbidities, treated with SSRI and without psychology accompaniment.

There are some limitations that must be taken into account because the sample was taken from a liaison psychiatry consultation, but in general terms, the results were similar to those described in the literature.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An approach to comorbidity between obsessive-compulsive disorder and schizophrenia

A. Gomez Peinado*, S. Cañas Fraile, P. Cano Ruiz
Hospital Nuestra Señora del Perpetuo Socorro, Psychiatry, Albacete, Spain

* Corresponding author.

Introduction An association has been observed between obsessive symptoms in Obsessive Compulsive Disorder (OCD) and psychotic symptoms in schizophrenia, being sometimes difficult to establish a clear limit between them. The term “schizo-obsessive disorder” was proposed to describe the resulting disorder of comorbidity of OCD and schizophrenia, although it has not been definitely settled.

Objective To analyze the incidence of coexistence of OCD and schizophrenia symptoms and the way it modifies the treatment and prognosis of the illness.

Method Review of some articles published in Mental Health journals such as “Salud Mental” and “Actas Españolas de Psiquiatria”.

Results Some studies about psychotic patients have determined 15% as the average of comorbidity of OCD and schizophrenia. The probability of having OCD is six times bigger if there is psychotic pathology associated.

The fact that obsessive and psychotic symptoms get together in some patients shades the prognosis bringing more negative symptoms, more depressive humor, a larger cognitive impairment, more resistance to treatment and more relapses than we can observe in OCD and schizophrenia isolated.

The pharmacological treatment usually consists in neuroleptic plus anti-obsessive drugs, together with cognitive-behavioral therapy. Sometimes, when there is a very bad evolution, it is required to consider psychosurgery as one necessary option, even though its use in this context is not much widespread.

Conclusions The simultaneous presence of OCD and schizophrenia is more common than we could expect only by chance and makes the prognosis worse, being difficult to find a truly effective treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Childhood OCD: The importance of an integrated approach

M.F. Molina López^{1,*}, J.M. Hernández Sánchez², M.C. Cancino Botello², A. Peña Serrano²

¹ Valencia, Spain

² Hospital General Universitario de Valencia, Psiquiatría, Valencia, Spain

* Corresponding author.

Introduction OCD is one of the most frequently diagnosed disorders during childhood. A prevalence of 1% is estimated, but according to the literature is an underdiagnosed pathology.

Aims To differentiate pathological rituals from those that children can have as normal behavior during their natural development. To perform a differential diagnosis and a current review of the literature.

Methods Descriptive analysis of a patient's medical record diagnosed of OCD and Tourette syndrome.

Case report Eight years old male diagnosed of Tourette syndrome (vocal and motor tics). Obsessive thoughts cancer related, self-examinations with compulsive pattern and anxiety with social and academic interference. Family history of tics in both parents during childhood. Currently, father with order rituals and mother with an Anxiety Disorder in treatment. Treatment with Sertraline 25 mg/day was tested with poor tolerance. Currently, the patient is being treated with Aripiprazole 1 mg/day with an important improvement of his symptoms and quality of life. OCD has comorbidity with affective and anxiety disorders, as well as Tourette syndrome. It's essential to differentiate pathology from certain behaviors considered normal during a child's development. For example, some children can have certain level of meticulousness, insecurity or a lucky object, but these behaviors shouldn't be confused with OCD symptoms. The treatment of choice is a combination of CBT with pharmacological therapy.

Conclusions An early diagnosis during childhood together with an appropriate comorbidity detection can reduce the tendency towards chronicity of this disorder leading to a better quality of life in these patients.

Koro syndrome in an obsessive-compulsive disorder patient

L. Silva¹, C. Raposo-Lima², C. Soares^{1,2}, J.J. Cerqueira², P. Morgado^{1,2,*}

¹ Hospital de Braga, Departamento de Psiquiatria e Saúde Mental, Braga, Portugal

² Life and Health Sciences Research Institute ICVS, University of Minho, Braga, Portugal

* Corresponding author.

Introduction Koro syndrome is a culturally related disorder characterized by intense anxiety that the penis (vulva or nipples in females) is shrinking or retracting and will recede into the body. Usually it occurs in epidemics in Southeastern Asia, being extremely rare in western countries. The condition is more common in males and is classified within Obsessive Compulsive and Related Disorders.

Case report A 27-year-old single man was referred to the psychiatric department. By the age of 23, he began worrying that his penis was shrinking and retracting into the abdomen. He described these thoughts as intrusive, ridiculous and repetitive. During the first months the thoughts were not very disturbing but he progressively developed an urge to verify the length of his penis several times a day. To diminish the anxiety provoked by the obsessive doubts on penis length, he started to have repetitive thoughts and mental images about sexual acts, to consume pornography compulsively and to increase his masturbatory behaviors (from some times a week to several times a day). He described those thoughts and behaviors as unpleasant and uniquely driven to reduce anxiety provoked by obsessions.

He was prescribed fluvoxamine 200 mg/day and initiated cognitive behavioral therapy with good response. Y-BOCS score decreased from 30 at initial evaluation to 18 after 3 months of treatment.

Conclusions Koro syndrome is a very rare condition in psychiatry in western countries, usually presenting secondarily to other psychiatric disorders. Awareness of this diagnosis and knowledge on its management are critical to provide optimal care to patients.

Exploring the role of dissociation dimensions in obsessive compulsive disorder

A. Pozza^{1,*}, N. Giaquinta², D. Dèttore³

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² Centre of Cognitive and Behavioural Therapy CTCC, Centre of Cognitive and Behavioural Therapy CTCC, Florence, Italy

³ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction In the last decade, accumulating evidence has been produced on the role of dissociation in Obsessive Compulsive Disorder (OCD). Understanding which dissociation dimensions are specific to OCD could suggest the integration of therapeutic strategies for dissociation in the treatment of patients with OCD.

Objectives The current study explored the role of dissociation in a sample of patients with OCD, patients with anxiety disorders and healthy controls with the aim to understand which dissociation dimensions could be specific to OCD.

Method One hundred seventy-one participants were included in the study (56% females, mean age = 35.96, SD = 12.61), of which 52 were patients with primary OCD, 59 were patients with Anxiety Disorders (AD), and 60 were healthy controls. The Dissociative Experiences Scale (DES), Beck Depression Inventory-II (BDI-II), Beck Anxiety Inventory (BAI), Yale-Brown Obsessive Compulsive Scale (Y-BOCS) were administered.

Results Patients with OCD had significantly higher dissociative amnesia symptoms than patients with AD and health controls ($F = 6.08, P < 0.01$) and higher depersonalization/derealization symptoms than healthy controls but not than patients with AD. Patients with OCD did not report significantly higher dissociative absorption than healthy controls and patients with AD.

Conclusions Strategies targeting dissociative amnesia and depersonalization/derealization symptoms in OCD are discussed. Future studies should examine which OCD subtypes are more strongly associated to dissociation dimensions.

Mindfulness skills deficits in pathological skin picking behaviours

A. Pozza^{1,*}, D. Dèttore²

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Pathological Skin Picking (SP) is a psychiatric condition with a 2–5% prevalence in the community and consists of repetitive picking behaviours associated to marked distress,

which can cause significant skin damage. Research has evidenced a Focused SP subtype, typically occurring in response to negative emotions, an Automatic subtype, occurring without awareness during activities not related to the picking behavior, and a Mixed one. Mindfulness skills have been studied as a protective factor involved in the treatment of several psychiatric disorders. Studying Mindfulness deficits in SP might help to identify interventions tailored for specific subtypes of SP behaviours.

Objectives The current study examined the relationship between Mindfulness skills and pathological SP behaviours.

Aims The study aimed to investigate whether Mindfulness skills deficits uniquely predicted SP subtypes behaviours after controlling for general distress in a community sample.

Methods Ninety-seven community individuals (mean age = 39.71, SD = 16.37, 59% females) completed measures of SP, Mindfulness skills and general distress (anxiety and depression).

Results Lower Mindfulness skills of Describing Internal Experiences ($B = -0.12, P < 0.05$) and higher anxiety ($B = 0.08, P < 0.05$) predicted more severe Automatic SP. Lower Mindfulness skills of Non-judging Inner Experiences ($B = -0.12, P < 0.05$), higher anxiety ($B = -0.12, P < 0.05$) and higher depression ($B = -0.12, P < 0.05$) predicted more severe Mixed SP. Focused SP was not associated to Mindfulness skills and general distress.

Conclusions Mindfulness skills deficits could be associated to Automatic and Mixed but not Focused SP. Future studies should investigate whether Mindfulness programs are effective for individuals reporting Automatic or Mixed SP behaviours.

Obsessive-compulsive disorder with comorbid schizotypal personality disorder: A novel clinical form?

F. Perris, M. Fabrizio, V. Prisco*, D. Giacco, F. Catapano
University of Naples SUN, Department of Psychiatry, Naples, Italy
* Corresponding author.

Different studies have identified specific clinical characteristics of patients with obsessive-compulsive disorder (OCD) in comorbidity with schizotypal personality disorder (SPD), although no perspective evaluations of prognosis and response to treatment have been conducted so far. The aims of the present study were to evaluate: (1) the clinical and demographic correlates of OCD patients with comorbid SPD (OCD-SPD) using standardized instruments; (2) the response of OCD-SPD patients to long-term naturalistic pharmacological treatment. Socio-demographic and clinical characteristics of patients with OCD-SPD were compared to patients with "pure OCD". OCD-SPD patients were characterized by a greater severity of obsessive-compulsive symptomatology, earlier age at onset, a higher rate of schizophrenia spectrum disorders in their first-degree relatives and a poorer insight. During the observational period, OCD-SPD patients were less likely to achieve remission of their symptomatology and required a greater number of trials with different antipsychotic drugs or received more frequently augmentation with antipsychotics. Our findings suggested that comorbidity with SPD is correlated to a poor treatment response in OCD patients and a reduced likelihood to recover from OCD symptoms, following standard pharmacological treatments. Further research is needed to identify alternative strategies for the management of this cohort of patients.

⁴ Erenköy Mental and Neurological Disease Training and Research Hospital, psychiatry, Istanbul, Turkey

⁵ Arnavutkoy State Hospital, psychiatry, Istanbul, Turkey

* Corresponding author.

Purpose Obsessive-Compulsive Disorder (OCD) is a mental disorder characterized by obsessions and/or compulsions. Although some epidemiological studies take part in literature, which claim that traumatic life events in childhood ages are observed more in patients with OCD compared to healthy population, the number of these studies is limited. In this study, it is aimed to compare OCD patients with healthy volunteers in terms of traumatic life events in childhood ages.

Method With 25 consecutive patients who are diagnosed as OCD and whose treatment continues, 25 healthy controls equivalent in terms of sociodemographic features are included in the study. Sociodemographic Data Form, Childhood Age Trauma Quarter (CTQ) and Maudsley Obsessive Compulsive Question List (MOCQL) are applied to the participants. Significance Value in statistical level is accepted as $P < 0.05$.

Findings In OCD patient group, CTQ scores are found high in statistical level compared to healthy controls. It has been determined that there is a significant relationship between total score of MOCQL slowness subscale scores, subscale scores of sexual and emotional abuse, MOCQL rumination subscale scores and CTQ sexual abuse scores.

Result Compared to healthy controls, more findings of traumatic life event in childhood age are observed within OCD patients.

Keywords Traumas in childhood age; Obsession; Compulsion

Psycho-oncology in Portugal: It is different from the rest of the world?

G. Da Ponte^{1,*}, M. Lobo², T. Neves¹, A. Paiva¹

¹ Centro Hospitalar Barreiro-Montijo, Psychiatry and Mental Health, Barreiro, Portugal

² Instituto Politécnico de Setúbal, Escola Superior de Saúde, Setúbal, Portugal

* Corresponding author.

Introduction Psycho-Oncology (PO) is a specific psychiatric approach to cancer patients. The main psychiatric disorders observed are delirium and adjustment disorders (AD) and the most frequent treatments used are pharmacologic and psychotherapeutic.

With regard to the type of cancer, the most frequent in Portugal are breast, digestive and prostate.

Objective Analyze the activity of PO in a district general hospital in Portugal.

Aims Demonstrate that the main core in PO is similar in the world.

Methods Prospective longitudinal study, during one year.

Results The sample had 130 patients (369 evaluations), mainly male, with the mean age of 64.22 years. The most frequent psychiatric diagnoses were delirium (56 cases; 43%) and AD (44; 34%) and the main interventions used were pharmacologic and psycho-education. The most common frequent cancers were digestive (54; 42%), urologic (16; 12%) and breast (15; 11%). This high frequency of urologic cancer was interpreted as a consequence of the sample and its geographic location, but it was also a reflection of the large number of requests made by this specialty. The majority of cancers had an advanced stage (84% vs 16%) that can be explained by the sample but also by health culture in Portugal, which is reflected in the inpatient services: Oncology (51; 39%) and Palliative Care (25; 19%).

Conclusions The type of psychiatric disorders and treatments offered in PO is preserved around the world. The authors propose to do more studies, namely if the relation with others specialties affects psychiatric treatment of the patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Lack of occupation and depression onset in oncology patient – Case report

L. Filipovic-Grcic¹, F. Đerke^{1,*}, M. Braš², V. Djordjevic²

¹ University of Zagreb School of Medicine, Student Society for Neuroscience, Zagreb, Croatia

² University of Zagreb School of Medicine, Centre for Palliative Medicine, Medical Ethics and Communication Skills, Zagreb, Croatia

* Corresponding author.

Being able to live an active and meaningful life is important for mental health of every individual. In this case report we examine the life of an oncology patient who developed depression six years ago. The patient is a fifty seven year old woman who has been suffering from Von Hippel-Lindau syndrome for the last forty years. Her father and two uncles died from the same disease. She had her first operation when she was seventeen years old and has had numerous operations since then. During this time she has undergone four neurosurgical operations, nephrectomy, spine and pancreas operation and eye enucleation. Despite the fact that by being a chronic oncology patient she was prone to depression, she did not develop depressive symptoms. It did not happen even as her husband went to war and left her to take care of their child. It did not come afterwards as they struggled financially. Only after they moved to a new apartment and as she finished decorating it, did depression finally occur. During entire life she was an active, outgoing person, who took pleasure in socialising and various hobbies. She only developed depression after she was pensioned, left with the responsibility to care for her old mother. Following the psychiatric treatment she regained interest in people and become active in different cancer support groups. This example accentuates the importance of every-day pleasurable activities as a defence mechanism against depression.

Caregiving experience of multiple myeloma patients

M. Gonçalves*, J. Teixeira Silva, A. Cabral, Z. Santos
Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrado em Psiquiatria, Coimbra, Portugal

* Corresponding author.

Introduction Multiple Myeloma (MM) is a cancer formed by malignant plasma cells. On a worldwide scale, it is estimated that about 86,000 incident cases occur annually. The aim of this report is to investigate the experience among multiple myeloma caregivers, assessing the mental adjustment to cancer diagnosis and the most prevalent psychopathology in the caregivers. This paper also attempts to establish the influence of the symptoms has in the caregiving experience.

Methods All eligible caregivers will be approached during a regularly scheduled patient clinic visit and informed consent will be obtained prior to study participation. Data will be collected using the Mental Adjustment Scale to the Cancer Scale Partner (EAMC-F), Memorial Symptom Assessment Scale – Short Form, and Depression, Anxiety and Stress Scale (DASS-21).

Results According to the literature caring for patients with MM can be different comparing with another form of cancer. It is an incurable form of cancer, although treatments improve life expectancy and quality of life. The authors are expecting to find high rates of depression, anxiety, unmet needs, and burden of care. The symptoms of the patients will probably influence the caregiving experience.

Conclusion MM accounts for about 14% of all newly diagnosed hematological cancer, and it is estimated that its incidence will rise. The importance of psychiatric intervention in the multidimensional approach is becoming a recognized reality. This is essential in the treatment of psychiatric disorders, to improve prognosis and quality of life but also to reduce side effects of treatments and symptoms related to cancer.

Portugal's history of psycho-oncology

A. Fonseca*, A. Batista, F. Malheiro, A. Poças,
R. Araújo
Centro Hospitalar de Leiria, Psiquiatria, Leiria, Portugal

* Corresponding author.

The psycho-oncology represents an interface between psychology and oncology. In Portugal, the creation of Psycho-oncology was due to the collaboration between oncologists with psychiatrists and psychologists. This partnership led to the creation of first Portuguese research works in Psycho-oncology, contributing to the enrichment of this discipline.

Objective Describe the history of psycho-oncology in Portugal. Research articles and theses related to Psycho-oncology in Portugal and do his description statistics.

Material and methods Literature review of articles and theses on Psycho-oncology made in Portugal, using the following search engines: "Pubmed", "Medline", "SciELOPortugal" and scientific repositories of Portuguese universities.

Results Until 1997, psycho-oncology did not arouse the interest of researchers; however, since then, the Psycho-oncology has grown exponentially, with regard to the investigation. There was a period of increase in publications between 2005 and 2012 as well as, increase in the number of undergraduate theses, master's and doctorate. Disclosure of publications within the Psycho-oncology lies spread by various magazines in different specialties, demonstrating that this area arouses the interest not only of psychiatrists and psychologists, but also of other health professionals.

Conclusion Despite growing research in Psycho-oncology and growing interest among clinicians and researchers, there is still some shortcomings, warning that the psychological support is also scarce in some Portuguese institutions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Multiple factors make children with oncological processes-and their families-as a population with a special psychological risk. Because of this matter, they are likely to benefit from an integrated approach in their assessment and treatment. Under this premise, for the last year it is been implemented a Consultation and Liaison Program between Clinic Psychology and Oncohematological Pediatrics at the Torrecardenas Hospital in Almería (Spain). **Objective** To facilitate the adaptation of the child and his family to the disease process; and to prevent possible future changes in the developmental and socioemotional development of the child. **Method** It is a coordinated effort between the pediatric ward and mental health services, and it is conducted by a clinical psychologist. It is performed in a hospital setting, and is directed to all pediatric patients that may require admission to the oncohematology plant and its closest relatives.

Results During the time of application, it was possible to make an initial assessment of each of the new revenues with cancer diagnosis and developed an initial plan of psychological intervention. The interventions have been individually designed, based on the needs identified in each case, including: family interventions, coordination and direction to health professionals, direct approach with children.

Conclusions Throughout this year we have seen the emotional impact of a cancer diagnosis means for a child and high psychological wear that brings the long process of treatment. There is a clear need presented by this population to receive a specialized care that takes into account the psychological and contextual aspect.

A brief exploration of the psychological support available for cancer victims/survivors and relatives in health system in Riga, Latvia

S. Kumar^{1,*}, E. Stengrevica²

¹ Liverpool, United Kingdom

² NA, Psychology, Riga, Latvia

* Corresponding author.

Introduction In Riga, Latvia, people who have been diagnosed with cancer at various stages, are not offered any group or individual psychological intervention. This applies for the immediate relatives as well.

Aim The aim of the study was to collate a homogenous understanding of the resources and standards of extant practice in psychological needs of patients and their family diagnosed with cancer. Further aims include to identify any deficiencies in the service delivery and make appropriate recommendations.

Method The collective survey tool is devised to reflect the psychological needs of the aforementioned patients were devised by the authors, one a practicing psychiatrist in UK and the other with background in group work and support in Riga. The tool extended to ask coping skills, understanding, impact on relationship, work and general well-being of patients and carers and their family members alike. The collated survey was distributed and results collated.

Discussion The results of the survey indicate number of deficiencies in the organization and service delivery. There is also a huge lack of psychological support to family members who have been affected by a diagnosis of cancer or loss to cancer in the family. We also discuss means of improving service delivery in groups for this sample.

Influence of family dynamics in the development and recovery of patients with cancer diagnosis. Report of two cases

L. Leon-quismondo*, M.F. Dieguez-porres

"Principe de Asturias" University Hospital, Psychiatry, Alcala de Henares, Spain

* Corresponding author.

Introduction Nowadays, it is well known that a cancer diagnosis has an important impact on the patient and his family. Given a stressful life event, such as cancer, the family is in crisis, so it is crucial how they facing the process. Two families with different adaptation process at the time of diagnosis are presented and the differences are analyzed.

Cases Family 1: Woman, diagnosis of breast cancer. She lives with her husband and she has two children. Troubled family relationships before the diagnosis. Following the cancer diagnosis, family conflicts increase, both with their children and with her husband. The family is not able to adapt to the new situation and the patient perception is that her family do not care what is happening to her.

Family 2: Woman, diagnosis of breast cancer. She lives with her boyfriend, she has no children. She has a good relationship with her family before the diagnosis, without unresolved conflicts in the past. Since cancer diagnosis the whole family has turned to the patient, being more available for her needs, physically and emotionally. She is feeling supported by them and this is making the adaptation process and family adjustment easier, feeling the patient stronger to cope with illness.

Conclusions In families with unresolved crisis before the disease, the psychological stress increases after diagnosis. The family finds it difficult to react and adapt to the changes caused by the disease and the relationships between its members deteriorate. Conversely, if the family dynamic is good, it is a positive factor in the recovery.

Psychiatric presentations of central nervous system tumors

L. Maia^{1,*}, A. Sofia Coutinho², G.C. Irina², L. Carneiro²

¹ Vila Nova de Gaia, Portugal

² Hospital Center of Vila Nova de Gaia e Espinho, Mental Health Service, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction For the most part, central nervous system (CNS) tumors present themselves with focal neurologic signs or manifestations resulting from increased intracranial pressure. However, in particular cases, these tumors may present exclusively psychiatric symptoms.

Objective This communication explores importance of CNS tumors as differential diagnosis of various psychiatric disorders.

Aims Highlight the need of acknowledging this important differential diagnosis (CNS tumors) in current psychiatry practice, while presenting a clinical case as an example of the subject.

Methods It is exposed a bibliographic review of the topic, followed by the description of a clinical case regarding a patient with pituitary adenoma and simultaneous installation of psychotic symptoms namely delusional paranoid ideation.

Results The authors present a case report of a 66-year-old patient admitted compulsively in a Psychiatric ward in the context of behavioral changes associated with delusional ideation of paranoid content. Multidisciplinary assessed by specialties of Psychiatry, Neurology, Neurosurgery, Endocrinology and Psychology, concluded by the presence of nonfunctioning pituitary adenoma associated with cognitive major disturbance.

Conclusions The tumors of the CNS can be associated with a whole variety of psychiatric symptoms such as psychosis, anxiety, depression or cognitive impairment, even in the absence of organic/neurological symptoms. Its role in the genesis of psychiatric symptomatology makes these neoplasias an important differential diagnosis, whose clinical approach should include different medical specialties integrated as a multidisciplinary team.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pancreatic cancer associated with psychotic depression – A case report

M.E. Perfene-Banu*, A.M. Cristache, I.A. Andrei, M.C. Tudorache, R.E. Popa, M. Manea

Psychiatry Clinical Hospital "Prof. Dr. Alexandru Obregia", IV, Bucuresti, Romania

* Corresponding author.

Pancreatic cancer is an aggressive form of cancer with increasing incidence and a 5-year survival rate of 4% for all stages. Depression and anxiety have a higher prevalence than the general population in all cancer types. Also, rates of depression in patients with pancreatic cancer are higher than in patients with other types of gastrointestinal neoplasms. Depression in pancreatic cancer has also been shown to impair quality of life, so early and adequate antidepressant treatment is an essential component of comprehensive supportive care.

We would like to report the case of a 67-year-old female patient, with no previous psychiatric history, brought to the psychiatry emergency unit by her husband for psycho-motor agitation, persecutory delusions, delusional jealousy and bizarre behavior. According to her husband, the symptoms started insidiously over the last few weeks and that she attempted suicide by drug overdose three days before admission to our clinic, which she denies. Three years prior to her hospitalization the patient received surgical, radiotherapy and chemotherapy treatment for a base of tongue tumor and 6 months prior to her psychiatric admission, the was diagnosed with cephalic pancreatic neoplasm for which she received seven cycles of chemotherapy. Treatment with mirtazapine, risperidone, and lorazepam was initiated. The evolution was favorable and the patient was discharged one week later.

Early recognition and treatment of mood disorders associated with cancer are important because, left untreated, they may lead to difficulty in managing symptoms, increased demand for health services and low adherence to treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Characterization of a referral to psycho-oncology liaison consults in a general hospital

J. Ramos*, A. Oliveira

Centro Hospitalar Tondela-Viseu, Psychiatry, Viseu, Portugal

* Corresponding author.

Introduction Liaison psychiatry is based on a practice that lies on the interface between psychological, sociological and biological factors of illness. Cancer is a devastating disease. For many patients the occurrence of it is synonymous of chronic, severe or lethal outcome. It is important for health professionals to be aware of the psychological suffering of these patients and promote a proper use of specialized consultations in order to increase and improve adherence to treatment.

Aims To make known the reality of referral to a Psycho-Oncology Liaison consult and its context in literature.

Methods Data collection on applications for the 1st request to Psycho-Oncology liaison consults occurred between 2010–2012 in the variables, gender, age, reason for referral, psychiatric history, cancer diagnosis, knowledge of the referral and who does (patient/family/service) and psychiatric diagnosis. Statistical analysis with Microsoft Excel 2010®.

Results It was found that there were 83 applications during the three years, 24 men and 59 women. The most prevalent cancer diagnoses were breast cancer (29.89%) and colorectal carcinoma (19.28%). Most patients had knowledge of the request (75.9%). The reason was mostly for Anxiety and Depression (33.73%).

Conclusion Cancer disease coupled with feelings of loss of autonomy, hopelessness and pain can lead the patient to develop psychopathology of anxious-depressive disorders. This condition may hamper the normal recovery of the patient. The promotion of mental well-being in cancer patients is critical to recovery and leads to a better adherence to treatment, inclusive can influence survival.

Cognitive decline induced by cerebral radiotherapy: What to do?

T. Silva*, T. Carvalhão, M. Fernandes, J. Silva

Hospitalar and University Center of Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Each year about 200 000 individuals undergo radiotherapy treatment to primary brain cancer or brain metastasis. The number of survivor has been rising with the improvement of treatment and techniques. The current evidence suggest a progressive cognitive decline in the years following brain irradiation, and show that 50% of the people that survive longer than 6 months are most affected.

Aim The authors propose to make a literature review, trying to expose the cognitive decline profile after cerebral brain therapy and how to choose the best therapeutic option.

Methodology Literature review using the data base available in the Documentation Service of the Central Library of the Centro Hospitalar e Universitário de Coimbra.

Results and conclusions The severity profile of cognitive decline influences the therapeutic options. The use of donepezil and

memantine presents as good therapeutic option, showing improvement in several cognitive domains. Methylphenidate still needs investigation but the evidence is that has positive impact in the improvement of fatigue and concentration. There are lack of studies using Gingko Biloba, but reveals high toxicity inducing gastrointestinal symptoms and risk of intracranial haemorrhage.

Computation and Cognition, Brazil

* Corresponding author.

Introduction The sedation could consist in a therapeutic strategy in advanced cancer conditions.

Objective To study the drugs administered to patients under Palliative Care Sedation (PCS) audits effects on vital signs.

Methods Our retrospective study included 101 oncological patients with mean age of 66.5 ± 13.4 years old and mean weight of 48.5 ± 3.36 kg, under PCS. The data were analysed applying the test of Wilcoxon.

Results The drugs administered to these patients under PCS were morphine 55 mg/kg/day associated to midazolam 52.5 mg/kg/day (Morph/Midazo) or the association of morphine 55 mg/kg/day, midazolam 52.5 mg/kg/day and neuroleptics such as chlorpromazine 54.5 mg/kg/day or haloperidol 13.25 mg/kg/day (Morph/Midazo/Neuro). The values of vital signs of these patients when the sedation was initiated were: systolic blood pressure 116.55 ± 16.98 mmHg, diastolic blood pressure 73.17 ± 10.55 mmHg, heart rate 83.41 ± 16.25 bpm, respiratory rate 19.39 ± 3.97 rpm and body temperature 35.91 ± 0.57 °C. No significant differences between these groups were observed. Vital signs measures were collected 48 hours before the patient's death. Significant reduction in systolic blood pressure 77.5 mmHg, diastolic blood pressure 43.3 mmHg were observed in the group (Morph/Benzo/Neuro). The Wilcoxon test for independent samples to a significance level of 5% we obtain a *P*-value of 0.01. The sedation period was 2.56 ± 0.23 days.

Conclusion Neuroleptic, a central nervous system (CNS) depressant drug, when associated to other two depressants (morphine/midazolam), conducted to the patient's vital signs reduction. Considering the short period of time between the beginning of sedation and the patients' death; and that palliative sedation should not include the hastening of patients' death, we suggest a better drug association criteria.

Symptom burden in cancer patients and caregiving experience

J. Teixeira Silva*, M. Gonçalves, Z. Santos
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Cancer patients typically experience multiple physical and psychological symptoms that may result from the disease or from treatment. The most common are pain, depression, anxiety, fatigue, insomnia, breathlessness, nausea, constipation, diarrhea and anorexia. The high symptom burden profoundly affects the patient but also the caregiver, which frequently experiences anxiety and depression.

Objectives Identify a correlation between patient symptoms and caregiver emotional disturbances.

Aims The aim of the present study was to improve the identification of vulnerable family caregivers who could require psychotherapeutic and psychopharmacological support.

Methods For this purpose, all eligible patients and caregivers were approached during a regularly scheduled patient clinic visit at a Portuguese psycho-oncology unit. Data was collected using the Memorial Symptom Assessment Scale-Short Form and Depression Anxiety Stress Scale-21. Sociodemographic and clinical data were also collected. Statistics were performed with SPSS.

Results High levels of psychopathology in caregivers were associated with female caregiver sex and worse patient physical and emotional well-being. Uncontrolled pain was related with high scores in DASS-21.

Conclusions Cancer patient's caregivers experienced high levels of anxiety and depression associated with worse patient well-being. The psychological stress of caregiving has a negative impact not only on the health of the caregivers but also on cancer patients. Early interventions directed at patient symptoms and caregiver support may improve quality of life in this population.

Pain management in context of emotionally unstable personality disorder

E. Dobrzynska^{1,*}, N. Clementi²

¹ Cygnet Health Care, Cygnet Hospital Kewstoke, Weston-super-Mare, United Kingdom

² NHS Grampian, Royal Cornhill Hospital, Aberdeen, United Kingdom

* Corresponding author.

Introduction Emotionally unstable personality disorder (EUPD) is characterised by Pain Paradox. The response for acute, self-induced pain seems to be attenuated while chronic, endogenous pain is usually intolerable. Pain management of this group of patients poses many difficulties, including discrepancies between subjective and objective pain assessment, patients' demands for strong analgesics and impact on relationship with other professionals.

Objectives and aims The purpose of the study was to review pain management options for persons diagnosed with EUPD and complaining of chronic pain.

Methods MEDLINE and PsycINFO databases were searched for all English-language articles containing the keywords "chronic pain", "pain management", "borderline personality disorder", and "emotionally unstable personality disorder".

Results Seventeen relevant papers were identified. Suggested first step in pain management was ongoing clarification with EUPD patients that analgesics are unlikely to fully treat their pain and support of non-pharmacological approaches to pain, including cognitive-behavioural strategies. Regarding pharmacology, liberal use of non-addicting analgesics was recommended with highly

conservative use of opioid analgesics. Importance of evaluation and treatment of any underlying mood and/or anxiety syndromes was stressed as well as liaison with other professionals (e.g. psychologists, neurologists, orthopaedics, and physiotherapists).

Conclusions Patients with EUPD often report chronic pain, which can only be managed by close collaboration of professionals from different disciplines.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Duloxetine added to tramadol in chronic pain syndrome

M. Domijan^{1,*}, Z. Lončar¹, S. Udovičić²

¹ "Sestre milosrdnice" University Hospital Center- Clinic for Traumatology, Department of Anaesthesiology, Reanimatology and Intensive Care, Zagreb, Croatia

² "Rebro" University Hospital Center- Psychiatric Clinic, Center for Crisis Intervention, Zagreb, Croatia

* Corresponding author.

Introduction About 15–20% of the population suffering from the chronic pain. Over time, chronic pain can result in different emotional problems, social isolation, sleep disturbances, which reduce the quality of life. Chronic pain syndrome (CPS) indicates persistent pain, subjective symptoms in excess of objective findings, associated dysfunctional pain behaviour and self-limitation in activities of daily living. Duloxetine is a potent antidepressant approved by the Food and Drug Administration for the chronic musculoskeletal disorder, diabetic neuropathic pain, fibromyalgia, generalized anxiety disorder and major depressive disorder.

Objective To determine the effect of duloxetine on the reduction of pain and psychosocial suffering.

Aims The goal of the treatment should be to effectively reduce pain while improving function and reducing psychosocial suffering.

Methods Thirty-six adult, nondepressed patients, already on tramadol therapy were included. Patients with VAS (visual analogue scale) ≥ 4 were treated with duloxetine for 13 weeks. We measured pain intensity with the McGill Pain Questionnaire-Short Form (MPQ-SF) and compared VAS before starting the treatment with duloxetine and weekly for 13 weeks.

Results Pain response was defined as a 30% decrease in the MPQ-SF. A total of 62.5% of the sample met these criteria for response. Among them, 13.8% of patients were discontinued because of adverse effects. Duloxetine significantly improved functioning and the quality of life in patients with CPS.

Conclusions Because of its analgesic properties, duloxetine in the lower antidepressant doses (60 mg taken once daily) combined with tramadol (another analgesic agent) can be useful in CPS for patients who do not respond satisfactorily to monotherapy.

Prevalence of different pain categories based on pain spreading in older adults in Sweden: A multilevel association with socio-demographic characteristics, comorbidities and drug consumption (Pain S65+)

E. Dragioti*, B. Larsson, L. Bernfort, L.Å. Levin, B. Gerdle
Linköping University, Department of Medical and Health Sciences,
Linköping, Sweden

* Corresponding author.

Introduction Understanding of factors related to chronic pain in elderly is limited.

Objectives and aims To estimate the prevalence of pain categories based on spreading of pain on the body and to investigate how such spreading is related to demographic variables, pain intensity, comorbidities and medication in an elderly general population in southeastern Sweden.

Methods A total of 6611 adults aged ≥ 65 years participated (mean age = 76.2; SD = 7.4). Pain categories were assessed by a self-reported postal questionnaire covering 45 anatomical predefined pain regions along with demographics, pain intensity during previous seven days, comorbidities and medication. Poisson regression models with robust error variance were used for data analyzing.

Results The prevalence of pain spreading categories was: chronic local pain (CLP) 16%; chronic regional pain medium (CRP-Medium) 17%; chronic regional pain heavy (CRP-Heavy) 5% and chronic widespread pain (CWSP) 2%. Overall, increased prevalence for CRP-Heavy and CWSP in subjects 75–79 years old compared to those 65–69, 70–74, 80–84 and ≥ 85 years were revealed. In men, 75–79 years old, CRP-Heavy was more common than in the other pain categories. In women, 75–79 years old CWSP, was more common than in the other pain categories. Pain intensity was strongly associated with all pain categories ($P < 0.001$). CLP was associated with trauma, rheumatoid arthritis, cancer, prescribed and non-prescribed analgesics. CRP-Medium was associated with rheumatoid arthritis, CRP-Heavy with rheumatoid arthritis and lung diseases and CWSP with rheumatoid arthritis and prescribed analgesics ($P < 0.001$).

Conclusions Our findings elucidate heterogeneity of pain in elderly which has to be further investigated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Distinct subgroups derived by cluster analysis based on pain characteristics and anxiety-depression symptoms in Swedish older adults with chronic pain (PainS65+)

E. Dragioti*, B. Gerdle, B. Larsson, L. Bernfort, L.Å. Levin
Linköping university, department of medical and health sciences,
Linköping university, Sweden

* Corresponding author.

Introduction There is a lack of research on subtypes of chronic pain (CP) characteristics in the elderly.

Objective To scrutinize major subgroups based on pain aspects and psychological factors on an elderly population.

Aims To determine possible differences between the derived subgroups with respect to pain aspects and anxiety-depression symptoms, health aspects and health care costs.

Methods A cross-sectional study was implemented. A large sample of 2300 individuals (M = 75.9 years, SD = 7.4) participated. Self-reported postal measurements regarding pain intensity, spreading of pain, anxiety and depression (General well-being schedule [GWBS]), and pain catastrophizing [PCS]) were used as classification variables. A two-step cluster analysis was employed. We further investigated whether the derived subgroups experienced different quality of life and general health. Calculations regarding health care costs were also performed.

Results Two major subgroups were identified: one low symptom severity subgroup (Cluster 1; $n = 1326$; 58%) and one high symptom severity subgroup (Cluster 2; $n = 974$; 42%). There were statistical significant differences on pain intensity, spreading of pain, anxiety, depression and pain catastrophizing between the two subgroups ($P < 0.001$). Significant lower levels for quality of life and general health ($P < 0.001$) were found for the high symptom severity

subgroup. Health care costs in the high symptom severity subgroup were significantly higher than those of the low symptom severity subgroup ($P < 0.001$).

Conclusions Our findings exhibit the necessity for subgroup-specific treatment services for improving pain management and reducing health care costs in the elderly.

Ziconotide and amnesia: A case report

S. Marini^{1,*}, V. Lalli², A. Costantini², F. Gambi¹

¹ University G. d'Annunzio, neurosciences and imaging, Chieti, Italy

² SS Annunziata hospital, health urgent and emergency care, Chieti, Italy

* Corresponding author.

Introduction Ziconotide is a new class of non-opioid analgesic that selectively blocks the neuron-specific (N-type), voltage-gated calcium channels, preventing the release of substance P and calcitonin gene-related peptide.

Methods A literature search was conducted in September 2015 using Pubmed and Scopus databases. No articles speaking about the direct correlation between ziconotide and amnesia were found.

Discussion A 56-year-old female patient, in treatment with ziconotide for chronic phantom pain syndrome, reported amnesia and dysgeusia symptoms. No psychiatric pathologies were diagnosed except for the high anxiety state correlated to the amnesia for recent events. The ziconotide treatment was reduced from 2.4 µg/day to 1.5 µg/day. Clonazepam was prescribed to treat the anxiety state. The subject clinical conditions did not require hospitalization.

Conclusions It is recommended that patients in treatment with ziconotide be monitored for changes in mood, suicidality ideation, thoughts or consciousness. Ziconotide could have serious neurological or psychiatric signs/symptoms (Table 1). Amnesia is a rare side effect of intrathecal administration of ziconotide. Severe psychiatric adverse effects may require ziconotide discontinuation, treatment with psychotropic agents and/or acute hospitalization.

Table 1

Psychiatric disorders	Nervous system disorders
Hallucinations	Dysgeusia
Delusions	Dizziness
Confusional state	Dysarthria
Anxiety	Ataxia
Insomnia	Nystagmus
Cognitive disorder	Areflexia
Mood disorder	Burning sensation
Suicidality ideation	Hypoaesthesia, paraesthesia

Psychiatric disorders in patients with atypical facial pain

V. Medvedev^{1,*}, V. Frolova¹, Y. Fofanova¹, A. Drobyshev²

¹ People's Friendship university of Russia, Chair of psychiatry-psychotherapy and psychosomatic pathology, Moscow, Russia

² Moscow State university of medicine and dentistry, Chair of maxillofacial and plastic surgery, Moscow, Russia

* Corresponding author.

Objective Maxillofacial surgeons and dentists often (up to 10%) deal with the phenomenon of atypical facial pain (AFP) – painful condition of maxillofacial area without clear organic pathology. Psychiatric studies of this disorder are almost lacking.

Aim The aim of this study was to define psychopathological disorders in patients with AFP and to set up psychopharmacological treatment strategies.

Methods The study used clinical psychopathological and psychometric (Pain measurement scales: Brief Pain Inventory, VAS, Pain Catastrophizing Scale) methods. We included patients with AFP examined in the clinic in December 2014 - September 2015.

Results Study sample consists of 54 patients with AFP: 45 women (83.3%), 9 men (16.7%), 18–70 years old (39.5 ± 14.7 years). In 67.8% of patients (33 women, 4 men), AFP was associated with affective disorders; among them, recurrent major depressive disorder was verified in 9.2% (4 women, 1 man), single depressive episode – in 33.6% (15 women, 3 man), bipolar II depression – in 3.6% (2 women), cyclothymic disorder – in 7.1% (4 women), dysthymia – in 14.3% (8 women). In 10.8% of patients (6 women), AFP was considered as a symptom of somatoform pain disorder. In 21.4% (6 women, 5 men), AFP was related with schizotypal personality disorder. Psychopharmacological agents used were SSRIs (fluvoxamine, escitalopram), SNRIs (venlafaxine, duloxetine), agomelatine and antipsychotics (quetiapine, amisulpride, alimemazine). The pain subsides in 87.04% of patients and the severity of pain decreased in 12.96% of patients.

Conclusion Patients with AFP should be examined by psychiatrist in order to determine psychopathological disorders and to elaborate psychopharmacological treatment strategies.

Psychosemantics of pain in patients with coronary artery disease

E. Pervichko^{1,*}, Y. Zinchenko¹, L. Pak²

¹ Lomonosov Moscow State university, faculty of psychology, Moscow, Russia

² Moscow State university of medicine and dentistry, faculty of general medicine, Moscow, Russia

* Corresponding author.

Introduction It is known for a fact that a number of psychological factors may affect heart pain perception in patients with coronary artery disease (CAD). However, psychosemantics of pain in CAD patients was hardly ever explored.

Objective To study the features of pain psychosemantics in CAD patients.

Methods There were applied McGill Pain Questionnaire (Melzack, 1975); the psychosemantic technique "Classification of sensations" (Tkhostov, Efremova, 1989); the 20-item Toronto Alexithymia Scale (Bagby, Taylor, Parker, 1994); and State-Trait Anxiety Inventory (Spielberger et al., 1983). Fifty-four CAD patients took part in the study, the mean age was 55.9 ± 7.6 years. CAD duration was 5.8 ± 2.6 years.

Results CAD patients with the high level of trait anxiety (28%) choose greater variety of descriptors for pain definition, revealing an impaired ability to differentiate between emotional states and physical sensations. They show higher scale values for McGill Pain Questionnaire. Patients with high indices of alexithymia (31%) require significantly fewer words for description of painful and dangerous perceptions within the "Classification of sensations". This may testify to a certain bafflement in verbal description of the pain. With that, intensity of alexithymia does not correlate significantly with the high level of state and trait anxiety ($P > 0.05$). The method of "Classification of sensations" revealed that patients with trait anxiety, as well as those with alexithymia, define the pain with

significantly more numerous metaphorical and affective descriptors (Pervichko, Zinchenko, 2013).

Conclusions Received results prove an important role of psychological factors in etiology of chest pain in CAD patients with the high level of trait anxiety and alexithymia, which supports the urgency of psychotherapy for them.

The analgesic efficacy of ketamine-magnesium combination is influenced by the order of medication administration

K. Savic Vujovic^{1,*}, S. Vuckovic¹, A. Vujovic², M. Prostran¹

¹ Medical faculty, department of pharmacology, clinical pharmacology and toxicology, faculty of medicine, university of Belgrade, Belgrade, Serbia

² Medical faculty, university of Belgrade, hospital for ENT- KBC Dragiša Mišević, Belgrade, Serbia

* Corresponding author.

Introduction Magnesium is an endogenous voltage-dependent NMDA receptor channel blocker and ketamine is a non-competitive NMDA receptor antagonist. Magnesium may potentiate the effect of ketamine in analgesia and anaesthesia, but may also interact in an opposing manner. This study aimed at evaluating type of the interaction between magnesium sulphate and ketamine administered systemically in rats with an acute nociceptive pain (tail-immersion test).

Materials and methods Analgesic activity was assessed by tail-immersion test in male Wistar rats (200–250 g). The distal 5 cm of the tail was immersed in a warm water bath (55 ± 0.5 °C) and the time for tail-withdrawal was measured as response latency.

Results Magnesium sulphate (2.5–30 mg/kg, s.c.) and ketamine (2.5–30 mg/kg, i.p.) administered alone did not produce any effect. However, significant antinociception (synergistic interaction) was revealed at the following doses of ketamine: magnesium sulphate of 5:5 mg/kg, 2.5:5 mg/kg and 10:5 mg/kg. The effect was not dose-dependent, and a greater response was obtained when ketamine was administered before magnesium sulphate.

Conclusions This study revealed that (1) magnesium sulphate and ketamine given alone were not effective against acute nociceptive pain in rats, but (2) a combination of both drugs resulted in synergistically inhibited nociception, (3) which occurred only at selected low doses and proportions of the medications in a combination and (4) suggested the importance of the order of drug administration.

* Corresponding author.

There are various safe non-pharmacologic methods for labor pain management, which mostly decrease suffering of mother and some of them significantly decrease pain too.

Aim To assess effect of pelvic tilt by birth ball, sacrum-perineal heat therapy and combination use of them on active phase of physiologic labor.

Method In this randomized control trial, 120 primiparous volunteer with age 18–35 years, gestational age of 38–40 weeks, in one of hospitals of Iran university of medical sciences were randomly selected and divided in four groups: Pelvic tilt by using birth ball, sacrum perineal heat therapy, combined use of two mentioned methods and control group. Tools had 3 main parts of personal characteristic, client examination form and pain visual analogue scale (VAS). All ethical points were considered.

Results Equality of four groups had been checked before intervention. Lowest pain score first belong to pelvic tilt by birth ball then combined group and finally in heat therapy, which all were significantly less than control group. Significant decrease of pain had been seen in birth ball group and combined group during after 30 minutes intervention, but in the heat therapy group, it was seen after 60 minutes intervention (P -value < 0.05).

Conclusion All three interventions of this study had significant effect and decreased labor pain during active phase, but highest decrease was in pelvic tilt by birth ball group and its effect started after 30 minutes intervention. It is suggested that that Obstetrics and Midwives consider these safe methods for labor pain management.

Chronic pain and alcoholism – A descriptive analysis of alcohol dependent inpatients

T. Van der Kleij^{*}, R. Lawrence

Royal Edinburgh hospital, psychiatry, Edinburgh, United Kingdom

* Corresponding author.

Introduction The co-existence of chronic pain and alcohol dependence has been demonstrated in the literature. This population has high rates of injury, and chronic pain may be a direct result of conditions such as pancreatitis and neuropathy. Management may be complicated by pharmacological and behavioural challenges, potentially leaving patients with suboptimal treatment.

Aims The aims of this survey were to: establish the prevalence of chronic pain within the study population, evaluate the multidimensional impact it had on their lives, and quantify levels of satisfaction with current treatment.

Methods Over a 2-month period, 30 consecutive patients within the Ritson Clinic with Alcohol Dependence Syndrome were recruited. Using a modified version of the Brief Pain Inventory, each patient was interviewed by a member of the study group.

Results The frequency of chronic pain within this population was 47% (14/30) of which the majority was due to back pain (57% [8/14]), followed by pain of the feet and hands (43% [6/14]). We found that 64% (9/14) of patients were receiving treatment, and the average levels of satisfaction (% relief of pain) within this group was 57%.

Conclusions Chronic pain and alcohol dependence are multifactorial and interlinked, with our analysis showing higher frequencies of chronic pain compared to the general population. We hypothesize that treating pain may lead to better outcomes as regards abstinence from alcohol as well as improved quality of life. Larger

studies are required to establish prevalence, and better service delivery to this population.

Gender differences in Hofstede's cultural dimensions among a Kuwaiti sample

A. AlAnezi*, B. Alansari

Kuwait university, psychology, Kuwait, Kuwait

* Corresponding author.

Introduction Hofstede's model of cultural dimensions has become the most widely accepted and most frequently cited model for cross-cultural research. His cultural dimensions included power distance index (PDI), individualism vs. collectivism (IDV), masculinity vs. femininity (MAS), uncertainty avoidance index (UAI), and long-term vs. short-term orientation (LTO).

Objective The objective of this study is to explore gender related differences in the Hofstede's five dimensions of national culture for work-related values among a sample from Kuwait.

Methods The participants were 540 first year secondary school Kuwaiti teachers (270 males: mean age = 28.95 ± 2.47; 270 females: mean age = 28.20 ± 2.04). The Arabic version of the Values Survey Module, VSM 08 was administered to participants. Data analysis include independent sample *t*-test was used to examine gender differences in Hofstede's five dimensions of national culture.

Results Internal consistency was satisfactory for the Power Distance, Individualism vs. Collectivism, Masculinity vs. Femininity, Uncertainty Avoidance, and Long-term vs. Short-term Orientation subscales respectively (Cronbach's alpha = 0.82, 0.84, 0.90, 0.74, 0.87) for males and (Cronbach's alpha = 0.77, 0.90, 0.83, 0.80, 0.88) for females. The results revealed significant gender differences where the males obtained a higher score than females on individualism ($t = 2.95, P < 0.002$), and masculinity ($t = 2.77, P < 0.005$), while females obtained a higher score than males on power distance ($t = 4.48, P < 0.000$), and long-term orientation ($t = 4.13, P < 0.000$).

Conclusion These findings suggest that the gender differences exist for cultural dimensions, and provide insight on leadership characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ Hospital de Donostia Osakidetza, Psiquiatría, Donostia, Spain

⁷ Consulta privada, Psicología, Madrid, Spain

* Corresponding author.

Introduction Recent studies suggest that Borderline Personality Disorder (BPD) could be regarded as an affective disorder within the Bipolar Affective Disorder (BP) spectrum. This is supported by evidence suggesting a clinical/neurobiological overlap between these two disorders. The Temperament and Character Inventory Revised (TCI-R) may help differentiate between the two disorders and orientate the clinical approach, considering the evidence of the medium-term temporal stability of TCI-R in a clinical population.

Objective We present a clinical case diagnosed with BD which underwent testing using TCI-R. TCI-R orientated towards a secondary diagnosis of BPD and the case further received a course of Dialectical Behavior Therapy (DBT) which led to clinical improvement. We therefore study the usefulness of TCI-R in this clinical setting.

Aims To study whether TCI-R may help differentiate between BD and BPD in mood stabilized patients.

Method Our patient is a 52-year-old married male diagnosed with BD. Considering his clinical features of impulsivity/instability of behaviors and pathological interpersonal relationships, patient was started on individual DBT (fortnightly, 4 months). Psychotropic treatment (paroxetine 30 mg/day, lithium 1000 mg/day, aripiprazole 15 mg/day) was not modified.

Results TCI-R scores: harm avoidance (100%), novelty seeking (53%), reward dependence (20%), persistence (18%), self-directedness (1%), cooperativeness (2%) and self-transcendence (48%). After 4 months of therapy, the patient improved in distress tolerance, acceptance, behavioral activation and assertiveness.

Conclusions TCI-R is an inventory for personality traits in which character scores differ markedly between PD and non-PD patients. It is a useful tool in BPD patients orientating the clinician in the differential diagnosis and the treatment approach.

The authors examined age and sex trends on the seven dimensions and 25 facets assessed by the Temperament and Character Inventory collected between 2006 and 2014. This cross-sectional study sought to better understand personality differences according to age and sex cohorts in a French non-clinical community sample (1181 participants). Our results show significant differences in age groups in Novelty seeking, reward dependence, harm avoidance and self-transcendence. Women scored higher than men in Harm avoidance, reward dependence and cooperativeness. Men between 18 and 29 years old reported higher Novelty seeking whereas older women had higher Harm avoidance. Among all the

dimensions of the TCI, only self-directedness presents a consistent gender \times age interaction. Our study confirmed that there were personality specific features in men and women. In addition, there were personality changes with age in both temperament and character dimensions. Our research highlighted the need to take into account both age and gender of subjects in the future analyses and interpretations of findings from the temperament and character inventories.

Many theories of personality have emerged, but currently, only dimensional approaches seem able to fully capture the complexity of this concept. The Cloninger psychobiological model is organized according to temperament and character from a psychobiological perspective that these variables would be related to individual differences. This model is evaluated by the Temperament and Character Inventory (TCI). Unfortunately, most of versions of this inventory are in the self-report form. Thus, these inventories cannot be used in a certain number of cases, especially in situations where the subjects cannot respond by themselves. This presentation describes the psychometric properties (internal consistency reliability, structural validity, concurrent validity, interrater reliability and test-retest reliability) of the French TCI-125 in peer-report form or hetero-questionnaire (TCI-125-HQ). Studies have shown satisfactory properties for internal consistency reliability, test-retest reliability and concurrent validity of the TCI-125-HQ. Temperament factorial analysis found a structure in three factors and not four, as in the theoretical model. Interrater reliability highlighted that the character dimensions seemed harder to assess compared with temperament dimensions, by the close entourage. The TCI-125-HQ will be useful when subjects cannot answer the TCI in self-report form because they have neurocognitive disorders, in particular, memory impairment or language disorders.

Recurrent depression over an schizoid personality. Case report

M.C. Cancino Botello*, F. Molina López, J.M. Hernández Sánchez, A. Peña Serrano, M.D.L.A. Canseco Navarro

Consorcio hospital general universitario, psychiatry, Valencia, Spain

* Corresponding author.

Introduction According to Millon, personality is a “complex pattern of psychological factors, which are mostly unconscious and express themselves automatically in almost every functional dimension of the subject”. It has been described how personality traits can modify the expression of other mental diseases, leading to confusion in diagnosis and treatment of the patient.

Method Systematic review of the literature in English (PubMed) and clinical history of the patient. Keywords: “recurrent depression disorder”; “schizoid personality”.

Objective To highlight the importance of making an accurate and detailed diagnostic formulation, in patients with both mental and personality disorders.

Case Sixty-seven-year-old woman, with many psychiatric hospitalizations, secondary to a recurrent depression disorder with psychotic symptoms and schizoid personality disorder. Both psychiatric monitoring and pharmacological treatment have been erratic. Initially, depressive episodes were considered as symptoms of her personality disorder. However, over the years, it was possible to make a more accurate diagnosis and a better treatment adjustment. In this case, lack of adherence is probably due to multiple factors, but no awareness of illness and personality disorder itself are the most important ones. This fact makes the patient less concerned about her personal care, leading to irregular treatment.

Conclusions People with schizoid, schizotypal or paranoid personality traits usually have a worse outcome, and they interfere with the functionality of the patient. This explains the importance of making an accurate and detailed diagnostic formulation, in order to benefit the course of the underlying mental disorders.

Introduction Fifty-year-old male. As a summary note that has a history of psychotic disorder from 25 years to coincide with the theological studies and your income as a priest. It has continued since then reviews and consultations in psychiatry, with two previous hospitalizations in private hospitals. It was stable with low doses of risperidone. Apparently, it makes a routine life linked to the activities of the church. Two months ago, he began to be irritable, suspicious, with discussions and problems at work, coinciding with the abandonment of treatment. Since the death of her mother a year ago has presented worsening.

Objectives It presents the case of a patient who has no awareness of illness.

Methods Psychopathological examination: conscious, oriented, scarcely manageable. Psychomotor restlessness. Expansive while maintaining distances, dysphoric and irritable. Verbiage. Ideas prejudice family-centered. There appears to be perceptual disturbances. Sleep-wake rhythms preserved.

Results Treatment was initiated with injectable paliperidone administered dose of 150 mg and 100 mg, with 12 mg of oral paliperidone with good response progressively. At high partial remission of symptoms, it is factual.

Conclusions The lack of awareness of the disease is non-pharmacological factors that can make it difficult to comply with neuroleptic treatment. These patients do not calibrate well how important that medication has on the evolution of his illness. Therefore, the therapeutic substance of such failure worsens the quality of life of patients and their families, as well as the prognosis of their disease presenting increasingly severe relapses.

How strange is everything

T. Casanova*, J.A. Blanco Garrote, R. Hernández Antón, A. Rodríguez Campos, S. Cepedello Pérez, S. Gómez Sánchez, G. Isidro García, L. Rodríguez Andrés, M. Hernández García, C. Noval Canga, A. Alvarez Astorga, H. De la Red Gallego
Hospital Clínico Universitario de Valladolid, Psiquiatría, Valladolid, Spain

* Corresponding author.

Introduction Twenty-year-old woman. In summary, we noted that a year ago, she had an episode of psychotic features secondary to cannabis in London. She then presented a depressing picture. In the current episode, the patient is anxious to be in a kind of dream. She says it is able to communicate through thought, and says his mind thinks fast. Make interpretations, giving meaning to everything that is new. Refer to hear voices in his head of his children. It is told with great emotional impact. Absence of previous consumption.

Objectives It presents the case of a patient with psychotic symptoms treated early.

Methods Psychopathological examination: conscious, oriented, collaborative. Good looks and touch. Tachypsychia and tachylalia. Speech inconsistent with loose associations of ideas. Dysphoria with emotional lability and continuous crying, feelings of guilt. Great anxiety component. Phenomena of derealization and depersonalization. Delusional interpretations of objects. Alterations of the experience of self. Possible auditory hallucinations. Insomnia.

Results During treatment with olanzapine, income starts to 20 mg and then proceeds to therapeutic change aripiprazole with good response, objectifying a partial remission of symptoms, quiet and adequate meeting, being aware of what happened.

Conclusions Schizoaffective disorder describes a mental disorder characterized by recurrent episodes of mood changes underway in all cases with psychotic symptoms. People with schizoaffective disorder are more likely to return to their previous level of function than do people with other psychotic disorders.

Introduction There is growing evidence of the importance of nutrition in mental disorders. Gut microbiota, influenced by environmental factors such as diet and stress, has been proposed as one of the players on a dynamic called gut-brain axis, which is thought to have an influence on behaviour and mental health.

Objectives and aims To summarize recent evidence on the topic, and its potential role in psychiatric interventions.

Methods The authors review updated literature collected from online scientific databases.

Results The development of the brain itself has been shown to be influenced by the gut microbiome. Research demonstrates that the composition of the microbiota has influence on behaviour through neuroendocrine and other neuroactive messengers production by the bacteria within the gut lumen. Studies in germ-free animals, animals exposed to bacterial infections, probiotic supplements or antibiotic drugs suggest a role for the gut microbiota in the regulation of anxiety, mood, cognition and pain. The gut microbiome has been implicated in brain disorders including anxiety

and depression, multiple sclerosis, Alzheimer's disease, Parkinson's disease, and autism.

Conclusions The treatment of mental disorders is usually based on pharmacological and psychotherapeutic interventions, and little attention is given to dietary interventions. The emerging field of research focused on the human microbiome suggests an important role for the gut microbiota in influencing brain development, behaviour and mood in humans, and points new strategies for developing novel therapeutics for mental disorders.

Borderline personality disorder and automatic processing of valence and self-other relevance information

U.S. Donges*, B. Dukalski, A. Kersting, T. Suslow
University of Leipzig, psychosomatic medicine and psychotherapy, Leipzig, Germany

* Corresponding author.

Introduction Enhanced sensitivity to emotion stimuli and poor differentiation between self and others have been proposed to be important features of borderline personality disorder (BPD). Automatic processing of affective stimuli provides information about valence (positive vs. negative) and relevance of valence (self vs. other).

Aims The objectives of our study were to investigate efficiency of automatic processing of valence and relevance at a semantic level in BPD compared to healthy individuals.

Methods A masked affective priming task, varying valence and relevance of prime and target adjectives, was administered to 33 women with BPD and 33 healthy women. The forward and backward masked primes were shown for 50 ms. Subjects had the task to evaluate target words.

Results In the whole sample, a significant affective priming effect and a significant relevance priming effect occurred. Presence of comorbid depressive disorder was positively correlated with extent of affective priming. BPD patients did not differ in affective priming from healthy individuals but they exhibited less relevance priming.

Conclusions According to our data efficiency of automatic recognition and processing of valence information at a semantic level is not impaired in BPD compared to healthy individuals. However, BPD patients appear to be less able to perceive and differentiate automatically self- vs. other-relevance during the perception of affective information than healthy controls. The present results indicate that patients with BPD could manifest impairments of self-other differentiation already at a very early or basic stage of emotion processing.

A life tiptoeing: Being a significant other to persons with borderline personality disorder

S. Ekdahl^{1,*}, I. Ewa¹, P. Kent-Inge², S. Mats³

¹ Malmö university, faculty of health & society, the department of care science, Malmö, Sweden

² Red Cross university college, psychiatric nursing, Stockholm, Sweden

³ Karolinska institute, department of neurobiology- care sciences and society, Stockholm, Sweden

* Corresponding author.

Introduction Borderline Personality Disorder (BPD) is a severe psychiatric health problem with a reputation of being difficult to deal with and to treat. Significant Others (SOs) of patients with BPD show higher levels of psychological distress compared with the general population. Strengthening the coping strategies of SOs has been shown to play an important role in the recovery of the person with psychiatric health problems. Research around SOs of persons with BPD is, to our knowledge, scarce, especially qualitative research exploring their experiences.

Objective We believe that if the personnel working in health care and psychiatric care are able to better understand SOs experiences and life situation, it could be an important step toward improved care.

Aim The aim of this study was to describe SOs experiences of living close to a person with BPD and their experience of encounter with psychiatric care.

Methods Data were collected by free-text questionnaires and group interviews and were analyzed by qualitative content analysis.

Results and conclusion The results revealed four categories: a life tiptoeing; powerlessness, guilt, and lifelong grief; feeling left out and abandoned; and lost trust. The first two categories describe the experience of living close to a person with BPD, and the last two categories describe encounter with psychiatric care.

Borderline personality disorder in adolescence. Prevention and early intervention from a cognitive analytic approach

E. Gimeno*, C. Chiclana

University CEU San Pablo, department of psychology, Madrid, Spain

* Corresponding author.

Introduction Borderline personality disorder begins in adolescence, however, its diagnosis is subject to some controversy and tends to be underdiagnosed. Stigma associated with its diagnosis, comorbidity with other axis I disorders or the changeable sense of identity during adolescence are some of the elements that obscure the diagnosis. Increasingly, recent studies have shown the utility of prevention programs as well as instituting early intervention in adolescents, with very hopeful outcomes.

Objectives The aim of this study is to review the benefits derived from early prevention and intervention programs in adolescents with borderline symptoms from a cognitive analytic approach.

Methods A systematic review for scientific articles extracted from research databases including Dialnet, EBSCO, Pubmed, Unika and Scholar Google was conducted. Other high-impact studies in the field were also included.

Results Evidence reported by reviewed articles supports Cognitive analytical therapy as one of the most successful approaches, the same as Mentalization based therapy, in the treatment of Borderline personality disorder. From this approach, prevention and early intervention have shown their effectiveness in reducing borderline symptoms and risk factors besides they contribute to interpersonal functioning improvement.

Conclusions Prevention and early intervention constitute the main pillars to prevent the potential development of Borderline personality disorder or its evolution in more complex and irreversible forms. But this intervention must be carried not only in young already diagnosed, but also in those who are on the diagnostic threshold, presenting risk factors for further development.

Keywords Cognitive analytic therapy; Borderline personality disorder; Adolescents; Early intervention; Prevention

* Corresponding author.

Introduction Personality disorders are chronic affectation of mood, impulsivity, aggression and anxiety. It is thought to have biological factors related to the development of personality disorders.

Aims To evaluate and compare the efficacy of injectable paliperidone in actual clinical practice of patients diagnosed with Personality Disorder, compared to other treatments.

Methods We conducted a descriptive, retrospective and observational study from January 2012 to June 2015 including all the patients who are treated with paliperidone palmitate extended-release injectable suspension with a diagnosis of Personality Disorder according to DSM 5. We included patients with at least 12 months of treatment and the results were compared with respect to the 12 months prior to taking said drug. Variables studied: medical diagnosis, hospital admissions, average length of stay, total number of emergency visits or other devices, maintenance doses.

Results We recruited 14 patients (7 women and 7 men) with a mean age of 36.2. 64.29% of patients had borderline personality disorder; 21.43% unspecified personality disorder. The mean dose of maintenance treatment is 105.357. Before the treatment, the quantity of total number of hospital admission are 1.14 versus 0.429 after treatment. The number of stay is also decreased from 13.7 to 3.5; like emergency room visits or to other devices. 78.57% of patients continue to psychopharmacological treatment. Fifty percent of patients undergoing treatment with another antipsychotic ($P < 0.05$).

Conclusions The present results show that paliperidone palmitate can be an effective way to control the most characteristic symptoms of Personality Disorders, and reducing emergency visits, hospitalisations and other devices.

Introduction Twenty-two years ago, the murder of the wife, the parents and the children of a doctor shook France. Some time later, it was discovered that the doctor was the murderer and that he had been faking his profession and social status. The prospect of being caught determined his decision of killing all his close relatives and trying – unsuccessfully – to commit suicide.

Objectives Review of the literature on the concept of pathological narcissism from the analysis of the notorious case of Jean-Claude

Romand and establish its differences from mythomania and psychopathy.

Aims Gaining a better understanding of the mechanisms and defenses of narcissism that determine certain behaviours and actions.

Methods Study of the biography and the psychopathological features of Jean-Claud Romand from books and interviews in relation to the concepts of pathological and malignant narcissism proposed by Otto Kernberg.

Results Features such as grandiosity, aggressive behaviors, hostility or paranoid traits can be found in both psychopathy and malignant narcissism. In Romand's case, the final diagnosis fits to malignant narcissism due to the ability to internalize the social contexts and to maintain constant representative and relational figures.

Conclusions It is important not to fall into reductionism habits and to study deeply each case to a better understanding of all the factors that contribute to the development of these kinds of personalities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Defensive misperception of the emotional contents of self/other communication

S. Movahedi

University of Massachusetts, Boston, USA

In this paper, I will be discussing a group of narcissistic patients who are not autistic, or psychotic but exhibit some autistic like symptoms in that they tend to misinterpret emotional communications and fail to detect aggression and attack in their own provocative language and behavior. As a result, they have very few friends, and often feel disrespected, discarded, and alienated by others. They easily feel insulted and get involved in interpersonal altercation. They fail to appreciate humor and show an inability to properly decode metaphoric language. They fit Piaget's description of developmental pathology in a paradoxical way, in that they exhibit an "absence of both self-perception and objectivity, whereas acquiring possession of the object as such is on a par with the acquisition of self-perception". Very similar to cases of autism, these patients show a relative incapacity to participate in an intersubjective field.

Introduction The personality disorders are defined according to the DSM-5 like "an enduring maladaptive patterns of behavior, cognition and inner experience, exhibited across many contexts and deviating markedly from those accepted by the individual's cultures. These patterns develop in adolescence and the beginning of adulthood, and are associated with significant distress or disability". The personality disorders can be a risk factor for different processes of the psychiatric pathology like suicide. The personality disorders are classified in 3 groups according to the DSM-5:

- cluster A (strange subjects): paranoid, schizoid and schizotypal;
- cluster B (immature subjects): antisocial, borderline, histrionic and narcissistic;
- cluster C (frightened subjects): avoidant, dependent and obsessive-compulsive.

Aims To describe the influence of personality disorders in suicide attempts.

Methodology Exhibition of clinical cases.

Results In this case report, we exhibit three clinical cases of suicide attempts which correspond to a type of personality disorder belonging to each of the three big groups of the DSM-5 classification, specifically the paranoid disorder of the cluster A, the disorder borderline of cluster B and the obsessive compulsive of cluster C.

Conclusions The personality disorders have a clear relation with the suicide attempts, increasing this influence in some of them, especially the borderline personality disorder.

A new look at personality disorders treatments

S. Neves^{1,*}, J. Tudela²

¹ Portugal

² Coimbra, Portugal

* Corresponding author.

Introduction Mental illness develops and is inseparable from the sociocultural context. The Disturbances may exhibit different symptoms in different cultures. In personality disorders, there is a pathological expansion of normal traits that often demonstrate a sociocultural change. The quality of life of these patients can improve with certain treatments, which appears to be relevant to be achieved.

Method Search on Pubmed and Medline for original research or review articles published in English or Portuguese in the last 10 years. It used a combination of terms: "personality", "treatment", "personality disorder", "borderline", "antisocial", "pharmacotherapy", and other named personality disorders.

Objectives/Aim Search the evidence base and the new perspectives for the effective treatment of personality disorders.

Results The same personality traits may be adaptive or non-adaptive in different contexts. So, without changing these characteristics, patients can learn to use them more effectively. In other words, although the therapy did not change the personality traits, it can be modified in the way they affect the behavioral expression.

Conclusions Psychological or psychosocial intervention is recommended as the primary treatment for borderline personality disorder and pharmacotherapy is only advised as an adjunctive treatment. The amount of research about the underlying, abnormal, psychological or biological processes leading to the manifestation of a disordered personality is increasing, which could lead to more effective interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Histrionic Personality Disorder is one of the most common personality disorders diagnosed in Psychiatry. This disorder has been known to be present in more than 40% of patients. There is also a high tendency for those diagnosed with this disorder to be female.

Objectives The case is to show all the difficulties caused by this pathology, differential diagnosis with other personality disorders, groups of characteristics from different clusters and also, complications produced in daily routine.

Methods The purpose is to study a clinical case of a 27-year-old woman, with a degree in journalism, who began with a depressive episode after a failed relationship. After being diagnosed of infertility, she debuted with dissociative episodes and somatization symptoms. After that, she suffered several depressive episodes. At the moment, all the clinical symptoms support the diagnosis of histrionic personality disorder.

Results Histrionic Personality Disorder can be found in the cluster B group of personality disorders. They often present in an overly dramatic, erratic or emotional manner. They may fulfil their need for attention through speech and behaviour that draws one's focus of attention toward themselves, and also demanding and manipulative in interpersonal relationships. There are high comorbidity rates in those who suffer from HPD with other diagnoses.

Conclusions Histrionic Personality Disorder appears to be one of the least threatening diagnosis among personality disorders as those affected are high functioning and do not seek relief for the disorder itself. There is also very little research on HPD which makes treatment options limitless.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Influence of temperamental and character traits on antidepressant response in patients affected by major depressive disorder

V. Prisco*, C. Di Puerto, M. Fabrizio

University of Naples SUN, department of psychiatry, Naples, Italy

* Corresponding author.

Several studies have been conducted to evaluate personality characteristics in patients affected by major depressive disorder. Temperamental and character traits may help clinicians to identify responders to antidepressive therapy. The aim of our study was to evaluate these characteristics as possible predictive indices of response to SSRIs or SNRIs. A cohort of 41 patients was included (30 F and 11 M), whose diagnosis was made according to DSM-IV criteria. Subjects were interviewed using the HAM-D and the HAM-A scale in basal condition (T0) and after 4 weeks (T1) of antidepressive treatment. Patients with a $\geq 50\%$ reduction of HAM-D and HAM-A score, have been considered as responders, when compared to basal conditions. All subjects were in monotherapy and evaluated using the TCI-R scale. In patients affected by major depressive disorder, personality assessment was characterised, from a temperamental point of view, by high levels of Persistence

and Reward Dependence and, from a character one, by high levels of Self Directiveness and Cooperativity. After 4 weeks of antidepressive treatment, responders to HAM-D had higher levels of Responsibility versus Guilt, which could be considered as a predictor of positive response to SSRIs or SNRIs. Conversely, responders to HAM-A showed higher values of Responsibility versus Guilt and of Safety versus Fear of uncertainty. These values were predictive of a recovery of anxious symptomatology associated with depressive disorder. Our results are in line with those reported in the literature, indicating that character dimensions "Self Directiveness" and "Cooperativity" could be important predictors of response to antidepressants.

Objective To review the current knowledge about Diogenes symptoms and organic personality disorder through systematic review of the literature and the analysis of a case.

Methods Case report. Review. Literature sources were obtained through electronic search in PubMed.gov database of 10 last years.

Results Background: Diogenes syndrome is a behavioral disorder characterized by severe self-neglect, hoarding, domestic dirt, and lack of shame regarding one's living state. Patients may present due to a range of reasons, few studies has been described hoarding symptoms secondary to brain injury. Early management could reduce their high-mortality condition.

Case presentation We present a case of a 67-year-old Caucasian female known with an organic personality disorder secondary to a head trauma with obsessive hoarding symptoms. After being hospitalized, we were authorized to explore her personal items through photographs. Her handbag and her house were filled with rubbish and rotting food. Our patient had no insight into any self-hygiene or public health problems.

Conclusions Information of the characteristics of Diogenes syndrome can help in earlier recognition of such persons, in order to decrease their morbidity and mortality.

Introduction As it has been for the last 30 years, male borderline personality are still misdiagnosed and herded into substance

treatment, anger management and prison. Gender matters from the failure of clinicians to identify it in men to the failure of researchers to study how it affects men differently and the treatment implications of those dissimilarities.

Methods The authors propose a retrospective study investigating all patients hospitalized with Borderline Personality Disorder diagnosis from 2000 to 2015 in Baixo Vouga Hospitalar Center.

Results From an average of 500 patients admitted per year, in the considered period, the number of men with this psychiatric diagnosis was irrelevant.

Conclusions Taking into account the results, it is important recognise some gender differences in borderline personality disorder with respect to specific types of self-harm behavior, such as self-cutting or levels of psychological distress at clinical presentation in order to prevent clinical diagnosis failure.

Introduction According to time perspective (TP), theory behaviour is influenced by the individual's perception of his/her past, present and future. Boyd and Zimbardo postulate that a healthy balance between orientation to the past, present and future exists.

Objectives Investigation of TP in the context of psychopathology.

Aims To investigate and compare TP in Obsessive Compulsive (OCD) and Borderline Personality Disorder (BPD).

Method Twenty-eight OCD and 28 BPD patients (36% of men), matched for age and education, completed the Greek version of the Zimbardo Time Perspective Inventory (ZTPI); a 56-item self-administered questionnaire measuring individuals' orientations to the past, present, and future. ZTPI consists of five factors: Past Negative (PN), Past Positive (PP), Present Hedonistic (PH), Present Fatalistic (PF) and Future (F).

Results BPD patients scored significantly higher in PH and PF and significantly lower in PP factors than OCD patients. No significant gender differences emerged for either group. In the BPD group, age correlated significantly negatively with PH, while education correlated positively with F.

Conclusion The study's findings suggest that BPD patients have a hedonistic orientation towards time and life and a helpless/hopeless attitude towards the future to a significantly greater degree than OCD patients, whereas OCD patients seem to have a more positive and nostalgic attitude towards the past than BPD patients. Further research would provide additional information concerning the role of TP in OCD and BPD patients.

Introduction Personality disorders designate a series of personality traits involving a behavioural pattern characterized by the recurrent violation of social norms, the importance of medico-legal implications associated to personality disorders being incontestable.

Objective This study aims to obtain a clear image regarding the particularities of violent behaviour, and also the mechanisms of anger in personality disorders, in relation with the legal implications of those reactions.

Methods The present study is a synthesis of recent literature (2012-2014) regarding the role of anger in violent behaviour with legal implications, in personality disorders. The research was made on PubMed, by the following keywords: personality disorder; violence in personality disorders; anger.

Results The core element that determines violent behaviour is anger. The physical effects of anger include increased heart rate and blood pressure, as well as an increase in the level of epinephrine and norepinephrine. Therefore, anger can be considered an integrant part of the response to a potential aggression or a potentially dangerous environment. Several general circumstances can activate anger. A strong example in supporting this theory is the bidirectional relation between anger within personality disorders and the use of alcohol and psychoactive substances. The individual gets extra stimulation, including through their psychopharmacological properties, thus exacerbating anger.

Conclusions In conclusion, it is necessary to conduct future studies focusing on the underlying causes of violence in personality disorders, as well as on the warning signs of potential violent acts, considering that personality disorders alone often cannot explain criminality.

Occurrence of addictions, self-harm behaviours, suicidal attempts in patients with personality disorder (PD)

M. Wypiór^{1,*}, A. Ziola², A. Sobieraj², K. Krysta²

¹ Katowice, Poland

² Medical university of Silesia, department of psychiatry and psychotherapy, Katowice, Poland

* Corresponding author.

Introduction According to previous researches, the risk of addictions and self-harm or suicidal behaviours seems to be higher in patients with personality disorders (PD) than in general population.

Objective To prove that patients with the diagnosis of PD are in the group of risk of addictions, self-harm behaviours and suicidal attempts.

Aims Analysis the occurrence of addictions, autoaggressive behaviours and suicidal attempts in patients with PD.

Methods Retrospective analysis of 123 patients diagnosed with PD and hospitalized over the years 2012–2015 in the Department of psychiatry and psychotherapy, medical university of Silesia, Katowice. Statistic analysis of variables and comparing with previous studies.

Results Three quarters of hospitalized patients were females. Average age in analysed population was about 48.5 years old. The frequency of suicidal attempts history was 38% among these patients.

Most popular method of suicidal attempts was drugs overuse. Nineteen percent of PD patients has revealed self-harm behaviours history.

PD's population have 46% risk of addictions.

Conclusion Hospitalized patients with personality disorders are in the group of risk of addictions, self-harming behaviours and suicidal attempts.

Care should be taken with patients revealing any risk of autoregressive behaviours and they should be advised accordingly. Preventive actions should be taken with these patients when any life-threatening behaviours suspecting.

Family and professional functioning in patients with personality disorders

A. Ziola^{1,*}, M. Wypiór², A. Sobieraj², K. Krysta²

¹ Katowice, Poland

² Medical university of Silesia, department of psychiatry and psychotherapy, Katowice, Poland

* Corresponding author.

Introduction Personality disorders (PD) are weight group of conditions. As possible causes of PD, literatures indicates being victim/witness of domestic violent. There is valid suspicion that PDs may have influence on marital status, education level and professional activity.

Objective Studying the PD influence on patients quality of life concerning both personal and professional areas of life.

Aim Analysis of the exposition to the violence in relation to PD diagnosis. Evaluation of the education level and professional activity in studied group, furthermore marital status.

Methods Retrospective analysis of 123 patients diagnosed with PD hospitalized over the years 2012–2015 in the Department of psychiatry and psychotherapy, medical university of Silesia hospital. Statistic analysis of variables and comparing with previous researches.

Results Three quarters of hospitalized patients were females. Average age was about 50 years old. Proximal martial status: 40% single, 60% formalized relationship (about 20% were divorced).

Among participants, 50% were employed, and 80% have completed at least 12 years of education.

About 40% had been victim/witness of domestic violence.

Conclusions The patients with PD had often experienced the domestic violence in childhood. Higher risk of impaired personality development with patients, who had been violence victim or witness is possible and they need to be advised accordingly. Research did not reveal PDs' influence on the education level. To define correlation between employment or marital status and PD further researches are needed.

Vulnerability and psychopathology. Reviewing a model in theory of psychiatry

I. Bone-Pina

Universidad Pontificia Comillas, psychology, Madrid, Spain

Introduction The vulnerability model is prevalent in the current Theory of Psychiatry. Systematic reflection after reviewing the historical proposition of this model can enrich its contents.

Objectives Complete and deepen the meaning of the concept “vulnerability” in Psychiatry.

Aims Review historical approaches to the concept of vulnerability in Psychopathology. The study starts with Zubin & Spring and reaches contemporary approaches especially in the writings of Giovanni Stanghellini.

Seek sources to deepen its meaning looking back to Karl Jaspers and Ludwig Binswanger's classical Psychiatry. They offer psychopathological notions that can be used to enrich a model of vulnerability.

Methods This is research in the context of Theory of Psychiatry, its method implies a historical literature review and a systematic philosophical reflection.

Results Vulnerability is still revealed to be the best concept to organize a model of mental illness. This study proposes to avoid any simple identification of vulnerability with statistical or genetic risk. Vulnerability in psychopathology should always be confronted with the horizon of human subjectivity. To keep in view this horizon – a limit impossible to grasp – is indispensable for clinicians and researchers if they want to understand patients who suffer mental illness. This process is helpful to avoid any reductionism about the image of mental illness and about the human being who suffers that illness.

Conclusion “Vulnerability” is shown as a concept that needs to be thought over thoroughly and to be present in psychopathology to overcome reductionism and to understand the very possibility of psychiatric illness.

The Bipolar II construct from the perspective of hacking's historical ontology framework

C. Cabrera Abreu

Queen's university, department of psychiatry, Kingston, Canada

Objective This oral presentation has two objectives: (a) to trace the origin of the contemporary criteria (DSM-III and its iterations) of the Bipolar II construct; (b) to highlight some conceptual problems in the context of its checkered contemporary history.

Methods In this oral presentation/paper, some of Ian Hacking's ideas and methods are applied, *sui generis*, to the Bipolar II disorder category. In particular, the “Historical ontology” framework, which has been applied with some success in historical studies concerning “Transient mental illness”.

Results The Bipolar II disorder construct is an intriguing DSM-IV category/construct that comfortably piggybacks on the category manic-depressive psychosis. Tracing the recent history of this construct is complex; its birth is associated with the Unipolar/Bipolar dichotomy suggested more or less simultaneously by Jules Angst and by Carlo Perlis in 1966 and in two different publications. The fundamental dichotomy introduced by them, has partially hidden some of the limitations of the construct Bipolar II. Its recent history

will be reviewed and some conclusions regarding the difficulties and limitations of this concept will be highlighted.

Conclusions (a) Hacking's "Historical Ontology" methodology suggest that attempts to differentiate Bipolar I and Bipolar II disorders by severity will always risk misdiagnosis, coinciding with Gordon Parker's *state of the art* conclusions; (b) the emergence of the man-made Bipolar II construct appears to be one of the end products – an unintended consequence – of Nancy Andreasen's "Death of phenomenology in America".

From DSM-5 to anthropopsychiatry: (Re)search for a renewed psychiatry

M. Calmeyn

Loppem Zedelgem, Belgium

Introduction "DSM is the Esperanto of psychiatry". Let it be? If DSM is to be considered as a symptom of contemporary psychiatry, the time for a change has come.

Objectives An important candidate towards an in depth move is anthropopsychiatry. Anthropopsychiatry is the original confluence of classical psychiatry, philosophy (phenomenology and structuralism) and psychoanalysis. An elegant evidence-based investigation (Roelandts and Schotte, 1999) exemplifies its importance.

Methods A search in literature with authors like Frances, Edward Shorter, Vanheule, Verhaeghe and Feys reveals several flaws in the DSM construction. A four-fold analysis by means of the epistemological terms nosography, nosotaxy, nosology and nosognosy makes clear that the DSM is a thinking under construction, culturally "child of its time". The concerns from the British Psychological Society and the objection by the NIMH are first moves towards another psychiatric classification, and consequently another vision on psychiatric theory and praxis.

Results Foregoing reveals anthropopsychiatry as an appeal towards present day psychiatry. It grounds modern psychiatry as an "autological" psychiatry (Kronfeld) with its own conceptualization and not "heterological" as an assemblage of all kinds of influences coming from neurobiological sources and human psychological findings.

Conclusion Anthropopsychiatry can be considered to be a serious candidate in the development towards a renewed psychiatry evidently based on clinical anthropology (Geyskens).

Mental health stigma: What's been done? Where to go?

P. Macedo*, A. Fornelos, A.R. Figueiredo, S. Nunes, M. Silva, F. Veríssimo

CHTMAD, Departamento de Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction Negative attitudes towards psychiatric patients still exists in our society. Persons suffering from mental illness frequently encounter public stigma and may internalize it leading to self-stigma. Discrimination occurs across many aspects of economic and social existence. It may represent a barrier for patients to receive appropriate care. Many anti-stigma campaigns have been

taken to decrease people's prejudice, but its effects are not well documented.

Objective To characterize anti-stigma initiatives and its effects on diminishing negative consequences of stigma.

Methods Bibliographical research on PubMed using keywords "stigma" and "mental illness".

Results Despite several approaches to eradicate stigma, it shows a surprising consistency in population levels. It was expected that focus on education would decrease stigma levels. The same was expected following concentration on the genetic causation of pathology. Most studies have revealed that education has little value and endorsing genetic attributions has led to a greater pessimism on the efficacy of mental health services, sense of permanence and guilty feelings within the family.

Conclusion Public stigma has had a major impact on many people with mental illness, especially when leading to self-stigma, interfering with various aspects in life, including work, housing, health care, social life and self-esteem. As Goffman elucidated, stigma is fundamentally a social phenomenon rooted in social relationships and shaped by the culture and structure of society. Social inclusion has been pointed as a potential direction for change.

¹ Hospital Universitari Mútua de Terrassa, Psychiatry, Terrassa, Spain

² Fundació Clínic, Recerca Biomèdica, Barcelona, Spain

³ Universidad Autónoma de Madrid, Facultad de Filosofía y Letras, Madrid, Spain

* Corresponding author.

Our aim is to discuss the notion of freedom in severe depression. We will address it considering several phenomenological conceptions of the matter, from Binswanger's *nicht können* to more recent Ratcliffe's loss of existential feelings and also by clinging to our own clinical experience, in particular a case of melancholic depression in a 67-year-old woman.

Our patient suffered a clear melancholic syndrome, with an intense psychomotor inhibition, she felt incapable of doing anything, spent hours brooding over menial tasks and thought much about dying, because she sensed the world as being devoid of possibilities and the future closed, experiences she considered "not related to disease" but to her own "incurable moral failure".

In order to discuss the notion of freedom in depression, we will particularly focus on one of her psychopathologic phenomena, the impoverishment delusion-like experience of having run-out of proper clothing, which we consider was based on an inhibited "perception" of reality, an unreflective experience of corporeal "not being able", a loss of the motivational force of intentionality. However, we will argue that this unreflective, pre-given experience showed striking connections to the patient's sub-depressive personhood, a classical Tellenbach's *typus melancholicus*.

An hermeneutical analysis of her existence will be performed using the anthropologic person-centered dialectic model developed by one of the authors, and building on it, we will introduce the distinction between lived experience (*Erlebnis*) and factual experience (*Erfahrung*) which we consider it is essential to enlighten the nature of the loss of freedom that severe depression entails.

On becoming ill: An exploration of the concept of “transition” to a mental disorder

B. Moura

Lisboa, Portugal

Introduction As a general problem in nosology, the moment when one becomes ill may be hard to define. In Psychiatry, the boundaries of disease may be more difficult to establish. In the last decade, we've been observing a growing interest in early diagnosis in this field, and the concept of “transition” to a mental illness became an important topic of discussion with implications in clinical practice.

Objective To review different author's models of evolution of symptoms and transition to mental illness and discuss their advantages and limitations in the actual context of Psychiatry research and clinical practice.

Aim To increase understanding on the different paradigms of becoming ill and their relevance to present and future psychiatric practice.

Methods Non-systematic review of literature devoted to the creation of models that describe the establishment of a mental disorder.

Results One of the first accounts of becoming mentally ill was developed by K. Jaspers within a phenomenological life-history analysis. Nonetheless, a cross-sectional approach to diagnosis has dominated Psychiatry for most of the time. With the advent of early intervention studies, longitudinal models of disease have been emphasized. The concept of a transition to disease was then operationalized but also highly criticized. Recently, McGorry proposed a staging model for psychiatric disorders in continuum with the non-clinical population. Finally, a dynamic systems approach to diagnosis in Psychiatry will be discussed.

Conclusion Driven by research in early phases of mental illnesses, current models of disease propose a longitudinal approach that emphasizes the complex and non-linear course of symptom clusters.

Introduction Justice is one of the fundamental concepts of right ordering of human relationships. Justice is a regulative idea for the arrangement of society preceding the law and already seen in animals; the sense of justice is observed as early as in young children. The ability to altruistic behavior, sense of fairness, reciprocity and mutual help are probably genetically determined as a disposition, which may further develop or be deformed by education. Although justice issues are common in psychotherapy, they may not be reflected and processed in the course of therapy.

Method Review of psychotherapeutic text and reflection of experiences of the authors.

Results In psychotherapy, justice issues appear directly in what the client says (mostly about injustice), but more frequently, the issues are implicitly contained in complaints and stories against a background of conflicts and problems. They may be related to the client's story, his or her problems with other people, and the therapeutic process itself, including client's selection of therapy, therapeutic relationship, and therapeutic change strategies. Problems with justice between the therapist and the client may be revealed by honest therapist self-reflection or high-quality supervision.

Conclusions Although justice issues are common in psychotherapy, they may not be reflected and processed in therapy. By increasing receptiveness to the issue of justice, the therapist may improve the therapeutic process.

Phenomenology of ADHD

C. Sanahuja^{1,*}, A. Suarez², C. Fernandez¹

¹ Hospital universitaria de Fuenlabrada, Mental health, Fuenlabrada, Spain

² Instituto Psiquiátrico José Germain, Mental health, Leganés, Spain

* Corresponding author.

Introduction Phenomenology is a term borrowed from philosophy which refers to the study of the structures of experience and consciousness. Founded as a school by Edmund Husserl in the early 20th century, it was later expanded and modified by many others, including Martin Heidegger, to include the analysis of existence and hermeneutics.

Objectives and aims To explain the clinic phenomenology of ADHD based on the historical bibliography regarding this term, making references to the heterogeneity of its phenomenological presentation depending on social context, age and gender.

Methods To go over the historical considerations of phenomenology and its evolution, as well as its clinical applications, in order to use this knowledge in a clinical context based on the observation of different cases in clinical practice.

Results We try to apply the phenomenological method as first inaugurated by Karl Jaspers' General Psychopathology (1913) to analyse the different clinical phenomena that can be observed in patients diagnosed with ADHD.

Conclusions We think that watching the psychiatric conditions, in this case ADHD, through the phenomenological lens can lead to a better understanding of the heterogeneity of their appearance in the clinical practice.

Wittengstein's private language argument: Does it pass the schizophrenic mind challenge?

G. Santos

Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal

Introduction The private language argument was introduced by Ludwig Wittengstein in his *Philosophical Investigations* (1953). For Wittengstein, language is a rule-governed activity and a language in principle unintelligible to anyone but its originating user is impossible, as even the originator would fail to establish meanings for its putative signs. The private language argument is of paramount significance in modern debates about the nature of language and mind and continues to be disputed. Language disorder has been described since the first accounts of Schizophrenia. Multiple studies have reported anomalies at multiple levels of language processing, from lexical and syntactic particularities to the discourse field, as well as structural and functional abnormalities in brain regions that are involved with language perception and processing.

Objectives and aims We aim to critically assess the Wittengstein's argument in the light of recent developments in neuroscience of language.

Results and conclusions We conclude that in some patients diagnosed with schizophrenia, presenting a significant language impairment, one can infer a dysfunctional process, in which the language becomes progressively more private and the meaning of utterances harder to ascertain in the realm of interpersonal communication. The privatization of language might contribute to the social cognition deficits and the so-called negative symptomatology of these patients.

EV901

The mechanistic property cluster view of mental disorder: A tenable form of non-reductionist realism?

D. Strijbos

Dimence, centre for developmental disorders, Deventer, Netherlands

Introduction The question what mental disorders are lies at the heart of the philosophy of psychiatry. In search of a valid taxonomy of mental disorders, it is a question that needs a proper answer. In recent work, Kenneth Kendler et al. (2011) have put forward the “mechanistic property cluster” (MPC) model of mental disorder. On this view, mental disorders are mechanistically mediated clusters of multi-level (bio-psycho-social) properties. Kendler et al. present the MPC-model as a non-reductionist form of realism – realist because it tries to account for mental disorders in terms of the causal structure of the natural world, non-reductionist because it views mental disorders as clusters of multi-level properties. For the project of psychiatric nosology, such non-reductionist realism would be a great step forward and indeed preferable to pragmatist and constructionist models of mental disorder.

Objective To critically assess the MPC-model in light of arguments against realism about mental disorders presented in the philosophical literature.

Aims To achieve a proper understanding of the ontology of mental disorders that can inform future psychiatric nosology.

Methods Literature study and conceptual analysis.

Results Despite appearances, the MPC-view fails to take into account the various (societal, practical, scientific) values that determine the delineation of mental disorders. It ultimately faces philosophical problems similar to those of more reductionist forms of realism.

Conclusions The MPC-model fails as a realist model of mental disorders. Its non-reductionism, however, is an important contribution to theories of explanation in psychiatry.

On the Carlos Castilla Del Pino “Axiom of behavioral significance” and its relevance in philosophy of psychiatry: The unification of clinical neuroscience

M. Vargas

Complejo Asistencial de Segovia, Grupo de Investigación en Neurociencia Clínica de Segovia GINCS, Psychiatry, Segovia, Spain

Carlos Castilla del Pino (1922-2009) was a Spanish psychiatrist and essayist with a wide work ranging from neuropsychiatry to social psychiatry. His essays include interesting psychopathological, anthropological and semiotic ideas.

The “axiom of behavioural significance” proposes that human behaviour is not an objective event but a meaningful act. As the objective of human behaviour is relation between human beings, it must be studied only under this communicative perspective.

Based in this axiomatic approach of Castilla del Pino, some arguments of interest to philosophy of psychiatry will be exposed:

- Mind is based in language and language is a communicative acts system in need of a dialogic community, namely, in need of a group of interacting brains. So, referring to the “brains-mind problem” is proposed to be preferred instead of referring to the “brain-mind problem”. Mind is a language-based emergent property of the social group, not a property of a single brain.

- The intention of human behaviour and the content of mental subjective phenomena should not be taken as a sign of any brain disease. Human behavior and mental representations always refers to a social group and a social context, not to a single brain. The only disease indicators we can take as disease signs are the formal aspects of behaviour and mind contents, as disexecutive syndrome or mental automatism are.

- As a corollary, it is proposed that neurology and psychiatry do not have any epistemic difference, leading to defence the unification of clinical neuroscience.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The other, role theory, key elements on the development of one-self and psychopathology

Associate prof F.I.Z. *, Dr. C.Z., Dr. J.V.

Clinica Psiquiátrica Universitaria, Universidad de Chile, Psychiatry, Santiago, Chile

* Corresponding author.

We plan to analyze the psychological and sociological concepts of the other and the role theory. We would describe the roles in psychopathology differentiating between the identity of the role and the identity of oneself and its entailment with the other, with respect to the development of the individual and its difficulties in the acquisition of roles, leading to different clinical entities. These pathologies show phenomenological differences observed in clinical situations such as schizophrenia, depression, bipolar disease, personality disorders and in psychopathological manifestations of epilepsy. We analyze the difficulties schizophrenic patients have in assuming roles, as well as in the recognition of “the other”,

depressive patients and their over identification of roles, the link to manic states, and a poor identity observed in patients with hysteria. Special considerations are made in the social interactions of epileptic patients with “the other” which takes the form of “being with”, and the dynamics established by epileptics in their social roles. These characteristics are also found in epileptic psychoses. When a psychotic state ends, and patients recover from a clear or lucid epileptic psychoses, they return to work recovering their social roles and interaction with others. In the case of cognitive impairment and organic dementia, there is a difficult adaptation due to this disability. Experiences lived under the psychotic episode are maintained, even reinforced and influence how they consider themselves and the others, in particular in terms of moral and religious ideas.

Metamorphosing histories: The narrative as a tool for psychological trauma's recovery

J. Becker

Coimbra, Portugal

Considering psychological traumatism as a subject in constant discussion, this study approaches the recovery of the patients that suffered violent events. Based on studies about the reflection of disasters and wars, we present trauma as a consequence of the unexpected event from where is originated intense fear. Trauma is a violation, an abruption, which disorganizes and incapacitates the victim. When a violence situation is experienced, the physical and

verbal abuses are not alone as the elements that interfere in the trauma's establishment, but also their representations. Thereby, the event that produces trauma is imposed, although its meaning depends of the history and beliefs of the subject. Understanding that the accident's representation is the cause of the trauma's establishment, we introduce the narrative as tool for psychological trauma's recovery, because it allows the victims relive their past and reframe their feelings. Regarding it, we highlight the relevance of the sociocultural context – before, during and after the trauma –, once it has direct influence over the way the person deals with adversities, as it can stimulate or stop a resilience process. This study takes in consideration that resilience is not something static, a faculty that the subject has or not, but a process that can be developed, improved or reduced. Thus, the narrative is presented as essential to initiate a resilience process, empowering the victims to confront the trauma and to rewrite their history and their return to life.

³ Universidad Nacional Autónoma de México, Ciudad de México, Facultad de Psicología, Ciudad de México, Mexico

* Corresponding author.

The forced displacement in Montería, a region from the Colombian Caribbean could become a risk factor for the existence of Post-Traumatic Stress Disorder (PTSD), nevertheless, there isn't data of the prevalence of this disorder.

Aim To identify the prevalence of the PTSD and associated events in adults victims of the displacement in the city of Montería.

Method Transversal and explorative study, 117 adults (M: 40,41; SD: 13,14). The PTSD was verified with the checklist for PTSD (Weathers, Litz, Herman, Huska & Keane, 1993) and according to criteria of DSM-5 (APA, 2014). The 3 factors associated with the disorder were analyzed according to age groups. To evaluate the events associated to the disorder was used the checklist of events (Blake, Weathers & Nagy, 1990). Occurred and witnessed by the subject events were analyzed. Descriptive were used to determine the existence of the PTSD and an ANOVA to contrast the symptomatology of the PTSD by age groups.

Results The 26,49% (n=31) of the sample had the clinic criteria of PTSD. An ANOVA of a factor evidenced that the activation was present in a biggest proportion in the range of 53-59 years old (M= 18.73); intrusion and avoidance was shown mostly in the range of 60-71 years old (intrusion M= 14.00; avoidance M= 14.85). In relation to the associated events occurred to the subjects, there was found that the highest incidence were: natural disasters (42.7%) and unexpected death (35.9%); the witnessed events with higher percentage where: unexpected death (19.70%) and traffic accidents (15.4%).

Posttraumatic stress disorder, violence and warM.A. Dos Santos^{1,2}¹ Instituto de Higiene e Medicina Tropical da Universidade Nova de Lisboa, Unidade de Ensino e Investigação de Saúde Pública Internacional e Bioestatística - Doutorado em Saúde Internacional, Lisboa, Portugal² Mestrado em Psiquiatria Social e Cultural, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Introduction In a globalized world, violence, present in all forms and in all places, is a public health problem with serious early or late consequences for the mental health of those who are direct or indirect victims. Violence is avoidable and preventable and is not evenly distributed by population groups or regions being among the top 20 causes worldwide of years lost due to disability and with a projected increase by 2030 according to the World Health Organization (Mathers, Fat & Boerma, 2008).

Methodology The search was made on ScienceDirect database, using the following keywords: posttraumatic stress disorder; violence and war. It was included documents in English published between 2004 and 2015; as well as textbooks and documents officers.

Discussion Violence is a risk factor for the disorder of post-traumatic stress disorder (PTSD) which, in turn, is also a risk factor for perpetrating violence. The PTSD can occur when a person faces or faces an unexpected traumatic stressor, such as war, violent personal assault, have been held hostage or kidnapped confinement as a prisoner of war, torture, terrorist attack, or serious car accidents (Javidi & Yadollahie, 2012). The costs of violence are high and its routinization for a living have important effects on mental health.

Considerations Studies in relation to PTSD and violence are necessary for us to have a better understanding of the phenomenon and its consequences for public health, as well as to promote the mental health of all.

Cognitive behavioral therapy in a group of militaries with posttraumatic stress disorder

H. El Kefi*, W. Abdelghaffar, A. Baatout, C. Bechikh Brahim, W. Krir, S. Eddif, A. Oumaya

Hôpital Militaire Principal D'instruction de Tunis, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Posttraumatic stress disorder (PTSD) has a high prevalence and severe impact in military populations. Cognitive behavioral therapy (CBT) is indicated in this condition but it is a structured therapy that requires patients' motivation and doctors' availability.

Objectives and aims Assess feasibility and effectiveness of CBT in a military group with PTSD.

Methods A group of six militaries that witnessed the same traumatic event (an armed attack) and were diagnosed with PTSD were involved in a structured individual session CBT with one therapist. An assessment using the PTSD checklist for DSM (PCL) was performed initially and in halfway therapy. The therapy included an education about PTSD, a cognitive restructuring, a behavioral approach via home tasks and relaxation techniques.

Results The initial PCL scores varied from 25 to 55. All patients were initially on sick leave. Five patients had adjunctive antidepressant medications and one patient was only on therapy. Three

patients showed no motivation and were excluded after 3 sessions. Two patients have had 7 weekly sessions and were able to return to work in the same place. One patient with severe PTSD had 2 sessions monthly, he had slight clinical improvement and could not come back to military work. The three patients who are still in therapy have improved PCL scores.

Conclusions CBT can be effective in PTSD. The outcome depends on initial severity of PTSD and assiduity.

EV909

Challenging MCMI-III results with in-depth psychometric assessment and Lacter & Lehmann (2008) complex trauma guidelines

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction Complex trauma resulting from neglect and abuse in early childhood is frequently misdiagnosed.

Objective This presentation shares emerging "best assessment practices" that help to differentiate complex trauma from Schizophrenia.

Aims The case study demonstrates that a wide-ranging psychometric assessment and the application of Lacter & Lehmann (2008) guidelines provide accurate results while MCMI-III results can be spurious.

Method "Unbelievable" disclosures of an adult survivor prompted a search for scientific references, experiences in the survivor scene and historical examples. Work-related personality questionnaires, in-depth ability tests and Lacter & Lehmann (2008) guidelines were deployed to differentiate complex trauma from an erroneous diagnosis based largely on MCMI-III results.

Results The research identified measurement issues with the MCMI-III clinical personality questionnaire that generated spurious elevations on Narcissistic, Delusional and Paranoid scales. Work-related personality questionnaires provided much more useful information showing no "personality disorder" risks at all. WAIS results confirmed an earlier "Twice Exceptional" ability pattern with very high verbal IQ (95%ile) and extraordinarily poor auditory working memory (2nd%ile) i.e. a "Dyslexia" performance pattern. Lacter & Lehmann (2008) guidelines showed that none of the 42 schizophrenia indicators applied and only 1/3 of the complex trauma indicators.

Conclusion Mental health professionals must remain cognizant to the chilling notion that extreme abusers may "frame" victims in order to make them "appear" schizophrenic. As MCMI-III was developed originally for those seeking therapy, its use in forensic settings with the general population should be avoided. Tests do not diagnose people – people do!

PTSD and quality of life among firefighters and municipal police forcesC. Lima^{1,*}, Â. Maia², R. Ferreira¹, A. Magalhães¹, H. Nunes¹, S. Pinheiro¹, L. Ribeiro¹, C. Rodrigues¹, P. Santos¹, V. Santos¹, R. Teles¹¹ Portuguese Red Cross, Vila Nova de Gaia, psychology, Vila Nova de Gaia, Portugal

² University of Minho, department of applied psychology, Braga, Portugal

* Corresponding author.

Research has shown that PTSD is prevalent among firefighters and police forces and that Quality of Life (QoL) is seriously compromised in individuals suffering from PTSD. However, QoL studies with these professionals are scarce. This study results from a screening program held by the Portuguese Red Cross (PRC) aiming to analyze predictors of QoL. Participants were 95 firefighters and municipal police officers. They answered the Posttraumatic Stress Disorder Checklist (PCL-5) in order to evaluate the prevalence of PTSD symptoms, as well as measures of social support (3-Item Oslo Social Support Scale) and QoL (EUROHIS-QOL-8). From the results, there were no group differences regarding total PTSD, social support or QoL and 10% of participants reported enough symptoms to PTSD diagnostic. Social Support and PTSD explained 25% of QoL variance, PTSD symptoms explaining 10% (negative beta) and, in the second step, social support explained 15%. The results suggest that it would be important to include QoL as an outcome measure in clinical and research work in these populations, with special attention to PTSD and social support.

Posttraumatic stress disorder, anxiety and depression in victims of road traffic accidents

K. Medhaffar^{1,*}, I. Feki¹, I. Baati¹, R. Sellami¹, D. Trigui¹, S. Moalla², H. Keskes², J. Masmoudi¹

¹ Hédi Chaker university hospital, Psychiatry "A", Sfax, Tunisia

² Habib Bourguiba university hospital, orthopaedic, Sfax, Tunisia

* Corresponding author.

Introduction Road Traffic Accidents (RTA) are most probably the leading cause of post-traumatic stress disorder (PTSD) in developed countries but it remains under-estimated.

Objective – To determine the prevalence of PTSD in our population.

– To determine the relationship between PTSD, anxiety and depression.

Method This is a cross-sectional study which involved 120 road traffic accidents victims, followed in the outpatient orthopedic department of Sfax in Tunisia. We assessed the severity of the injuries by the AIS scale, post-traumatic stress by the PCL-S and anxiety and depression by the HADS scale.

Results Our population was relatively young (average age ≈ 37 ans). In our population, AIS score (assessment of the severity of injuries) was higher than 3 in 62.5%. According to the HADS score, 36.7% suffer from depression and 27.5% from anxiety. In our series, the prevalence of PTSD in road accident victims was important: 54.17%. The risk factors identified were: female gender ($P=0.043$); rural origin ($P=0.015$); and the handicap caused by the accident ($P=0.013$). Concerning comorbidities, anxiety and depressive disorders were significantly associated with PTSD ($P=0.000$).

Conclusion Psychological consequences of RTA such as PTSD, depression and anxiety are not easily apparent. These people who have suffered from the most severe emotional shock are often neglected and/or forgotten.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional disorders in displaced residents from antiterroristic operation territory

V. Mykhaylov^{1,*}, A. Kogyna²

¹ Kharkov, Ukraine

² Kharkiv National medical university, psychiatry, Kharkiv, Ukraine

* Corresponding author.

Objective To study developmental peculiarities of emotional disorders in displaced residents from Antiterroristic Operation Territory (ATOT).

For conducting of research, 60 persons who were transferred from ATOT were involved.

Methods of research Clinical methods, psycho-diagnosical methods (Hamilton scale of depression [HDRS], Spylberger scale of anxiety, Mini-Mental State Examination [MMSE]), quality of life test (Mezzych I., Cohen N., Ruiperez M., 1999), statistical methods. The results that we got showed patho-psychological syndromes diagnosed in the persons of displaced residents from ATOT: astheno-depressive (75.9%), astheno-anxiety (82.5%), astheno-phobic (13.2%), astheno-hypochondriacal (3.3%). Results of the psycho-diagnostic investigations showed up that in men the indices of a reactive anxiety (average score: 37.7 ± 3.0) were higher than the indices of a personal anxiety (average score: 32.6 ± 2.9). In women, the indices of a personal anxiety (average score: 38.6 ± 2.9) were higher than the indices of a reactive anxiety (average score: 34.7 ± 3.0). An average score on the HDRS in men: 17.0 ± 2.3 points, in women: 18.0 ± 2.3 points. On the life quality scale, investigation of the individuals did not reveal any substantial differences among men and women. In the lowest level, the scales were evaluated as follows: "Psychoemotional state", "Interpersonal interaction" and "Overall comprehension of the life quality".

Conclusion The multimodal based system of psychotherapeutic correction of depressive spectrum disorders and associated disorders in persons who were transferred from ATOT were developed which demonstrated a significant improvement in 73,3% of patients.

The relationship between internal and external resources, coping strategies, PTS and death-anxiety of elderly caregivers' Philippine immigrants and local workers after the Gaza war

P. Ron

University of Haifa, school of social work, Haifa, Israel

Introduction Wars are a part of the Israelis' population daily experience along the years. The immediate victims of such events, the general population, as well as the work immigrants, are at high risk of suffering distress, acute stress disorder etc. as a reaction to the traumatic events.

Objective There would be a relationship between internal resources, social support, and reduction of the participants' PTS and death anxiety levels. The tendency to use problem-focused coping strategies would reduce the participants' PTS, and the death anxiety levels.

Aims To examine the relationship between internal resources, social support, coping strategies and the PTS and death anxiety of Philippine immigrants in comparison to those of local workers taking care for the elderly after the Gaza War.

Methods A self-reported questionnaire of 147 immigrants' workers and 126 Israeli' local workers was collected. The study participants agreed to undergo assessments of their PTS and death anxiety levels after the Gaza war as well as internal resources and social support.

Results The study SEM design indicated that the Philippine work immigrants had experienced higher levels of PTS and death anxiety than the local workers did. Internal resources and social support were found to be associated with lower levels of PTS and higher levels of death anxiety within the entire sample.

Conclusion The study emphasizes the importance of internal and external resources and coping strategies in the reduction of PTS severity while broadening an understanding of the death anxiety in the context of wars and military events.

⁴ Psychiatric hospital and university of Southern Denmark, research unit of psychiatry Odense, Odense, Denmark

* Corresponding author.

Introduction Mental trauma may precede persistent changes in a person's mental health in the form of psychosis and dissociation. Presently, there are no subtypes to the diagnosis of PTSD. A psychotic subtype of PTSD has been proposed, and studies show that these patients differ as well in symptoms as biologically from patients with non-psychotic PTSD. Dissociation and psychosis are generally viewed as different phenomena. Where dissociation is understood as a disintegration of the mind, psychosis is viewed as a neurodegenerative disorder on a mainly biological/genetic basis. The delineation of psychotic and dissociative symptoms is not clear however.

Objectives Our objective is to clarify, whether psychologists and psychiatrists describe trauma-related changes of consciousness (TCC) differently as dissociative or psychotic. Furthermore, we wish to compare scientific journals, and look for differences in how psychiatrists' and psychologists' make use of the terms dissociation and psychosis in relation to TCC.

Aims We aim to investigate whether TCC are interpreted differently among psychiatrists and psychologists.

Methods This study is a systematic critical review of the literature. The databases PubMed, Embase and PsychInfo will be used. Articles involving PTSD with TCC will be included. Studies will be classified as viewing TCC's as either psychotic or dissociative, based on the terms the authors use to describe the observed phenomena.

Results The results will be presented at the EPA in March 2016 in Madrid.

Conclusion The study will reveal differences in how psychiatrists and psychologists classify TCC's in PTSD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The psychological and psychiatric services in emergencies

S. Shport

V.P. national research center for social and forensic psychiatry, administration, Moscow, Russia

The department of psychological and psychiatric care in emergencies is functioning more than 20 years. The department organized emergency care in 22 emergency situations for last 10 years. There are air crashes, fire, acts of terrorism, natural disasters, technological disasters, accidents in transport, military operations. In air crashes is an important work with families, assisting in the formal procedures (identification of dead bodies), social issues. Support of the psychiatrist is necessary at all stages of the identification dead bodies and completion of the different forms. In case of fire are emergency concerns relatives of victims and injured in clinics. Burns is the cause of intoxication and changing the behavior of patients. The main help is an ensure bed rest and medication help to correct the behavior. Specialized help is diverse in the terrorist attacks. Psychiatrists serve as a link between the injured and relatives. Psychiatrists help investigators during questioning injured. Help is organized in hospitals, ambulances, telephone and interaction with the media. Natural disasters are of special character. They are always sudden and incorrect organization help can bring a lot of casualties. Psychiatrists decide health issues and are involved social issues injured. Helping to refugees is a special character. Medical care is complicated. They are citizens of another country. Organization of psychological and psychiatric care to the population in emergency situations involves the creation of psychological and psychiatric services, which provide the necessary measures at the federal, regional and local levels and in epicenter of emergency.

Dimensions of DSM-5 posttraumatic stress disorder (PTSD) symptoms

C. Soberón*, M. Crespo, M. Gómez-Gutiérrez, V. Fernández-Lansac

Complutense university, clinical psychology, Madrid, Spain

* Corresponding author.

Introduction Despite the four factor model of PTSD proposed in the DSM-5 (APA, 2013) has received a better empirical support than three factor model of DSM-IV (APA, 1994), some alternative models proposed can provide a better representation of PTSD's latent structure.

Objective The current study tested the fit of seven models, including the 3-factor DSM-IV model (APA, 1994), the 4-factor DSM-5 model (APA, 2000), the 4-factor dysphoria model (Simms, Watson & Doebbeling, 2002), the 5-factor dysphoric arousal model (Elhai et al., 2012), the 6-factor anhedonia model (Liu et al., 2014), the 6-factor externalizing behaviors model (Tsai et al., 2014) and the 7-factor hybrid model (Armour et al., 2015) that combines key features of the anhedonia and externalizing behaviors models.

Aim It expected that the 7-factor hybrid model (Armour et al., 2015) would be the best fitting model.

Methods PTSD symptoms were assessed using the Global Assessment of Posttraumatic Stress Disorder (EGEP-5; Crespo, Gómez & Soberón, 2016) in a sample of 165 victims of different traumatic events. Confirmatory Factor Analysis (CFA_s) were conducted on each of the seven models using Maximum Likelihood (ML) estimation method.

Results All the models tested (except for DSM-IV model) yielded an adequate fit to the data. However, 7-factor hybrid model

(Armour et al., 2015) provided a better fit than other competing models.

Conclusions The current findings suggest that the dimensional structure of DSM-5 PTSD symptoms may be best represented by the 7 factors proposed in the hybrid model instead of 4 factors of DSM-5.

Adaptation skill improvement through communication skills analysis of individuals with over-adaptation

Y. Aida

Meijigakuin university, clinical psychology, Tokyo, Japan

Japanese society, which culturally focuses more on harmony rather than individuals, tends to promote making society members to have over-adaptation, one of the psychological characteristics. The research embraced the definition of over-adaptation, as “the tendency to lose the authority due to one’s excessive efforts to meet others’ expectations rather than their own needs”. Individuals with over-adaptation have higher risks for suffering depression, violent behaviors, and psychosomatic disorders, potentially creates risks for suicide and death from over-work.

The recent Japanese studies mostly focused on examining the methods that balance internal adaptation by lowering external adaptation. However, this method has risks such as inducing resistance and coincidentally making professional helps more difficult. Our research focused on one of the internal maladjustment, self-inhibition, which is the necessary communication skill.

The research focused on individuals with over-adaptation, and set the objectives to reveal their imbalance of communication skills including self-inhibition. It farther aimed to examine the preventing methods the over-adaptation, which induce people to have another psychological maladjustments.

The research conducted a questionnaire to students in a university and high school. It suggested that individuals with over-adaptation tendency were less skillful in representation and self-assertion, and that they had stronger skill in other areas, such as capability for others, empathy, internal relationship adjustment skill, and self-control. Since these skills were high, they coincidentally made total balance worth. Additionally, their bad physical conditions were noted.

The research suggested the effectiveness of the self-expression and assertion training to improve adaptation, which coincidentally prevents physical problems.

Introduction The triangular theory of love posits intimacy, passion and commitment as the necessary components of romantic love (RL). Different attachment styles – secure, preoccupied, fearful-avoidant and dismissive – may influence the psychological variables of (RL).

Aims To explore the relationship between the different attachment styles and intimacy, passion and commitment in RL in a sample of the general population in Serbia; and to ascertain the attachment style which correlates most closely with the components of RL.

Method Attachment style was assessed by the Experiences in close relationships scale, and the components of RL by the Sternberg’s Triangular love scale. The study sample comprised 312 persons of both sexes, aged between 18 and 50 years old, and who had been in RL for at least 3 months.

Results The most frequent attachment style was secure (70.8%), followed by dismissive (14.4%), preoccupied (11.5%) and fearful-avoidant (3.2%). Persons with secure attachment style expressed a higher level of intimacy in RL as compared with persons with preoccupied and dismissive attachment styles ($P < 0.001$); persons with preoccupied attachment style expressed a higher level of intimacy in RL as compared with persons with fearful-avoidant attachment style ($P < 0.05$). There were no significant differences with regard to the passion and commitment scores.

Conclusion Persons with secure attachment style realize the highest levels of intimacy in RL, while those with fearful-avoidant the lowest. Passion and commitment were not influenced by attachment style. The psychotherapeutic intervention dealing with fearful-avoidant attachment style may have influence on realization of intimacy in RL.

⁴ *Massachusetts general hospital and Harvard medical school, department of psychiatry, disparities research unit, department of medicine, Boston, USA*

* *Corresponding author.*

Introduction The use of valid and practical screening scales might ease the burden for greatly needed universal testing for mental health, substance use and dual disorders, but do they work well with all populations? Do they miss correct identification of certain groups?

Objective To understand discrepancies in diagnostic prediction using the AC-OK screen in conjunction with other standardized assessment scales.

Methods Two hundred and twenty-six Latino participants were recruited from primary care and community clinics in Madrid, Barcelona and Boston and assessed with standardized mental health and substance abuse measures including the AC-OK screen

and with a Computerized adaptive test for mental health (CAT-MH). A measure of frequency of discrepancies and an adjusted and unadjusted comparison of results and demographic characteristics or respondents were made for mental health, substance abuse or for discrepancies in both categories.

Results 35.4% of cases were discrepant in mental health (AC-OK-Mental Health vs. Patient Health Questionnaire-9, Generalized Anxiety Disorder 7 or PTSD Checklist) and 14.2% in substance abuse (AC-OK-substance abuse vs. drug abuse screening test or Alcohol use disorders identification test). When CAT-MH scale was incorporated, discrepant results were found in 24.3% and 14.2%, respectively. No association was found between substance abuse discrepancies and patient demographics. In logit regressions being from Barcelona, of younger age and male were significant predictors of discrepancies.

Conclusions Discrepancies were observed in the diagnostic prediction, with differences detected for site and sociodemographic characteristics of participants suggesting the importance of testing screeners for site and population differences. Evidence for the misclassification of young males is discussed. Caution is warranted in the implementation of screeners for at risk populations.

Emotional regulation of mothers bringing up children with burn injury

D. Dovbysh

Moscow state university, clinical psychology, Moscow, Russia

Introduction Burn injuries occupy 11th place in the list of causes of infant mortality and 5th in the list of the most common non-fatal childhood injuries (WHO, 2014). The situation of getting a burn injury, prolonged hospitalization, painful medical procedures, the threat of a child's life results in mother's unusual and heavy emotional experience. Adequate processing of this experience will be an important factor in her future mental health. The study involved 35 mothers hospitalized with their children because of burn trauma.

Objectives The aim of the study was to describe the characteristics of emotional regulation and emotional response of mothers bringing up children with burn injury.

Goals (1) Describe the phenomena of emotional regulation, found in mothers whose children have experienced a burn injury; (2) determine factors that cause appearance of special emotional phenomena among these mothers.

Methods Clinical interview, Beck Depression Inventory, State Trait Anxiety Inventor, Cognitive Emotion Regulation Questionnaire (CERQ).

Results A significant numbers of mothers shows a high level of anxiety and depression, which may be predictive of the development of PTSD. The main cognitive strategies of emotion regulation – self-blame and disasterization are maladaptive. An important role played by unconscious strategy of emotion regulation, basically – situation selection and attentional deployment, as well as the social regulation of emotions: the availability of a good support from family members with adaptive strategies of emotional regulation, adequate reactions of other mothers in hospital associated with less emotional distress above mothers. There is no correlation between the severity of burn injury and the emotional response of the mother.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Preventing attachment disorder (AD): Attachment-focused dyadic group therapy with borderline personality disorder – and former AD – mothers

C. Compés, A. Iniesta, V. Pereira, C. Martínez, C. Justo, M.E. Herrero*

Proyecto Sirio, H. Menchu Herrero, Madrid, Spain

* Corresponding author.

Children with mothers with Borderline Personality Disorder (BPD) have a high risk of developing attachment difficulties, and this risk is like to grow when their mothers experienced severe neglect and/or abuse in their childhood and early adolescence. Our objective was to clinically assess and lend support to a small group of young mothers at risk. We recruited mothers aged 18–25, with 1–12 month-old children. None was married, had a stable residence and sexual partner, and most were unemployed. All had early diagnosis of AD, had at present BPD, and had received extended global and residential psychiatric treatment in our Therapeutic Community (SIRIO Project) along their adolescence. We conducted six consecutive 4 h weekly sessions, which were attended by mothers with their babies in the familiar setting of the Community. The explicit aim proposed to them was: “to come to be listened and accompanied and to share their motherhood experiences” with members of our multidisciplinary team (nurse, social worker, therapeutic educator, psychologist and psychiatrist), who were known to them. Fears, somatizations, more-or-less concealed rejection of her baby, apathy, sadness, suspiciousness, jealousy, relational difficulties with their couples and family figures... were common findings that were addressed in the sessions.

Main conclusion Minor but positive changes occurred in the dyadic mother-baby relationship. This was more patent concerning breastfeeding, relationships with their couple and extended family and pediatricians, and attitudes toward job seeking. In addition, the frequent contact with these mothers elicited markedly positive reactions in the 8–9 children/adolescents currently residing in our community.

⁴ Hospital Universitario de Álava, Psiquiatría, Vitoria-Gasteiz, Spain

* Corresponding author.

Many patients with severe mental illness are admission in hospital; but little is known about psychiatric re-hospitalization in this population. Our objective was to identify motives of psychiatric re-hospitalization in Dr. Rodríguez Lafora hospital. It is an observational, descriptive and retrospective study. We collected information about patients aged 18 to 64 who were hospitalized during the month of January of 2015 in the acute psychiatric hospitalization by Selene software. We reviewed psychiatric re-hospitalization for 6 months later and the results were analyzed by SPSS software. The percentage of inpatients with a diagnosis of

schizophrenia spectrum and other psychotic disorders was 29.4%, 13.7% bipolar disorders, 13.7% personality disorders, 11.8% depressive disorders, 9.8% alcohol use disorders, 3.9% schizoaffective disorders, 3.9% intellectual disabilities, 3.9% adjustment disorders with depressed mood, 3.9% obsessive-compulsive and related disorders, 2% substance-related and addictive disorders, 2% feeding and eating disorders and 2% adjustment disorders with mixed anxiety and depressed mood. The percentage of psychiatric re-hospitalization in patients with alcohol use disorders was 60%, 57.1% personality disorders, 50% obsessive-compulsive and related disorders, 50% schizoaffective disorders, 28.6% bipolar disorders, 26.7% schizophrenia spectrum and other psychotic disorders and 0% in the other inpatients. Why the percentage of psychiatric re-hospitalization is higher in patients diagnosed with personality disorder and alcohol use disorders? It would be important to establish an approach through more appropriate units as alcoholic detoxification unit and personality disorders unit.

* Corresponding author.

Background Ubiquitous negative emotional states such as depression, anxiety and stress in adulthood are related to individual life scenario, particularly influenced by exposure to environmental risk factors. Here, we investigated if sub-threshold negative emotional states in general population can be predicted by experience of trauma in the childhood.

Method A sample of 106 healthy young adult participants from Belgrade and surroundings (43.4% male, age 29.2 ± 6.6 years, mean IQ 106.4 ± 15.9) fulfilled Childhood Trauma Questionnaire (CTQ) to identify emotional or physical abuse/neglect or sexual abuse. Present level of negative affectivity was measured by Depression Anxiety Stress Scale (DASS). Hierarchical linear regression analysis was conducted to identify subtypes of trauma as predictors of the negative affectivity.

Results Mean CTQ and DASS scores were 31.2 ± 6.7 and 16.4 ± 16.8 , respectively. An exposure to given risk factors in the past correlated significantly with intensity of the present negative affective states ($r=0.290$, $P=0.004$). For the prediction of anxiety, the most important traumatism subtypes were emotional abuse, emotional neglect and physical abuse ($P=0.001$; 0.028 ; and 0.041 , respectively). Depressive symptoms were predicted only by the emotional abuse in the past ($P=0.008$).

Conclusion Based on clinical samples, findings from the literature yielded greater risk for mood and anxiety disorders after exposure to emotional, in comparison to the physical trauma. We confirmed the same pattern of correlations in the healthy subject's sample, who had no history mental disorders. Evaluation of the interaction effects among emotional trauma and genotype is strongly recommended in the identification of subjects at risk and for the prevention.

Clinical-psychopathological peculiarities of the prodromal stage of psychosis

N.O. Maruta*, O.Y. Kutikov, V.S. Bilous, K.Y. Zakal, S.O. Yaroslavtsev

Institute of neurology, psychiatry and narcology, NAMS of Ukraine, department of neuroses and borderline conditions, Kharkov, Ukraine

* Corresponding author.

Introduction Under conditions of growing of mental pathology in population, the European Psychiatric Association proposes an early detection of such pathology and timely medical interventions as the main strategy. First of all, this concerns psychoses at whole, and schizophrenia particularly, as the most disabling mental disorders. Here, a special role belongs to early interventions in the prodromal stage of psychosis (PSP). Such interventions might prevent development of the pathological process, promote solving of everyday and financial problems of patients, an early restoring of cognitive deficits and social functioning.

Aim To investigate clinical-psychopathological peculiarities and quality of life (QoL) of patients with PSP 72 patients (first hospitalization) with acute polymorph psychotic disorder (F23.0, F23.1) were examined both in the format of real time and retrospectively.

Methods A clinical-psychopathological and psychometric (PANSS, Scale of Suicidal Risk, SOPS, Scale for Detection of Clinical-Dynamic Variant of Course of Prodromal Period, PAS-SI) methods; the Method for Assessment of Integrative QoL Index.

Results In the patients clinical-psychopathological impairments in the PSP period manifested in form of a lowered stress tolerability (80.5%), agitation (40.2%), anxious conditions (72.2%), tension, concentration and attention problems (68.0%), sleep disorders (93.0%), contents of thoughts (56.9%). The patients had low QoL indexes on scales of personality realization (81.9%), psychological well-being (87.5%), and a general QoL impression (95.8%).

Conclusions The abovementioned clinical manifestations should be considered as PSP diagnostic criteria, which open possibilities for an early interventions and prevention of consequences of this pathology.

Low intensity microwave frequency electromagnetic fields (EMFs) produce extensive brain damage and widespread neuropsychiatric effects

M. Pall

Portland, USA

Low intensity microwave/lower frequency EMFs have been shown to act via activation of voltage-gated calcium channels (VGCCs). Pathophysiological effects of such exposures are produced through excessive Ca²⁺ signaling and elevated peroxynitrite. VGCCs are found at very high densities in neurons and such EMFs produce diverse effects in animal brains. Elevated VGCC activity increases susceptibility to various neuropsychiatric effects in humans. Fourteen different neuropsychiatric effects in humans, considered established, have been repeatedly reported to occur following exposures to microwave frequency EMFs: Sleep disturbance/insomnia, headache, fatigue/tiredness, depression/depressive symptoms, dysesthesia, concentration/attention/cognitive dysfunction, dizziness/vertigo, memory changes, restlessness/tension/anxiety/stress/agitation/feeling

of discomfort, irritability, loss of appetite/body weight, skin tingling/burning/inflammation/dermographism, nausea, EEG changes. Twenty additional apparent neuropsychiatric effects of such exposures will be listed (not considered established); these 20 suggest, however, that the neuropsychiatric effects go well beyond the 14 established effects. Various types of EMFs have been reported to produce neuropsychiatric effects including living near cell phone antennae, heavy cell phone usage, occupational exposure to radar, UHF or VHF transmission, smart meter radiation, WiFi field exposure, digital television signal exposure, living near a radio station antenna, or living near a short wave broadcasting antenna.

Conclusions The ever-increasing human exposures to such EMFs threatens us with near universal widespread neuropsychiatric effects and should be viewed as a major threat to the survival of human civilization. Current safety guidelines are based only on thermal effects and are therefore without any scientific merit.

Dietary pattern and mental health: review of literature

A. Tarelho*, M. Duarte, J. Melim, A. Batista, S. Almeida
Centro hospitalar de Leiria, EPE, psychiatry service, Leiria, Portugal
* Corresponding author.

Introduction If we are what we eat, are we eating ourselves into depression and anxiety? There has been an emerge evidence supporting a role for lifestyle factors in the development of these conditions.

Objective To review evolving concepts and gain insight on the phenomenon of dietary pattern and mental health.

Methods Bibliographic search in Pubmed for articles published between 2010 and 2015, using the keywords words mental health, diet and depression, from the 220 articles found, 68 were included.

Results From the 68 selected articles, 19 were reviews, 3 randomized controlled trials and 2 meta-analysis. The scientific community agrees that substantial global changes in the food system have had a highly detrimental impact on dietary patterns. Thirty-three articles found a positive correlation between unhealthy dietary patterns and poorer mental health or better mental health with healthy eating habits, such as a potential protective role of mediterranean diet (or similar) with regard to the prevention of depressive disorders. A recent systematic review by Baskin et al (2015) revealed positive associations between poor quality and unhealthy diets and antenatal depressive and stress symptoms. Healthy diets were inversely associated with antenatal depressive and anxiety symptoms.

Conclusion Although there is some evidence on the association between dietary quality and mental health, we can't tell if it's a casual linkage or what are the biological pathways that mediate these relationships. Therefore, randomized control trials of diet are necessary to disentangle the effects of multiple health behaviors on mental health.

A mental health promotion program among Iranian female high school students

H. Heizomi, H. Allahverdipour*

Tabriz university of medical sciences, health education & promotion, Tabriz, Iran

* Corresponding author.

Background Female adolescents have a higher prevalence of psychological disorder especially in the developing countries and tradition communities. Adolescence is due to accompanied with puberty and transitional age are suffering of mental health problems. Main purpose of this study was to assess the effectiveness of "psychological well-being promotion program" on the mental health status of female high school students in Iran.

Methods The non equivalent group, pretest-posttest design was applied to conduct this study from November 2013 to December 2013 in Tabriz, Iran on 289 participants (148 in the experimental and 141 in the control groups). One of the sub-regions of Tabriz city was chosen randomly and within the area two high schools were selected with almost same environmental conditions randomly as the experimental and control groups. Participants who were in the 9th grade were recruited randomly and classified in the both groups of intervention and control. After diagnostic evaluation, the planned program was performed based on two approaches of: (1) environmental changes (playing music during breaks, sports competitions, and interior decorating classes); (2) stress management skills development program.

Results The results were indicative of the intervention's positive impact. Based on the findings, the mean scores of the happiness significantly increased in the intervention group ($P \leq 0.001$). The mean scores of the stress significantly decreased in the intervention group ($P \leq 0.001$).

Conclusion The study results suggested that implementation mental health promotion program improved mental health indices which indicates effectiveness of comprehensive school health programs.

² Tbilisi state university, department of psychiatry, Tbilisi, Georgia

³ Ministry of labour, health and social affairs of Georgia, mental health, Tbilisi, Georgia

⁴ Council of Europe Office in Georgia, Senior Project Officer, Tbilisi, Georgia

* Corresponding author.

The stigma, discrimination and human rights violations that individuals and families affected by mental disorders suffer are intense and pervasive.

In order to study attitude toward mental health problems, more than 1000 population from the different region of Georgia have been interviewed within 3 months (May-July 2015) in their household.

The scope of questions used in the survey were based on the questionnaire proposed by the NHS Information Centre, Mental Health and Community.

The population of Georgia showed high levels of understanding and tolerance of mental disorders. Despite of this, the fear and exclusion toward people with mental illness were almost twice as more, compare to the countries, where community mental health services are developed. More than half of the interviewed reported that institutional care is quite sufficient for providing treatment and suggested that person with mental disorder should not have rights to a job. Social status, income and occupation did not play any role in terms of attitude.

Majority of the respondents thought that mentally ill patient is a person who is violent or who need isolation due to the disturbed or inadequate behavior.

The survey revealed that the attitude toward persons with mental disorders in the republic of Georgia less likely is based on evidence and objective information. The lack of knowledge and awareness of mental health issues increase stigma and discrimination regarding the people with mental health problems and prevent them from the integration into the society.

Relationship between attitude toward spirituality and attitude and performance of spiritual care among nurses

M. Farahaninia^{1,*}, N. seyedfatemi², M. Abbasi¹

¹ Iran university of medical sciences, community health nursing, Tehran, Iran

² Iran university of medical sciences, nursing care research center, Tehran, Iran

* Corresponding author.

Introduction Although spiritual care is commonly regarded as a nursing task, in practice, it is often provided inadequately.

Objective The purpose of this study was to examine relationship between attitude toward spirituality and the attitude and performance of spiritual care among nurses who working in hospitals of Iran university of medical sciences.

Methods This was a correlative-descriptive study. Spiritual Perspective Scale (SPS) and Nursing Spiritual Care Perspective Scale (NSCPS) were used to gather the data. A number of 166 nurses participated in this study.

Results Findings showed that of nurses' spirituality attitude score was 4.98 ± 1.1 which indicated high attitude toward spirituality. The total average of nurses' attitude about spiritual practices was 3.67 ± 0.51 , which signified the positive attitude of nurses about spiritual practices. Findings revealed that positive spiritual attitude had a significant correlation with 6 out of 12 expressed spiritual interventions. In addition, spiritual attitude generally had a significant positive correlation with spiritual interventions. The positive spiritual attitude had a significant correlation with only 3 items out of 11 for the attitude toward spiritual practices. There was no correlation between spiritual attitude and the attitude toward spiritual practices.

Conclusion In spite of the positive attitude, nurses did not perform half of the spiritual interventions which most of them were in line with fulfilling the patients' religious needs. Establishment of in-service education program regarding spiritual care practice by role play and modeling methods are recommended.

Keywords Nurse's attitude; Spirituality; Spiritual care practice

Resilience, coping, personality traits, self-esteem and quality of life in mood disorders

A. Feggi^{1,*}, C. Gramaglia¹, C. Guerriero¹, F. Bert², R. Siliquini², P. Zeppego¹

¹ Università degli Studi del Piemonte Orientale "A. Avogadro", department of translational medicine, Novara, Italy

² Università degli Studi di Torino, dipartimento di scienze della Sanità Pubblica e Pediatriche, Torino, Italy

* Corresponding author.

Introduction Resilience is a dynamic, context- and time-specific process that refers to positive adaptation or ability to maintain or regain mental health despite experiencing adversity. Pathways to resilience include biological, psychological, social and dispositional attributes. In mood disorders, resilience may influence frequency of relapse, severity of episodes and response to treatment.

Aims To evaluate resilience as well as personality features, coping abilities, self-esteem and quality of life in a sample of mood disorder patients.

Methods We recruited mood disorder patients at the Psychiatry institute AOU Maggiore della Carità, Novara. Socio-demographic data were gathered and patients filled in the following self-administered scales: Resilience Scale for Adult (RSA), Brief Cope, Rosenberg Self-Esteem Scale (RSES), Paykel list of stressful events, Temperamental and Character Inventory (TCI), Quality of life (SF-36).

Results We collected data from 61 patients. Statistical analysis was performed by calculating the Pearson Correlation Coefficient between the RSA and the other tests. We observed a positive correlation between RSA and coping "Emotion" and coping "Problem". A negative correlation was found between RSA and coping "Avoidance". Resilience was also positively related to self-esteem and physical, mental and general health. As far as personality traits are concerned, resilience was positively correlated with Reward dependence, persistence, self transcendence, self directedness and cooperativeness.

Conclusions Since higher resilience levels are related with better physical and mental health, constructive coping and self-esteem, strategies aimed at enhancing resilience could improve treatment and quality of life in patients with mood disorders.

The impact of early affiliative memories on psychological health: The mediator role of external shame and cognitive fusion

C. Ferreira^{*}, A.L. Mendes, J. Marta-Simões, I.A. Trindade
Faculty of psychology and educational sciences, university of Coimbra, CINEICC, cognitive behavioural centre for research and intervention, Coimbra, Portugal

* Corresponding author.

Early positive interactions have been positively associated with positive mental health outcomes. In contrast, the lack of these early affiliative experiences of warmth and safeness can have negative consequences on the individual's physical, emotional and social development.

The current study tests a mediation model that examines the mediator effect of external shame and cognitive fusion on the association between early affiliative memories with attachment figures and

with peers, and psychological quality of life. These analyses were conducted using a sample of 453 participants from the community. The final model explained 47% of psychological quality of life and presented excellent model fit indices. Results from path analysis showed that both early affiliative memories of warmth and safeness with peers and attachment figures present a significant impact on psychological quality of life through the indirect effect of external shame and cognitive fusion. In fact, although early affiliative memories with peers also presented a direct effect on psychological quality of life, the impact of early affiliative memories with attachment figures on this outcome was totally mediated through the mechanisms of external shame and cognitive fusion.

These findings seem to provide an important contribution to the field of early affiliative memories of warmth and safeness with attachment figures and with peers by uncovering the mediating role of external shame and cognitive fusion. Furthermore, these data highlighted the relevance of developing intervention programs in the community, especially in a context of early adverse experiences, for the promotion of mental health well-being.

Image of psychiatric hospitals among general population in 2015, views from four countries

A. Fontaine

Lille 2 university of health and law, psychiatry, Lille, France

Introduction In recent years, numerous studies about the image of psychiatry have been conducted. However, to our knowledge, a significant part of psychiatry has been very little explored: the vision of psychiatric hospitals (PsH). For instance, “PsH” on google images reveals a long list of frightening pictures of ravaged places.

Objectives/Aims With such an image spread by the medias, we wanted to evaluate the vision of PsH and treatment modalities among general population in 2015, in 4 countries: France, Spain, England, and Brazil.

Methods An online survey in 4 languages has been sent via facebook and emails. Two hundred and fifteen responses were collected during September 2015: 178 French, 11 Spanish, 17 Brazilians, 9 English.

Results Thirty-nine percent of participants consider PsH as a place of care, and 16% as an asylum. There were differences among countries: for example, asylum is more represented in France than Spain. Regarding patients admitted in PsH, they are not all dangerous (90%), nor all irresponsible (94%) and have specific rights (66%). Concerning diseases: delirium, bipolar disorders, and perversity are to be treated in PsH, while depression, addiction, and autism are to be cured in psychiatric structures other than hospital. Moreover, 2% of participants believe abuses are common practice, whereas a majority consider therapeutic activities instead.

Conclusions These results are quite different from the studies based on the perception of mental illness and patients. Here, on the overall, they are quite encouraging. So, PsH could lead the path on the improvement of the image of psychiatry.

Acceptability and feasibility of the mindfulness based program for infertility (PBMI)

A. Galhardo^{1,2,*}, M. Cunha^{1,2}, J. Pinto-Gouveia²

¹ Miguel Torga institute, psychology, Coimbra, Portugal

² Faculty of psychology and educational sciences, university of Coimbra, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Infertility is described as a low-control stressor that may induce psychopathological symptoms. The Mindfulness Based Program for Infertility (MBPI) is a structured intervention targeting infertile women that aims to cultivate mindfulness and acceptance skills. The MBPI efficacy was tested in 55 infertile women who completed the program and 37 women in a control group. By the end of the MBPI, women who attended the program revealed a significant decrease in depressive symptoms, internal and external shame, entrapment and defeat. Inversely, they showed significant improvement in mindfulness skills and self-efficacy to deal with infertility.

Aims Determine the MBPI feasibility and acceptability.

Methods The MBPI includes 10 weekly sessions, in a group format, with the duration of about 2 hours each. Participants' recruitment was supported by the Portuguese Fertility Association. Fifty-five female participants with an infertility diagnosis who were pursuing medical treatment for infertility completed a questionnaire specifically developed to address the acceptability and satisfaction with the MBPI at the end of the 10th session.

Results Participants scored as “very useful” most of the MBPI components (mindfulness practice, acceptance skills, values clarification, psychoeducation on stress and fertility-related lifestyle factors), except for the yoga component. The same pattern was found for the utility information, group support, small group exercises, contact with the therapist, progress notes and MBPI materials. The mean score for satisfaction with the therapist knowledge/competence was 9.55 (maximum: 10), the MBPI quality 8.91 and the MBPI global utility 8.95.

Conclusions The MBPI showed to be feasible and well accepted by participants.

Applications of classical and traditional folk music in psychiatric settings

V. Giannouli*, N. Syrmos

Aristotle university of Thessaloniki, school of medicine, Thessaloniki, Greece

* Corresponding author.

Introduction Although there is an augmenting interest for the applications of classical music in psychiatry, traditional folk music is not properly highlighted in the literature.

Objective In this paper, we examine the possible benefits that psychiatric patients who attend music therapy in psychiatric settings may have when traditional folk music and/or classical music are used in the process of rehabilitation.

Method A literature search of the electronic databases was performed to identify relevant studies published before June 2015.

Results A meta-analysis of the existing research revealed the positive influence of passive and active music listening on different groups of neurological and psychiatric patients' anxiety, pain, tension and stress, and a series of cognitive and emotional changes that occur due to music interventions on patients and doctors alike. A general finding from the 700 diverse retrieved articles is that classical music has a positive influence on psychiatric patients. In contrast to that, there is scarce research for traditional music in psychiatric settings.

Conclusions Music has a strong influence on psychiatric patients. Future research should focus on different questions such as how the knowledge of the varieties of the different types of (folk) music can enrich the music therapy in psychiatric settings.

Burnout Y health professionals

S. Goretti^{1,*}, M.C. Sanchez Sanchez¹,
M.T. Lorente Molina¹, A. Rodriguez Chinchilla²,
B. Gongora Oliver³, P. Ortega Gutierrez¹

¹ U.G.C Almeria, UHSM Torrecardenas, Almeria, Spain

² U.G.C. Almeria, USMI-J Almeria, Almeria, Spain

³ U.G.C. Almeria, Aecc Almeria, Almeria, Spain

* Corresponding author.

Introduction The “Burn-out” syndrome is a kind of labour stress produced in professions that require constant and direct relationship with other people. Health professionals, and particularly especial-care services such as Oncology, live under stressful labour conditions linked to the great responsibility that goes with their job. The emotional attachment with the patient, which may be in grave conditions and could even die, or a professional care which may not bring about improvement for the patient, represent a source of burn-out for many professionals resulting in psychopathological symptomatology.

Objective If we know the triggers and sources of burnout, we can find several coping strategies that facilitate the management of stress in health professionals.

Method Managing stress entails being aware and handling the various factors that intervene in the relationship of the professional with people and the social and labour environments.

Results The control of the patient, professional and contextual factors is of paramount importance in order to avoid the direct consequences of the burn-out of health professionals and health institutions themselves. This control over the factors which trigger off the burn-out will provide the preventive aspect that an advanced society pursues for the improvement of health and quality of life.

Conclusions The burn-out is an inappropriate confrontation or a failure of the adjustment responses to the demands that exceed the capacity of the individual. This syndrome give rises to negative attitudes towards work, life and people.

Exploratory study about the image of mental illness in health professionals

S. Goretti^{*}, M.T. Lorente Molina, P. Ortega Gutierrez,
M.C. Sanchez Sanchez

U.G.C. Almeria, UHSM Torrecardenas, Almeria, Spain

* Corresponding author.

Introduction Stigma towards people diagnosed with a mental disorder is a phenomenon that has been observed in different contexts (labor, health, social, media), affecting therefore to different walks of life of the person who has it. One area where greater negative impact exerted by the stigma and discrimination associated is in health care.

Objective Knowing what is the image of mental disorders and people who experience them by health professionals from different specialist who don't work in mental health area.

Method Exploratory, observational, cross-sectional study.

Participants One hundred and fifty medical professionals from different specialties Torrecardenas CH.

Instruments Castilian translation of the Opening Minds Stigma Scale for Health Care Providers, developed by the Mental Health

Commission of Canada. Score from 0 to 80. Higher scores indicate a stigmatizing attitude.

Results Of established comparisons have only found statistically significant differences between men and women in attitudes towards disclosure of diagnosis and seeking help.

Conclusions Despite the study's limitations, the data show a trend of response points to a positive attitude towards people diagnosed mental disorder in the health field, while being reflected as feelings of guilt and fear of a possible employment discrimination continue to differentiate mental illness with respect to other diseases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“The wounded healer” challenging the stigma attached to mental health conditions in medical students and doctors

A. Hankir^{*}, R. Zaman

Cambridge university, psychiatry, Cambridge, United Kingdom

* Corresponding author.

Despite the perception that medical students and doctors should be “invincible”, mental illness is over-represented in this group. Fear of exposure to stigma is a major barrier to accessing the health services and many people with mental illness continue to suffer in silence despite the availability of effective treatment. In 2014, we conceived the contact-based, anti-stigma intervention, “The Wounded Healer” (TWH) which has been described as an innovative method of pedagogy that blends science with art. The main aims of TWH are to engage, enthuse, enthrall and to educate in order to challenge mental health stigma, debunk myths and encourage help-seeking. Hitherto, TWH has been delivered to more than 10,000 people in 15 medical schools throughout the UK and worldwide in USA, Canada, Colombia, Portugal, Italy, Slovenia and Lebanon. TWH has been integrated into the curricula of several UK medical schools and filmmakers from the London College of Communication have successfully secured funding to commission the production of TWH film. The written feedback received from audiences (which has been published in peer-review journals and book chapters) is that TWH is inspirational and the best performance they have ever experienced. Moreover, TWH was delivered in the 2015 iMed 7.0 Congress in Lisbon, Portugal (the largest medical student congress in Europe, $n = 1000$) alongside a Noble Laureate and students report that it inspired them to consider a career in psychiatry. AH is the only early-career psychiatrist to have been shortlisted for the 2015 RCPsych Communicator of the Year Award in recognition of TWH.

Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The work describes a well-succeeded experience in the utilization of art therapy in a psychiatric clinic in the city of Rio de Janeiro, Rio de Janeiro, Brazil. The clinic is concentrated on the treatment of diverse mental disorders, in special, the disorder due to the use of psychoactive substances.

Objective To present new and creative therapeutic ways inside the hospital for the treatment of patients having diverse psychiatric

disorders, especially disorders due to the use of psychoactive substances.

Aims Demonstrate the decrease of resistance to the treatment under the hospital system, the strengthening of the therapeutic alliance, the appreciation of the therapeutic space and the well-being promotion during the treatment.

Methods One hundred and twenty patients, in a clinic for psychiatric treatment, participated in this therapeutic project, which offered psychological treatment through artistic and creative processes, promoting the possibility of experiencing their recovery through the realization of a Carnival programming inside the therapeutic setting.

Results All patients showed good acceptance to the workshops and participated in the presentations. Over the workshops, the patients also received therapeutic approaches and worked personal difficulties, which came up along the therapeutic process.

Conclusions Through the project development, the patients showed excellent investment and appreciation of the alliance and therapeutic space, demonstrating the great potential of the psychological treatment, through the creative processes of art therapy.

Mental health, self-compassion, organizational virtuosity and commitment in workers from local administration

D. Simões, S. Simões, H. Espírito-Santo, D. Simões, M. Marques, L. Lemos*

Miguel Torga institute, psychology, Coimbra, Portugal

* Corresponding author.

Introduction Positive and organizational psychology can offer an important contribution to strengthen human virtues that protects intra- and interpersonal functioning, which, in turn, might enhance worker's well-being and the success of organizations.

Objective To study the associations between a psychological construct, self-compassion, and some organizational constructs, organizational commitment and organizational virtuosity and to explore differences in each construct by gender, age, working time (in the organization), type of employment bond and professional group.

Aims Positive actions inside organizations promote positive emotional states.

Method One hundred and thirty workers from local administration (men, $n = 78$; 60%; age, $M = 44,22$; $SD = 8,67$; range = 19-63 years old) filled in the Self-Compassion Scale, the Organizational Commitment Questionnaire, the Organizational Virtuosity Questionnaire and the Depression, Anxiety and Stress Scales.

Results There was a positive association between organizational commitment and organizational virtuosity. Optimism and integrity (organizational virtuosity dimensions) positively correlated with the self-criticism dimension and with self-compassion total score. Some dimensions of mental health (depression and stress) were negatively associated with organizational virtuosity. Employees with less education, belonging to a professional group less qualified or with an unfavourable employment bond perceived the organization as less virtuous, and were less committed.

Conclusion Promoting positive actions inside organizations seem to encourage positive emotional states in individuals. The development of a compassionate capacity, by self-compassion and mindfulness, humanize both individuals and organizations. These workers, with their leaders, can promote affective and normatively committed workforces, presenting positive perceptions about organizational virtues.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The use of drugs to improve cognitive performance (pharmacological enhancement) is a practice that increases in frequency, especially in individuals with a high degree of academic education, university students, and workforce with high responsibilities. Legal substances such as alcohol and caffeine, prescription drugs such as modafinil or methylphenidate and some illegal drugs such as amphetamines or cannabis are utilized to improve cognitive performance, maintain wakefulness, or induce sleep. Perception of risk is low in many cases. Internet has facilitated the illicit access to prescription drugs with astonishing ease.

Objective and methods We want to exemplify through a clinical case, how the access to some of these substances through internet is very easy, and how, in this case, the use of Modafinil (drug indicated for narcolepsy) with the objective of maintaining academic performance aggravates symptoms of anxiety in a 22-year university patient.

Results Exposition of clinical case in the poster.

Conclusions The use of substances ("smart drugs") presents risks for both physical and psychological health that sometimes are not perceived by the user. It is surprising that a highly educated individual has taken Modafinil without researching for a deep understanding of the side effects of the drug.

Internet access of regulated substances that should only be prescribed by a physician to be used on very concrete symptoms is extremely easy. In the case of the Modafinil, it is possible to access its purchase by simply searching the words "purchase/buy Modafinil" in any internet browser.

Mental health and empathy: Do nursing students have better attitudes to psychiatric patients?

M. Pascucci^{1,*}, F. Capobianco¹, M. La Montagna¹, E. Stella¹, A. Ventriglio¹, G. Rubini¹, A. De Angelis², P. Parente³, L. Janiri², G. Pozzi², V. Di Nunzio¹, G. Piemontese¹, A. Bellomo¹

³ *Catholic university of the Sacred Heart, institute of hygiene and public health, Rome, Italy*

* Corresponding author.

Background Stigma towards mental illness has a major impact on the quality of life and the health care of psychiatric patients. Several studies have reported that health professionals have more negative attitudes than general population.

Aims To explore empathy and attitudes towards mental illness in nursing students (NS) and non-health university students. Our purpose is to see how NS have more empathic and less stigmatizing attitudes towards psychiatric patients, compared to other university students.

Methods We tested 96 university students (50 NS and 46 non-health university students), with the following questionnaires anonymously filled out:

- Community attitudes towards mental ill (CAMI), to evaluate the different students' attitudes towards mental illness;
- Empathy quotient (EQ), to assess empathy.

Results NS differs from the other group in 5 items of CAMI ($P < 0.05$ in 3 items and $P < 0.01$ in 2 items), and Authoritarianism subscale ($P = 0.023$). This shows that NS have a greater general awareness and less stigmatizing attitudes about the need to hospitalize the mentally ill, the difference between psychiatric patients and general population, the wrong need of segregation and the real causes of mental illness. There is also a significant difference in EQ (items 6, 21, 25, 44, 59): future nurses seem to have a slightly higher empathy, even though the EQ total score does not differ in the two groups.

Conclusions These results suggest that there is a difference with respect to the attitudes towards psychiatric patients in NS and students who do not follow health-care courses: NS have more empathetic and less stigmatizing attitudes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Different attitudes toward psychiatry and psychiatric patients in nursing students: Can personal experiences reduce stigma?

M. Pascucci^{1,*}, G. Rubini¹, E. Stella¹, M. La Montagna¹, F. Capobianco¹, A. Ventriglio¹, A. De Angelis², P. Parente³, L. Janiri², G. Pozzi², V. Di Nunzio¹, G. Piemontese¹, A. Bellomo¹

¹ University of Foggia, institute of psychiatry, Foggia, Italy

² Catholic university of the Sacred Heart, department of psychiatry, Rome, Italy

³ Catholic university of the Sacred Heart, institute of hygiene and public health, Rome, Italy

* Corresponding author.

Background Psychiatric patients often do not receive the same health treatment reserved for patients with no mental disorders. Stigma in mental-health nurses can worsen the patients' healing time and quality of care.

Objective To explore the different attitudes towards mental illness and psychiatry in nursing students (NS) of the first and the final year of university, and the importance of having visited a psychiatric ward and having known a psychiatric patient.

Methods Fifty NS completed the following tests:

- Community attitudes towards mental ill (CAMI);
- Attitudes towards psychiatry (ATP-30);
- Empathy quotient (EQ).

Results NS of the final year differ significantly from those of the first year in 4 CAMI items, in Authoritarianism subscale ($P = 0.041$), Social Restrictiveness ($P = 0.029$) and Community Mental Health Ideology ($P = 0.045$), indicating a more mature and responsible approach to psychiatric patients, without considering them a threat to be secluded. EQ does not show a significant difference in empathy, not even considering the individual items. Final year NS also have more positive attitudes toward Psychiatry in 3 ATP-30 items

and total score ($P = 0.01$). Those who visited a psychiatric ward have more positive attitudes towards mental illness and Psychiatry, in 6 CAMI items and 3 ATP-30 items. Having personally known a psychiatric patient leads to positive attitudes in only a few CAMI items.

Conclusions Last-year NS, who have had more direct relationships with patients through practical training, have more empathetic and less stigmatizing attitudes. It is also very useful to attend a psychiatric ward during the nursing training.

The development of headucate in mental health awareness

A. Patel*, V. Soundararajan, J. Beezhald
University of East Anglia, Norfolk and Suffolk NHS foundation trust,
Norwich, United Kingdom

* Corresponding author.

Introduction Headucate is a pioneering student-led society at the University of East Anglia (UEA), founded in 2012. Mental health stigma exists widely and is a well-known barrier to accessing support. This presents a need for education and raising awareness about mental illness.

Objectives The goal is to spread mental health awareness locally, measured by school outreach and events organised. This is achievable through Headucate's collaboration with the university and schools to convey the message each year.

Aims Headucate aims to raise mental health awareness and tackle stigma, with the intention of reaching the university, schools locally and communities nationally.

Methods Headucate delivers workshops for secondary schools. This involves interactive sessions to stimulate discussions about mental health and illness, and where to find help. Additionally, there are university-held talks from a variety of guest speakers who are experts in this field.

Results It has expanded beyond medical students to involve the whole university, with a shared interest in mental health awareness. Research conducted by Headucate in 2014-2015 has indicated there is a statistically significant ($P < 0.001$) increase in the knowledge about mental illness and knowing where to get help following school workshops.

Conclusions The success has transformed from starting as an idea into one of UEA's largest student societies which will continue to expand. Future goals include a mental health awareness campaign and collaborating with student groups at the university, to host events that link mental health to other causes. Furthermore, Headucate is hoping to expand outreach to the elderly community.

Factors influencing attitudes towards seeking professional psychological help: Findings from a multi-ethnic Asian population-based study

L. Picco*, E. Abdin, S.A. Chong, S. Pang, S. Shafie, J. Vaingankar, M. Subramaniam

Institute of mental health, research, Singapore, Singapore

* Corresponding author.

Introduction Various socio-demographic variables have been shown to influence attitudes towards seeking professional

psychological help (ATSPPH), while negative ATSPPH can act as a barrier to mental healthcare, resulting in under-utilization of psychological services.

Aims and objectives To explore the factor structure of the ATSPPH scale and determine whether any significant socio-demographic differences exist in relation to ATSPPH among a nationally representative sample.

Methods Data was extracted from a population-based, cross-sectional survey conducted between March 2014 and March 2015 among Singapore Residents aged 18–65 years ($n = 3006$). Respondents completed the 10-item ATSPPH scale and also provided socio-demographic information. Exploratory factor analysis (EFA) was performed to establish the factor structure of the ATSPPH scale. Multivariable linear regression analyses were conducted to examine socio-demographic factors associated with ATSPPH.

Results EFA revealed that the ATSPPH scale formed three distinct dimensions comprising “Openness to seeking professional help”, “Value in seeking professional help” and “Preference to cope on your own”. Higher “Openness to seeking professional help” scores were significantly associated with 18–34-year-olds and unmarried respondents, whilst Malay ethnicity and lower education were significantly associated with lower openness scores. Malays, Indians and lower education were significantly associated with lower “Value in seeking professional help” scores, whereas higher “Preference to cope on your own” scores were significantly associated with lower education.

Conclusion Population subgroups including those with lower educational levels and different ethnic groups have more negative ATSPPH. Tailored, culturally appropriate educational interventions which reduce negative ATSPPH are needed, which effectively target these populations.

Risk factors for mental health in higher education students of health sciences

R. Porta-Nova

Escola Superior de Saúde da Cruz Vermelha Portuguesa, Lisbon, Portugal

Introduction The mental health of students, attending higher education in the area of Health Sciences, may be conditioned by factors which may affect them as a person, their relationships and their academic performance, placing in cause its adaptation.

Objectives Identify the main risk factors for mental health, associated with the academic life experiences in students of Health Sciences.

Aims Contribute to the implementation of prevention strategies of mental health problems in these students.

Methods The research dealt with a sample of 620 people, medical students, nursing students and allied health students: physiotherapy, cardiopulmonary technology and radiographer, whose average age is 20.3 and ranges between 18 and 25 years old, being 81% female. The instruments used were a Demographic Questionnaire; Academic Life Experiences Questionnaire (Almeida & Ferreira, 1997, 1999) and Mental Health Inventory (Veit & Ware, 1983).

Results The results show that attend the 1st year in the course of physiotherapy, belong to the female gender, being displaced, have a lower expectation of career, not be autonomous, show a negative perception of their cognitive skills, lower self-confidence, decreased of psychological and/or physical well-being, academic difficulties resulting from deficient knowledge bases and high levels of anxiety in the evaluation situations, are associated with poorer mental health.

Conclusions Calls up a special attention from the different structures of Higher Education institutions, namely, governing bodies, teachers and academic services, to reduce the negative impact of these risk factors and implementing strategies to prevent the incidence of mental health problems in this population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dermatologists, acne and psychological counseling

C. Rebelo-Neves^{1,*}, C. Amaral Dias², J. Torgal³

¹ Lisboa, Portugal

² ISMT, psychology, Coimbra, Portugal

³ FCM-UNL, Public Health, Lisboa, Portugal

* Corresponding author.

Introduction In psychotherapeutic clinic, patients without visible marks of acne report this experience with great emotional charge, even when it occurred many years before.

Objectives This observation arose the interest in investigating the psychological impact of acne, which led us to find out what acneic subjects think of their disease, how they deal with it and, simultaneously, evaluate the beliefs of dermatologists on it. The present work is part of an investigation whose aim is to develop a program for the promotion of skills to deal with acne and its effects.

Methods The inventory of beliefs, behaviours and treatment of acne – ICA – was developed through the content analysis of non-structured interviews to health care professionals and to patients with acne and/or who had it. This inventory was applied to a convenience sample ($n = 367$), to a university sample ($n = 1666$) and to a sample of 95 dermatologists – the 16 questions related to the beliefs on acne.

Results We found general agreement with some statements. Most respondents agree with a group of statements, though opinions are divided. Most respondents “disagree” or “disagree more than agree” with “...ingestion of chocolates or dairy products would cause acne”. Finally, there is no consensus about “...caused by the combination of psychological and hormonal factors”.

Conclusions Further studies are needed, on the impact of acne in patient’s quality of life. We also found great interest of promoting a close collaboration between dermatologists and psychology.

The perceived problem solving skill of Iranian nursing students: A cross-sectional study

Z. Moshirabadi^{1,*}, H. Haghani², L. Borimnejad³

¹ Iran university of medical sciences, faculty of nursing and midwifery, Tehran, Iran

² Iran university of medical sciences, biostatistics, Tehran, Iran

³ Iran university of medical sciences, nursing care research center, Tehran, Iran

* Corresponding author.

Background The ability to solve problems and make decisions creatively has become paramount to new nursing graduates, as these skills assist them with recognizing and evaluating situations that require prompt attention. The purpose of this study was to determine and compare nursing student’s perceived levels of own problem solving skills in various years of their 4-year program.

Methods This is a cross-sectional study. Three hundred and twenty-two undergraduate nursing students in BSc nursing

program participated in this study. The study setting was nursing School of Iran university of medical sciences. The Problem solving inventory (PSI) was used to data gathering. The scale was divided into three subscales including: problem-solving confidence (PSC), approaching avoidance style (AAS), and personal control (SC). Students involved in the study signed the study Informed consent.

Results Findings showed that the mean score of total problem solving skill was 89.52 ± 21.58 . The mean score of the 4th year students in PSI was less than other year students (84.18 ± 27.47 vs 89.13 ± 18.71 , 91.57 ± 21.87 , and 91.52 ± 20.8). This study finding revealed that 4th year students in 3 factors of problem solving (PSC, AAS, PC) considered themselves more successful than others. Meanwhile, when the results are compared according, no significant differences occurred among the student in different years ($F: 1.46, P \leq 0.22$).

Conclusion Educating should help students to reach the desired levels of problem solving skills by allowing them to acquire and practice these abilities in the field. Nursing students with advanced problem solving skills will be essential for this changing society.

Stigma: Dimensions and correlates in a multi-ethnic population

M. Subramaniam^{1,*}, E. Abdin¹, L. Picco¹, S. Pang¹, S. Shafie¹, J. Vaingankar¹, K.W. Kwok², K. Verma¹, S.A. Chong¹

¹ Institute of mental health, research, Singapore, Singapore

² Nanyang technological institute, sociology, Singapore, Singapore

* Corresponding author.

Introduction Mental health stigma is a multidimensional concept that encompasses many different themes and definitions. Public stigma is defined as the degree to which the general public holds negative views and discriminates against a specific group.

Objective To understand the context and correlates of stigma in multi-ethnic Singapore.

Aims The current study aimed to (i) explore the factor structure of the Depression Stigma Scale and the Social Distance Scale using an exploratory structural equation modelling approach and (ii) examine the correlates of the identified dimensions of stigma in the general population of Singapore.

Methods Data for the current study came from a larger nationwide cross-sectional study of mental health literacy conducted in Singapore. All respondents were administered the Personal and Perceived scales of the Depression Stigma Scale and the Social Distance scale to measure personal stigma and social distance respectively.

Results The findings from the factor analysis revealed that personal stigma formed two distinct dimensions comprising "Weak-not-Sick" and "Dangerous/Unpredictable" components while social distance stigma items loaded strongly into a single factor. Those of Malay and Indian ethnicity, lower education, lower income status and those who were administered the depression and alcohol abuse vignette were significantly associated with higher weak-not-sick scores. Those of Indian ethnicity, 6 years of education and below, lower income status and those who were administered the alcohol abuse vignette were significantly associated with higher dangerous/unpredictable scores.

Conclusion There is a need for well-planned and culturally relevant anti-stigma campaigns in this population.

Hospitalization durations and remission rates of patients in a psychiatry clinic

R. Tutuncu*, H. Kullakçı, B. Hakan, A. Algul, A. Ates, C. Basoglu
Gulhane military medical academy, Haydarpaşa research and training hospital, psychiatry, Istanbul, Turkey

* Corresponding author.

Objective The duration of hospitalization is related to many well-documented factors in literature. However, little is known about psychiatric patients and psychiatric service delivery in non-Western developing countries. It is supposed that major contributing factors in discharge are remission rates and functional levels. Therefore, this naturalistic preliminary study aimed at analyzing and describing the hospitalization duration and remission rates of a psychiatric population treated in the mental health inpatient facility.

Methods A total of 88 male patients, who were hospitalized in a psychiatry clinic were included in the study. They were evaluated at admission and before discharge using the Brief Psychiatric Rating Scale (BPRS) and the Clinic Global Impression Scale (CGI). Other variables, including length of stay, number of previous admissions, demographic characteristics, and diagnosis were also assessed.

Results Mean of the total scores on BPRS were declined from 24.95 to 13, and the mean CGI scores were declined from 3.85 to 2.04 during hospitalization period. Mean length of hospitalization was 7.91 days.

Conclusion Our study shows that patients are discharged from the hospital with approximately 50% decrease in symptom severity. Such research can contribute to understand better, the needs of psychiatric patients, and help to develop continuously improved service delivery and optimize therapeutic options.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Positive mental health in individuals with mental disorders

J. Vaingankar*, M. Subramaniam, E. Abdin, R. Sambasivam, A. Jeyagurunathan, E. Seow, S. Pang, L. Picco, S.A. Chong
Institute of mental health, research division, Singapore, Singapore

* Corresponding author.

Introduction Given the emphasis on inclusion of well-being interventions in the treatment and rehabilitation of individuals with mental disorders, it is important to understand the level and determinants of positive mental health (PMH) among them.

Objective To conduct a cross-sectional study among patients with schizophrenia, depression and anxiety spectrum disorders to estimate PMH.

Aims (i) To estimate the level of PMH among patients with mental disorders and compare these with the established general population estimates; (ii) to identify socio-demographic and clinical determinants of PMH.

Methods Following ethics approval, 353 patients aged 21-65 years, receiving treatment at a psychiatric hospital in Singapore for schizophrenia, depression or anxiety spectrum disorders were included. Patients provided socio-demographic information and completed the multidimensional PMH instrument that provides total and domain-specific scores ranging from 1 to 6; higher scores indicate better PMH. Functioning was assessed with the Global Assessment of Functioning (GAF) scale and clinical data were obtained from administrative databases.

Results Sample comprised 142, 139 and 72 patients with schizophrenia, depression and anxiety spectrum disorders respectively, with a mean age of 39.2 years. Mean total PMH scores among them were 4.2, 3.7 and 3.8 respectively which were significantly lower than the general population mean of 4.5 ($P < 0.001$). Patients of Chinese ethnicity, with lower education, depression or anxiety, and lower GAF scores were more likely to have lower PMH.

Conclusions This study identified patient subgroups that are likely to have poorer PMH. Interventions facilitating PMH among these patient groups would be beneficial and are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV951

To the question of destigmatization of psychiatry and mentally ill persons in the modern society

S. Vladimirova^{1,*}, V. Lebedeva², E. Gutkevich³, A. Semke³, N. Bokhan⁴, N. Garganeeva⁵

¹ Mental health research institute, department of coordination of scientific research, Tomsk, Russia

² Mental health research institute, clinics, Tomsk, Russia

³ Mental health research institute, endogenous disorders department, Tomsk, Russia

⁴ Mental health research institute, addictive states department, Tomsk, Russia

⁵ Siberian state medical university, department of primary care therapy, Tomsk, Russia

* Corresponding author.

In recent decades, new medications have been developed that entailed possibility of rehabilitation and socialization of mentally ill persons.

Purpose To consider a phenomenon of destigmatization of mentally ill persons on the example of the analysis of screening-questioning in mental health service.

Methods Randomized screening-questioning of participants of Open Doors Day in the clinics of Mental Health Research Institute (Tomsk, Russia) in connection with World Mental Health Day in October, 2015.

Results One hundred and forty-six residents of Tomsk and inhabitants of the Tomsk Region as well as other cities visited Mental Health Research Institute. 76.5% of them visited mental health service for the first time. More than a half of visitors (51%) was the most able-bodied age group – 20–50 years old; elderly people – 20%. According to many-year observation of authors of the work, there is a gradual destigmatization of people with mental health problems. Process of destigmatization will develop further, and mass media should also be engaged in it. One more moment should be emphasized – reduction of self-stigmatization. Though people do not still aim to seek for psychiatric help at the appropriate institutions (they prefer to visit the psychiatrist of the catchment area polyclinic), they after all started recognizing presence of the problem, understanding the need of its overcoming, and possibility of its correction.

Conclusion The attitude of society towards people with mental health problems and towards psychiatry reasonably changes, and this promotes further development in the field of help to patients and their relatives.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effectiveness of a school-based universal prevention program for enhancing self-confidence: Considering the extended effects associated with achievement of the direct purposes of the program

K. Yamasaki^{1,*}, Y. Murakami², T. Yokoshima², K. Uchida¹

¹ Naruto university of education, department of human development, Naruto, Japan

² Naruto university of education, center for the science of prevention education, Naruto, Japan

* Corresponding author.

Introduction We have developed a group of school-based universal prevention programs for children's health and adjustment. The programs are characterized by new theories such as the somatic-marker hypothesis and enjoyable methods that utilize animated stories and games. This study adopted one of the programs for the development of self-confidence.

Objective The aim was to examine the effectiveness of the program. In addition to the direct purposes of the program, children's adjustments at school and homeroom class were evaluated as extended effects.

Methods Participants were third grade children in six public elementary schools in Japan. The final sample included 442 children (219 boys and 223 girls). The program was implemented weekly in one regular 45-minute class over 8 weeks. Participants completed a battery of three questionnaires three times, 1 month before the start of the program (T1), 1 week before the start of the program (T2), and during 1 week after the last class of the program (T3).

Results Results showed that all of the main endpoints of the program significantly improved in the intervention condition (i.e., changes from T2 to T3), compared to the control condition (i.e., changes from T1 to T2). Moreover, children's adjustment at school and homeroom class increased in the intervention condition, compared to the control condition. However, implicit affect was unchanged.

Conclusion This study suggests that the program is effective for enhancing self-confidence, along with adjustments at school and in class. Future research that examines the sustainability of the effectiveness of the program is planned.

* Corresponding author.

Introduction The prevalence and impact of allergic diseases continues to grow, yet the etiology remains unclear. Adverse childhood experiences (ACEs) have shown to influence the risk of various chronic diseases, but little research has been done on the risk of allergic diseases, and only on asthma.

Objective To conduct a prospective study that assess the relationship between ACE and risk of various allergic diseases.

Aims To examine the association between ACE and risk of allergic diseases in the context of: (1) relevant ACE and allergic disorder grouping; (2) temporal association; (3) dose-response relationship.

Methods A prospective population-based study linking Danish register data on 1.1 mio parent-child pairs. With objectives, measures of ACE and allergic diseases survival analyses with relevant covariates adjusting will be used to estimate relative risk of allergic diseases when exposed to ACE.

Results This study will provide results on the relative risk of allergic diseases when exposed to ACE compared to those without, while also describing the temporal and dose-reponse of the relationship.

Conclusion This preliminary study will help to further advance our understanding on ACE influence on physical health, specifically in regards to immune-related disorders. As such, this study may help to build a framework for future prevention and treatment initiatives of allergic disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Isolated psychiatric presentation of anti N-methyl-D-aspartate receptor encephalitis: A case report

P. Azevedo^{1,*}, F. Monteiro¹, A.P. Correia², A. Norton¹, A.M. Moreira¹

¹ Magalhães Lemos hospital, inpatient unit C, Porto, Portugal

² Magalhães Lemos hospital, department of neurology, Porto, Portugal

* Corresponding author.

Introduction Anti N-Methyl-D-Aspartate receptor (NMDAR) encephalitis is an autoimmune disorder with a presentation that includes acute behavioral changes, psychosis, cognitive impairment and autonomic instability. In some cases, there are isolated psychiatric symptoms without neurological involvement.

Aims To raise awareness of the disorder among psychiatrists, considering it a differential diagnosis in a first psychotic episode since a prompt diagnosis and treatment can dramatically affect the outcome.

Objectives To summarize the latest literature about this field and to present a case report.

Methods A brief review of the latest literature was performed on PubMed using the keywords “anti N-methyl-D-aspartate receptor encephalitis”, “anti-NMDA encephalitis”, “psychiatric symptoms”.

Results A 20-year-old male was admitted to our inpatient unit with bizarre delusions of grandious and religious content, somatic hallucinations, sleep cycle inversion and strange behaviour. These symptoms had been present for 1 week and remitted after 10 days of treatment with risperidone. On follow-up, he developed anhedonia, apathy and blunt affect. Brain MRI showed multiple hyperintense changes in T2 and T2-FLAIR, highly suggestive of demyelinating lesions. The cerebrospinal fluid showed mild lymphocytic pleocytosis, mildly increased proteins, oligoclonal bands and anti-NMDAR antibodies of intrathecal production. He was treated with corticoids and the antipsychotic was discontinued. No neurologic symptoms were ever present.

Conclusion This is an atypical case of anti-NMDAR encephalitis because of its isolated psychiatric presentation. Most patients develop neurological symptoms 2 to 3 weeks after onset of psychiatric symptoms. Monosymptomatic syndromes arise in less than 5% of patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV955

A phenotype of resiliency? Cross-sectional psychobiological differences between caregivers who are vulnerable vs. resilient to depression, and controls

F.S. Bersani^{1,*}, O. Wolkowitz², E. Epel²

¹ Sapienza university of Rome, department of neurology and psychiatry, Roma, Italy

² University of California San Francisco, department of psychiatry, San Francisco, USA

* Corresponding author.

Introduction Being a caregiver of chronically ill children is a source of chronic-psychological stress affecting general physical and mental health. However, there is tremendous variance among caregivers: some may develop stress-related depression, whereas others are more “resilient”. The objective of the study was to phenotypically differentiate on psychobiology caregivers who developed depressive symptoms (“vulnerable”) vs. those who did not (“resilient”) from each other and from age-matched controls.

Methods Forty-five mothers of chronically-ill children and 18 controls have been examined. Caregivers were divided via a median split of Center for Epidemiological Studies Depression Scale scores in “resilient” (RCs) and “vulnerable” (VCs). We assessed cognitive, affective, metabolic, neuroendocrine and oxidative markers at rest and in response to a laboratory social stressor. ANCOVAs and Bonferroni post-hoc tests were used to examine between-group differences.

Results Although RCs compared to VCs had similar levels of objective parenting-related burden ($P=0.51$), they had lower subjective distress ($P<0.01$) and higher levels of positive affect ($P=0.04$). Although RCs compared to controls had higher levels of objective parenting-related burden ($P=0.04$), they had greater cortisol suppression post-dexamethasone ($P=0.05$), lower F2-isoprostanol/vitamin E ratio ($P<0.01$) and lower fasting insulin levels ($P=0.06$).

Discussion Our results suggest that caregivers with higher resiliency demonstrate more salutary stress-related functioning in comparison with less resilient caregivers and, more surprisingly, non-caregiver controls. These findings might be interpreted in the spirit of Nietzsche’s quote “What does not kill me, makes me stronger” and of the idea that successfully overcoming adversity may be more psychobiologically beneficial than not having been exposed to any adversity.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric symptoms as onset of anti-NMDAR encephalitis

M.C. Cancino Botello^{1,*}, A. Cercos López², V. Chavarria Romero³, G. Sugranyes Ernest⁴

¹ Consorcio hospital general universitario, psychiatry, Valencia, Spain

² Hospital universitario de Santa María, psychiatry, Lleida, Spain

³ Hospital del Mar, psychiatry, Barcelona, Spain

⁴ Hospital clinic, psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Every more often, there is evidence that shows a relationship between psychiatric symptoms and autoimmune disorders. Such is the case of anti-NMDAR encephalitis, in which it

has been recently described the development of psychotic symptoms. Anti-NMDAR encephalitis is an autoimmune disorder that involves IgG autoantibodies against the NMDA receptor subunit GluN1. This last fact could support the relationship with the glutamatergic model of schizophrenia.

Objective To conduct a current review to deepen the detection and management of anti-NMDAR encephalitis, due to the frequent existence of psychiatric symptoms at onset, which have contributed to the difficulty of diagnose.

Method Systematic review of the literature in English (PubMed), with the following keywords: “Autoimmune encephalitis”, “psychosis”, and “NMDA receptor”.

Results Autoimmune encephalitis appears more frequently in children and young adults and it is characterized by a prodromal period, in which there usually are non-specific symptoms of headaches or fever. Next, it could progress to cognitive deficits, seizures, catatonic symptoms and psychosis. However, sometimes in the rarest clinical presentations, there is nothing but psychiatric symptoms at the onset of encephalitis, which leads to misdiagnose and lack of proper treatment. This fact has stimulated the curiosity of the psychiatry scientific community, since the anti-NMDAR encephalitis may mimic the glutamatergic model of schizophrenia.

Conclusions To make an accurate and detailed diagnostic formulation in people with psychiatric symptoms as onset of any disorder is essential to determine whether it is a primary psychiatric disorder or symptoms associated to another disease.

New-onset psychosis in patient with untreated HIV

A.T. Carter (MD)*, A. Bulbena (MD), N. Dunn (MD), R. Gersh (MD), R.G. Swift (MD)

Metropolitan hospital center, psychiatry, New York City, USA

* Corresponding author.

Introduction An infection by the human immunodeficiency virus (HIV) causes damage to the central nervous system directly and indirectly which can result in different psychiatric syndromes associated with the onset and progression of the infection including cognitive impairment, dementia, depression, mania, obsessive-compulsive disorder, and psychosis. We present the case of a patient that came to the outpatient psychiatric clinic with acute psychotic symptoms in the context of HIV infection and antiretroviral treatment non-adherence. She reported new onset of disruptive auditory hallucinations and paranoid delusions; at that time, all her laboratories (including for infectious disease) were within normal limits except for decreased level of CD4+ T cells and high viral load. She denied any illicit substance use and her head CT was negative for any acute disease. Patient required a brief psychiatric hospitalization where she was started on low doses of risperidone and her symptoms resolved after her CD4+ T cells and the viral load values improved secondary to the antiretroviral treatment. A review of the literature shows that psychiatric symptoms are common in patients infected with HIV. Whether these complications are due to the direct or indirect effects of HIV careful diagnosis and treatment are necessary.

Limbic encephalitis – notes for psychiatric clinical practice

F. Couto Gomes

Centro hospitalar psiquiátrico de Lisboa, psychiatry, Lisboa, Portugal

Introduction Limbic encephalitis is a neuropsychiatric syndrome with an autoimmune basis, treated with. Differential diagnosis with psychotic and mood disorders is thus essential for effective treatment and the best outcome possible.

Objectives To systematize up-to-date clinical procedures to identify possible limbic encephalitis cases and conduct proper evaluation and treatment of those cases.

Aims To improve differential diagnosis between limbic encephalitis and psychotic and mood disorders, in psychiatric clinical practice.

Methods Systematic review.

Results Limbic encephalitis presents sub-acutely with convulsions and mood, cognitive and perceptive alterations. EEG, neuroimaging, antibody testing and liquor analysis can be useful in diagnosis, and the later also in treatment response prediction. TPO, NMDA receptor, AMPA receptor, GABA-B receptor and K+ channel antibodies are etiological factors for this neuropsychiatric syndrome. Treatment consists of corticoids, immunoglobulin, plasmapheresis, rituximab, cyclophosphamide, azathioprine, mycophenolate, or the treatment of an underlying tumor.

Conclusion Proper diagnosis of limbic encephalitis may prevent disease progression and may improve outcome, according to its etiology.

Psychoneuroimmunology alternations as a comorbidity of post-traumatic stress disorder in veterans – case report

F. Đerke^{1,*}, L. Filipovic-Grcic¹, M. Braš², V. Djordjevic²

¹ University of Zagreb school of medicine, student society for neuroscience, Zagreb, Croatia

² University of Zagreb school of medicine, centre for paliative medicine, medical ethics and communication skills, Zagreb, Croatia

* Corresponding author.

Post Traumatic Stress Disorder (PTSD) is defined as an extensive response to a major traumatic event. Psychoneuroimmunology represents an integrative approach in tackling and understanding various human diseases and disorders such as cardiovascular, autoimmune and physical complaints/chronic pain. Psychosocial context influences brain stress response pathways and modifies stress-related behavior. In this case report, we observed 5 patients, veterans from Croatian War of Independence (1990-1995), who suffer from PTSD. They have altered stress reactivity, as well as distinct expression for genes involved in immune activation. Those patients have been found to exhibit a number of immune changes including increased circulating inflammatory markers, increased reactivity to antigen skin tests, lower natural killer cell activity, and lower total T lymphocyte counts. The traumatic event (Croatian War of Independence) generates downstream alterations in immune function. This case report imply that immune dysfunction caused by PTSD may mediate or facilitate somatic conditions.

Possible anti-inflammatory role of perivascular macrophages in a model of depression induced by chronic mild stress in rats

A. Sayd^{1,*}, K. MacDowell¹, L. Monteagudo¹, D. Martin¹, J.L. Madrigal¹, J.C. Leza¹, J.R. Caso¹, L. Orío², B. Garcia-Bueno¹

¹ Complutense university, pharmacology, Madrid, Spain

² Complutense university, psychobiology, Madrid, Spain

* Corresponding author.

Perivascular macrophages (PVM) are hematopoietic cells that migrate to the brain perivascular space modulating the interactions between the immune and central nervous systems (CNS). Previously, their depletion with the icv administration of the proapoptotic drug clodronate encapsulated in liposomes increased the vascular production of the proinflammatory prostaglandin E₂ (PGE₂), the release of ACTH, corticosterone and fever, induced by the intravenous administration of Lipopolysaccharide (LPS). Further studies also demonstrated a decrease in the synthesis of the anti-inflammatory prostaglandin 15d-PGJ₂.

With this background, we decide to deeper explore the mechanisms involved in the anti-inflammatory profile of PVM by depleting them in a model of depression induced by chronic mild stress (CMS) exposure in rats.

Our results showed an increase of the proinflammatory cytokines TNF α , IL-1 and IL-6 at mRNA levels in the prefrontal cortex of the groups of animals where the PVM were depleted, as well as in the protein levels of the pro-inflammatory nuclear factor NF- κ B, the enzymatic pro-inflammatory enzymatic sources iNOS, COX-2 and m-PGES-1 and their product PGE₂. A concomitant decrease of the 15d-PGJ₂ mediator was also observed. In addition, we also checked whether the depletion of PVMs could regulate the expression of molecules implicated in the leukocyte traffic and infiltration in the CNS in our CMS model. Thus, the mRNA levels of the chemokines MCP-1, fractalkine and the adhesion molecule VCAM appeared increased in the animals without PVMs.

In summary, our results could suggest a potential anti-inflammatory role for PVMs in a depression model chronic stress-induced as CMS.

Management and psychiatric manifestations of anti-NMDA receptor encephalitis, a case report

R. Gallego*, A. Flores

La Paz hospital, psychiatry, Madrid, Spain

* Corresponding author.

Introduction Anti-NMDA receptor (NMDAR) encephalitis, formally recognized in 2007 by Dalmau et al, is an autoimmune disorder with a complex presentation that includes psychiatric symptoms, memory deficits, and autonomic instability. The exact incidence is unknown but age, gender, and ethnicity may all play a role. Presence of antibodies against the GluN1 subunit of the NMDAR in the CSF and serum confirm the diagnosis of NMDAR encephalitis.

Case report We report the case of a previously healthy, 19-year-old woman, 6 weeks pregnant. She had a generalized tonic-clonic seizure followed by psychiatric symptoms, including insomnia, emotional lability, delusions, and disorganized behavior. During the course of the disease, she demonstrated speech impairments and catatonic features associated with abnormal movements. She was provided lorazepam 1 mg twice a day to treat her catatonic symptoms, her insomnia and her speech improved. Olanzapine was

introduced, reaching a dose of 20 mg/day for managing psychosis and agitation.

Discussion NMDA-R encephalitis is a novel disorder with prominent psychiatric manifestations that is widely underdiagnosed. Neuroleptics may be helpful for managing psychosis and agitation, but may exacerbate movement abnormalities. Benzodiazepines are helpful for agitation, insomnia and catatonia associated with this condition.

Conclusion Earlier recognition of this illness is crucial as prompt diagnosis and multidisciplinary treatment, can potentially improve prognosis. There is an increasing need for psychiatrists to become aware of the disorder and consider it in their differential diagnosis, specially in patients with new onset psychosis, history of encephalitis or subtle neurological symptoms. Careful selection of psychopharmacological interventions may reduce suffering.

* Corresponding author.

Introduction Many neurological, oncological and autoimmune diseases may have psychiatric symptoms; these diseases sometimes start with these symptoms, so the diagnosis may be confused and the treatment is delayed.

Objective Review the relationship between the secondary immune deficiency and increased predisposition to infectious processes and the psychopathological conditions which manifest themselves in some cases in these situations.

Methods A 17-year-old male patient, who began psychiatry consultations when he was 3 years old due to psychomotor delay and behavior disorders. He was diagnosed with ADHD and mild mental retardation. Medical history: Viral encephalitis; Perthes disease; recurrent urinary tract infections; intestinal giardiasis; Alport syndrome. He's being treated with aripiprazole 5 mg (1/2-0-0).

The patient presents an episode of perplexity, psychotic anguish, auditory hallucinations and paranoid delusion. The patient presented an infectious process with general malaise, diarrhea and vomiting during previous days.

Results The patient was assessed by the Departments of internal medicine, neurology and psychiatry. A cerebral TAC, lumbar puncture, EEG and urine porphyrins were requested. The secondary immune deficiency makes the patient more vulnerable in an infectious process.

Discussion The diagnosis of psychotic disorder due to medical condition may be transient or recurrent. Treating of the medical condition often gets resolution of psychosis, although the symptoms can persist in some cases. There is often a prodromo of viral syndrome weeks before the rest of symptoms appear. The differential diagnosis should be made with primary psychotic disorders, affective disorders, confusional syndromes, impulse control disorder or sleep disorders, neuroleptic malignant syndrome, serotonin syndrome and substance-induced psychotic disorders.

Depression among HIV-infected patients—a reality that must not be forgotten

M. Marinho^{1,*}, M. Mota-Oliveira¹, M.J. Peixoto¹, J. Marques^{2,3}, M. Bragança^{1,3}

¹ São João hospital centre, clinic of psychiatry and mental health, Porto, Portugal

² Local healthcare unit of Matosinhos, clinic of psychiatry, Matosinhos, Portugal

³ Faculty of medicine of Porto university, department of clinical neurosciences and mental health, Porto, Portugal

* Corresponding author.

Introduction HIV-infection is a very stigmatized, chronic disease with increased rates of psychiatric disorders, being major depression the most common.

Objective To review the recent research related to depression in HIV-infected patients.

Methods Literature review based on PubMed/Medline, using the keywords “HIV” and “depression”.

Results HIV-infected patients have a chance 2–7 times higher of developing major depression, around the time of diagnosis or during the course of their illness. However, only fewer than 50% of the cases are recognized clinically. Several factors contribute to its under-recognition and under-treatment, such as the overlap between the neurovegetative symptoms of depression, the somatic symptoms of HIV disease, and the effects of comorbid diseases; the mistaken belief that depressive symptoms are expected in this group; the neuropsychiatric side effects associated with some antiretrovirals. Besides, major depression presents important diagnostic challenges due to biological, psychological, and social components associated with the infection. The authors will analyze the clinical presentation.

Depression has been associated with a negative impact on quality of life, poorer HAART adherence, faster HIV disease progression and increased mortality risk. Importantly, however, appropriate psychiatric intervention can do it over. In fact, studies suggest that patients receiving SSRI treatments for depression have rates of adherence and CD4⁺ T-cell counts similar to non-depressed patients receiving HAART.

Conclusions The high prevalence of major depression in HIV-positive individuals and its serious consequences if untreated, increase even further the importance of its effective identification and subsequent treatment in this group of patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Faculty of medicine of Porto university, department of clinical neurosciences and mental health, Porto, Portugal

* Corresponding author.

Introduction HIV infection is a chronic disease characterized by a great deal of uncertainty and unpredictability, being anxiety disorders a frequent psychiatric problem.

Objective To provide an overview of anxiety in HIV-infected patients.

Methods Literature review based on PubMed/Medline, using the keywords “HIV” and “anxiety disorders”.

Results HIV-infected individuals can experience symptoms of anxiety across the spectrum of anxiety disorders. Adjustment disorder with anxious mood is the most common diagnosis, followed by generalized anxiety disorder and panic disorder. Some patients present with these disorders prior to notification, others develop them during the course of their illness, mainly at key moments. In HIV-infected patients, anxiety can be a manifestation of side effects of medication; a symptom of an illness associated with HIV disease; or, most commonly, the psychological response to the stressors of the illness. In fact, many issues are responsible for the anxiety experienced by people living with HIV. The authors will analyze them. Besides the distress of anxiety disorders, these lead to a decrease in adherence to antiretroviral treatments, resulting in adverse progression of HIV disease and increased risk of mortality. Importantly, however, appropriate psychiatric intervention can do it over.

Conclusions Careful diagnosis and treatment of anxiety disorders in the context of HIV disease is even important, given the serious effects if untreated. Thus, anxiety should never be seen simply as a natural reaction to a life-threatening illness.

AIDS mania – is it a potential indicator to initiate HAART?

M. Marinho^{1,*}, J. Marques^{2,3}, M. Bragança^{1,3}

¹ São João hospital centre, clinic of psychiatry and mental health, Porto, Portugal

² Local healthcare unit of Matosinhos, clinic of psychiatry, Matosinhos, Portugal

³ Faculty of medicine of Porto university, department of clinical neurosciences and mental health, Porto, Portugal

* Corresponding author.

Introduction Mania occurs in higher rates among individuals with HIV/AIDS, especially with the progression of HIV infection, and constitutes an additional risk factor for facilitate the HIV spread.

Objective To provide an overview of secondary mania in HIV-infected patients.

Methods Literature review based on PubMed/Medline, using the keywords “HIV”, “AIDS” and “mania”.

Results Secondary mania or AIDS mania may be due to illicit or prescribed drugs, CNS infection with HIV, medical illness, including opportunistic infections. Of these, HIV neurotoxicity has been proposed to be the most important factor in its pathogenesis. Mania AIDS differs from primary mania with regard to clinical presentation, course, management and prognosis. The authors will analyze them. Besides decrease to treatment adherence, manic symptoms also predispose to HIV risk behaviors, which may lead to further HIV transmission. Importantly, the occurrence of HIV mania may announce the transition from HIV infection to AIDS perhaps before other clinical signs are evident. Early recognition and treatment of manic symptoms with mood stabilisers, antipsychotics and HAART improve quality of life, protect from further cognitive deterioration and decrease mortality. In these patients, medication side-effects toxicity, drug interactions, and adherence require special attention.

Conclusions Mania has been associated with HIV/AIDS and in many instances acts as a barrier to achieving best treatment outcomes. Thus, psychiatrists need to be aware of the complexities involved in the emergence of manic episodes in HIV-infected patients in order to deal with them in the most appropriate and effective manner.

Modulation of the nuclear factor (erythroid 2-derived)-like 2 pathway by antidepressants in rats

D. Martín Hernández*, Á.G. Bris, K.S. MacDowell, A. Sayd, D. Azpiazu, M.T. Alba, G. Torres, B. García-Bueno, J.L.M. Madrigal, J.C. Leza, J.R. Caso
Complutense university of Madrid, school of medicine, CIBERSAM, pharmacology, Madrid, Spain

* Corresponding author.

Introduction Patients with major depression who are otherwise medically healthy have activated inflammatory pathways. It has been described that depression is not only escorted by inflammation but also by induction of multiple oxidative/nitrosative stress pathways. Nevertheless, there are finely regulated mechanisms involved in preserving cells from damage, such as the nuclear factor Nrf2.

Aims To explore in a depression-like model the Nrf2 pathway in the prefrontal cortex (PFC) and the hippocampus of rats and to analyze which classic antidepressants affect the antioxidant activity of the Nrf2 pathway.

Methods Male Wistar rats were exposed to chronic mild stress (CMS) and some of them were treated with desipramine, escitalopram or duloxetine. We studied the expression in the PFC and hippocampus of upstream and downstream elements of the Nrf2 pathway and the oxidative damage induced by the CMS.

Results After exposure to a CMS protocol, in the PFC, there is an inhibition of upstream and downstream elements of the Nrf2 pathway. Moreover, antidepressant treatments, particularly desipramine and duloxetine, are able to recover some of these elements and to reduce the oxidative damage induced by the depression model. In the hippocampus however, Nrf2 pathways are not that affected and antidepressants do not have many actions.

Conclusions Nrf2 pathway is differentially regulated by antidepressants in the PFC and hippocampus. The Nrf2 pathway is involved in the oxidative/nitrosative damage detected in the PFC after CMS exposure. However, it seems that Nrf2 is not very involved in the effects caused by the CMS in the hippocampus.

Auditory hallucinations in a deaf patient? – A clinical report

M.A. Aleixo^{1,*}, C.A. Moreira², G. Sobreira¹, J. Oliveira³, L. Carvalhão Gil²

¹ Centro hospitalar psiquiátrico de Lisboa, Ward 1, first psychotic episode unit, Lisboa, Portugal

² Centro hospitalar psiquiátrico de Lisboa, Ward 6, schizophrenia and schizoaffective disorders unit, Lisboa, Portugal

³ Centro hospitalar psiquiátrico de Lisboa, Ward 2, neuropsychiatry and dementia unit, Lisboa, Portugal

* Corresponding author.

Introduction According to some studies, deaf psychiatric inpatients have prevalence rates of psychotic disorders ranging from 20 to 54%. There are descriptions of the paradoxical finding that prelingually deaf patients with psychosis may hear voices.

Objectives To present a case report and conduct a database review in order to understand if deaf patients with psychosis can have auditory hallucinations.

Aims The authors' aim is to describe a case, highlight the clinical and scientific relevance of auditory hallucinations in deaf patients and the difficulties and limitations of this process.

Methods A Pubmed database search using as keywords “auditory hallucinations”, “deaf” and “deafness” and retrieved papers were selected according to their relevance.

Results The authors report a case of a 47-year-old female patient apparently suffering from congenital deafness. The patient had no previous psychiatric history until 4 months prior to her admission at our institution, when she started having psychotic symptoms. The patient was admitted into a Neurology ward but because no neurological sign was found psychiatric liaison consultation was requested. Four months later, she had the same symptoms, describing a voice that said to “shut up” and was admitted to a psychiatric hospital. After medication, the symptoms relapsed and now she is followed in an outpatient setting.

The presence and nature of auditory hallucinations in deaf patients is not fully elucidated and there are methodological problems in the investigation of this subject.

Conclusions Current evidence is still inconclusive and the fact that prelingually deaf patient hear voices needs further research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“Yo Soy La Desintegración”: Helplessness and sublimation through Frida Kahlo's history

J. Becker
Coimbra, Portugal

Considering the relevance of studying the pathologies of emptiness for contemporaneous clinic, this work approaches the correlation between helplessness and sublimation concepts. Helplessness is considered a new theory, developed by David Maldavsky that uses the term *desvalimiento* to define a clinical condition described by the feeling of emptiness. To understand this concept, it is necessary to return to a primitive period, when the baby is beginning to qualify his affections. Thus, using historical construction, we start at Freud's works (focusing in the primitive period and the affections qualification), explore the “good-enough mother” importance, from Winnicott, and reaching the helplessness from the present-days Maldavsky's studies. The Frida Kahlo's history illustrates this work as much because of her toxic current as because of her talent to sublimate. The maternal failure, the toxic relationships, the trauma's imposition, the abuse of alcohol and drugs and the viscosity denounce her helplessness. Nevertheless, the art expresses her fight for life. The Frida Kahlo's works represent her suffering, but they also are her attempts to understand her feelings and to reframe her traumatic events. Therefore, we introduce the sublimation as an alternative to the helplessness. Although helplessness is the lack of the symbolic life, we present the art as an opportunity to confront experiences, which can allow the representation of the traumas and the qualification of affections. Through the sublimation, Frida Kahlo recreated her inner world and returned to life.

Psychopathology and spiritual experiences: Criteria for differential assessment

I. Bone-Pina

Universidad Pontificia Comillas, Psychology, Madrid, Spain

Introduction There is a plurality of differing opinions defining borders between mental disorders and spiritual experiences. This research proposes criteria for clarifying those boundaries.

Objectives Summarize practical criteria for clinicians to assess psychopathological symptoms with spiritual content and to attain a differential diagnosis from healthy spiritual experiences.

Aims Merge different approaches from psychopathology, psychology of religion and religious studies to attain practical criteria.

Methods Literature review using a phenomenological and critical approach.

Results 1. Severe psychiatric symptoms with religious content: (1) are usually in the context of personal impoverishment; (2) appear odd in cultural environments and within a person's biography; (3) do not enhance action or, in the phenomenological tradition, (4) these symptoms come from a weakening of the "intentional arc". 2. A guiding map is suggested to evaluate spiritual expressions and their relationships with mild or moderate mental disorders and with mental health and personal growth. This map is developed by combining different traditions from the psychology of religion. 3. Psychiatric and psychological judgment of religious/spiritual experiences should be self-limited. There is a judgment about its content and about its validity or truth, which is only possible within the different spiritual traditions.

Conclusions Psychopathology establishes principles to discriminate some psychotic symptoms from healthy spiritual experiences. Psychology of religion offers some general rules to guide the psychological evaluation of spiritual beliefs and their influence on mental well-being and personal growth. This review opens fields for future research in relating psychopathology and the study of religious experience.

Consorcio Hospital General Universitario, Conselleria de Sanitat, Valencia, Spain

* Corresponding author.

A clinical case is presented. The reason for admission was for behavioral disturbances and agitation psicomotriz episode in the street: she had gone to a library to "denounce" the police for entering the subway without paying several times. The patient was very distraught because she was heavily guarded (someone had tapped her phone, entered her house, changed objects place, she was chased down the street. . .). In the psychopathological examination revealed the sphere of language, her speech was fluid, with pressured speech, full of details, with loss of thread and highlighted the presence of neologisms and grammatical errors (changes of subject and predicate. . .) and changes some letters by others in the same word. She often used sayings incorrectly and, when you are exploring about this fact, objectively presenting alteration in abstract thinking. In addition, it presents self-references on television. The diagnostic impression was chronic psychotic process of years of evolution. In this case, it was decided to administer intramuscular

antipsychotic treatment because she was not aware of the disease but presenting good tolerability profile because, otherwise, leave the track and also a good social functioning was sought. Currently, she continues in mental health, she has not reported new crisis and a progressive scan objective improvement in the organization of thought and speech, leaving the psychotic symptoms.

Emotion dysregulation: A review of the concept and implications for clinical practice

A. D'Agostino^{1,*}, S. Covanti¹, M. Rossi Monti¹, V. Starcevic²¹ University of Urbino, Department of Human Sciences, Urbino, Italy² University of Sydney, Discipline of Psychiatry–Sydney Medical School, Sydney, Australia

* Corresponding author.

Introduction Over the past decade, emotion dysregulation has become a very popular term in the psychiatric and clinical psychology literature and it has been described as a key component in a range of mental disorders. For this reason, it has been recently called the "hallmark of psychopathology" (Beauchaine et al., 2007). However, many issues make this concept controversial.

Objectives To explore emotion dysregulation, focusing on problems related to its definition, meanings and role in many psychiatric disorders.

Aims To clarify the psychopathological core of emotion dysregulation and to discuss potential implications for clinical practice.

Methods A literature review was carried out by examining articles published in English between January 2003 and June 2015. A search of the databases PubMed, PsycINFO, Science Direct, Medline, EMBASE and Google Scholar was performed to identify the relevant papers.

Results Although, there is no agreement about the definition of emotion dysregulation, the following five overlapping, not mutually exclusive dimensions were identified: decreased emotional awareness, inadequate emotional reactivity, intense experience and expression of emotions, emotional rigidity and cognitive reappraisal difficulty. These dimensions characterise a number of psychiatric disorders in different proportions, with borderline personality disorder and eating disorders seemingly more affected than other conditions.

Conclusions This review highlights a discrepancy between the widespread clinical use of emotion dysregulation and inadequate conceptual status of this construct. Better understanding of the various dimensions of emotion dysregulation has implications for treatment. Future research needs to address emotion dysregulation in all its multifaceted complexity.

Ice bucket at first. . . and then? – Psychopathology in amyotrophic lateral sclerosis patients and their caregivers, a review

A.R. Figueiredo^{1,*}, V. Espírito Santo², R. Almendra², A. Costa²¹ Centro Hospitalar Trás-os-Montes e Alto Douro, Psychiatry and Mental Health Department, Vila Real, Portugal² Centro Hospitalar Trás-os-Montes e Alto Douro, Neurology Department, Vila Real, Portugal

* Corresponding author.

Introduction Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disorder that affects motor neurons in the cerebral cortex, brainstem and spinal cord. The progressive loss of motor function creates profound changes on patient's lives and their caregivers.

Objective Assessment of eventual existence of psychopathology in ALS patients and their caregivers.

Methods Literature review using the terms: ALS, Amyotrophic Lateral Sclerosis, psychopathology, psychiatric disorder; depression; anxiety, caregivers.

Results Moderate depressive or anxious symptoms are often observed. The results are not consistent, some studies showing that major depression is less common than in general population, others that is mildly increased. Some studies show that depressive symptoms are related to poorer QoL and with faster disease progression, others suggests no correlations. Coping strategies, cognitive appraisal and social support are important factors to psychological adaptation to ALS. After the diagnosis, high levels of anxiety can be observed. Psychopathological features are observed at this time, and generally depression does not increase as death approaches. Beyond loss of physical functions, it seems that patients' neurobehavioral symptoms, such as aggressiveness, disinhibition and impulsivity, cognitive impairment, and also lack of social support have a negative effect on caregivers' mental health. Concordance between patient and caregiver distress was found.

Conclusions It is important to assess potential psychological distress in ALS patients and their caregivers, given that cope with disease can affect its course. Caregivers' needs should be addressed, to benefit their well-being and consequently patients' QoL. There are few studies about psychopharmacotherapy and/or psychotherapy in these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Paraphrenia: Evolution of the concept

C. Freitas^{1,*}, A.R. Figueiredo², T. Abreu¹, S. Queirós¹

¹ Centro Hospitalar do Tâmega e Sousa, Departamento de Psiquiatria e Saude Mental, Penafiel, Portugal

² Centro Hospitalar de Trás-os-Montes e Alto Douro, Departamento de Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Paraphrenia was identified as a psychopathological entity characterized by chronic delirium, described next to schizophrenia, but with rich and fanciful elaborations, without social and cognitive impairment associated. Despite having been extensively described, paraphrenia fell into disuse. With this work, the authors intend to carry out a literature review on the concept of paraphrenia, since its first report to the extinction from the current practice of psychiatry. The term paraphrenia (para "near" phrenia "pathological mental state") was first noted by Kahlbaum in 1863, who identified dementia and subdivided it into three types: "neofrenia", "paraphrenia hebética" and "senilis paraphrenia"). Magnan and Manager suggested the concept of "chronic hallucinatory psychosis" in 1963, while Kraepelin started jobs with similar characteristics, defining the concept of paraphrenia. Kraepelin distinguished dementia praecox from the later onset dementia, despite considering them closer to one another than any of them to paranoia. Paraphrenia would be characterized by less formal disturbances of thought and greater preservation of affection. In 1911, with "schizophrenia" expression, Bleuler broke with Kraepelin concept, as Mayer, who reviewed Kraepelin patients, concluding that more than half had progressed to a diagnosis of schizophrenia. At this time, paraphrenia was virtually abolished from the practice of psychiatry. Despite the observations made over the years, the concept of paraphrenia have revealed that the description proposal does not correspond

to an isolated and distinct psychiatric condition, several times, in clinical practice we have encountered with patients presenting diagnostic criteria for schizophrenia but with the evolution of the disease showing no significant deterioration in several areas.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Folie à deux: Shared or "infected" madness? About a case report

M.Á. Soriano^{1,*}, C. Garcia²

¹ University Hospital, Mental Health service, Málaga, Spain

* Corresponding author.

The shared madness or *Folie à deux* was described in France in the nineteenth century by Charles Lasage and Pierre Falret, as a condition where a person (the primary) builds a delusional system, sharing it with another (the secondary), who must be very close to the first affected, becoming delirious with the same subject. Several theories attempt to explain the phenomenon that challenges theories of personality structures, rooted in relational and/or environmental features of psychosis. Theoretically, there are many attempts to classify this psychotic experience: in some manuals they distinguish various types of partners: the simultaneous psychosis, where the two people start to become delirious at once; imposed psychosis, in which the disorder arises first with one, then going on to "healthy" individual and symptomatology disappears after being separated; and communicated psychosis, where the first transmitted the psychotic experience to the second, and he or she develops his or her own delusion not interrupted even while separated. Other classifications about shared madness not only between two people, but three, and four, even a whole family show us how complicated the delirium systems can become. In our paper, we will discuss the different theories explaining this rare psychiatric condition based on a case about two brothers of 35 and 37, who live together with the rest of the family, and also come together to the same mental health center, although with different psychiatrists.

Which type of management is most suited for patients with a diagnosis of false self personality (FSP) within a psychodynamically-oriented institutional day hospital? A study

G. Giorgio*, F. Marmo

Fondazione Villa Camaldoli, Psychodynamic Day Hospital Integrated Psychodynamic Psychiatric Department, Naples, Italy

* Corresponding author.

Introduction Our work team have already found that our Institutional Psychiatric Open Light Treatment (IPOLT) model allows the patient affected by severe mental illness (SMI) to more easily express her/his personal coping skills rather than behaving passively thanks to the "real free spaces" separating a structured intervention from another. Our work consisted in evaluating how patients with FSP respond to IPOLT.

Objectives This paper describes observations of psychotic patients operating from the position of FSP in order to evaluate how they respond to IPOLT compared with other patients according to three standards (day hospital attendance, psychotic episodes and hospital admissions).

Aims Identify the core factors for management of patients with FSP in the context of IPOLT.

Methods We isolated a sample including patients affected by severe mental illness (SMI); within this sample, we selected a small group of patients with FSP. During the last three years, we have been evaluating patients with FSP in terms of day hospital attendance, number of psychotic episodes and number of hospital admissions compared with data obtained from other patients with SMI without diagnosis of FSP.

Results The two data sets revealed no statistically significant differences in terms of the three standards.

Conclusions Our preliminary study showed a good effect for IPOLT treatment on patients with SMI. We expected that patients affected by SMI with FSP would have a different response to IPOLT, but it was not. We do not know whether such results depend on a too small sample of patients or inappropriate descriptors.

⁵ University of La Laguna, Medical School-Health Sciences Campus, Santa Cruz de Tenerife, Spain

* Corresponding author.

Introduction Nowadays, observation reinforces earlier research suggesting that psychological factors may be one of the many contributory factors to the initiation of the disease. Initial blood pressure increases may impact cognitive and/or affective function. There is some evidence for an impact of blood pressure on the perception and experience of affect. On the other hand, essential hypertension so far is often symptomless, so screening is vital before damage is done.

Objectives and aim This study aims at studying minor psychopathology profile in a sample of hypertensive outpatients in a primary health care facility setting.

Methods The psychopathology profile pattern in a sample of 46 hypertensive patients in a primary healthcare setting, mean age: 48.16 (SD: 9.32), 18 males/30 females, is studied. Derogatis SCL-90-R Self-Report Questionnaire was used. The Statistical Package for Social Science was applied.

Results The psychopathology profile in the overall sample is marked by a main score in the dimensions of Anxiety (1.88), Depression (1.72) and Interpersonal Sensitivity (1.62), and lower scores recorded in Obsession-Compulsion (1.42) and Hostility (1.38). These scores mainly portrait the minor psychopathology pattern in our hypertensive patients. A significant relationship between the Global Severity Index (GSI) and hypertension recorded figures was observed as well ($r = .886$).

Discussion and conclusions Anxiety and affective symptoms are highlighted in our sample as the main psychopathology complaints alongside with other studies. Management implications of the outlined psychopathology profile should be considered in understanding and treating hypertensive patients regarding their lifestyle and therapeutic assessments.

Late onset psychosis. Review

J.M. Hernández Sánchez^{1,*}, M.Á. Canseco Navarro², M. Machado Vera², C. Garay Bravo², D. Peña Serrano³

¹ Valencia, Spain

² Hospital General de Valencia, Psychiatry, Valencia, Spain

³ Hospital General de Valencia, Psychiatry, Valencia, Spain

* Corresponding author.

Introduction Several risk factors make older adults more prone to psychosis. The persistent growth in the elderly population makes important the necessity of accurate diagnosis of psychosis, since this population has special features especially regarding to the pharmacotherapy and side effects.

Objectives To review the medical literature related to late-life psychosis.

Methods Medline search and ulterior review of the related literature.

Results Reinhard et al. [1] highlight the fact that up to 60% of patients with late onset psychosis have a secondary psychosis, including: metabolic (electrolyte abnormalities, vitamins deficiency...); infections (meningitides, encephalites...); neurological (dementia, epilepsy...); endocrine (hypoglycemia...); and intoxication. Colijn et al. [2] describe the epidemiological and clinical features of the following disorders: schizophrenia (0.3% lifetime prevalence > 65 years); delusional disorder (0.18% lifetime prevalence); psychotic depression (0.35% lifetime prevalence); schizoaffective disorder (0.32% lifetime prevalence); Alzheimer disease (41.1% prevalence of psychotic symptoms); Parkinson's disease (43% prevalence of psychotic symptoms); Parkinson's disease dementia (89% prevalence of visual hallucinations); Lewy body dementia (up to 78% prevalence of hallucinations) and vascular dementia (variable estimates of psychotic symptoms). Recommendations for treatment include risperidone, olanzapine, quetiapine, aripiprazole, clozapine, donepezil and rivastigmine.

Conclusions Differential diagnosis is tremendously important in elderly people, as late-life psychosis can be a manifestation of organic disturbances. Mental disorders such as schizophrenia or psychotic depression may have different manifestations in comparison with early onset psychosis.

Keywords "Psychosis"; "Elderly"; "Late onset schizophrenia"

Introduction The presence of elderly people is more and more common in developed countries. Unlike other medical conditions,

late onset psychosis includes organic and mental precipitants in its differential diagnosis.

Objectives To present a case of late onset schizophrenia.

Methods Medline search and review of the clinical history and the related literature.

Results We present the case of a 71-year-old woman with organic medical history of rectum adenocarcinoma in 2008 that underwent radiotherapy, chemotherapy and surgical resection with successful results. According to the psychiatric history, this patient has needed two admissions to the psychiatry ward, the first of them in 2012, (when the delusional symptoms started), due to deregulated behaviour in relation to persecutory delusions and auditory pseudo-hallucinations. In 2012, she was diagnosed with late onset schizophrenia. Blood tests (hemogramme, biochemistry) and brain image were normal. Despite treatment with oral amisulpride and oral paliperidone and due to low compliance, delusional symptoms have remained. We started treatment with long-acting injectable papiiperidone 75 mg/28 days having reached clinical stability.

Conclusions Late onset psychosis is due to a wide range of clinical conditions. In this case, our patient had no organic precipitants. The evolution and presentation of delusional symptoms in this patient made us think of late onset schizophrenia as main diagnosis.

Introduction The proportion of elderly people and affective syndromes are more and more common in developed countries. Elderly people have physiological conditions that may limit our intervention.

Objectives To present a case of a major depressive disorder with psychotic symptoms in a 72-year-old woman.

Methods Medline search and review of the clinical history and the related literature.

Results We present the case of a 72-year-old woman with psychiatric history of a major depressive disorder 14 years ago with ad integrum restitution after pharmacological treatment. In 2015, our patient was admitted to the psychiatry ward due to major depressive symptomatology (apathy, anhedonia, global insomnia, weight loss) that associated mood-congruent delusions (nihilistic, ruin, guilt, catastrophic) with deregulated behaviour. The patient was resistant to combined pharmacological treatment with aripiprazole, desvenlafaxine, mirtazapine and lorazepam, therefore, we decided to administer ECT, with successful results after 5 sessions. Brain tomography, blood and urine tests were normal. Clinical signs of dementia were not present.

Conclusions Inpatients with deregulated behaviour; it is important to rule out organic causes, especially in elderly, in whom

dementia, brain tumors or metabolic disturbances may simulate psychiatric syndromes.

Keywords “Major depressive disorder” ; “Psychosis” ; “Late onset psychosis”

The interpretation of anhedonia in a structure of affective disorders and schizophrenia

P. Kananovich

Mental Health Research Center of the Russian Academy of Medical Sciences, Department of endogenous mental disorders and affective states, Moscow, Russia

Objective To identify clinical and psychopathological features of anhedonia in the framework of affective disorders or schizophrenia, as well as patterns of a process, development of the criteria of differential diagnosis and prognosis.

Material and methods Using psychopathological method, we examined 37 patients (average age was 27.6 + 1.2 years).

Results It was studied that anhedonia appears to be a non-specific symptom, but with differences in terms of its dynamics and characteristics, which are realized in differences regarding to prognostic significance of the phenomenon. We selected 3 main types of anhedonia: an anhedonia in the framework of depression in affective disorders (1), in the framework of depression at the prodromal stages of schizophrenia with preservation and further intensification its particular components (2), an anhedonia without associated mood disorders (or their minor expression) in the framework of schizophrenia, registered at initial stage and persisted in the future (3). In affective pathology, anhedonia was observed in a structure of a manifest depressive state with its further reduction in remission. In schizophrenia, anhedonia appeared at prodromal stages as a structural part of depression or without associated mood disorders, with a following persisting retention of its components at the later non-manifestation states, suggesting reflection affinity of anhedonia to schizophrenia. Anhedonia without concomitant mood disorders in schizophrenia correlated with a poorer outcome and more severe psychotic symptoms.

Conclusions The presented differences in a structure of anhedonia allow to speak about its correlation with a risk of manifestation of endogenic psychosis, the course of illness and its prognosis.

Obsessive versus delusional jealousy: Destruction in a form of creation – A review

R. Almeida Leite*, E. Conde, T. Queirós Santos, M. Almeida, T. Azevedo Santos, A. Mesquita Figueiredo

Baixo Vouga Hospital Centre, Psychiatry and Mental Health Department, Aveiro, Portugal

* Corresponding author.

Introduction Jealousy is a complex emotional state and some degree is considered normal in mature love, but when does it become destructive in a relationship? There's a thin line between

what is normal and what is pathologic. Pathological jealousy differs from normal by its intensity and irrationality. Obsessive and delusional jealousies are different types of pathological jealousy, difficult to distinguish, which is important, since they have different treatment. Despite the differences, both result in significant distress and carry the risk of homicide/suicide, so it's a matter deserving the psychiatrists' attention.

Objective Explore the psychopathological differences between obsessive and delusional jealousy and list the characteristics and difficulties in the approach to pathological jealousy.

Methods The results were obtained searching literature included on the PubMed and Google Scholar platforms.

Results Delusional jealousy is characterized by strong and false beliefs that the partner is unfaithful. Individuals with obsessive jealousy suffer from unpleasant and irrational jealous ruminations that the partner could be unfaithful, accompanied by compulsive checking of partners' behavior. This jealousy resembles obsessive-compulsive phenomenology and should be treated with SSRIs and cognitive-behavioral therapy. Delusional jealousy is a psychotic disorder and should be treated with antipsychotics.

Conclusion The common issue in pathological jealousy is the problem of adherence to treatment and bad prognosis. In order to achieve better treatment outcomes, we should follow-up the patient regularly. One key factor is to explore the psychopathology and motivate the sufferer for the proper pharmacological and psychotherapeutic interventions, trying to reduce the suffering caused by ideas of unfaithfulness.

Differential diagnosis between schizophrenia and in major depression: The importance of abnormal bodily phenomena

M. Mancini^{1,*}, G. Stanghellini²

¹ University "G. D'Annunzio", Department of Psychological – Humanistic and Territorial Sciences, Chieti, Italy

² University "G. d' Annunzio", Department of Psychological – Humanistic and Territorial Sciences, Chieti, Italy

* Corresponding author.

Introduction Anomalies of bodily experience have for long been described as relevant features of schizophrenia and major depression, yet such experiences are usually neglected in clinical examination. Bodily experience is the implicit background of our experiences against which we develop a coherent sense of self as a unified, bounded entity, naturally immersed in a social world of meaningful others. Such tacit experiential background is often perturbed in schizophrenia and major depression. Empirical research shows that patients with schizophrenia and major depression frequently present many different kinds of anomalies of bodily experience in the course of their illness.

Objective To characterize the abnormal bodily phenomena in both schizophrenia and major depression.

Aim To improve differential diagnosis based on the identification of typical features of abnormal bodily experiences in persons affected by schizophrenia and major depression and to provide supplementary diagnostic criteria.

Method Analysis of empirical and theoretical research published in the last 25 years.

Result Ongoing bodily feelings of disintegration/violation and nothingness/mechanization (e.g. one's body experienced as a object-like mechanism) are the most typical experiences in people with schizophrenia whereas major depressives are not able to detach themselves from the experience of bodily failure or chrematization (from chrema = corpse, i.e., feeling like a corpse) and

therefore, feel worthless, guilty, or decaying. They feel chrematized in their very self.

Conclusion These experiences might be considered as specific and they can contribute to differential diagnosis of somatic complaints in schizophrenia and in major depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosis in a blindness patient: A case report

M. Marinho*, C. Moreira, F. Catarina

Centro Hospitalar Psiquiátrico de Lisboa, Lisbon, Portugal

* Corresponding author.

Introduction Using a clinical case as illustration, the present work engages the different psychopathologic alterations that blindness patients could present.

Methods The presentation and discussion of a clinical case of psychosis in a blind patient are addressed. The scientific documentation used as support was obtained from PubMed/Medline search engines using as keywords blindness and psychosis.

Results A 43-years-old male patient, with a medical history of arterial hypertension, heroine dependence (presently with methadone schema) and bilateral blindness caused by a bilateral retinal detachment 20 years ago, was admitted in the psychiatric ward. The patient's historical record includes a previous personality with paranoid characteristics, as well as a hospitalization due to persecutory and auto-reference ideas and kinaesthetic hallucinations with 1 month of evolution, coincident with address changes. Lab tests revealed the following results: haemoglobin 13.8; Leucocytosis 13,400; CRP: 6.2; ALT > AST. Positive results were obtained in the drug tests for cannabinoids, as well as for the anti-HCV antibody (IgG). Finally, the patient was medicated with an antipsychotic and humour stabilizer, achieving a significant improvement after 10 days of hospitalization.

Conclusions Although studies reveal that mental and behavioural disorders, especially those with symptoms of psychosis and mental retardation, are common among people with congenital blindness, more knowledge of the prevalence and aetiology of mental and behavioural disorders among people suffering from blindness is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cycloid psychosis: A case report

G. Martinez-Ales*, I. Louzao, A. Irimia, M.F. Bravo,

J. Marin

Hospital Universitario La Paz, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Episodes of time-limited acute psychosis, with full recovery in between, are categorized as acute polymorphic psychotic or brief psychotic disorders. Leonhard described the three forms of cycloid psychosis (CP). Perry considers it a separate entity.

Case report We report the case of a 54-year-old male, with a 9-year history of brief psychotic disorders. He was admitted to an inpatient unit after a 4-day episode of persecutory delusion, leading to high emotional repercussions and isolation at home. Euthymia was present. Previous admissions, 9 and 5 years before, presented similar clinical pictures. Treatment with low dose paliperidone during 6-month periods had led to the complete resolution of the episodes (restitutio ad integrum: no psychotic manifestations and the ability to run his business). In this episode, 8 days after the reintroduction of 12 mg of paliperidone per day, cessation of the

symptoms took place. Careful reconstruction of the clinical history showed no stressors or drug consumption. And immediately previous 5-day phase of insomnia, hyperactivity and expenditure was described by the patient's wife.

Discussion Three inpatient admissions, a careful clinical history and a thorough review of the evidence regarding Perris criteria led to a diagnosis of CP.

Conclusion CP, a classical nosological approach, is helpful in a clinical setting, as it might imply different prognosis and treatment. Recognition of CP, not included as an entity by the major diagnostic systems, requires a high index of suspicion.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cryptococcal meningitis in acute onset psychosis: A case-study

P. Michielsens^{1,*}, M. Arts²

¹ Mental Health Western Northern Brabant, Halsteren, Netherlands

² University Medical Center Groningen, Old Age Psychiatry, Groningen, Netherlands

* Corresponding author.

Introduction Cryptococcal meningitis is a frequently observed opportunistic infection in patients with late-stage HIV-infection, especially among people living in South-East Asia and Central Africa. The worldwide incidence is estimated at one million cases. The worldwide mortality of HIV-associated cryptococcal meningitis remains high (10–30%), due to the inadequacy of antifungal treatments and complications of increased intracranial pressure. Clinical symptoms of cryptococcal meningitis are fever, headache, vomiting, and altered mental status. Neck stiffness, papilledema, and focal neurological symptoms are sometimes present.

Objectives We describe the case of a patient who first developed a delirium, and a few months later an acute-onset psychosis, after a past cryptococcal infection.

Aims To report a case-study describing acute-onset psychosis as a neuropsychiatric consequence of HIV-infection.

Methods A case-study is presented and discussed, followed by a literature review.

Results A 49-year-old African-born male was admitted to hospital with an acute psychosis. He had been treated by an internist after being found to have HIV. As a result of non-compliance over a period of about four months, his cd4-count had dropped to 40. Six months earlier he had developed cryptococcal meningitis, which left him a number of neurological and psychiatric symptoms. During his stay in hospital, there had to be good collaboration with the specialist in internal medicine whose dual task was to manage the patient's dramatically low cd4-count as well as his psychosis.

Conclusion Cryptococcal meningitis is a risk factor for psychiatric disorders and mortality in HIV-infected persons.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“Bouffée délirante” induced by meditation

R.A. Baena Mures^{1,*}, L. Niell Galmes², Y. Lázaro Pascual², M.D. Saiz Gonzalez²

¹ Hospital Clinico San Carlos, Psychiatry, Madrid, Spain

² Hospital Clinico San Carlos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Meditation is frequently applied in Western as well as non-Western countries for different purposes; we know little about adverse events. The symptomatology of a meditation-related

psychosis appears to show similarities with that we call “bouffée délirante”.

Methods A female patient is described who developed an acute and transient psychosis with polymorphic symptomatology after meditating (Bikram-yoga). We made a literature search for psychotic states related to meditation.

Results There are some case reports of psychosis disorder induced by meditation. Some cultural syndromes like Qi-gong appear on DSM-IV as psychotic reaction. In this case, the syndrome is not culture bound.

Conclusions Meditation can act as a stressor in vulnerable patients who may develop a transient psychosis with polymorphic symptomatology (confusion, panxiety, mood swings and mood dystonic psychotic symptoms) with a short duration.

Erotomania – A review of De Clérambault's syndrome

C. Oliveira*, S. Alves, C. Ferreira, C. Agostinho, M.J. Avelino
Centro Hospitalar Psiquiátrico de Lisboa, SETA, Lisbon, Portugal

* Corresponding author.

Introduction Erotomania (also known as De Clerambault's syndrome) is usually described as a rare delusional syndrome characteristically involving an individual who believes that another person, typically of higher social, economic or political status, is in love with the individual. De Clerambault's syndrome remains a ubiquitous nosological psychiatric entity with uncertain prognosis that remains recognised as a subtype of delusional disorder in DSM 5.

Objectives and aims To review the history of Erotomania as a nosological psychiatric entity, its clinical characteristics and course. Also to report some selected clinical cases.

Methods The authors have conducted an online search on PubMed with MeSH words “erotomania”, “erotomaniac delusion” and “Clérambault” and systematically reviewed some case reports.

Results Erotomania is a relatively uncommon and misunderstood disorder characterised by the presence of a persistent erotic delusion. The individual (usually described as a woman) has had little or no contact with the other person who is perceived as watching over, protecting or following the individual. Despite various authors have described and named this syndrome, it was Clérambault who first classed the symptoms into the disorder he referred to as “psychose Passionelli” (1942). There are numerous theories as to the aetiology of this illness that is not uniquely associated with any specific disorder. We reviewed some clinical cases.

Conclusions Erotomania is a relatively uncommon psychiatric disorder. An increased awareness and understanding of this illness will assist in the recognition of patients affected, opening doors for future progress on its aetiology and, therefore, the development of new treatment options.

Disclosure of interest The authors have not supplied their declaration of competing interest.

ADHD-associated risk-taking: The role of benefit and risk perceptions

Y. Pollak^{1,*}, H. Aloni², R. Shoham^{2,3}

¹ Hebrew University, School of Education, Jerusalem, Israel

² Hebrew University, Psychology, Jerusalem, Israel

³ Talpiot College, Special Education, Holon, Israel

* Corresponding author.

Attention deficit and hyperactivity disorder (ADHD) is associated with increased engagement in risk-taking behaviors. The present study aimed to further our knowledge regarding the extent and the reasons for the association between ADHD symptoms and risk-taking, using a theory-driven behavioral economy theory. The Domain Specific Risk-Taking scale was used, on which 244 adults rated the likelihood of engagement in a range of risky behaviors, across five real life domains, as well as the magnitude of perceived benefit and risk they ascribed to these behaviors. Level of ADHD symptoms was positively correlated with engagement in risky behaviors and benefit perception, but not with risk perception. Mediation analysis confirmed that benefit perception, but not risk perception, mediated the association between ADHD symptoms and engagement in risk-taking behaviors (Fig. 1). These findings emphasize the role of benefit perception in facilitating risk-taking by people with ADHD symptoms.

The delusion of aurora (a structural and dynamic analysis)

D. Porta Pelayo^{1,*}, L. López Alonso²

¹ Hermanas Hospitalarias, Mental Health Area, Málaga, Spain

² Psiquiatría, Psiquiatría, Las Palmas de Gran Canarias, Spain

* Corresponding author.

Introduction The classical authors associate the insanity with delusions, without delusions there was not insanity. This axiom has changed nowadays, and it's also accepted that insanity can exist without delusions.

Aim We aim to know and describe which factors are involved in the development of the delusion. Use these conclusions to drive the patient to the comprehension and acceptance of the reality.

Objective (a) Unravel the mechanism of delusion, (b) seek the causes, (c) find out an explanation about the origin and development of the delusional thematic.

Method Clinical biographic review, carried on in 2 steps: (a) review the delusions store in the Hermanas Hospitalarias Spanish hospitals (17 centres), (b) choose one of them, (c) use the inductive method for analyzing the details and for making conclusions in order to be apply in the delusional process.

Results (a) Understand the internal dynamic of delusion and how the delusion becomes the main axis of the patient life. (b) The patient finds on the delusion a life motive, which did not exist before.

Conclusion Paraphrasing Dr.Castilla del Pino, "the delusion is a necessary mistake". From the emotional point of view, it can be said "the delusion is a cry of a captured heart".

EV990

The psychopathology scan from the phenomenology

S. Rodríguez Vargas

Almería, Spain

Introduction This is a doctrinal movement that seeks to analyze mental illness without reductionism and seeks to grasp the nearest as possible to the reality of the patient.

Aims This is the analysis of an event, a concept, a feeling, trying to grasp as it is lived by the subject and in the direction you may have for him.

Methods Review of literature.

Results It was the first approach to the knowledge of the pathological experience and was the first scientific model to characterize the mental pathology. It was the central doctrine of psychiatry until the end of World War II, when the hegemony of the German psychiatric science gave way to the views that are primarily developed in Anglo-Saxon countries (psychoanalysis and behavioral psychology), although some European countries such as Germany and Spain continued growing until the 1980s, when it culminated in the publication of the DSM-III (1980).

Conclusions These approaches are "old fashioned" but are essential to understand and know the reality of human sick, "mentally ill man."

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Late paraphrenia. A case report

B. Serván Rendón-Luna^{1,*}, L. Reyes Molón¹,

R. Fernández García-Andrade¹, J. Fernández Aurrecochea²

¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

² Hospital Rey Juan Carlos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Paraphrenia is a chronic delusion, which may or may not be accompanied by hallucinations, usually with a late onset, and whose chronic course, unlike what it usually happens in schizophrenia, is not typically associated to the schizophrenic defect. When it appears in over 60-years-old people, we talk about late paraphrenia.

Objective Highlighting relevant aspects of paraphrenic symptoms and excluding entities such as dementia.

Methods Bibliographical review in literature and pub med using as keywords: "paraphrenia"; "megalomania"; "mystic-religious"; "late psychosis".

Results We present the case of a 69-years-old woman who showed megalomania, mystic-religious delusions, demonic presence and kinaesthetic and visual hallucinations. Brain SPECT: data within normal limits, neuropsychological study: possible mild cognitive impairment. First contact with psychiatry at age 63. History of 3 psychiatric income with different diagnoses: "dissociative state", "acute polymorphic psychotic disorder" and "frontotemporal dementia". The patient has been treated with different treatments (lithium, neuroleptics and benzodiazepines). Along the track has never been asymptomatic, presenting psychotic and affective semiology.

Conclusions A late paraphrenia case is shown. The study of senile psychoses has been traditionally full of controversies. Entities such as paraphrenia have been relegated in the current, however, it is a disorder with differential characteristics within the psychotic spectrum, so it seems wrong to do without the diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comparisons of psychological characteristics between schizophrenia, bipolar disorder and depressive disorder patients

M.S. Shin

Seoul National University College of Medicine, Psychiatry, Seoul, Korea

Introduction and objectives This study was conducted to examine the psychological characteristics of the schizophrenia ($n=20$), bipolar disorder ($n=20$) and depressive disorder ($n=13$) patients on MMPI-2 and Rorschach responses.

Methods MMPI-2 and Rorschach was individually administered to all patients, and their Rorschach responses were scored by Exner's comprehensive scoring system. The means of T scores of MMPI-2 subscales and Rorschach scores were compared among the three groups.

Results The schizophrenic and bipolar disorder groups showed significantly higher scores on the MMPI-2 K scale than the depressive group, while the depressive group showed significantly higher score on MMPI-2 Si scale than the schizophrenic and bipolar groups. In Rorschach responses, the bipolar and depressive groups obtained significantly higher scores on two variables (FM + m, m) than the schizophrenic group. The bipolar group obtained significantly higher scores on three variables (es, CP, a), suggesting hyperactivity and mood dysregulation.

Conclusions These results suggested that patients with depressive disorder might subjectively suffer from more severe emotional and social discomfort than patients with the schizophrenia and bipolar disorder, while patients with bipolar disorder and schizophrenia would be more defensive than the depressive patients.

Cotard's syndrome in the context of psychotic depression can be successfully treated with electroconvulsive therapy (ECT): A case report

R.F. Soldatos, E. Tzavellas*, D. Karaiskos, E. Oikonomou, T. Paparrigopoulos

Eginition Hospital of Athens, Psychiatry, Athens, Greece

* Corresponding author.

Introduction Cotard's syndrome is the delusional belief that one is dead or missing organs. Cotard's syndrome has been observed in mentally ill persons with psychotic disorders (such as schizophrenia and psychotic depression). Electroconvulsive therapy (ECT) was originally used for the treatment of catatonic schizophrenia. Additionally, case reports have suggested a possible role for ECT in two specific atypical psychotic disorders: Cotard's syndrome and cycloid psychosis.

Aim The aim of our study was the evaluation of ECT in situation such as Cotard's syndrome.

Methods-results We report a case of Cotard's syndrome associated with depressive symptoms. A 57-year-old man was admitted to our department with the diagnosis of psychotic depression. His presenting symptoms, which had started eight months before hospital admission, were somatic delusions of gastrointestinal and cardiovascular malfunction and the absence of brain. Head Magnetic Resonance Imaging had been occurred. The patient did not respond to antipsychotic therapies, so he started with

electroconvulsive therapy. After two months (ECT three times per week), the patient was successfully treated.

Conclusion This report emphasizes that electroconvulsive therapy could be the first-line therapy in such patients with psychotic disorders.

A case report: Sanchís-Banús syndrome

J. Valdés Valdazo*, C.M. Franch Pato, C. Martínez Martínez, A. Serrano García, J. De Santiago Sastre, A. Ugidos Fernández, J. Min Kim

Caule, Psychiatry, Leon, Spain

* Corresponding author.

Introduction There are few reported cases relating visual acuity and psychosis. The Spanish psychiatrist Sanchís-Banús focused on two patients who became blind and who, due to stress developed paranoid and jealousy delusional ideas. He called it "Sanchís-Banús syndrome" (SBS) that is mentioned in the psychiatry literature.

Methodology A case report. We present a case of "paranoid delusion of the blind" (SBS), quite similar in its clinical characteristics to those of the original patients of the valencian psychiatrist Sanchís-Banús. In our case, we met a 46-years-old woman, who worked as a lottery seller because she had a visual problem: retinitis pigmentosa. She had had her first psychotic decompensation when the blindness started. In spite of having achieved good social and work performance with quetiapine 400 mg/daily, laboral conflicts and stress caused her delusional ideas again. She began to think that her mother was not her real mother (Capgras syndrome) and that she was being persecuted. She also did not eat the meal and did not drink water because she thought that they were contaminated.

Results We started treatment with clozapine at doses of 300 mg every day (50-50-200) combined with aripiprazole 15 mg/day tolerating the medication without notable effects. After this adjustment of medication, remission and good criticism of hallucinatory and delusional clinical course. The nosological, clinical, and prognostic features of SBS are discussed in light of the current literature.

Preliminary data from a longitudinal 3-year study of patients with adjustment disorder

B. Vallejo-Sánchez^{1,*}, J. Martínez Arnaiz², C. García Blanco², A.M. Pérez-García³¹ Santa Bárbara Hospital, Mental Health Unit, Puertollano-Ciudad Real, Spain² Santa Barbara Hospital, Mental Health Unit, Puertollano-Ciudad Real, Spain³ UNED, Psychology Faculty, Madrid, Spain

* Corresponding author.

Introduction Adjustment disorder (AD) is a common diagnosis, but there are relatively few studies, in part because the current definition is still poorly specified, inadequate and controversial. Some clinicians and researchers have pointed out that a psychiatric diagnosis should present a clinical description, as well as date based on psychological, biological and/or sociofamiliar studies, and follow-up investigation about outcome and prognosis, to increase the reliability and validity diagnosis and permits exclusion of other possible disorders and normality. There is much empirical evidence

to indicate that AD is a transient disorder with a tendency to spontaneous remission. However, some studies have shown that patients with AD often develop major psychiatric disorders, presenting a higher rate of psychiatric morbidity, e.g., higher suicide rates.

Aim The aim of this study was to analyze the clinical and sociodemographic characteristics, as well as some possible personal vulnerability factors in patients with AD.

Method This longitudinal study was carried out on 80 outpatients diagnoses with AD at a Mental Health Unit, who were followed up for 3 years. It was analyzed different clinical and sociodemographic characteristics.

Results Significant differences between groups were found in some of the variables considered.

Conclusions The results add empirical evidence to a controversial and little-researched diagnostic category and provide guidelines for assessment and intervention. They also may contribute to improve diagnostic classifications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Soft neurological signs in schizoaffective disorder – Indicator of psychotic spectrum or diagnostic bias (case report)

V. Vukovic^{1,*}, S. Nikolic Lalic¹, J. Mitic², M. Stojanovic³

¹ Special hospital for psychiatric disorders “dr Slavoljub Bakalovic”, Affective disorders and borderline states unit, Vršac, Serbia

² Special hospital for psychiatric disorders “dr Slavoljub Bakalovic”, Unit for geriatric psychiatry, Vršac, Serbia

³ Special hospital for psychiatric disorders “dr Slavoljub Bakalovic”, Acute psychosis unit “P”, Vršac, Serbia

* Corresponding author.

Introduction Neurological soft signs (NSS) refer to a group of neurological deficits with no apparent pathognomonic substrate and comprise phenomena such as disorders of simple motor coordination, sensory integration, as well as disinhibition signs. Schizophrenia and other neuropsychiatric disorders are associated with a higher prevalence of NSS.

Case summary A 21-year-old male presented to our hospital with symptoms including anxiety, delusions, mood alterations, insomnia, and hypomania. Neurological assessment revealed presence of soft neurological signs. Personal history was positive for hypoxic birth injury and psychiatric heredity. During his stay, the patient showed not only partial response to treatment during several months, but also extrapyramidal symptomatology (limb hypertonia, decreased associated movements during walking, arm dropping, and rigidity of the neck, as well as elevated blood levels of CK, CRP, and high body temperature). There was no progression of NSS. The addition of valproate to antipsychotic treatment led to mild improvement. An MRI exam indicated presence of lesions in the white mass.

Discussion Although NSS have been more frequently associated with schizophrenia, especially in patients with dominant negative symptoms, there are findings, which suggest their presence in schizoaffective and bipolar disorders. Their presence is often an indicator of poor outcome, they can resemble EPS, and their association with frequency and severity of EPS is unclear.

Conclusion The presence of NSS is not enough to discriminate schizoaffective disorder, a “vague” diagnosis from others in what is considered the psychotic spectrum.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Special hospital for psychiatric disorders “dr Slavoljub Bakalovic”, Neurology unit, Vrsac, Serbia

⁴ Special hospital for psychiatric disorders “dr Slavoljub Bakalovic”, Acute psychosis unit, Vrsac, Serbia

* Corresponding author.

Introduction It is difficult to establish whether a patient has late onset schizophrenia or frontotemporal dementia. The object of the following case report is to point out the difficulty of making a differential diagnosis between these two entities.

Case summary A 49-year-old female patient was admitted to our hospital after presenting with auditory and visual hallucinations, formal thought disorder, persecutory delusions, ideas of reference, insomnia. Memory, executive function and attentional tasks were severely compromised. Computerized tomography showed incipient frontal lobe atrophy. There were no significant abnormalities found in blood and urine samples or physical and neurological examinations. After showing no response to olanzapine, and extrapyramidal side effects to fluphenazine, risperidone was initiated which subsequently led to complete withdrawal of positive symptoms.

Discussion Patients presenting with psychotic symptoms after the age of 40 presented a diagnostic quandary, as they were less likely to present with negative symptoms, formal thought disorder or affective blunting, and more likely to have systematised delusions and visual hallucinations. Frontotemporal dementia is a disorder that can present itself with cognitive decline and a large range of psychiatric symptoms. The risk of late onset schizophrenia is greater in women, possibly implicating a causative role of female sex hormones. Atypical antipsychotics risperidone and olanzapine seem to be an adequate treatment.

Conclusion Schizophrenia is a heterogeneous disease with a large variety of clinical manifestations. Special care should be given to patients with age over 40, including neurocognitive assessment, laboratory and hormone tests, and a long-term follow-up.

Disclosure of interest The authors have not supplied their declaration of competing interest.

N. Merola Fontoura, M. Ribeiro Garcia de Rezende,

C. Lima de Melo, A.F. Macedo de Queiroz

Hospital Municipal Jurandyr Manfredini, Ambulatório de Psiquiatria, Rio de Janeiro, Brazil

* Corresponding author.

Introduction Some kinds of hallucinations are misdiagnosed due to primary psychotic disorders. Hallucinations can be classified into 3 categories: true hallucinations, pseudo-hallucinations and hallucinosis. True hallucinations are different from the others due to incapacity of insight of the unreal and pathologic character of the phenomenon.

Objectives This study reports a case initially diagnosed as psychotic depression that after a rigorous psychopathologic investigation revealed to be an unspecified dissociative disorder.

Case presentation Twenty-four-year-old female, with a past of psychiatric treatment since 18-years-old, reports brief dysphoric episodes associated with visions of bleeding clowns and skulls that were always connected to a psychosocial stressor. At the interview she asserts that she understands those symptoms as pathological and caused by her mind, and associate them with external stressors. These episodes were brief and remitted spontaneously. The mental state examination did not show any psychopathological disturbance. The reduction and suspension of antipsychotics did not result in worsening of these symptoms.

Results The psychopathological disturbances reported by the patient did not represent a true hallucination. The presence of insight, the evolution and duration of the symptoms, and the association with psychosocial stressors has shown that the phenomena and symptoms are associated to a dissociative disorder. Therefore, the prescription of antipsychotics involves unnecessary pharmacological and clinical risks for this patient at the moment.

Conclusion Despite the use of psychopathology is considered by some as outdated, it is still an important semiological instrument for an accurate diagnosis and planning therapeutic conduct.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Atypical cognitive dysfunction due to brain damage: A case report

C.A. Welte-Santana*, A.F. Macedo de Queiroz, N. Merola Fontoura, C. Lima de Melo,

M. Ribeiro Garcia de Rezende, P.C. Ferreira da Silva, L. Oliveira, L. Carvalho de Toledo

Hospital Municipal Jurandyr Manfredini, Ambulatório de Psiquiatria, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The diagnosis of a primary psychiatric disorder requires the exclusion of an organic etiology. However, Brazilian public hospitals commonly lack resources. Diagnostic precision requires also the congruence of the clinical history and the natural history of the investigated disorder.

Objectives This study reports a rare case of hallucinations and retrograde amnesia, due to organic brain lesion but without other cognitive impairments.

Case presentation Fifty-three-years-old male Brazilian, was evaluated after one year in Brazil after being missing for 25 years in USA. Encountering his family, he did not recognize his mother, did not remember his life in Brazil, including his infancy, nationality and mother language. He was found as a homeless in poor hygiene. In the exam, he only presented retrograde amnesia, without any disturbances of fixation memory, intelligence, formal thought, affect or psychomotor function. Patient reported hallucinations. Blood tests showed no abnormalities. EEG showed diffuse slow rhythms. Brain MRI showed cortical and hippocampal atrophy. After weekly evaluations for 5 months, he remained stable despite lack of prescription. Some weeks after MRI, patient reported frequent alcohol and inhalant use when missing. No hints of secondary gain were found until present.

Discussion Organic etiology was suspected due to atypical presentation: hallucinations, evocative amnesia, with no further cognitive and affect disturbances. This is not compatible with schizophrenia, dementia or dissociative disorder. The brain

abnormalities and recent data highly suggest this etiological hypothesis.

Conclusion Since this clinical presentation does not fit into any specific psychiatric category, the case will continue to be studied.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Recent studies suggest that aripiprazole (ARP) shows a better profile in terms of mental state and extrapyramidal symptoms (EPS) in psychosis. However, other studies consider that a combination of atypical antipsychotics (AAP) may also be an option for some refractory patients. We present a case of a schizoaffective disorder, manic type (SAFM) (F25.0, ICD-10 criteria) that improved in terms of EPS adverse effects after switching from long-term fluphenazine (LTF) to Long-acting injectable aripiprazole (LAIA) but showed relapse symptoms.

Objective We present a clinical case of SAFM that improved clinically in our outpatient clinic after 1 month of bi-therapy with low doses of oral risperidone and standard dose of LAIA. We study oral AAP-LAIA drug combination utility in this clinical setting.

Aims To study "oral AAP-LAIA combo" benefits in refractory SAFM cases.

Methods Our patient is a 68-year-old female diagnosed of SAFM clinically stable with a combination of lithium and LTF. She presented severe cogwheel stiffness in the upper limbs and postural tremor. We switched from long-term fluphenazine to LAIA and 4 weeks later, she showed discrete cogwheel stiffness but also persecutory delusions and dysphoria.

Results We maintained LAIA (400 mg/28 days) and lithium (800 mg/day) doses and added-on risperidone 1 mg/day. She presented clinical relapse 1 month later. She kept her better EPS tolerance as she only had discrete cogwheel in upper limbs only by using attention distraction techniques.

Conclusions Oral risperidone-LAIA drug combination appears as an effective and well-tolerated treatment in refractory SAFM cases.

The practitioner cope with adverse events on atypical antipsychotics: About 63 patients with schizophrenia

I. Berrahal^{1,*}, R. Triki¹, R. Chebbi², B. Ghanjati¹, R. Ghachem¹

¹ Razi Hospital, Pinel, Mannouba, Tunisia

² Centre Hospitalier Universitaire Vaudois, Médecine et psychiatrie pénitentiaires, Lausanne, Switzerland

* Corresponding author.

Introduction The propensity of atypical antipsychotics (AAP) for having a therapeutic effect with fewer side effects and the balancing of these supposed benefits with tolerance are the subject of many studies.

Aims and objectives We focused on adverse drug events (ADEs), occurred under AAP, in a population of patients with schizophrenia to assess the prevalences and describe how the practitioner deal with these ADEs.

Methods We have used a retrospective and descriptive study of 63 Tunisian patients with schizophrenia, consulting in the adult outpatient of Razi hospital and treated by one type of AAP. The study period was 6 months from the 1st January 2015. We used the Birchwood Insight Scale (BIS), Positive and Negative Syndrome Scale (PANSS) and Udvalg for Kliniske Undersogelser (UKU) to assess the insight, psychotic symptoms and ADEs.

Results Twenty-four patients were on risperidone, 22 on olanzapine, 8 on amisulpride and 9 on clozapine. Antiparkinsonism drug (15.9%) was associated because of neurological ADEs mainly Parkinsonism. Asthenia had a prevalence of 20.6%. Hypersalivation and palpitation were estimated at 7.9% both. Weight gain's prevalence was 25.4%, including 1 case associated with hypercholesterolemia and 1 case of unbalanced non-insulin-dependent diabetes. The erectile dysfunction's prevalence was 36.3% and decreased libido 27%. There were 2 cases of neutropenia and thrombocytopenia. The management of these ADEs was observed when they moderately began to influence the patient's daily activity.

Conclusion ADEs must be subject to an appropriate treatment and if necessary resort to a specialist consultation to confirm or deny imputability to AAP.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Relapse prevention is one of the major goals in psychiatry because it will mark the prognosis and quality of life in patients. In this aspect, plays a very important role insight and adherence to treatment. Some studies show that long acting injectable treatments improve adherence as compared with oral medications.

Objective The objective of this study is to analyse the degree of insight and adherence to treatment of a group of patients with aripiprazole long acting injectable ALAI treatment.

Methodology Descriptive study in a group of patients treated with ALAI. Three months of follow-up. To assess the insight we had use the 3 first items of the Unawareness of Mental Disorder SUMD. Adherence to treatment is evaluated by monitoring if patients come to administrate ALAI.

Results $n=6$, 2 women (33.3%) and 4 men (66.7%). The mean age of the sample was 37 years. Diagnoses were 4 patients with psychotic disorder (66.7%); 2 with bipolar disorder (33.3%). At the SUMD, mean score for the items consciousness of having a disorder and awareness of the effects of medication was 3, and for the item awareness of the social consequences of mental disorder 4. The mean score for the total punctuation was 10. Five (83.3%) had a 100% of adherence, just 1 patient discontinued de treatment on the third month.

Conclusions On our sample adherence, it was almost complete in all patients. To highlight the scores for SUMD which means low insight. A large sample is required to increase the reliability of the study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessing quality of life following long-acting injection treatment: 4 cases register

C.M. Calahorro^{*}, M. Guerrero Jiménez, J.C. Navarro Barrios
Hospital Santa Ana, Unidad de Salud Mental, Motril, Spain

* Corresponding author.

Introduction Quality of life is defined by the World Health Organization as "Individuals' perceptions of their position in life in the context of the culture and value systems in which they live, and in relation to their goals, expectations, standards, and concerns." Schizophrenia is a severe, disabling, lifelong disorder, associated with severe social and occupational dysfunction. Aripiprazole Long Acting Injection (LAI) is indicated for maintenance schizophrenia treatment in adult patients stabilised with oral aripiprazole. It is the fourth second-generation antipsychotic depot formulation approved for treating schizophrenia.

Objectives Assessing quality of life in 4 patients treated with aripiprazole LAI.

Methods In this paper, we evaluate of quality of life in 4 subjects with diagnosis of paranoid schizophrenia (less 10 years of diagnostic), male, age between 42 and 50 years, with poor adherence to oral treatment. These patients received aripiprazol LAI 400 mg/month. We evaluate quality of life at baseline and after 3 months. We used the Quality of Life Scale (QOLS) and WHO-Quality of Life-Bref (WHOQOL-BREF).

Results Results demonstrated significant greater improvements in all QLS scores. No significant changes in the WHOQOL-BREF total, but improvement in subscale scores.

Conclusion Quality of life in schizophrenia is adversely influenced by the presence of clinical symptoms, especially negative and depressive. Depot medications can improve treatment adherence, however, long-term antipsychotic use can lead to irreversible adverse effects (dyskinesias), which in some cases were reduced by using newer antipsychotics (risperidone, paliperidone, aripiprazole). Aripiprazole LAI can be useful to improve quality of life. Further methodologically robust studies are needed to generate evidence-based conclusions.

Treating ADHD in people with intellectual disabilities

K. Courtenay

UCL, Department Mental Health Sciences, London, United Kingdom

Objectives Attention Deficit Hyperactivity Disorder (ADHD) is more prevalent in people with intellectual disabilities (ID). Drug therapy is the primary treatment for ADHD targeting the core signs of inattention, impulsivity, and hyperactivity (NICE 2013). Knowledge on ADHD has been gleaned from studies in children and children with ID. People with ID have comorbid disorders for example, autism and epilepsy that can complicate the management of ADHD. Knowledge of the effects of treatment is essential in managing ADHD in people with ID. The current evidence on the application of drug therapy for ADHD in ID is described.

Method A literature review of publications in English language was undertaken.

Results Using medication to treat ADHD is effective in treating the signs of ADHD in people with ID. The response rates in ID to drug therapy for ADHD approximates to 55% that is lower than in the general population. People with ID experience more side effects from medication that can lead to withdrawal from treatment. Guidelines exist internationally on the appropriate prescribing of medication. Methylphenidate, a psycho-stimulant drug is the drug of first choice. Atomoxetine, a non-stimulant drug, is effective in people with ID.

Conclusions ADHD in people with ID is treatable but clinicians need to be knowledgeable and skilled in managing the disorder in people with ID. Newer drugs could offer more because of their different profile of more tolerable side effects.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Analysis of the diagnoses of patients treated with palmitate paliperidone

C. Diago Labrador*, A.M. Álvarez Montoya, T. Ruano Hernández

Clínica privada, Clínica privada, Algeciras, Spain

* Corresponding author.

Objectives Review of the diagnoses of the treated patients with palmitate paliperidone for one year in a mental health unit, as well as some of their key sociodemographic characteristics, the length of the hospital stay and the average treatment according to clinical diagnosis.

Methods Descriptive epidemiological study including patients admitted to our hospital. It covers the period from January 2014 to December 2014.

Results For the period between January and December, a total of 315 patients were admitted in our mental health hospital unit, of which 45 were treated with paliperidone palmitate. The diagnosis were: schizophrenia (25 patients; 55.56%), schizoaffective disorder (7 patients; 15.56%), delusional disorder (5 patients; 11.11%), bipolar disorder (1 patient; 2.22%), personality disorder (2 patients; 4.44%), obsessive-compulsive disorder (1 patient; 2.22%), organic brain disorder (1 patient; 2.22%), schizophreniform disorder (1 patient; 2.22%) and mental retardation (1 patient; 2.22%). The mean age of patients was 35.7 years old. The most common marital status was unmarried state (30 patients; 66.6%). The average stay per hospital admission was 19.33 days. The most abused drugs were tobacco (31 patients; 68.8%). The mean dose of paliperidone palmitate was 137.5 mg. Schizophrenic patients need higher doses of treatment.

Conclusions A significant improvement in functionality was observed in our patients. What's proven efficacy and good

tolerability and adherence, so we consider paliperidone palmitate as a drug of first choice in the treatment of schizophrenia.

Nalmefene and alcohol use disorder

M.D. Díaz Piñeiro*, M.A. Gutiérrez Ortega, M. Mateos Agut, E. Martín Martínez, B. Sanz Cid

University Hospital of Burgos, Psychiatry, Burgos, Spain

* Corresponding author.

Introduction Psychopharmacology study.

Objective To evaluate Nalmefene effectiveness in clinical practice in patients diagnosed with alcohol use disorder.

Method Descriptive, prospective and observational study with patients diagnosed with alcohol use disorder, treated with Nalmefene during 6 months.

Results Twenty-seven patients (9 women and 18 men); average age: 47.92. A total of 64.28% with F10 as an exclusive main diagnosis. Drink urge perception at the beginning: 6.37 points over 10.6 months later, 3.25 points. Loss of alcohol drinking control perception at the beginning: 6.03 points over 10. Six months later, it is reduced down to 2.37 points. GGT reduction (from 107.18 to 36.5 U.I./L) and Mean Corpuscular Volume reduction (from 90.2 to 88.9 fl). The average of days/month with binge drinking at the beginning was 16.18 SD (standard drinks); and monthly total of alcohol consumption is 182.75 SD. After a month: 4.6 days and 66.52 SD. After 6 months, it decreases to 4 days/month and 63.3 SD. The results of the Rhode Island Change Assessment scale are: 7.4% in pre-contemplation stage, 70.37% contemplation stage, 3.7% action stage and 18.5% in maintenance stage. Six months later: 75% contemplation, 12.5% action and 12.5% maintenance stage. The main side effects were: nausea and vomiting, 22.22% at the beginning and 12.5% that persist with intakes; sexual side effects in 22.22% throughout the treatment; the 14.8% report increased sleeping and dreaming, 14.8% report restlessness, after six months drowsiness prevails with a 18%. At first, orthostatic dizziness appears in a 14.8%, disappearing 4 weeks later.

Conclusion Nalmefene is effective in reducing alcohol consumption, with few side effects and good acceptance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antipsychotic polypharmacy at the clinic of psychiatry, clinical centre of SerbiaN. Divac^{1,*}, A. Damjanovic², R. Stojanovic¹, K. Savic Vujovic¹, B. Letunica³, M. Prostran¹¹ Faculty of Medicine, University of Belgrade, Department of Pharmacology-Clinical Pharmacology and Toxicology, Belgrade, Serbia² Clinical Centre of Serbia, Clinic of Psychiatry, Belgrade, Serbia³ University of Belgrade, Faculty of Medicine, Belgrade, Serbia

* Corresponding author.

Introduction Antipsychotic polypharmacy is not supported by current guidelines. However, it is often present in practice. A common reason for this is to gain a greater, faster therapeutic response and reduce the doses of individual drugs, thus reducing the adverse effects.

Aims and Objectives The aim of this study is to analyze the prevalence of antipsychotic polypharmacy at the Clinic of Psychiatry,

Clinical Centre of Serbia and to compare it with the data from 10 years ago when similar research was conducted.

Material and methods This is a cross-sectional study conducted in 2015. The data were obtained from the patients' charts and compared with the results of a more extensive study conducted at the same hospital during 2002–2005 period. Statistics was performed using standard statistical methods.

Results Of the total number of patients ($n=44$), 81.8% ($n=36$) were on antipsychotic monotherapy, while in the previous study, which included 198 patients, monotherapy was noted in just 32.3% hospitalizations ($n=64$) ($\chi^2=34.5$; $P<0.001$). Among patients treated with polypharmacy, the majority was prescribed the combination of a first- and second-generation antipsychotic ($n=7$, 87.5%), while just one patient was treated with two first-generation antipsychotics ($n=1$, 12.5%). In the 2002–2005 period, the combination of two first-generation antipsychotics was dominant (58.9%, $n=79$).

Conclusion This study indicates that in Serbian psychiatry there is a strong tendency towards reduction of antipsychotic polypharmacy. However, this is a single-centre study with a relatively small number of participants and more extensive research on the national level is warranted to confirm this trend.

Lithium-induced acute intermittent dystonia in a patient with schizoaffective disorder

A. Engel*, T. Bilbruck, S. Hossain, R. Leahy
University of Tennessee, Psychiatry, Memphis, USA

* Corresponding author.

While lithium is well known for its neurotoxicity, there are very few publications about lithium-induced acute dystonic reaction. We are presenting a clinical case of lithium-induced acute intermittent dystonic reaction in a patient with schizoaffective disorder (SAD). The patient is a 69-year-old African-American male with a long history of SAD, who was treated for many years with ziprasidone and divalproex and was admitted with SAD exacerbation. Due to increased QTC interval, we switched patient to lurasidone. After 2 weeks, due to increased ammonia level, divalproex was switched to lithium (600 mg loading dose and then 450 mg twice/day). Three days later, patient developed a series of intermittent episodes of acute dystonia, manifested as mutism, dysarthria, upper and lower extremity muscle rigidity, dysphagia, and tremor (Table 1). Dystonic reactions responded to benztropine. Eventually, lithium was discontinued and patient did well on a combination of carbamazepine and olanzapine. In this case, we would like to emphasize not only the intermittent but also the atypical presentation of acute dystonic reactions with involvement of large muscle groups, the resemblance to NMS, and a "spectrum" of dystonic reactions rather than one clear-cut presentation. We can only speculate the role lurasidone played in this presentation but reoccurrence of dysarthria on day 54 after lithium was restarted points to its major role.

Table not available.

Tolerability and side effects of an extended-release injectable suspension of aripiprazole in a series of inpatients in a dual diagnosis unit

A. Farre*, A. Palma, G. Mateu, J.L. Perez de Heredia, R. Martinez, C. Castillo, M.G. Hurtado, J. Martí, R. Sanchez, M.T. Campillo, M. Torrens

Parc de Salut Mar, Institut Hospital del Mar d'Investigacions Mèdiques-IMIM-UAB, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain

* Corresponding author.

Introduction The integrated care in dual diagnosis units involves selecting pharmacological treatment strategies for both substance use disorder and the non-addictive psychiatric disorder. It is recommended to choose drugs with a favorable balance between efficacy/tolerability, an adequate side effects profile and the minimal drug interactions.

Objectives and aims To evaluate the tolerability and side effects after first administration—first dose of an extended-release injectable suspension of aripiprazole in a group of patients admitted to an acute dual diagnosis unit.

Methods The study included a series of patients admitted in our unit from May to August 2015 that received the first dose of the aripiprazole preparation (400 mg). Evaluations included different scales for side effects (SAS, ESRS, UKU) and the clinical global impression scale (CGI).

Results A total of 9 patients were included and evaluated (all men, mean age: 39-years-old). Diagnoses were: bipolar disorder (5/9), schizophrenia (2/9), schizoaffective disorder (1/9) and delusional disorder (1/9) with concomitant substance use disorder (6 cannabis, 2 alcohol, 1 cocaine). All of them without outpatient control and treatment at admission. The results of the clinical scales conclude that none of them had significant side effects, including extrapyramidal, with an improvement in the ICG scale.

Conclusion Tolerability of extended-release injectable suspension of aripiprazole was good in all cases. In the future, new cases should be included to extend the sample and to evaluate other aspects such as the craving for substances.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment efficacy with paliperidone palmitate in patients after the first psychotic episode

S. Galiano Rus^{1,*}, A. Soler Iborte², S. García Marín³

¹ Servicio Andaluz de Salud-UGC Jaén Norte, Unidad de Salud Mental Hospitalaria San Juan de la Cruz, Úbeda-Jaén, Spain

² Servicio Andaluz de Salud-UGC Jaén Norte, Unidad de Salud Mental Comunitaria Linares, Linares-Jaén, Spain

³ Servicio Murciano de Salud, Unidad de Salud Mental Comunitaria Lorca, Lorca-Murcia, Spain

* Corresponding author.

Objectives To evaluate factors of therapeutic efficacy of paliperidone palmitate, such as the speed of action and its maintenance in patients who experienced a first psychotic episode that led to a hospital admission in the acute unit.

Materials and methods Two-year observational and descriptive study. Patients admitted to the Mental Health Hospital Unit (MHU) from January 2013 to July 2014, with a first psychotic episode and under paliperidone palmitate treatment. Monitoring and evaluation six months after hospital discharge. They were evaluated using the PANSS and BPRS scales at four different time points of the evolutionary process.

Results Average scores of the BPRS scale: 39 on admission day, 27 on day of discharge, 23 on the third month and 20 on the sixth month. Average score of PANSS scale: PANSS-PG: 64 on admission day, 48 on day of discharge, 25 on the 3rd month, and 20 on the 6th month. PANSS-P: 41 on admission day, 21 on day of discharge, 12 on the 3rd month, and 10 on the 6th month. PANSS-N: 21 on admission, 11 at discharge, 8 on 3rd month and 7 on 6th month. No clinically significant side effects were observed that would lead to the modification of the doses or the abandonment of the treatment in this period.

Conclusion The results of this observational study show that the start of the treatment with PAP is associated with an observable clinical response on the 4th day. The evaluation scales at the 3rd and 6th months also suggest the maintenance of efficacy of the treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1011

Effective doses of paliperidone palmitate (PAP): Retrospective analysis from three years of treatment

S. Galiano Rus^{1,*}, A. Soler Iborte², C. Quesada González³

¹ Servicio Andaluz de Salud-UGC Jaén Norte, Unidad de Salud Mental Hospitalaria, Úbeda-Jaén, Spain

² Servicio Andaluz de Salud-UGC Jaén Norte, Unidad de Salud Mental Comunitaria, Linares-Jaén, Spain

³ Servicio Andaluz de Salud-UGC Jaén, Unidad de Salud Mental Hospitalaria, Jaén, Spain

* Corresponding author.

Introduction The use of PAP is already much extended in general. The recommended doses in the technical specifications of the drugs, as the result of trial studies, differ from the doses administered in habitual clinical practice. Therefore, the justification of this study is to monitor the average doses prescribed, to be able to reach an agreement on the best doses. To retrospectively analyze the first 32 patients in our area of healthcare, who were prescribed PAP, the doses used at the start of treatment and after 3 years.

Materials and methods Two initial doses of PAP were analyzed, maximum and current (outpatient) in 32 patients attended in the area of mental health of North Jaen, who started the treatment with PAP between 2012 and 2013, with an average length of time of 2.55 years (SD 2.02). We evaluated the diagnosis (schizophrenia and related disorders, ICD-10 F20), the number of hospital admissions previous and posterior to the start of the treatment and change in weight.

Results Average doses: initial: 110.15 mg (SD 32.83), maximum: 165.51 mg (SD 29.76) and maintenance: 146.81 mg (SD 29.59). Average hospital admissions: prior and posterior to the start of treatment: 1.5 and 0.83. An average reduction of 44.06% in admissions was observed.

Conclusions The data obtained suggests that a dose of 75–200 mg could be effective in the maintenance of patients with schizophrenia and for decreasing the number of new hospital admissions. Fifty percent of the cases can be compensated with long acting paliperidone as a monotherapy.

Discontinuation, readmissions and polytherapy with long-acting antipsychotics: An observational study

I. García Cabeza^{*}, P. Pérez Marín, H. De Diego

Hospital General Universitario Gregorio Marañón, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction and aim Long-acting antipsychotics (LAIs) provide certain advantages over oral medications. The aim of our study is to determine whether there are differences between the various long-acting injectable antipsychotics available in our environment. **Methods** A retrospective observational study with psychotic patients discharged with LAIs was designed. Data on discontinuation, relapses and associated drugs in the discharge and in a year follow-up were collected. Fifty-seven patients were included: 21 risperidone (RLAI), 20 paliperidone palmitate (PP) and 16 first-generation LAIs (FG). Odds ratio was used to compare discontinuation, χ^2 test for categorical variables and Kruskal-Wallis test for independent samples.

Results Discontinuation was lower with PP: $OR_{RLAI/PP} = 2.74$ and $OR_{FG/PP} = 3.09$. There were significant differences in readmissions: rehospitalizations ($\chi^2 = 7.072$, $P = 0.029$) and days of stay ($\chi^2 = 8.251$; $P = 0.016$), both lower in the PP group. We found less use of psychoactive drugs with PP, with significant differences in the discharge ($\chi^2 = 11.518$; $P = 0.003$) and in the follow-up ($\chi^2 = 7.097$; $P = 0.029$). There were also significant differences in the use of oral antipsychotics in the discharge ($\chi^2 = 27.049$, $P = 0.000$); anticholinergic drugs in the discharge ($\chi^2 = 7.001$, $P = 0.03$) and in the follow-up ($\chi^2 = 11.699$, $P = 0.003$) and benzodiazepines in the follow-up ($\chi^2 = 8.493$, $P = 0.014$), always lower in the group of patients treated with PP.

Conclusions Treatment with paliperidone palmitate may be more suitable than other long acting antipsychotics when it starts during the acute episode.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Economic evaluation of long acting aripiprazole as maintenance therapy for paranoid schizophrenia

C. Gómez Sánchez-Lafuente^{1,*}, R. Reina Gonzalez²,

E. Mateos Carrasco¹, F. Moreno De Lara¹, A. De Severac Cano¹

¹ Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

² Hospital Regional Universitario, General Practitioner, Málaga, Spain

* Corresponding author.

Introduction Patient adherence to a treatment regimen is of utmost importance for successful outcomes in schizophrenia. Long acting aripiprazole (LAA) is a new drug of depot antipsychotic type placed in the market recently that could prevent non-adherence and in reducing relapse in schizophrenia administered every 28 days.

Objective A descriptive, observational study designed to explore the efficacy and tolerability of long acting aripiprazole in a sample of patients diagnosed with paranoid schizophrenia that were admitted to Acute Unit in 2014. LAA was introduced on the admission.

Methods Sociodemographic variables: age, sex, and marital status. Clinical variables: average time since diagnosis, concomitant consumption of toxic substances, reason to change medication, subsequent readmissions after LAA was introduced, evaluation of

the modification of the oral regimen. PANSS and CGI. Metabolic profile: weight, glycaemia, and total cholesterol, LDL and HDL, triglycerides. Cost at the beginning and after 6 months.

Results Mean age: 44.50 years, 54% women. Marital status: 54% single, 27% married, 27% divorced. Mean time from diagnosis: 11 years. Toxic consumption: 27% active, 18% ex-drug users. Three patients were readmitted after introducing LAA, 2 of them were for abandoning medication (including LAA). PANSS at 6 months showed statistically significant differences in negative subscale (3 points). No statistical differences in positive and general psychopathology subscales. No metabolic side effect was found. Average saving per patient 37.05 euros per month (Fig. 1).

Conclusion This study signalizes that LAA is an effective treatment. Clinically, it has been shown that our patients improve adherence and prevent relapse. Moreover, no metabolic side effects were found. Besides, LAA is also efficient and we would save 407,55 euros per month.

Twenty-four months experience of paliperidone long-acting injection in a Spanish psychiatric service: A mirror image analysis

C. Gómez Sánchez-Lafuente^{1,*}, R. Reina Gonzalez², F. Moreno De Lara¹, A. De Severac Cano¹, E. Mateo Carrasco¹, A. González Moreno¹

¹ Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

² Hospital Regional Universitario, General Practitioner, Málaga, Spain

* Corresponding author.

Introduction Lack of adherence is a common cause of relapse in schizophrenia. Long-acting antipsychotics have shown in recent

studies that they improve compliance. However, some randomised controlled trials showed no difference in relapse rates between oral medication and long-acting injections.

Objective To report the use of paliperidone palmitate in an Acute Psychiatrist Unit in Spain.

Method Retrospective observational study of 42 patients prescribed paliperidone palmitate (PLAI) during an admission at Acute Psychiatric unit in Málaga. In the mirror image analysis, the main outcome measure was the total number of days of psychiatric inpatient care twelve months before and after patients started Paliperidone palmitate.

Results Most common reason for starting paliperidone palmitate was lack of adherence to oral medication (54%) followed by lack of efficacy on previous medication (31%). Olanzapine (47%) and risperidone (41%) were most commonly antipsychotics prescribed before PLAI. Thirty-four patients continued PLAI over twelve months (80%). Poor compliance was the most common reason of withdrawal. Three patients had a movement disorder adverse effect. Only one was lost because adverse effects. Total admissions and inpatient days were significantly reduced from the previous treatment to PLAI-treatment period (Table 1).

Conclusion PLAI was associated with a reduction in total inpatient days. The financial saving from reduced admissions stays exceeded the acquisition and administration cost of PLAI. Improved compliance because of PLAI is the most plausible explanation of this result (Fig. 1).

Table 1

	Previous treatment period	PLAI period
Total Admissions	81	45
Inpatient stays in days	943	516
Mean reduction in inpatient stays		10 days
Financial saving (euro/patient/year)		2905

The psychotropic effects of anti-epileptic drugs: A review

A. Guerra*, D. Ferreira, C. Pereira, M. Carvalho

Hospital de Santa Maria – Centro Hospitalar Lisboa Norte, Psychiatry and Mental Health Department, Lisbon, Portugal

* Corresponding author.

Anti-epileptic drugs (AEDs) are psychotropic agents that are widely used for the treatment of a variety of neurological conditions and psychiatric disorders. Although the association between psychopathology and AED therapy has long been recognized, a systematic evaluation of its effects on mood and behaviour has taken place only more recently. A literature review, based on a PubMed research, takes stock of the studies that have investigated this subject in the latest years. Depending on the drug, its efficacy and the individual's biological and psychological predisposition, all AEDs may lead to positive or negative psychotropic effects. The exact frequency of psychiatric adverse events related to AEDs is difficult to estimate, but behavioural problems seem to be the most common, followed by depressive disorders. Psychosis is a relatively rare, although severe, complication. The AEDs' potential psychotropic effects will be addressed in detail, with special focus on their mood, behavioural and cognitive profile, as well as the mechanisms underlying these events. When recognized at an early stage, psychiatric complications are in most cases mild and reversible. Risk factors are not a strict indication for any particular drug, but side effect profiles, including negative and positive psychotropic effects, must be considered in the choice of the optimal drug for the individual patient. The studies regarding this subject are limited as they are designed to test anti-epileptic efficacy and psychiatric adverse events are not systematically reported. This subject also warrants further research since many relevant aspects concerning pathological mechanisms, frequency, psychopathology and prognosis are not well understood.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antipsychotic medications and cardiometabolic risk – A review of current literatureS. Gunturu^{1,*}, K. Shah², P. Korenis², S. Lawler³, M. Kucheria²¹ New York, USA² Bronx Lebanon Hospital Centre, Psychiatry, New York, USA³ American University of Caribbean, Psychiatry, Sint Maarten, Trinidad and Tobago

* Corresponding author.

In the USA, 68% of adults and 31% of children are overweight or obese. Obesity doubles mortality rates and has significant associated medical costs with an average obese person spending \$1500 or more per year. In addition, 10% of all adults and 23% of adults over 60 years have type 2 diabetes, with an average person spending \$2257 or more per year. In 2009, 1 out of every 10 healthcare dollars was spent on type 2 diabetes, totalling \$174 billion. People with serious and persistent mental illness die on average 25 years earlier than the general population. Cardiovascular disease is the primary cause of death in persons with mental illness and accounts for 60% of the increased mortality. Furthermore, 46.24% of individuals with cardiometabolic risk factors who are also on antipsychotic medications take high- to moderate-risk antipsychotics. The cluster of cardiometabolic syndrome includes: type 2 diabetes, hypertension, dyslipidemia, obesity and pre-existing cardiovascular disease. There are, however, modifiable risk factors including smoking cessation, diet change, physical activity, medical care and choice of antipsychotic medication (on which

the physician has direct control). More information is therefore needed on various antipsychotic medications and their associated cardiometabolic risk factors in order to educate physicians. In this review article, we examined 10 articles on antipsychotic medications, and their effect on the 5 domains, including type 2 diabetes, hypertension, dyslipidemia, obesity and pre-existing cardiovascular disease. Overall, there was a clear trend, which found a significant difference in the associated risk factors amongst various antipsychotic medications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical predictors of clozapine responseK. Hajji^{1,*}, I. Laajmi², I. Marrag², S. Fathallah², M. Nasr²¹ Boulogne Billancourt, France² Hospital of Mahdia of Psychiatry Mahdia, Mahdia, Tunisia

* Corresponding author.

Introduction Schizophrenia is a chronic, severe, and disabling mental disorder. An evaluation of clinical predictors to clozapine was described.

Object Identify clinical predicting factors to clozapine.

Methods This is a cross-sectional study including patients diagnosed with schizophrenia or schizoaffective disorder according to the DSM 5 criteria and treated with clozapine.

Results Of the 33 patients, 78.8% were males and 69.7% of them were single. The mean age was 36 years old. The mean age at the onset of the disorder was 24 years old. The mean number of hospitalizations was 6. The beginning of the mental disorder was acute in 21.2% of the cases. The mean duration of the disease course before starting clozapine treatment was 11 years. The mean duration of treatment was 19 months. The diagnosis according to DSM 5 criteria was schizophrenia in 87.9 and schizoaffective disorder in 12.1% of cases. The outcome was assessed by PANSS and BPRS scales with a symptomatic remission in 63.63% of cases. The analytical study revealed a significant correlation between favorable evolution and the latest onset of the disorder ($P=0.04$), the number of previous hospitalizations ($P=0.009$), disorder's duration ($P=0.032$), male sex ($P=0.0004$) and secondary resistance ($P<10^{-3}$).

Conclusion The evaluation of clinical factors is important in our practice in order to improve the response to clozapine. Otherwise, adherence to treatment and quality of insight are determining factors of the treatment response.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Paliperidone palmitate versus other antipsychoticsP. Hervías Higuera^{1,*}, L. Maroto Martín¹, S. Raffo Moncloa¹, M. Leonor del Pozo²¹ Hospital Dr. R. Lafora, Psiquiatria, Madrid, Spain² Hospital Dr. R. Lafora, UHB Psiquiatria, Madrid, Spain

* Corresponding author.

The aim of the study was to describe the psychopharmacological treatments received by inpatients diagnosed with spectrum disorders schizophrenia and other psychotic disorders in Dr. Rodriguez Lafora Hospital. It is an observational, descriptive and retrospective study. We collected information about patients aged 18 to 64 who were hospitalized during the month of January of 2015 in the acute psychiatric hospitalization by Selene software. We reviewed treatments and number of psychiatric re-hospitalization six months later and we analyzed the results by SPSS software.

From a sample of 51 inpatients, 15 of them were diagnosed with disorders of the spectrum of schizophrenia and other psychotic disorders. Of the patients, 13.3% was treated with haloperidol, 26.7% with olanzapine, 26.7% with risperidone although it was modified by paliperidone in mental health center, 6.7% with quetiapine, 6.7% with amisulpride, 13.3% with oral paliperidone and 13.3% patients with intramuscular paliperidone. Of these, 40% are readmitted to hospital. Patients were readmitted due to ineffectiveness and adverse effects of haloperidol, olanzapine, risperidone. 73.3% of inpatients were treated with monotherapy. Of the patients, 26.7% were treated with polytherapy, who received olanzapine, risperidone and amisulpride. It would be important to use psychoactive substances that allow monotherapy to reduce adverse effects and psychiatric re-hospitalization.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effects of using psychotropic drugs in the etiology and prevention of deviant behavior

S. Ibrahim

Albanian University, Psychology, Tirana, Albania

Objective The objective of the article is to explore the main features of the relationship between these components that produce the effect in the etiology of deviant behavior.

Methods The study is a comprehensive and comparative of data in the pharmaco-epidemiology groups of Mental Health Care and Community Centers in Albania in 2014–2015. The methods used are explorative, qualitative and epidemiologic as to the reports of subjects and official data.

Results The psychiatry of changing behavior is certainly a milestone of the nowadays health. Data collected from a 6-month follow-up of new cases of youth with an uncontrolled impulse and a low ego resilience on a psychotropic prescription have given a clear view of connection between the type of psychotropic drug used and the level of reaction the drug has created in the prevention of a further development of deviant behavior.

Conclusions In the end of this approach, we could reach to confirm that the more the knowledge on the usage and effects of psychotropic drugs, the better will be the preventive efforts to their effects over the deviant behavior in the individual.

Keywords Psychotropic; Deviant behavior; Etiology; Prevention; Adverse effect

EV1020

New models for research and development in the treatment of mental illness

J.N. Kjær

Aarhus University Hospital, 1 Department of Organic Psychiatric Disorders and Emergency Ward, Risskov, Denmark

The pharmaceutical industry's investments in research and development of novel treatments for mental illness have heavily declined in the past decade. Major private investments are, by most experts, seen as necessary to develop new treatments. However, psychiatry is not the only area overlooked by the industry. For decades infectious diseases have also lacked investments in research and development.

Aims The aims of this study were to investigate the new models of research and development in infectious diseases that emerged

after the pharmaceutical industry ceased their investments and to model how these can be used in psychiatry.

Method A systematic review. We searched PubMed, EMBASE and Web of Science for the keywords “infectious diseases”, “research and development” and “pharmaceutical industry”.

Preliminary results The searches gave a total of 248 references. Among the findings, we want to highlight the Drugs for Neglected Diseases initiative (DNDi) and the WHO Research and Development Treaty (R&D Treaty). DNDi is a non-profit organization that has developed six new drugs since 2003. The development costs were €150 millions per drug, which is considerably below the costs for drug development claimed by the pharmaceutical industry. The R&D Treaty will commit member states of the WHO to fund development for neglected health needs using alternative incentives like milestone prizes, patent pools and direct grants. The treaty has not yet been agreed upon.

Conclusions Though a low priority from the pharmaceutical industry, other funding models have proven able to deliver new treatments. This could also lead to more development of non-patentable treatments, e.g. psychotherapy.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Clinical and socio-demographic characteristics of a sample of outpatients with long-acting injectable antipsychotic treatment

J. Moreno Monmany*, I. Tinoco Calero, N. Bagué Gomez, B. Samsó Buxareu, V. Chavarria Romero, S. Castillo Magaña, S. Oller Canet

Parc de Salut Mar, INAD, Barcelona, Spain

* Corresponding author.

Introduction There are relatively few studies of Long-acting injectable antipsychotics (LAI), although poor adherence to treatment is one of the main problems in patients with psychotic disorders.

Objectives The aim of the study is to describe socio-demographic and clinical characteristics of a sample of outpatients with LAI treatment.

Methods This is a cross-sectional study. A randomized sampling was performed among the outpatients that were receiving LAI in an outpatient clinic in Barcelona (Spain). For each patient, socio-demographic, clinical and pharmacotherapeutic data were collected through interviews and clinical history.

Results The sample consisted of 30 subjects (50% men, average age 48 years). Most of the patients in the sample have basic education (50%) and are unemployed, receiving permanent disability pension (39.3%). In addition, 44.8% of the subjects were living with family members and were not married (56.7%). Of the patients, 70% were diagnosed with schizophrenia, 13.3% schizoaffective, 10% bipolar and 6.7% delusional disorder. The main reason to initiate LAI treatment was due to non-compliance of the prescribed oral treatment (85.7%). The 40% of patients were also with oral antipsychotic treatment. Average punctuation in the 3 first items of the Scale to Assess Unawareness of Mental Disorder: 11. Average punctuation in the short version of the Simpson-Angus Scale: 1.68.

Conclusions In our sample, the outpatients with LAI treatment had a low functioning and disease awareness. Although the main reason to start LAI is the non-compliance, 40% of the patients were concurrently treated with oral antipsychotics. The extrapyramidal side effects are mild.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1022

Delay in initiating clozapine therapy in a Sri Lankan setting

C. Kapugama*, W. Kotalawala

National Hospital of Sri Lanka, Department of Psychological Medicine – Ward 59, Colombo, Sri Lanka

* Corresponding author.

Introduction Treatment resistance occurs in one third of patients with schizophrenia. The only licensed drug for this is clozapine. Guidelines recommend that clozapine be offered at the earliest opportunity for patients with treatment resistance. Sometimes, delays occur in initiating clozapine.

Objectives and aims To study the delay in offering clozapine to patients with resistant schizophrenia.

Methods Descriptive study. Random sample of patients on clozapine attending NHSL, 'clozapine clinic' were interviewed, and their clinical records reviewed.

Results Sample 63 (25 males, 39.68%). Mean age: 34.95 years; mean duration of illness: 13.42 years. Clinical diagnosis in all was schizophrenia. Mean duration on treatment with clozapine was 6.80 years. In 28 (44.44%), two drug trials were tried prior to clozapine; three drug trials in 26 (41.26%); four drug trials in 9 (14.28%). In 49 (77.77%) patients, two second-generation antipsychotics (SGAs) tried prior to clozapine while in 14 (22.22%) three SGAs tried. Entire sample was given both risperidone and olanzapine. Antipsychotic polypharmacy was used in 18 (28.57%). Higher than recommended doses of antipsychotics either alone or in combination, were used in 36 (57.14%). Olanzapine up to 30 mg daily was tried in 25 (39.68%).

Conclusion There is a considerable delay in offering clozapine to patients with resistant schizophrenia. Multiple drug trials, antipsychotic polypharmacy and administration of higher than recommended drug doses seem to precede clozapine in a large percentage of patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aripiprazole is effective for the improvement of psychotic symptoms in patients with dementia with lewy bodies

Y. Kikuchi*, T. Kanbayashi, T. Shimizu

Akita University School of Medicine, Neuropsychiatry, Akita, Japan

* Corresponding author.

Objective Dementia with lewy bodies (DLB) is commonly considered the second most common form of dementia. The purpose of this study is to investigate the treatment effects of aripiprazole in patients with DLB.

Methods Eleven patients who had meet the criteria for DLB participated in this study. The presence of psychotic symptoms was confirmed by scores of either the delusions or hallucinations items of the Neuropsychiatric Inventory (NPI) score. Patients who had 25 or more on the Mini-mental State Examination Scale (MMSE) at the entry or having brain damage were excluded. Aripiprazole was initiated at a low dose (3 or 6 mg/day) and titrated to higher doses at 2-weeks intervals or more rapidly based on investigator's judgment. Previous medications prior to aripiprazole administration were not changed through this trial. Patient's clinical status was assessed at baseline, then 2 weeks during the study by using NPI, Clinical Global Impression (CGI) and Brief Psychiatric Rating Scale (BPRS) to measure psychotic behavioral symptoms, and Simpson-Angus Scale (SAS) to measure parkinsonism symptoms. Clinical Dementia Rating (CDR) and MMSE were carried out at screening and end point to evaluate cognitive function.

Results The mean scores of the SAS and CDR were significantly decreased at the study endpoint compared to baseline. The mean scores of the NPI and BPRS improved up until 4 weeks after having started aripiprazole. After 4 weeks, improvements slowed. The mean score of the CGI-S was decreased up until 8 weeks.

Conclusion This study shows that aripiprazole may be effective for the treatment of psychotic symptoms in patients with DLB.

Tropicamide eye drops reduce clozapine-induced hypersalivation: A case reportO. Kilic^{1,*}, H.M. Ozturk², E. Ata²¹ Beykent University, Psychology, Istanbul, Turkey² Abant Izzet Baysal University Izzet Baysal Mental Health Research and Training Hospital, Psychiatry, Bolu, Turkey

* Corresponding author.

Introduction Clozapine-induced sialorrhea (CIS) is a common, treatment-limiting and stigmatizing side effect. All systemic agents that are used for hypersalivation may increase clozapine side effects such as blood pressure changes, constipation, or arrhythmias. Oral application of topical anti-muscarinic agents may be a low side effect option for treatment of CIS.

Objective The aim of this case report was to propose an off-label treatment of tropicamide drops to CIS and to stimulate further investigation.

Case report A 33-year-old male inpatient with schizophrenia has been on clozapine 800 mg and amisulpride 600 mg/day. His drooling was occasional and severe as drool drips off his chin during the day and night. Wet area over the pillow, visual analog scale (VAS), the short form of health survey (SF-36), UKU side effect rating scale, scale for the assessment of negative symptoms (SANS), scale for the assessment of positive symptoms (SAPS) were applied at baseline and in one-week intervals. Oral application of one drop of tropicamide % 0.5 (5 mg/mL) to left and one drop to right side before going to bed in the first week and two drops to each side were administered subsequently. Informed consent was given by the patient.

Results No psychological, neurological, autonomic and other side effects were observed associated with tropicamide. On VAS, the patient rated hypersalivation 5/7 at baseline, 4/7 after one drop each, 3/7 after two drops each.

Conclusions The reduction of CIS by oral use of tropicamide eye drops is promising and should be explored with randomized controlled trials.

* Corresponding author.

Alzheimer's disease (AD), a neurodegenerative neuropsychiatric disorder, is often comorbid with depression and anxiety. Neuropsychiatric disorders are also characterized by sex differences. However, most preclinical pharmacological studies are conducted using only males. Herein, we used male and female twelve-month-old mice (3xTg) expressing mutated forms of human proteins Tau, APP and Presenilin1. These mice are considered a valid animal model of AD. We investigated the effects of the natural compound trans-crocin-4 (TC-4), which is derived from *Crocus sativus* and the olive compound oleuropein on the cognitive, depressive and anxious profile of 3xTg mice. We found that male and female 3xTg mice exhibited reduced locomotor activity and oleuropein treatment (100 mg/kg i.p., for 21 days) did not reverse this phenotype. In addition, anxiety- and depressive-like behaviors were not affected by genotype, sex or oleuropein treatment. Interestingly, oleuropein exhibited a tendency to enhance cognitive performance in male 3xTg mice. Treatment with TC-4 (50 and 150 mg/kg, i.p., acutely or chronically for 10 days) affected locomotor activity in a sex-differentiated manner. Interestingly, acute TC-4 clearly enhanced cognitive performance in all groups although it reduced center entries in the open field. Additionally, chronic TC-4 treatment enhanced novel object discrimination mainly in male 3xTg mice. Our findings highlight the potential of those natural compounds, which warrant further investigation but also emphasize the benefits of including both males and females in preclinical pharmacological studies.

A comparison of risperidone and olanzapine in the acute treatment of persistent delusional disorder: Data from a retrospective chart review

K. Kulkarni^{1,*}, R. Arasappa¹, K. Prasad¹, A. Zutshi², P. Chand¹, K. Muralidharan¹, P. Murthy¹

² Epworth Hospital, Psychiatry, Melbourne, Australia

* Corresponding author.

Introduction There is a lack of pharmacological trials studying drug response in Persistent Delusional Disorder (PDD) to guide clinical practice. Available reviews of retrospective data indicate good response to second-generation antipsychotics, but even such data from India is sparse.

Objectives and aims We aimed to compare the response of acute PDD to risperidone and olanzapine in our retrospective review.

Methods We conducted a retrospective chart review of patients diagnosed with PDD (ICD-10) from 2000 to 2014 ($n=455$) at our Center. We selected the data of patients prescribed either olanzapine or risperidone for the purpose of this analysis. We extracted data about dose, drug compliance and response, adverse effects, number of follow-up visits and hospitalizations. The study was approved by the Institute Ethics Committee.

Results A total of 280/455 (61%) were prescribed risperidone and 86/455 (19%) olanzapine. The remaining ($n=89$; 20%) had received other antipsychotics. The two groups were comparable in socio-demographic and clinical characteristics of PDD. Compliance was good and comparable in both groups ($>80\%$, $P=0.2$). Response to treatment was comparable in both groups (85% partial response

and $>52\%$ good response, all $P>0.3$). Olanzapine was effective at lower mean chlorpromazine equivalents than risperidone (240 vs. 391, $P<0.05$).

Conclusion Our study indicates a good response to both risperidone and olanzapine, if compliance to treatment can be ensured. In the absence of specific treatment guidelines for PDD, second-generation antipsychotics like risperidone and olanzapine offer good treatment options for this infrequently encountered and difficult to treat psychiatric disorder.

Effects of typical and atypical antipsychotics on spontaneous neuronal network activity in vitro

C. Lange-Asschenfeldt*, U. Henning, P. Görtz
Heinrich-Heine-University Duesseldorf, Psychiatry and Psychotherapy, Duesseldorf, Germany

* Corresponding author.

Introduction Microelectrode arrays (MEAs) with cultured neuronal networks are highly suitable to quantify neuroactive activity and neurotoxicity of applied substances.

Objective Multiparametric characterization of functional alterations of in vitro-neuronal network activity by different typical and atypical antipsychotics.

Aims To identify differential effects of antipsychotics on spontaneous neuronal network activity as a functional readout.

Methods Cultured networks of dissociated cortical cells of post-partial mice coupled to MEAs were exposed to increasing doses of aripiprazole, clozapine, haloperidol, olanzapine, raclopride, and risperidone.

Results We found a concentration-dependent inhibition of firing patterns for all substances except olanzapine. All other substances mediated a concomitant irreversible suppression of burst and spike rates, a decrease of the burst duration and the number of spikes in bursts as well as dose-dependent network desynchronization (decrease of Cohen's kappa). The comparison of the different antipsychotics with regard to their half-maximal effective dose values (EC_{50}) for inhibiting the spike rate yielded an increasing order of EC_{50} values, i.e. a declining order of toxic potency, of aripiprazole ($8.77 \mu\text{M}$) < clozapine ($9.36 \mu\text{M}$) < haloperidol ($9.77 \mu\text{M}$) < risperidone ($15.9 \mu\text{M}$) < raclopride ($22.7 \mu\text{M}$). No significant correlations were identified between EC_{50} values of the distinct antipsychotics and their binding affinity to the dopamine D(2), the serotonin 5-HT(1A), 5-HT(2A), 5-HT(2C), and the M(1) and M(2) muscarinic acetylcholine receptors.

Conclusion In MEAs, a dose-dependent neurotoxic effect of typical and atypical antipsychotics alike occurred at supratherapeutic doses via a yet unknown mechanism that did not involve actions on major receptor targets of these compounds.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Increased libido as a bupropion-SR side effect: Clinical description of a case

L. Gallardo Borge*, C. Noval Canga, L. Rodríguez Andrés, I. Sevillano Benito, M. Hernández García, A. Álvarez Astorga, R. Hernández Antón, S. Gómez Sánchez, G. Isidro García, P. Marqués Cabezas

Hospital Clínico Universitario, Servicio de Psiquiatría, Valladolid, Spain

* Corresponding author.

Introduction Bupropion is a dual antidepressant, a norepinephrine and dopamine reuptake inhibitor. Its main use is in affective disorders as major depression. Antidepressants have been commonly associated with sexual side effects in the libido, sexual arousal, orgasm and erectile function. Bupropion has negative influence in sexual function, even it could increase the libido. Due to this, it could be a good option in patients with active sexual life and affective disorder.

Clinical report A 58-year-old female with a long history of depression disorder for 5 years. History of lots of side effects with different treatments, sexual dysfunction with serotonin-antidepressants. Treated with bupropion SR 150 mg/day and alprazolam, she suffered a relapse. The bupropion was increased to 300 mg/day. Three days later she appeared in the consultation room, presented a sense of pre-orgasmic of 72 hours of evolution, high increased libido, tiredness, muscle tension and insomnia. This sense did not improve after the sexual act. It had never happened previously. The side effect improved when the bupropion was reduced to 150 mg/day and disappeared with its withdrawal.

Conclusions The case made a relationship between the increased of bupropion's dose and the appearance of unusual sexual side effects (increased of libido and pre-orgasmic sense). Not only bupropion is one of the antidepressants that do not cause sexual dysfunction, if not it was reported in some trials that could be a treatment against this dysfunction due to its prosexual effects. The mechanism is unknown but could be related with norepinephrine or dopamine transmission.

Lithium treatment and thyroid dysfunction – data from an inpatient psychiatric department

M. Lázaro^{1,*}, A. Mota¹, A. Moreira², R. Alves¹, M.A. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5, Lisbon, Portugal

² Área de Pedopsiquiatria, Centro Hospitalar Lisboa Central, H.D.

Estefânia, Lisboa, Portugal

* Corresponding author.

Introduction Lithium is among the most effective therapies for bipolar disorder. Lithium treatment may cause hypothyroidism, goiter or to a lesser extent hyperthyroidism, since it can affect several aspects of thyroid functioning. The prevalence of lithium-associated hypothyroidism varies extensively between studies, reaching up to 47%, and affecting more females than males (5:1).

Objective Determine the prevalence of thyroid dysfunction in an acute inpatient psychiatric department dedicated to affective disorders and its association with lithium therapy.

Aims To review the relation between lithium treatment and thyroid dysfunction.

Methods Observational, descriptive and retrospective study with clinical and laboratorial data concerning all inpatient episodes of 2015 in our Psychiatric Department. A non-systematic literature search was performed in PubMed.

Results The present study documented a high prevalence of thyroid dysfunction, particularly in women. Most cases were due to either hypothyroidism or subclinical hypothyroidism. Patients treated with lithium were more often under thyroid hormone replacement therapy (levothyroxine).

Conclusions The evidence that lithium treatment is associated with hypothyroidism is well established and this condition is easily treatable with levothyroxine. This study highlights the importance of baseline screening of thyroid function and regular long-term monitoring in patients treated with lithium.

* Corresponding author.

Introduction Prevalence of tobacco use in patients with psychotic disorders (PD) is 40–70%. It has been described use of tobacco induces Cytochrome P450 activity, increasing some antipsychotic drugs metabolism, thus reduces their plasma levels.

Aim We carried out the present study to analyze the association between tobacco use and doses of antipsychotics in patients with PD and to determine whether patients suffering from PD who smoke may require antipsychotic dose adjustments.

Methods We designed a cross-sectional study of patients between 18 and 55 years, with a PD, treated with the same antipsychotic and dose for the last 6 months:

- consumption of cigarettes per day was determined;
- the doses of the used antipsychotic drugs were converted into chlorpromazine equivalents;
- statistical analysis was performed with STATA.

Results The sample consisted of 30 women (29.7%) and 71 men (70.3%). Mean age was 43.7 years old (SD: 8.0). Sixty-three patients were smokers (63.6%), being the other 36 non-smokers (36.4%). Mean dose of chlorpromazine in smokers was 1088.04 mg/day (SD: 697.17 mg/day) whether in non-smokers was 699.16 mg/day (SD: 556.07 mg/day). Mean differences of antipsychotic dose were statistically significant between the two groups of smokers and non-smokers ($P=0.005$). We also found significant association between consumption of cigarettes and antipsychotics doses ($P=0.0001$), so that, per each cigarette/day, dose of Chlorpromazine increased 19.81 mg/day.

Conclusion Patients suffering from PD smoke required higher doses of antipsychotics. These results suggest that patients who smoke might need higher doses of antipsychotic and that, if consumption of tobacco varies, antipsychotics doses might need to be adjusted.

Metabolic syndrome and its association with psychotropic medications in psychiatric patients from CAISM-IGSS (Center for Comprehensive Care Mental Health/Guatemalan Institute of Social Security)

J. Lopez
Guatemala

Introduction The use of antipsychotics represents an integral part of the psychiatric practice, unfortunately the use seems to

be associated with an elevated frequency of metabolic alterations causing an important weight disorder and glucose and lipid homeostasis, diminishing life expectations for these patients, likely to develop metabolic syndrome without proper control.

Objectives This study intended to find the association between metabolic syndrome in patients with psychotropic treatments used in the Guatemalan Institute of Social Security (IGSS).

Methodology Cohort Study ($n=43$ patients) who were treated combined with antipsychotics and mood stabilizers or antidepressants, conducting checkups at the beginning, then two to four months after, evaluating diagnosis of metabolic syndrome according to the criteria stated by the International Diabetes Federation (IDF).

Results Risk factor with the use of clozapine and valproic acid was revealed after four months of exposure ($RR=2.32$). With the use of clozapine and mood stabilizers a risk factor was prevalent with exposure after four months ($RR=2.67$), and with the use of antidepressants a protective factor for the development of metabolic syndrome was revealed at four months of exposure ($RR=0.3741$).

Conclusions the use of antipsychotics in combination with mood stabilizers represents a risk factor for developing metabolic syndrome, especially the association with valproic acid.

Keywords Metabolic syndrome; Clozapine; Stabilizers; Antidepressants

Antipsychotics-induced leukopenia and neutropenia: A case report and review of literature

H. Maatallah*, H. Ben Ammar, M. Said, A. Aissa
Razi Hospital, Tunis, Tunisia

* Corresponding author.

Introduction Antipsychotic drugs effectively control psychotic symptoms, but may cause important side effects, significantly increasing morbidity and mortality. Hematologic abnormalities are frequent and may be life-threatening in some patients. Many prospective investigations confirmed neutropenia as a frequent occurrence with virtually all atypical antipsychotics.

Objective and methods Define epidemiological, clinical and therapeutic characteristics of antipsychotics – induced leukopenia and neutropenia through a case report and a review of literature.

Case report Patient 28 years old native of Tunis, with family history: brother who suffer of undifferentiated schizophrenia. Since the age of 16 years he has been followed for disorganized schizophrenia (DSM IV). He was initially put under Haldol Decanoate (2 months), fluphenazine (2 months), amisulpride (3 months), sulpride (2 months), olanzapine (3 months), Risperidone (1 month), aripiprazole (5 months) leukopenia/neutropenia is occurring during treatment with each molecule and which promptly resolved after discontinuation. Reduced white blood cell count has also been reported after addition of lithium. Actually an ECT is proposed for this patient.

Conclusion This case report shows the importance of hematological monitoring during the course of typical or atypical treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Psychotic disorders are serious mental illnesses that compromise the quality of life of patients. It is important to know the characteristics of the affected population, seek to improve the adhesion and functionality.

Objectives To describe the sociodemographic characteristics of patients treated with Palmitato Paliperidona (PP). Analyze the efficacy variables, adherence to treatment.

Methods Cross-sectional study of 15 patients in outpatient follow-up after 12 months of treatment with PP. Sociodemographic characteristics are collected, mean dose of PP, through a mirror study. Scales to measure the functionality, clinical status and attitude towards medication apply: Scale of personal and social functioning (PSP), Brief Psychiatric Rating Scale (BPRS), Clinical Global Impression Scale (CGI-SI) and attitudes toward Inventory Medication (DAI).

Results The sample consists of 15 patients (54% male). 81% are single; 77% live alone and 94% not working. The mean dose of PP is 147 mg/month. DAI shows a good attitude to the treatment (80%). The PSP shows that 22% of patients have serious difficulties in its development. The CGI-SI shows that 67% are moderately sick and the BPRS that 33% of patients have a serious disorder.

Conclusions The demographic profile of patients after 12 months of treatment with PP coincides with male, unmarried, unemployed, living alone. Most have good adherence. The variables measured by the CGI-SI, BPRS and PSP, displayed moderately ill patients with severe difficulties or marked on their autonomy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1034

About existence of overmedication in patients with depressive symptoms and the appearance of un-induced movement disorder

P. Manzur Rojas*, M.A. Carrillo Cordoba, A. Sanchez Bahillo, M.R. Raposo Hernandez, P. Botias Cegarra, M.I. Ibernón Caballero
Centro de Salud Mental de Cartagena, Psiquiatria, Cartagena, Spain

* Corresponding author.

Overmedication and the combined use of various antidepressants while increasingly seen in daily clinical practice. The drug-induced Parkinsonism, often presented as tremor, rigidity, bradykinesia and impaired postural reflexes. The syndrome is caused by multiple drug drugs can be classified into high risk, intermediate and low. This case is a 75-year-old woman diagnosed with recurrent depressive disorder, which after several adjustments in medication for depressive symptoms with poor response to treatment. It is referred by her family doctor to the neurologist at the onset of tremors in limbs, dyskinesia orolinguales, rigidity and bradykinesia. After studies to rule out organic neurology disease, is derived psychiatry for changing inducing drugs parkinsonism. The last scheduled treatment was: Mirtazapine 15 mg/day, quetiapine 25 mg/day, Clonazepam 2 mg/day, paroxetine 40 mg/day, Sulpiride

50–150 mg daily. After confirming parkinsonism signs, psychiatry proceeds to changing pharmacology, with slow decline until suspension of antipsychotics, paroxetine by venlafaxine change, and also change of antihypertensive (captopril). After review at 2 months it is seen signs of improvement parkinsonism, appreciating the mental patient improvement with decreased physical discomfort and keeping the improvement in the last review (4 month) with venlafaxine 150 mg/day, Lorazepam 1 mg casual. The prevalence of drug-induced Parkinson's can go from 15 to 32% of the population. Risk factors identified are: advanced age, family predisposition, doses and drug power inductor, female gender and the presence of brain atrophy. The main objective should be to prevent the onset of Parkinson drug, to monitor patients that may be at higher risk of developing it.

Doctor I have painful erections

F. Medini*, L. Menif, G. Jmii, F. Ghali, M. Zeghal, L. Robbana, S. Derouiche, W. Melki

Hospital razi, psychiatry D, Jardin D El Menzah, Tunisia

* Corresponding author.

Introduction Ischemic (veno-occlusive, low flow) priapism is a painful and persistent penile erection unrelated to sexual desire or stimulation. In some cases, it is an adverse event of antipsychotic medications.

Materials and methods An Internet search was initiated using the search engines: Direct Sciences; Medline and keywords "Penile erection; priapism; Antipsychotic agents; Side effects" and we illustrated our literature review by a clinical vignette of a man aged 38 years followed for schizophrenia placed under Fluphenazine 125 mg/month from 5 years who consulted us in may 2015 because of priapism and he described painful and prolonged erection episodes evolving for approximately 5 days.

Discussion Medical literature mentions many cases of venous priapism in patients treated by conventional or atypical neuroleptics. About 30% of venous priapisms could be related to drugs of which approximately 50% to neuroleptics. This side effect is related to alpha1-adrenergic blocking properties of these treatments, more or less important depending on the drugs in this class. After emergency treatment, the priapism is the problem of the continued neuroleptic treatment. The substitution of one molecule by another alpha-1 blocking properties to the less marked is recommended.

Conclusion The venous priapism is a uro-andrological emergency requiring prompt treatment to prevent erectile sequelae.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Hackensack University Medical Center, Psychiatry and Behavioral Medicine, Hackensack, NJ, USA

⁴ Seton Hall University, Health and medical sciences, South Orange, USA

* Corresponding author.

Introduction Valerian officinalis roots extract is a popular medication for insomnia and anxiety treatment. Sedative effect of Valerian is mainly attributed to the modulation of gabaergic transmission, but its pharmacodynamics has not been fully elucidated. **Objects** To investigate the acute effects of Valerian Officinalis extracts intake on corticoexcitability as measured by TMS.

Aims To obtain further data on Valerian pharmacodynamics.

Methods Twelve healthy volunteers participated in a double-blind randomized crossover placebo-controlled study. They were required to take either 900 mg of Valerian officinalis extract (valerenic acid 0.8%) or placebo. Focal TMS of the hand area of left motor cortex was used to test Resting motor threshold (RMT), Motor evoked potentials (MEPs) amplitude and silent period duration (SP). We also tested Short-interval Intracortical Inhibition (SICI), Intracortical facilitation (ICF), Short and Long afferent Inhibition (SAI and LAI). All parameters were investigated at baseline, 1 hour and 6 hours after drug intake. After a 3-week washout period the subjects switched to the alternate arm of the study.

Results A mixed RMANOVA revealed a significant main effect of "time" [$F_{(1,22)} = 4.03, P = 0.02$] and a significant "treatment × time" interaction [$F_{(1,22)} = 6.3, P = 0.003$]. Post-hoc analysis indicated that the amount of ICF was significantly reduced 1 hour after Valerian intake ($P = 0.01$) returning to baseline values after 6 hours. No significant changes between the Valerian and placebo groups were observed for the other parameters investigated.

Conclusions The modulation of ICF induced by Valerian officinalis is likely due to glutamatergic antagonism and might underlie the anti-anxiety therapeutic effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Tolerability of desvenlafaxine in clinical practice: An observational phase-IV study

B. Navarro^{1,*}, I. Perez², L. Perez¹, L. Erkoreka¹, A. Arroita¹

¹ Red de Salud Mental de Bizkaia, CSM Barakaldo, Bilbao, Spain

² Hospital Universitario Cruces, psiquiatría, Barakaldo, Spain

* Corresponding author.

Introduction Desvenlafaxine is a SNRI which presents low affinity for muscarinic, H1 and $\alpha 1$ in vitro receptors and a marginal hepatic metabolism. Different studies have shown effectiveness and a favorable tolerability profile, but only a few of them have been realized independently.

Objectives and aims To study the incidence and characteristics of short-term desvenlafaxine side effects (SE) in daily clinical practice.

Methods A total of 123 patients with recently introduced desvenlafaxine treatment are recruited from Barakaldo and Uribe-Kosta Mental Health Centers, and UKU scale is administered to measure SE. Descriptive data are calculated using SPSS v.22.

Results SE are observed in 30.09%. Among these, 5.69% experienced improvement or disappearance of SE with dose reduction, whereas 16.26% had to stop DVF treatment. The most frequent SE was nausea/vomiting (7.3%), followed by dry mouth (4.9%), blurred vision (4.9%), tachycardia (4.1%), sexual SE (4.1%) and tension/inner unrest (4.1%). Among the patients with anxiety disorders, 27.78% present SE versus 30.47% of patients with other diagnoses.

Conclusions The characteristics of SE with DVF in daily clinical practice are comparable to those found in previous studies, and the overall profile is more benign than other AD. Aspects such as gender and sexual function must be considered. In patients with anxious symptoms DVF is also effective and ES are presented

similarly, opening a new line of research and treatment of conditions with these characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The patient suffering a schizophrenic disorder with a comorbid drug use is a challenge for the technical team of psychiatrists who provide to control this disorder. In some guides that include a revision of the efficacy of several psychopharmacological and/or psychological treatment shows that there any treatment has no efficacy in this group of patients. But it suggests that long-acting antipsychotic may play a role in some cases with no adherence. We study prospectively some data in a group of patients of these characteristics treated with paliperidone palmitate as main psychopharmacological treatment, using as measurements of outcome the number of psychiatric admissions, dosage of oral treatment, use of drug before and after the beginning of Paliperidone Palmitate. Our results show that it exists a decrease of number of admissions, dosage of oral concomitant treatment and drug use, with a very good adherence and no dropouts in the follow-up. We conclude that Paliperidone Palmitate may be a very good alternative for the psychopharmacological treatment in schizophrenic patients with comorbid drug use.

Introduction Cannabis consumption is known to be increased in both schizophrenic and first psychotic episode patients. Contrary to what has been reported in studies with healthy people, all published studies so far have reported no impairments or even beneficial effects on neurocognition associated with cannabis consumption in schizophrenia and first psychotic episode patients. However, these studies did not address the effects of very high cannabis consumption.

Objective Our aim in this study was to assess the effects on neurocognition of regular and heavy cannabis consumption in first psychotic episode patients.

Methods A total of 74 patients were included in the study and assigned to 3 different groups according to their mean cannabis consumption during the last year (non-users, regular users, and heavy users). Participants were administered verbal memory, attention, processing speed, working memory, vocabulary, arithmetic and spatial orientation tasks.

Results Our results showed the heavy cannabis group of first psychotic episode patients to be significantly impaired in all the verbal memory measures with respect to the non-users group. There were no significant differences between regular users and non-users. Moreover, regular cannabis consumption was associated with an improvement in some attention and processing speed measures.

Conclusions Our data showed heavy cannabis consumption to impair verbal memory in first psychotic episode patients and suggest a dose-related effect of cannabis consumption, since regular consumption did not impair verbal memory and may be beneficial for other tasks.

Choosing an antipsychotic on a case of late-onset psychosis – A challenge on everyday practice

M. Oliveira^{*}, M.J. Peixoto, C. Novais, C. Santos

Centro Hospitalar São João, EPE, Psychiatry and Mental Health Clinic, Porto, Portugal

* *Corresponding author.*

Introduction Psychosis with onset in late adulthood already constitutes a challenge on the differential diagnosis and treatment, especially in polypharmacy patients.

Methods and aims We present a case report of a 61-year old woman with a late-onset psychosis and discuss the clinical evolution and the pharmacological treatment.

Results The patient suffered from obesity, type II diabetes mellitus with poor glycemic control, and hypertension. She had a first psychotic episode at the age of 56, having persecutory delusional ideas and auditory hallucinations with psychomotor agitation and insomnia. She was first medicated with an atypical antipsychotic (olanzapine) with little response and worsening of the glycemic control. A switch was performed to haloperidol with remission of symptomatology with low doses (4mg/day). Through follow-up the doses of haloperidol was decreased and eventually suspended, but having a relapse a few months later. Haloperidol was again introduced and the symptoms remitted. Stability was maintained, but the patient started to show lower limbs symmetrical rigidity and psychomotor retardation. It was decided to switch haloperidol to risperidone, but the patient reported side effects with its use, and had to stop it. Haloperidol was again introduced, but had to be discontinued after motor symptoms got worse. Again the patient had another recurrence of psychotic symptoms and it was decided to introduce paliperidone (6 mg/day) with good response and tolerability.

Conclusions The safety and tolerability of antipsychotic medication is variable. When choosing a treatment in a patient with

comorbid medical conditions, it can severely influence the desirable outcome.

Subacute psychiatric hospitalization unit: The role of clozapine

O. Orejas*, C. Masferrer Herrera, C. Macías Castellví, P. Flores Martínez

Neuropsychiatry and Addictions Institute INAD, Parc de salut Mar, Psychiatry Hospitalization, Barcelona, Spain

* Corresponding author.

Introduction Several studies report that Clozapine is more effective in reducing symptoms of schizophrenia, producing clinically meaningful improvements and postponing relapse than other antipsychotic strategies.

Objectives To analyze the prescription of Clozapine in a sample of 88 inpatients admitted to a subacute psychiatric hospitalization unit.

Methods This is a transversal study. All patients admitted for a medium-term psychiatric treatment since 01/06/2014 to 30/11/2015 were included. Data about socio-demographical status and clinical situation were obtained and compiled in a database. This study compares patients receiving clozapine treatment with those who receive other psychopharmacologic treatment. Statistics were performed using SPSS Software.

Results Eighty-eight patients (52% men; mean age: 48.6 years) composed the sample. In 58% of cases, schizophrenia and schizoaffective disorder were the diagnoses motivating the admission. Within the 51 patients with Schizophrenia or Schizoaffective Disorder, 16 of them (31.4%) received Clozapine. Comparing clozapine group vs non-clozapine group, there were no significant differences between the groups in terms of sex, civil state or working state. Instead, Clozapine group patients were older, had a major number of previous hospitalization admissions and had a larger trajectory of their disorder.

Conclusions Patients requiring treatment with Clozapine had a major number of hospital admissions and had more often committed suicide attempts, suggesting a more severe course of the disorder. They were older than the non-clozapine group. Clozapine is delayed in its use among resistant-treatment patients. It is worth highlighting that only 16 cases of Schizophrenia inpatients received Clozapine. It could mean that Clozapine is underprescribed.

The treatment of autism with pipamperone: A case report

B. Petrosino^{1,*}, M.S. Signorelli², F. Magnano di San Lio², C. Petrosino³, E. Aguglia²

¹ Psichiatria, Medicina clinica e sperimentale, Caltagirone, Italy

² Psichiatria, Medicina Clinica e sperimentale, Catania, Italy

³ Psichiatria, ASP Catania, Caltagirone, Italy

* Corresponding author.

Introduction Adults with autism spectrum disorders (ASD) often have behavioral disorders, like aggression, agitation and self-injury. These problems are frequently severe enough to limit educational and developmental progress. Only risperidone and aripiprazole have so far been approved by the FDA for the treatment of behavioral disturbance associated with autism. These drugs are not very effective in the long term, with little benefits to the social

functioning and they are associated with side effects. This case report describes the use of pipamperone, in treating behavioral disorders of a patient with autism spectrum disorder and severe mental retardation.

Case presentation Here is presented the case of a 32-year-old man with autism spectrum disorder, severe mental retardation (caused by undiagnosed phenylketonuria for the first 3 years of life) treated with antipsychotics since childhood. He showed numerous episodes of psychomotor agitation, hetero-direct physical aggression and self-injury, and movement disorders induced by drugs. Treatment with pipamperone reduced drastically crises of psychomotor agitation, and behavioral disorders, without extrapyramidal side effects, and led to an improvement in social functioning. The control of behavioral symptoms associated with adherence to treatment was maintained for 6-month follow up. These clinical observations are supported by ratings using: ABC, CGI-S and CGI-I, VABS, SAS, AIMS.

Conclusion This case report provides the first potential evidence that pipamperone may be effective in treating behavioral problems associated with autism spectrum disorders. Moreover, the improvement of social functioning and the lack of extrapyramidal side effects make this drug notable for its effectiveness and tolerability.

Effect of metformin treatment on metabolic parameters in atypical antipsychotic-treated schizophrenic patients

V. Prisco^{1,*}, S. Sorice¹, F. Franza², M. Fabrazzo¹

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² Neuropsychiatric nursing home "Villa dei pini", Avellino, Department of Neuropsychiatry, Avellino, Italy

* Corresponding author.

Few studies have compared the effect of Metformin treatment on metabolic parameters in atypical antipsychotic-treated schizophrenic patients. The present study examined metabolic abnormalities due to clozapine or olanzapine in schizophrenic patients and, secondly, the effect of metformin treatment on these parameters. Twenty-six patients (19 M and 7 F) from neuropsychiatric nursing home "Villa dei pini" (Avellino) were enrolled, in collaboration with our Department of Psychiatry, University of Naples SUN. All patients had been diagnosed according to DSM-IV criteria. They were recruited from July 2013 to January 2015. Clozapine or olanzapine-related hyperglycemia required metformin introduction in therapy. All prescribed drugs were maintained at the same therapeutic daily dose during our study. We performed 1, 3 and 6 months follow up after metformin initiation. For each patient fasting cholesterol, glucose, triglycerides, body weight (BW), body mass index (BMI), systolic and diastolic blood pressure (BP) were evaluated. SPSS 16.0 (Statistical Package for Social Science) was used for data analysis. After antipsychotic treatment BMI, fasting glucose and triglycerides were significantly higher respect to basal values ($P < 0.01$, $P < 0.0001$, $P < 0.05$, respectively). After metformin treatment, a significant improvement in fasting glucose, cholesterol and triglycerides was registered ($P < 0.001$). Conversely, BMI values, although not significant ($P < 0.168$), showed a trend in increasing. This observational study underlines that metformin in antipsychotic-treated patients could be useful in preventing clozapine or olanzapine related metabolic abnormalities in schizophrenic patients.

Pro-BNP as a biomarker of asymptomatic clozapine-related heart dysfunction: Possible usefulness for clozapine management

V. Prisco^{1,*}, M. Petrosino², M. Fabrazzo¹

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² ASL Salerno- Department of Mercato San Severino, Department of Psychiatry, Mercato San Severino, Italy

* Corresponding author.

Cardiovascular clozapine-related side effects such as tachycardia and orthostatic hypotension are well recognized, but are rarely clinically important. However, the increasing number of life-threatening drug-related complications are giving rise to concerns about cardiac adverse reactions (myocarditis, cardiomyopathy, pericarditis and heart failure). The diagnosis is usually made considering patient's symptoms, such as tachycardia, slightly increased body temperature, subjective chest pain, dyspnea. However, this symptomatology is not always present in a clozapine-related pericarditis. Some authors suggest measuring BNP levels to detect early and asymptomatic cardiac dysfunction. We here report the clinical cases of two women, respectively 22 and 28 years old. They both suffered from an early onset resistant schizophrenia. Clozapine was gradually introduced, at a dose of 200 mg/day, in both patients. After about one month in both cases, while the first patient was nearly asymptomatic, apart from the intermittent fever (only PCR and pro-BNP values were elevated, 16.88 mg/dL and 1004 pg/mL, respectively), the second one showed a classic symptomatology suggestive of pericarditis. Clozapine was discontinued in both patients, resulting in progressive resolution of pericarditis. Interestingly, in the patient in which pro-BNP was elevated, after clozapine cessation, the pro-BNP fell down dramatically. Pro-BNP plasma levels appears to be an interesting test in identifying subjects with asymptomatic cardiac impairment. It would be useful to evaluate if early treatment with beta-blockers and ACE-inhibitors may allow the prosecution of clozapine treatment after developing of mild signs of cardiac toxicity in drug resistant schizophrenic patients responsive to clozapine.

Pseudoakathisia in a patient with clotiapine abuse: Report of a case

P. Quandt*, M.D.R. Cejas Méndez

Hospital Universitario de Canarias, Psiquiatría, La Laguna, Spain

* Corresponding author.

Introduction Objective symptoms of akathisia in the absence of subjective symptoms is known as pseudoakathisia, more often diagnosed in older patients with long-term antipsychotic treatment.

Objective To describe a case of pseudoakathisia in a patient with clotiapine abuse.

Aims Pseudoakathisia management.

Methods X is a 47-year-old male with chronic insomnia treated with clotiapine 40 mg/day for four years. He admits abusive neuroleptic consumption in the past eight months (160 mg/day), without any psychiatric control for years. In recent months he has experienced different organic complications, requiring multiple hospitalizations. During psychiatric examinations due to confusional states, repeated lower limbs movements were objectified. X reported he presented these movements for at least six months, without complaints of inner restlessness feeling. Neurological examination showed normal DAT-SCAN result. Clinical progression was evaluated using BARS scale (Barnes Akathisia Rating Scale).

Results Following the results of tests and statements of drug history, X was diagnosed with clotiapine-induced pseudoakathisia. Neuroleptic treatment was suspended, and clonazepam 6 mg/day and propranolol in ascending doses up to 80 mg/day were initiated. In subsequent evaluations, progressive decrease in movement intensity was observed. However, complete remission after four months from clotiapine suspension was not achieved.

Conclusions Pseudoakathisia is a concept not well defined at this moment and different hypotheses about its nature are considered. It has been suggested that it is a form of delayed dyskinesia, or a clinical progression from akathisia, with acquired subjective discomfort tolerance. The most widely used treatment includes benzodiazepines, beta-blockers and anticholinergics, although their effectiveness is limited.

Reduction in medication expenditure: Review of strategies at a children's psychiatric facility

B. Reddy*, M.W. Azeem, J. Smiles, L. Carrabetta

Albert J. Solnit Children's Center, Child and Adolescent Psychiatry, Middletown, CT, USA

* Corresponding author.

Prescription drug costs rise about 15% annually. Solnit Center has been exploring ways to reduce overall expenditure on medications while promoting best practice of care. Lack of facility-based pharmacy has posed specific challenges in ordering medications, optimal usage and minimizing wastage of drugs. Each of these areas were examined and reviewed at Pharmacy and Therapeutics Committee of the facility. This information was shared with the ordering physicians and standard prescribing practices were established. This project was aimed at tracking medication costs over a 11-year period while monitoring supplies and destruction of unused medications.

Aims 1. Reduce overall medication expenditure while maintaining standard of care. 2. Develop a program to return unused medications for refund.

Methods 1. Monthly review of pharmacy cost by facility, patient and medication. 2. Development and legislative approval of a program to return drugs. 3. Collaborate with contracted pharmacy to explore ways to cut costs. 4. Train nurses and physicians to understand optimal ordering practice. 5. Demonstrate medications wasted with associated financial impact to the facility.

Results The expenditure to the facility over 11 years has gradually decreased despite increase in medication costs. In 2004, the facility spent \$ 712,904 and in 2014, the expenditure was \$ 584,022.

Conclusions Awareness about costs and optimal ordering practices led to significant savings to the facility.

Mega-review of meta-analyses investigating the short-term efficacy of pharmacologic augmentation strategies of antipsychotics in patients with schizophrenia

J.M. Rubio^{1,*}, G. Inczedy-Farkas¹, S. Leucht², J.M. Kane^{1,3}, C. Correll^{1,3}

¹ Zucker Hillside Hospital, Department of Psychiatry, Glen Oaks, NY, USA

² *Klinikum rechts der Isar, Technischen Universität München, München, Germany*

³ *Feinstein Institute for Medical Research, Department of Psychiatry, Manhasset, NY, USA*

* *Corresponding author.*

Antipsychotics are the cornerstone of treatment for schizophrenia, but they have limited effectiveness, as most patients require subsequent strategies at some point of their treatment. Despite being widely used, the efficacy of pharmacologic augmentation of antipsychotics is controversial and no combination treatment has been approved for schizophrenia. We conducted a systematic review in PubMed and PsycInfo on June 1st 2015 and a random effects meta-analysis of meta-analyses of short-term, placebo-controlled studies of pharmacological augmentation strategies of antipsychotics in schizophrenia. Methodological quality of meta-analyses was measured using the AMSTAR, plus 6 additional items developed to rate the content quality of the meta-analyzed trials. Out of 3062 publications, we identified 36 eligible augmenting strategies. For total symptom reduction, 25 strategies augmenting antipsychotics and 5 strategies augmenting clozapine were eligible and examined. Eleven strategies were more efficacious than placebo, none of them augmenting clozapine. Significant effect sizes ranged between SMD -1.03 and -0.23 . Efficacy was not correlated with the quality of the meta-analyses. Only the meta-analysis for NSAIDs augmentation had a score greater than half of the possible points for content quality. Only antipsychotics, azapirones, antidepressants and lithium were less discontinued than placebo. Serotonin-3-receptor antagonists, lamotrigine, mirtazapine/mianserine, minocycline and estrogens had large effect sizes augmenting antipsychotics. However the quality of the content of most meta-analyses was low. The NSAIDs augmentation meta-analysis had the best content quality, yet with a low effect size for efficacy. The evidence for short-term augmentation strategies of antipsychotics in schizophrenia is inconclusive, due to the limited quality of the available trials.

California rocket fuel: And what about being a first line treatment?

J. Silva^{1,*}, J. Mota², P. Azevedo¹

¹ *Magalhães Lemos Hospital, Inpatient C Unit, Porto, Portugal*

² *Magalhães Lemos Hospital, Inpatient C Unit, Electroconvulsive therapy Unit, Porto, Portugal*

* *Corresponding author.*

Introduction The association venlafaxine-mirtazapine is currently known as California Rocket Fuel (CRF). Studies show advantage in terms of efficacy and rapid control of depressive symptoms compared to other associations. Venlafaxine is a selective serotonin-noradrenalin reuptake inhibitor and mirtazapine is a noradrenergic-specific serotonergic antidepressant: the result is a potent noradrenergic and serotonergic effect. Studies say that CRF should be performed only for drug-resistant depression; however, there are case reports of its use as a first line treatment, in selected patients.

Objectives To summarize the latest literature about this field and to present a case report.

Aim To explore and critically review the controversies of venlafaxine-mirtazapine association as a first line antidepressants strategy.

Methods A brief review of the latest literature was performed, using PubMed and the keywords “venlafaxine-mirtazapine association”. A case report about a depressed woman is presented.

Results Despite most studies are referent to its utility in drug-resistant depression, there are recent pilot studies that recommend CRF as a first line option.

M., a 64-year-old woman, had her first psychiatric consultation. She had been depressed for 2 years, she lost 10 kg, had total insomnia and suicidal thoughts. CRF was started up to 150/15 mg, daily. An improvement was noticed after two weeks of treatment and the stabilization of depressive symptoms were achieved by the fourth month.

Conclusions CRF seems to be effective and useful. Patients with insomnia and weight loss may benefit from CRF as a first line option. However, more studies are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1049

The impact of tobacco smoking in patients taking long-action injection drugs – A retrospective comparative study between haloperidol and risperidone

J. Silva^{1,*}, H. Prata-Ribeiro²

¹ *Magalhães Lemos Hospital, Inpatient C Unit, Porto, Portugal*

² *Júlio de Matos Hospital, General and Transcultural Psychiatry Unit, Lisbon, Portugal*

* *Corresponding author.*

Introduction Smoking rate seems to be higher among patients with schizophrenia, comparing to other psychiatric entities, mainly in those who are on typical antipsychotics. Tobacco is known to have enzyme inducer properties, due to cytochrome P450 complex activity: CYP1A1, CYP1A2, CYP2E1 and CYP2D6. CYP2D6 and CYP1A2 play an important role in antipsychotics metabolism, mainly in the first generation ones, like haloperidol, despite its importance in risperidone metabolism.

Aim To analyze the importance of tobacco smoking in patients taking long-action injections.

Objectives To investigate how sexual dysfunction varies with tobacco smoking, in patients taking long-action injections.

Methods Individuals from both sexes, from 18 to 55 years old, taking antipsychotic long-action injections, answered the Arizona Sexual Experience Scale (ASEX).

Results In the studied population ($n = 44$), there were 20 individuals on haloperidol and 24 individuals on risperidone. In a total of 18 (40.9%) positive results for sexual dysfunction, 6 were on haloperidol (30%), 12 (50%) were on risperidone. Seventeen individuals of the 20 who were on haloperidol were smokers, but only 4 were considered to have sexual dysfunction, 35.3%; 12 of the 24 individuals who were on risperidone were smokers, but only 5 were considered to have sexual dysfunction, 41.7%.

Conclusions Patients treated with haloperidol smoke more, comparing to risperidone. Sexual dysfunction is more frequent in patients taking risperidone than in patients taking haloperidol. This data supports that CYP2D6-CYP1A2 induction by tobacco, mainly interacts with haloperidol, which may be helpful for patients to try less side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Interferon-induced psychosis: Myth or reality?

A. Antunes*, L. Sousa

Hospital de Santa Maria, Lisbon Academic Medical Center, Psychiatry and Mental Health, Lisbon, Portugal

* Corresponding author.

Introduction Interferon combined with ribavirin is widely used to decrease the burden of Hepatitis C virus (HCV), but some serious side effects might limit its usefulness. There has been recently a growing awareness about neuropsychiatric complications of many drug treatments. Anecdotal case reports of HCV treatment induced psychosis were published but there seems to be no consensus about the causative relation and no systematic reviews were done to the date.

Objective To describe a paradigmatic case that was managed as an iatrogenic psychotic episode following interferon associated with ribavirin.

Aim Call attention to problems that interfere with the recognition, diagnosis and management of drugs induced psychosis.

Methods Bibliographic research was conducted through the PubMed in the Medline library and clinical information was obtained through medical records and clinical interviews with the patient.

Results A 50-year-old Brazilian woman, with a previous episode of postpartum depression, presented with paranoid psychosis six months after initiating HCV antiviral therapy. Psychotic symptoms consisted of persecutory delusions and auditory hallucinations and developed together with agitation and aggressive behavior. Psychiatric hospitalization was required and psychosis resolved with discontinuation of therapy and initiation of risperidone. Laboratory tests and brain images were of no help in the etiologic investigation.

Conclusions There are many drugs known to possibly cause neuropsychiatric symptoms. It is the job of every physician to be aware of this hypothesis especially in cases with acute onset and atypical presentations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of cannabis components in the treatment of mental disorders

C. Tsopelas*, M. Dimitraka, P. Ntounas, A. Gatos-Gatopoulos, D. Karadima, T. Charalampos

Psychiatric Hospital of Attica, 5th Dept of Acute Admissions, Athens, Greece

* Corresponding author.

Introduction There is evidence that supports the increased risk of developing psychosis or psychotic like symptoms in vulnerable populations after use of cannabis. Cannabis' main psychoactive component, Δ 9-tetrahydrocannabinol (THC), induces acute psychotic effects and cognitive impairment. But there is also evidence to suggest that molecules in the cannabis plant could have an antipsychotic affect.

Aims In this review we are trying to explore the possibilities of cannabis use as a therapeutic agent in mental disorders.

Methods Thorough research of the main databases, and web search engines for relevant studies, using appropriate keywords. We scrutinize them independently, before reaching consensus about appropriateness.

Results In animal models repeated treatment with cannabis constituent cannabidiol CBD or the atypical antipsychotic clozapine attenuates or reverses the schizophrenia-like behavioral disruption.

In humans there are data that CBD counteracts psychotic symptoms and cognitive impairment associated with cannabis use. Also CBD may lower the risk for developing cannabis use associated psychosis. There are opposite effects of CBD and THC on brain activity patterns in key regions implicated in the pathophysiology of schizophrenia, such as the striatum, hippocampus and prefrontal cortex.

Conclusions The possible mechanism of action of CBD is not fully clarified, as it may involve anti-inflammatory or neuroprotective properties. These initial clinical studies with CBD treatment of psychotic symptoms argument the potential of CBD as an effective antipsychotic compound. Mechanisms responsible for these effects need to be further investigated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1052

Nicotine as therapeutic agent in treatment of mood disorders

C. Tsopelas*, N. Petros, D. Maria, P. Dimitris, G.G. Angelica, K. Dimitra, T. Charalampos

Psychiatric Hospital of Attica, 5th Department of Acute Admissions, Athens, Greece

* Corresponding author.

Introduction The plant that has as active ingredient nicotine was chewed or smoked for many years from American natives, for its therapeutic properties. Nowadays after the extensive negative attitude towards smoking, the main provider of nicotine, researchers are now pointing out the therapeutic possibilities of nicotine in mood disorders, as a substance that is acting in the acetylcholine receptors in the brain.

Aims In this review we are trying to explore the possibilities of nicotine use as a therapeutic agent.

Methods We did a detailed research of the main medical databases, and web search engines for relevant studies. We scrutinize them independently, before reaching consensus about appropriateness for inclusion in the study.

Results Diadermal administration of nicotine has a positive effect in depressive disorder in 3–8 days, an effect that in one study was reversed after cessation of nicotine. Patients with depression and/or healthy subjects show improvement of attention and working memory after diadermal use of nicotine. Research is not conclusive in the sustainability of these positive affects as other researchers emphasize their short effect in mood.

Conclusion Nicotine presents as part of novel and promising therapeutic agents with complex interactions with other neurotransmitters in the brain. Before condemning nicotine along with smoking we should acknowledge the potential use of nicotine as a therapeutic compound since research shows that some of these positive effects appear not only to smokers after abstinence but also to non-smokers.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Awkward movements: Extrapyramidal symptoms in a group of patients treated with aripiprazole long acting injectableC. Victor^{1,*}, S. Berta¹, T. Ivan², O. Silvia³, C. Sandra³, M. Estanislao³, M. Luis Miguel³, J. Moreno¹¹ Parc de Salut Mar, INAD, Hospital del Mar, Barcelona, Spain² Parc de Salut Mar, INAD, Barcelona, Spain

³ Parc de Salut Mar, INAD, CSMA, Santa Coloma de Gramanet, Spain

* Corresponding author.

Introduction Extrapyramidal symptoms are well known as side effects in therapy with antipsychotics. Explore this side effects is mandatory because they normally are a cause of treatment discontinuation or assess a change in medication. Some studies notice how long acting injectable antipsychotic cause less extrapyramidal symptoms than oral treatment, others does not find differences.

Objective The aim of this study is to analyze the extrapyramidal symptoms presented on a group of patients treated with aripiprazole long acting injectable (ALAI) follow-up in a mental health care center.

Methods Descriptive study of a group of patients treated with ALAI. To assess the possible extrapyramidal symptoms due to treatment we have used the Simpson-Angus Scale (SAS). The follow up was 3 months after initiation of treatment.

Results Six patients were included in the study, 2 women (33.3%) and 4 men (66.7%). The mean age of the sample was 37 years old. The different diagnoses of the group were 4 patients with psychotic disorder (66.7%; 2 schizophrenia, 1 schizoaffective disorder and 1 delusional chronic disorder) and the other 2 had an affective disorder (33.3%; both bipolar disorder). The average score for the SAS was 1.2 meaning normal results and therefore no significant extrapyramidal symptoms.

Conclusions In our sample the average of the results obtained by applying the SAS is considered within normal limits. In our case as to extrapyramidal effects ALAI treatment has been well tolerated. A larger sample would be needed to obtain more reliable results.

* Corresponding author.

Introduction The potential role of antipsychotic treatment in increasing cardiovascular risk and in explaining the increased mortality due to somatic disorders is still debated. The aim of this study was to assess the sequences of atypical and atypical neuroleptic prescriptions in relation to cardiovascular medication and death occurrence.

Methods We conducted a retrospective longitudinal analysis involving 84,881 patients who had drug insurance benefits in Pomeranian voivodship and who were receiving a typical or atypical antipsychotic medication between 2008 and 2012. Data on deaths have been collected from National Death Registry. The sequence creation was performed according to algorithm that iterates over neuroleptic prescriptions in chronological order and appends them to the end of patient's prescriptions sequence. Patients were also assigned to cardiovascular groups depending on the use of cardiovascular or diabetic medications before, simultaneously or after the treatment with neuroleptics.

Results There were 1,095,518 neuroleptic prescriptions and 16,010 deaths among antipsychotic users in analyzed period. The most prevalent sequence was consisting of typical neuroleptics. Less frequent were sequenced with use of both typical and

atypical drugs or only atypical medications. The least frequent were sequenced with clozapine or clozapine with other neuroleptics. The highest occurrence of death and occurrence of cardiovascular drug after introducing antipsychotic treatment was observed for clozapine. There was lower occurrence of death in atypical neuroleptic sequence compared to typical drug sequence but similar prevalence of cardiovascular drugs.

Conclusion These results suggest that conventional antipsychotic medications are associated with increased risk of death compared to atypical drugs.

Indication of depot antipsychotic treatment in the view of slovak psychiatrists

M. Zelman

Psychiatricka Nemocnica, Hronovce, Slovakia

With the increasing number of atypical antipsychotics in depot form, there emerges question about plus and cons of their use in schizophrenia patients. We focused on the opinion of Slovak psychiatrists about use of this treatment in some specific situations of schizophrenia treatment. Research was realized via questionnaire on psychiatrists ($n=47$) from ambulant and hospital care, during one conference in June 2015. First part of the questionnaire was focused on the preference of oral or depot form of antipsychotic treatment. Depot form would be indicated by psychiatrists (in more than 89%) when low compliance, anosognosia or frequent episodes. On the contrary, oral antipsychotic treatment is preferred in young patients or employed patients. The type of symptoms (e.g. positive, negative) has relatively small impact on the preference of treatment, where the preferences of each type were the lowest (fewer than 36%). According to the opinion of psychiatrists, depot antipsychotic treatment is not suitable in first episode of disorder (according to 81% of respondents), otherwise in second or third episode it would not be chosen by 6% of asked psychiatrists.

From the aspects of the choice between atypical or typical depot, atypical antipsychotics in depot form were favored when presence of adverse reactions (80%), occurrence of negative symptoms (65%) and short duration of disorder (58%). Typical depot was preferred by psychiatrists in patients with chronic states.

Asenapine modulates nitric oxide release and calcium movements in cardiomyoblasts

P. Zeppego*, C. Gramaglia, E. Gattoni, S. Gili, E. Gambaro, E. Di Tullio, M.C. Rizza, S. Farruggio, L. Camillo, D. Mary, G. Vacca, E. Grossini

University of Eastern Piedmont, Traslatinal Medicine, Novara, Italy

* Corresponding author.

Objective To examine the effects of asenapine on NO release and Ca^{2+} transients in H_9C_2 , which were either subjected to peroxidation or not.

Materials and methods H_9C_2 were treated with asenapine alone or in presence of intracellular kinases blockers, serotonergic and dopaminergic antagonists, and voltage Ca^{2+} channels inhibitors. Experiments were also performed in H_9C_2 treated with hydrogen peroxide. NO release and intracellular Ca^{2+} were measured through specific probes.

Results In H₉C₂, asenapine differently modulated NO release and Ca²⁺ movements depending on the peroxidative condition. The Ca²⁺ pool mobilized by asenapine mainly originated from the extracellular space and was slightly affected by thapsigargin. Moreover, the effects of asenapine were reduced or prevented by kinases blockers, dopaminergic and serotonergic receptors inhibitors and voltage Ca²⁺ channels blockers.

Conclusions On the basis of our findings we can conclude that asenapine by interacting with its specific receptors, exerts dual effects on NO release and Ca²⁺ homeostasis in H₉C₂; this would be of particular clinical relevance, when considering their role in cardiac function modulation.

Psychosurgery and stimulation methods (ECT, TMS, VNS, DBS)

EV1057

A tribute to Johann Gottlieb Burckhardt-Heussler (1836–1907), the pioneer of psychosurgery

M. Arts^{1,*}, P. Michielsen², S. Petrykiv³, L. de Jonge¹

¹ UMCG, Old Age Psychiatry, Groningen, Netherlands

² GGZWNB, Psychiatry, Bergen op Zoom, Netherlands

³ GGZ Friesland, Emergency Psychiatry, Leeuwarden, Netherlands

* Corresponding author.

Introduction Johann Gottlieb Burckhardt-Heussler was a Swiss psychiatrist, who pioneered controversial psychosurgical procedures. Burckhardt-Heussler extirpated various brain regions from six chronic psychiatric patients under his care. By removing cortical tissue he aimed to relieve the patients of symptoms, including agitation, rather than effect a cure.

Objectives To present the scientific papers of Johann Gottlieb Burckhardt-Heussler on psychosurgery.

Aims To review available literature and to show evidence that Burckhardt-Heussler made a significant contribution to the development of psychosurgery.

Methods A biography and private papers are presented and discussed, followed by a literature review.

Results The theoretical basis of Burckhardt-Heussler's psychosurgical procedure was influenced by the zeitgeist and based on his belief that psychiatric illnesses were the result of specific brain lesions. His findings were ignored by scientists to make them disappear into the mists of time, while the details of his experiments became murky. Decades later, it was the American neurologist Walter Freeman II, performing prefrontal lobotomies since 1936, who found it inconceivable that the medical community had forgotten Burckhardt-Heussler and who conceded that he was familiar with, and probably even influenced by, Burckhardt's work.

Conclusion It is partly thanks to Burckhardt-Heussler's pioneering work that modern psychosurgery has gradually evolved from irreversible ablation to reversible stimulation techniques, including deep brain stimulation.

The Introduction of electroshock in the Spanish asylum's practice after the Spanish civil war

A. Conseglieri Gámez^{1,*}, R. Candela Ramírez², P. Vázquez de la Torre Escalera²

¹ Hospital Universitario Infanta Cristina, Psiquiatría, Parla, Madrid, Spain

² Hospital Universitario de Fuenlabrada, Psiquiatría, Fuenlabrada, Madrid, Spain

* Corresponding author.

Introduction During the first decade's of the 20th century, biological therapies in psychiatry were introduced, amongst them electroshock (Cerletti and Bini, 1938). The quick reception received in Spain can be found at the Congreso de la Sociedad Española de Neurología y Psiquiatría (Barcelona, 1942), in journals such as Actas Españolas de Neurología y Psiquiatría, or through the interventions of psychiatrists such as Dr. López Ibor in the Primer Congreso Internacional de Psiquiatría (París, 1950). On a practical level, many asylums after the end of the Spanish war used electroshock (Leganés, Navarra, Santa Águeda en Guipúzcoa, Valladolid y Ciempozuelos) at the same times.

Objectives/aims Study the Introduction of electroshock in the Spanish asylum's practice in the 40s, focusing on the asylum of Leganés, through the analysis of the technique and its repercussion. Review journals in the first electroshock's decade.

Methods We analyzed 615 clinic histories from the Asylum of Leganés (1939–1952), and compared them with other Spanish asylums (SPSSv21). Publications from this decade are reviewed.

Results This therapy was the most used in the Asylum of Leganés (46%) and Navarra, occupying a central place in other asylums (along with Sakel and cardiazoltherapy). Electroshock was easy to use and had low costs, so the use of other shock therapies decreased.

Conclusions After the Spanish civil war, electroshock was introduced and used in most Spanish asylums without a big delay in spite of the war. Many journals have, and continue to, appear regarding this therapy and it is still used nowadays.

Electroconvulsive therapy outpatient program recently established in a psychiatric day hospital

A. Duque Domínguez^{1,*}, R. Duque Domínguez², C. García Montero¹, L. Martín Díaz¹, M. Palomo Monge³,

E. Pérez Arévalo¹, M.D.L.N. Vaquero López¹, A. Barreiro de Lucas¹

¹ Complejo Asistencial de Ávila, Servicio de Psiquiatría, Ávila, Spain

² Hospital Universitario de Fuenlabrada, Servicio de Psiquiatría, Madrid, Spain

³ Complejo Hospitalario de Talavera de la Reina, Servicio de Psiquiatría, Talavera de la Reina Toledo, Spain

* Corresponding author.

Introduction ECT outpatient program recently created in the Psychiatric Day Hospital in Ávila was designed to assess the safety and efficacy of continuation/maintenance electroconvulsive therapy (ECT) in patients after ECT remission.

Objectives Description of the activity and objectives of an ECT outpatient program in a Psychiatric Day Hospital.

Methods Retrospective cross-sectional descriptive Study. The three patients who received the continuation/maintenance electroconvulsive therapy during the 10 months this unit has been opened were chosen as a sample.

Results From the opening of Psychiatric Day Hospital 10 months ago, 58 patients have been admitted; among them, three patients come to the hospital monthly to receive the electroconvulsive therapy, maintaining their psychopathological stability over time.

Conclusions With the creation of this new program we considered three types of objectives:

- therapeutic: a therapy applied in a more comfortable and satisfactory for the patient and family regime. To prevent relapse and exacerbations;
- management: benefits on the best use of existing resources:
 - reduction in hospital admissions and readmissions,
 - decrease in the average stay,
 - reduction in visits to Emergency Services,
 - allow referrals from outpatient department,
 - individual monitoring of patients that complements the check at their Mental Health Team;
- teaching, training and investigation.

The use of electroconvulsive therapy (ECT) in the Czech Republic

L. Kalisova*, K. Madlova, J. Albrecht, J. Michalec
1st Medical Faculty and General Hospital, Charles University,
Psychiatric Department, Prague, Czech Republic

* Corresponding author.

Aim The aim of this study was to monitor the use of electroconvulsive therapy (ECT) in the Czech Republic for the purpose of harmonizing national practice.

Method A 13-item questionnaire was sent to all Czech inpatient psychiatric facilities. This questionnaire assessed technical background of ECT, indications for the treatment, procedure in detail, way of documentation and monitoring of side effects.

Results ECT is used 23 centers (10 psychiatric hospitals, 5 university psychiatric departments and 8 psychiatric wards) across the Czech Republic. There is no special legal act regulating the use of ECT in the CR, but there are guidelines issued by the Czech Psychiatric Society available. All centers use instruments delivering brief pulse stimuli. All patients have to be indicated for this treatment and have to sign informed consent form/excluding situation when patient's life is endangered/. Somatic state is assessed/EKG, blood tests, eye check-up regularly and other examinations in individual cases/. Thiopental and succinylcholine are used most often for anesthesia and myorelaxation. Bitemporal electrode placement is the preferred option in all centers. The ECT is provided 2–4 times a week in special ECT rooms in the presence of staff team/psychiatrist, anesthetist, psychiatric and anesthesiological nurses/. Continuation ECT and outpatient ECT is not used. The procedure including side effects is documented in individual patient's documentation, but summarizing documentation is conducted only in some centers.

Conclusion ECT is widely used in the Czech Republic. Procedures in all centers follow national guidelines. There is need to improve documentation system to harmonize national practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Public stigma of electroconvulsive therapy (ECT) in the Czech Republic

K. Mádlová*, L. Kališová, M. Zajíčková

General Hospital Prague, Psychiatric Department of the 1, Medical Faculty of Charles University and General Hospital Prague, Praha, Czech Republic

* Corresponding author.

Aims To find out how the use of ECT in psychiatry is perceived by the public in the Czech Republic.

Method The questionnaire (8 questions monitoring awareness, knowledge of ECT and its use in modern psychiatry) created for the purpose of this study was shared through internet and also distributed in paper version to public.

Results The sample consists of 365 respondents – age average 28.9 years, 62% of females, 53% of university graduates, 44% with secondary education, 3% other education, 27% of healthcare professionals outside the field of psychiatry, 20% of medical students before the start of the traineeship at psychiatry, 53% of the public. Among the respondents, 98% have heard about ECT, 7% of them think that ECT is no longer used. Among the respondents, 62% learned about ECT from the media (film, print). Among the respondents, 22% do not believe in the effectiveness of ECT, 30% think that ECT is abused by psychiatrists, 86% believe that ECT has side effects (personality changes, permanent memory disorders, brain damage, epilepsy). Among the respondents, 77% would agree with ECT, if it should be applied to their relative.

Discussion ECT is an effective method in treating of severe mental disorders. But until now the public view is influenced by media. Due to the negative stereotype of the method many people are afraid of this treatment. The interesting fact is that also health professionals and medical students are influenced by public stigma of ECT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

First experience of electroconvulsive therapy in Belarus

T. Dokukina*, A. Pinchuk, M. Makhrov, P. Korolevich, N. Misuk, S. Marchuk

Republican Scientific and Practical Center for Mental Health, Department of mental and behavioral disorders, Minsk, Belarus

* Corresponding author.

Electroconvulsive therapy (ECT) – a method of psychiatric and neurological treatment in which a large epileptiform seizure caused by passing an electric current through the brain of the patient in order to achieve a therapeutic effect. Clinical research of efficiency of application ECT with anesthesia, muscle relaxation and hardware analysis of EEG in patients with resistant forms of mental and behavioral disorders was held in the Republic of Belarus. The duration of the course of ECT, the frequency of sessions, as well as the method of applying electrodes for stimulation were determined by the doctor conducting the sessions of ECT. Sessions were conducted with general anesthesia with the use of muscle relaxants. Analysis of EEG data (Average Seizure Energy Index [ASEI]; Postictal Suppression Index [PSI]; COH–Maximum Sustained Coherence), on the basis of which the dose of stimulation was corrected, was conducted to assess the duration and quality of convulsive seizure during ECT. Significant clinical improvement in patients who underwent ECT sessions was achieved as a result of the study. Application of the method allowed to achieve persistent clinical remission in a short time. The clinical study showed that the

use of ECT with anesthesia, muscle relaxation and hardware analysis of the EEG in the Republic of Belarus may be effective against drug-resistant forms of mental and behavioral disorders.

A review of transcranial magnetic stimulation for treating negative symptoms of schizophrenia

J. Oliveira^{1,*}, G. Sobreira², C.A. Moreira³, M.A. Aleixo², S. Brissos¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Neuropsychiatric and Dementia Unit, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, First Psychotic Episode Unit, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Schizophrenia and Schizoaffective Disorders Unit, Lisbon, Portugal

* Corresponding author.

Introduction The finding of prefrontal dysfunction in schizophrenia patients with negative symptoms (NS) has raised interest in using transcranial magnetic stimulation (TMS), which can modulate prefrontal function and dopamine release, as potential treatment for NS.

Objective To briefly review current literature concerning the use of TMS as treatment for NS.

Aims To assess whether current evidence supports the use of TMS for NS.

Methods Narrative review of articles found through a PubMed database search using the keywords “transcranial magnetic stimulation”, “schizophrenia”, and “negative symptoms” between 1998 and 2015.

Results Up to date, reviews of randomized sham-controlled studies found positive effects of TMS in NS. However, they exposed several methodological difficulties. More recent studies, reviewed in this poster, tried to overcome these, using results from multiple centers, larger samples and blinding. Various TMS techniques were studied, differing in frequency, motor threshold (MT), stimulus location, and treatment duration. Overall, TMS continues to show promising results in reducing NS; particularly rTMS 10 Hz, for at least 15 sessions on the left dorsolateral prefrontal cortex (DLPFC) at a 110% MT.

Conclusions TMS may be a useful treatment for NS for patients not responding to pharmacological treatment alone. Studies remain difficult to compare due to different measures of outcome (PANSS and SANS being the most commonly used) and techniques. Furthermore, possible modulators of response include duration of illness, cognitive symptoms amelioration, medication and their dose, and different NS may respond differently to TMS. More studies are needed to better understand the utility of TMS in NS.

Posterior vitreous detachment and electroconvulsive therapy: Insights from a case

F. Pavez*, A. Alcántara, N. López, A. García, M. Sánchez, M. Roca, E. Moral, J. Russo

Hospital General Universitario Reina Sofía, Psychiatry, Murcia, Spain

* Corresponding author.

A case of bilateral posterior vitreous detachment after electroconvulsive therapy (ECT) has been reported previously in the literature.

There is not enough evidence about ocular side effects of this treatment. The literature supports a slight increase in intraocular pressure (IOP), although no ocular complications have been reported in normal, glaucomatous or postsurgical eyes. In this case report, we describe a 73-year-old female patient suffering a recurrent depressive disorder, who was admitted to acute psychiatric unit because a treatment-resistant major depressive episode (after an adequate trial of antidepressant drugs and transcranial magnetic stimulation) and clinical suspicion of visual delusions by her reference psychiatrist. The nonpsychiatric history consisted of hypertension, glaucoma and ulcerative colitis in treatment with azathioprine and mesalazine. After a careful examination in the emergency room, we consulted to ophthalmologist because miodesopsias and glaucoma history. The IOP was normal, but a bilateral posterior vitreous detachment (PVD) was identified. Because this entity is not an absolute contraindication for ECT, and there is scarce evidence, we informed the patient and her family. After that, and through informed consent, we decided to undergo ECT. After fourteen sessions, the patient could be discharged because significant clinical benefit and no ocular complications. Outpatient continuation ECT was indicated.

Conclusions ECT can be a safe treatment choice in cases of PVD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1065

Maintenance electroconvulsive therapy for catatonia

R. Perez*, M.D.L.D. Perez, A. Hidalgo, J. Prados, C.P. Gonzalez, M. Soto, B. Herrejon

Hospital provincial de toledo, Psiquiatría, Toledo, Spain

* Corresponding author.

Introduction We describe a case of a woman admitted to the psychiatric unit with characteristics of excited catatonia. Two years ago she had an episode of catatonia triggered by social and economic problems presented with mutism, psychomotor retardation and compromised oral intake. She recovered with 15 ECT sessions and was discharged in a stable state on quetiapine, divalproex sodium, venlafaxine and diazepam. This time she was treated with 13 ECT sessions and was discharged on previous maintenance treatment. Three weeks after her condition gradually deteriorated again. She recovered with 7 ECT sessions and was derived to our ECT maintenance program.

Objective To describe and discuss the use of maintenance electroconvulsive therapy (m-ECT) in catatonia.

Methods Clinical case report and PubMed search with the keywords “catatonia” and “maintenance electroconvulsive therapy”.

Results Catatonia is characterized by motor disorders, mutism and negativism, autonomic dysfunction is also possible, sharing symptoms and severity with neuroleptic malignant syndrome. In the DSM 5 catatonia is as a specifier of a primary disorder (Tr. Psychotic, affective, substances or unspecified) and not a schizophrenia subtype. Benzodiazepines are most utilized as first-line treatment for catatonia, and/or electroconvulsive therapy (ECT). The role of antipsychotics is unclear. Use of maintenance ECT in responders appears beneficial.

Conclusion Catatonia guidelines recommend ECT treatment if benzodiazepines are not effective. Maintenance ECT is a good option in long-term prevention of recurrent catatonia. More specific research is required.

Electroconvulsive therapy in depressed older adults with unrepaired abdominal aortic aneurysm: Safety first!

S. Petrykiv^{1,*}, M. Arts², L. de Jonge³, P. Michielsens⁴

¹ GGZ Friesland, Emergency Psychiatry, Groningen, Netherlands

² GGZ Friesland, Geriatric Psychiatry, Leeuwarden, Netherlands

³ UMC Groningen, Epidemiology, Groningen, Netherlands

⁴ GGZ Westelijk Noord Brabant, Psychiatry, Bergen op Zoom, Netherlands

* Corresponding author.

Introduction It is not clear whether electroconvulsive therapy (ECT) is a safe procedure in depressed older adults with unrepaired abdominal aortic aneurysm (AAA). ECT is potentially incriminating to the cardiovascular system due to a transiently elevation of blood pressure and heart rate during the seizure.

Objectives To report a case of an older adult presenting a psychotic depression complicated by an unrepaired AAA.

Aims To report a case study, describing the safety of ECT in patients with unrepaired AAA.

Methods A case report and retrospective review was conducted.

Results A 75-year-old male was admitted to hospital for the treatment of a psychotic depression. Treatment was complicated since for one year he was diagnosed with an AAA (diameter 4.7 cm). In collaboration with vascular surgeons and anesthesiologists we decided to start ECT. After fourteen ECTs an improvement of mood was achieved. Post-ECT we noticed an AAA expansion of 0.1 cm.

Conclusions Our findings indicate that ECT may be a safe procedure for patients diagnosed with unrepaired AAA. Published data suggest that the risk for aortic aneurysm rupture during ECT is low. However, multidisciplinary collaboration among psychiatrists, anesthesiologists and vascular surgeons is essential for a positive outcome.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Repetitive Transcranial Magnetic Stimulation (rTMS), through modulation of cortical activity, has become an invaluable tool in experimental and clinical neurosciences. Although this form of noninvasive treatment is considered safer than other means of brain stimulation it has been associated with adverse effects (AE).

Objective To make a brief review, concerning the AE of rTMS, their prevention and management.

Aims To understand and be able to deal with the most common AE associated with rTMS.

Methods A PubMed database search, using as keywords “Transcranial magnetic stimulation”, “Repetitive Transcranial magnetic stimulation”; “adverse effects”; “management” and “guidelines” between the year 1998 and 2015.

Results AE caused by rTMS are rare. They can be classified into severe (seizures) and mild (syncope, and transient hearing

impairment, acute psychiatric changes, headache, local pain, neck pain, toothache, paresthesia and cognitive/neuropsychological changes) and into early and late AE. In order to obviate and avoid them, guidelines have been created; some state that to apply rTMS the technician needs to obtain the patient’s informed consent and assess the risks/benefit ratio. To meet these criteria, screening tools have been created, and since then the number of AE has reduced.

Conclusions Even though rTMS is considered safer than other forms of brain stimulation it is still associated with AE. In order to avoid them, screening tools have been created allowing the clinician to assess the risks and benefits of applying this technique.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Electroconvulsive therapy (ECT) treatments in late-onset schizophrenia: Report of a case

M. Valverde Barea^{1,*}, F. Cartas Moreno², M.E. Ortigosa Luque¹

¹ USMC-Jaén Sur, Servicio de Psiquiatria, Jaen, Spain

² USMC-Ubeda, Servicio de Psiquiatria, Jaen, Spain

* Corresponding author.

Female patient, 66 years old, who goes to the doctor because of behavioral disorders and delusional injury 8 months of evolution. She showed no personal history of psychiatric disorders. In the psychopathological examination some relevant symptoms are seen delusions of prejudice with their immediate surroundings, self-referential regarding neighbors and walls. Delusional interpretations of sexual content. Punitive pseudo hallucinations hearing which are identifies with her daughters and sex with her son-in-law. Behavioral disorders consisting of going out naked into the street overnight and rebuking pedestrians; furthermore, she showed heteroaggressivity towards objects. Logical psychotropic treatment is initiated as indicated by the guidelines having no effect. Electroconvulsive therapy being tested an effective result. The late-onset schizophrenia symptoms should be taken into account in people with psychotic symptoms start at an advanced age, but is most prevalent at younger ages. Electroconvulsive therapy (ECT) may be used as an adjunct to drug therapy or as second-line treatment in patients with affective or psychotic disorders resistant to treatment with psychotropic drugs. It is essential a differential diagnosis with dementia symptoms previously established, given that part of the late-onset schizophrenia evolves to dementia.

Social media group parallel to dialectical behavior therapy skills training group, the pros and cons

A. Abdelkarim^{1,*}, D. Nagui Rizk¹, M. Esmail², H. Helal²

¹ Alexandria Faculty of Medicine, Neuropsychiatry, Alexandria, Egypt

² Alexandria Faculty of Arts, Psychology, Alexandria, Egypt

* Corresponding author.

Introduction In the past few years, social media has gained a high popularity as a dynamic and interactive computer-mediated

communication tools. Although it has become a part of everyday life for most of our clients, yet we did not have the opportunity to study its impact on compliance to therapy.

Objective Assessment of impact of parallel social media group to dialectical behavior therapy (DBT) skills training group in a sample of Egyptian patients suffering from borderline personality disorder (BPD).

Aim The aim of the current study was to estimate impact of parallel social media group on compliance to DBT skills training group and its adverse events.

Methods Patients with BPD enrolled to an outpatient comprehensive DBT program in Alexandria were assigned either to group (A) skills training, where a parallel Facebook group was created aiming at increasing to compliance to the original group, or group (B) skills training alone and dropout rates were calculated based on completion of 6 months full skills training. We considered patients out of the group if they missed 4 sessions in a row.

Results Two patients of 15 patients who joined group (A) missed four consecutive sessions with a dropout rate of 13%, whereas group (B) showed 43% drop out rate as 10 out of 23 patients did not complete the group. The difference was statistically significant. We reported only one privacy issue dealt with it immediately.

Conclusion Utilization of social media group could lead to increase patient compliance to DBT skills training group.

Cognitive-behavioral therapy for bipolar disorder

T. Abreu
Penafiel, Portugal

Introduction Bipolar disorder is a chronic disease with a major impact on patient's functioning and quality of life, not only during episodes of mania/hypomania or depression, but also during euthymic periods. In recent years, it has been noticed that pharmacotherapy, albeit its great value, is not enough to prevent recurrences of the disease. Therefore, it has been a greater investment in psychosocial interventions as adjuvant treatment. The utmost studied of these interventions is Cognitive-Behavioral Therapy (CBT).

Objectives and aims Gather information about the efficacy of CBT in bipolar disorder.

Methods Literature review.

Results Several studies have compared groups of bipolar patients submitted to CBT to controls submitted to treatment as usual. The methods and size of samples differ, but the results are in general concordant. Individual or group CBT has had positive results in reducing symptoms, increasing the euthymic periods, decreasing duration of episodes and improving global functioning and quality of life.

Conclusions There are limitations on the application of CBT in bipolar patients, mainly the decrease of its effects over time; less efficiency in patients with more severe disease; major impact on depressive symptoms than manic; and lack of human resources trained to apply these techniques. Notwithstanding these limitations, the demonstrated gain in the use of CBT on bipolar disorder is evident; hence, investment in this area is undoubtedly important.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Can mindfulness bring post-traumatic stress disorder patients to focus on the present?

A.R. Figueiredo^{1,*}, T. Abreu², C. Freitas³

¹ Centro Hospitalar de Trás-os-Montes e Alto Douro, Department of Psychiatry and Mental Health, Vila Real, Portugal

² Centro Hospitalar do Tâmega e Sousa, Department of Psychiatry and Mental Health, Penafiel, Portugal

³ Centro Hospitalar do Tâmega e Sousa, Department of Psychiatry and Mental Health, Amarante, Portugal

* Corresponding author.

Introduction Over the last years, literature has dedicated increased interest to post-traumatic stress disorder (PTSD), a mental disorder that was initially included in Diagnostic and Statistical Manual of mental disorders in 1980. Trauma is any event that overwhelms the individual coping strategies. Patients with PTSD experience symptoms of hyper-vigilance, intrusive thoughts, flashbacks, re-experiencing the trauma event, avoidance of stimuli related with trauma or exaggerated startle response. Mindfulness is the process of being aware, paying attention in the present moment, in a non-judgmental way. Research has been showing that mindfulness has positive effects on mental health.

Objectives and aims Assessment of eventual benefits of mindfulness in patients with PTSD.

Methods Literature research.

Results Many studies have reported on correlations between self-reported mindfulness and mental health. Literature suggests that mindfulness training can enhance life skills and its effectiveness is being studied in several mental disorders. Its positive effects on enhancing emotion regulation and decreasing anxiety, hyperarousal and depressive symptoms, led to investigation in the context of PTSD's treatment. Some studies show decreased perceived stress and post-traumatic avoidance symptoms and increased positive states of mind. Most studies reviewed were related with war veterans with PTSD and showed that mindfulness-based treatments could enhance their quality of life. Other results imply that mindful awareness alone may not be sufficient to help reduce symptoms.

Conclusions Mindfulness based therapies could be useful on improving PTSD symptoms but, to assess its efficacy, further research is needed, in different samples of patients.

Impact of expressive writing on everyday memory functioning

B. Abuhamda*, A. Soliman

Qatar University, Social Sciences, Doha, Qatar

* Corresponding author.

Introduction The suppression of negative feelings and traumatic events has detrimental effect on mental and physical health. One of the promising techniques to reduce stress related to trauma is expressive writing. Expressive writing has been found successful with different types of maladaptive behaviors e.g., pain, depression, anxiety and cognitive dysfunctioning.

Objectives This study investigates the impact of different categories of expressive writing on improving every day memory performance and cognitive functioning.

Aims Examining the impact of cognitive functioning and everyday memory.

Methods A sample of 90 participants took part in this study. The participants aged (21 and 65 yrs.) 47 of them are females aged between average of (21.64 yrs.), and 43 males aged between average of (21, 49 yrs.). The participants were classified randomly into three groups (a control group, and two experimental groups [pen and oral writing]). The three groups were administered the Every Memory Questionnaire and Taranto Alexithymia Scale.

Results The results showed that there were no significant differences among the three groups in each of the Alexithymia and Everyday memory, which indicates random distribution of the three groups. The results showed that both of the experimental groups were improved on everyday memory functioning. More importantly, the results indicated that there were no significant differences between using pen or figures in expressive writing to improve Everyday memory.

Conclusion Study results showed the significant impact of expressive writing on every day memory functioning, furthermore, the study results are used to empathize on the cognitive rehabilitation of the individuals as well as to improve self-esteem on general psychological individual cases.

Patient's outgroup socialization in the psychotherapeutic group

I. Baños Martín^{1,*}, K. Eaton Itúrbide¹, E. Guerra Gómez¹, B. Unzeta Conde¹, P. Vilarinho Besteiro¹, P. Pérez Bustillo¹, J. Sanz Mendoza¹, C. Pérez Franco¹, G. Lahera Forteza²

¹ H. U. Santa Cristina, Eating Disorder Department Psychiatry, Madrid, Spain

² University of Alcalá de Henares, CIBERSAM, Madrid, Spain

* Corresponding author.

Introduction Patient's outgroup socialization may be a problem in the psychotherapeutic group functioning. Disadvantages – and even benefits – of this common issue in psychotherapy have been described (Vinogradov S., Yalom I.). However, the impact of new social networks – that facilitate other ways of immediate and easy communication – on this phenomenon is still unknown.

Aims and objectives To explore the risks of spontaneous “self-help groups” supported by new technologies for the psychotherapeutic group functioning.

Method Course description of a psychotherapeutic group, composed by patients with eating disorders (bulimia nervosa and binge eating disorder) in the context of a specialized hospital day.

Results A patient – who has recently had a breakup – asked help to the group through a non-reported whatsapp chat. Gradually, patients used this new channel to express distress and daily interpersonal difficulties, showing less implication in the supervised group sessions. The patient presented a symptomatic relapse with self-harm injuries and severe eating symptoms. Finally, she left the therapy and, in the next weeks, other patients also left the group, due to different reasons, in a “drag phenomenon”. The analysis showed that the formation of this outgroup socialization changed the relationships between members and new roles were taken.

Conclusions It is necessary to early address the formation of outgroup socialization in the pre-group interview, emphasizing its high risk for the future group functioning. Therapists should consider that out-group communication is common and easy due to new technologies, so the use of specific questionnaires about this issue may prevent or detect pathological events.

Flexible eclectic psychotherapy (FEP): A model for psychotherapy integration

D. Coira*, M. Grady

Hackensack University Medical Center, Psychiatry and Behavioral Medicine, Hackensack, USA

* Corresponding author.

Introduction Most experienced psychotherapists use an eclectic approach in their practice, combining techniques of different schools of psychotherapy to treat their patients. However, there are no good teaching models to train the new generation of psychotherapists in the technique of psychotherapy integration. FEP is a form of psychotherapy that combines techniques from four different psychotherapies: psychodynamics, CBT, IPT and supportive therapy. It also incorporates mindfulness, motivational interviewing, exercise and nutrition. A strong therapeutic alliance is crucial to the success of FEP. Techniques are tailored to the patient's current clinical state. Several techniques from different psychotherapies may be used in the same session. The therapist is empathic, flexible adaptive to the patient's needs and assumes an active role in the therapeutic process.

Objective To present a model of psychotherapy integration that can be used by psychotherapists in their clinical practice.

Aims We aim to present a model of psychotherapy integration that can be taught and implemented by psychotherapists in their clinical practice.

Results We present ten case examples where FEP was effective clinically and we compare it to the standard of care received by these patients and show the savings to the healthcare system.

Conclusion The results of our study suggest that FEP could be a cost effective treatment that could be added to the psychotherapists toolbox. Teaching and training methods, like manuals and workshops can be developed to train the new generation of psychotherapists.

² Mashhad University of Medical Science, Radiology, Mashhad, Iran

³ Islamic Azad University, Mashhad Branch, Shahinfar Medical Faculty, Mashhad, Iran

* Corresponding author.

In the past century, psychotherapy methods have been improving along with pharmacotherapy methods. Today's psychotherapy treatments are more effective, faster and highly accessible. Psychotherapy is getting more favor by patients and therapists than pharmacotherapy due to its long-term effectiveness and less side effects. However, for a young and recent graduate psychiatrist who works in small city of a developing country, psychotherapy involves more concerns. Here, there is still a social stigma attached to visiting a psychiatrist, even for a very simple adjustment disorder. Also we have an ineffective insurance system and many people are not able to pay the treatment costs. Moreover, psychological mindedness is rare and many people believe that the symptoms like obsession, depression, and anxiety in a person are intentional and have to be

solved by his own, with no need to visit a therapist. Also, most of the times, religious and ethnic beliefs, along with existing micro cultures are interfering with psychiatrist's treatments.

Introduction Systemic lupus erythematus is a chronic inflammatory disease of the multimedia system that appears on renal involvement, cortical-mucous, bloody, and neurotic.

Aim The target of this study is to examine the effect of treatment recognition based on mental conscious on decreasing depression intensity on lupus disease and three month follow up.

Method The method of study is semi-test by targeted random selection in access in which we have used of pretest by observe group. Volume of sample includes 200 women afflicted by lupus and among them about 20 were ready to cooperate and in study duration were in related improvement situation and have been evaluated. They have been grouped in the two test group (ten persons) and observe one (10 persons) in which two persons has been excluded from test group and we have excluded two persons from observe group, too. Test group has received eight MBCT treatment sessions but observe group has not received any treatment. Beck depression questionnaire (BDI-II) and brief signs of psychology questionnaire (BSI-53) have been performed as pretest and after clinical test, post test and three-month-follow up has been done. We have used of descriptive statics and co-variance for analysis.

Results Findings has shown that treatment recognition based on mental consciousness, meaningfully have an effect on decreasing remained signs of depression.

Conclusion Three-month-follow up has shown that treatment recognition based on mental consciousness, had an effect on depression disorder, anxiety disorder, and lupus patients.

Keywords Treatment recognition based on mental consciousness; Depression; Erytmatosus systematic Lupus

Integrative psychotherapy model on somatoform disorders patients

B. Fedak

Healthcare Utility Regional Clinical Hospital, Centre of urgent medical care A, chief medical officer, Kharkiv, Ukraine

Last 12 years in Ukraine the special priority has the problem of somatoform disorders.

The most significant role belongs to the patient's self-evaluation of the influence of the disease on their social functioning, influence essential past of the self-picture of the disease and the important point of therapeutic rehabilitation intervention.

On the basis of the examined 300 patients on somatoform disorders and 210 patients on ischemic cordial disease, we have elaborated a formal test that allows evaluating quantitatively the influents of the disease on various spheres of patients' social status.

It was absolutely unrespectable the common for ischemic cordial and somatoform disorders patients rise of significance of personal individual, common life factors in cases of aggravation of the main disease course. We created the integrative psychotherapy system with cognitive-behavioral, suggestive and autosuggestive implementations.

Elucidation of peculiarity of personal perception of the disease served as basis of elaboration of purposeful system of psychotherapy, consulting, psychological support for patients with high-effectiveness 1.5–3 years catamnesis in 85% patients.

The retrospective results showed the necessity the target-oriented integrative models of psychotherapy, parted on stages. On the first stage-sedative-adapting the receptions of cognitive and suggestive psychotherapy are used. There is group therapy on second-main-stage. On the third stage-supportive-elements of the autogenic training mastered.

Group therapy with eating disorders

E. Garcia^{1,*}, R. Martinez², M. Leon², F. Polo²

¹ Ciudad Real, Spain

² Hospital General de Ciudad Real, USMIJ, Ciudad Real, Spain

* Corresponding author.

The aim of this abstract is shown the results obtained working, into a group model, with adolescents that suffer eating disorders.

One issue that is common with that group of patients is a social dysfunction that makes them to isolate or start risk conducts as a way to integrate with partners.

In some cases, isolation or risks conducts are difficult to work in a individual or family therapy model, as both of them are lack of the generational issues that adolescents live daily.

So, although they may accept the need to improve their relations and social functioning, they will argue that it is not possible and that parents or therapists do not know about how difficult is that in their world.

That way, in this group of patients, it is not rare that therapy become a frustrating experience that enworse patients.

One solution could be group therapy because it solves generational issues and let patients help other patients to improve.

The problem is that when we put together patients with eating disorders one risk is that eating conduct hidden other goals.

We analyse our experience with adolescents with eating disorders and group therapy, explaining our model, goals, problems and solutions.

EV1079

Retrieving and projecting Jung's transcendent function with complexes and the Rosarium Philosophorum

M. Gildersleeve

Brisbane, Australia

This presentation will retrieve Jung's work on the transcendent function and complexes as well as a phenomenological and ontological interpretation of Jung's work on the *Rosarium Philosophorum*

to project a new meaning of the use of the transcendent function in psychotherapy. This presentation enables complexes and the *Rosarium Philosophorum* to be understood in connection to the ontology of the transcendent function that was presented in the author's article *Unconcealing Jung's Transcendent Function with Heidegger*. This presentation will also highlight how Nietzsche's work in *The Gay Science* and *Thus Spoke Zarathustra* inform the use of Jung's transcendent function in psychotherapy.

More specifically, this presentation will demonstrate that stage 1 of the transcendent function involves discovering the meaning of a guilty mood of a complex from having-been. Stage 2 of the transcendent function focuses on removing the obstructiveness of a complex from being in the world by retrieving missing possibilities from the readiness to hand. Stage 3 of the transcendent function involves the practical application of the intellectual discoveries from psychotherapy which can provide further "insight into one's mistakes" which "are not really seen at all, only the idea of them" (Jung, 1966, p. 291). By applying the insights from psychotherapy to everyday relationships where the obstructiveness of a complex is encountered, mistakes and possibilities missing from the readiness to hand are highlighted as they are "noticed by the other person as well as by oneself. Then and then only can they really be felt and their true nature recognized" (Jung, 1966, p. 292). *Disclosure of interest* The author has not supplied his/her declaration of competing interest.

Motivational interview in drug abuse

H. Guillen Rodrigo*, R. Alonso Diaz, E. Cortázar Alonso 
Hospital Juan Ramon Jimenez, Salud Mental, Huelva, Spain
* Corresponding author.

According to the treatment plan from the motivational interviewing model, we have worked with a 25-year-old male, single and childless. He is currently unemployed and he lives with his grandparents. His parents divorced about 20 years ago, he has a paternal brother of two years and his mother lives in Barcelona. He went to the USMC Huelva for the first time in 2014.

The patient and the family reported emotional and behavioral disorders for several years, which were getting worse since 4 months. He has been convicted for rash driving and he resisted to police officers for several times. The patient was also abusing of several substances like cigarettes, cannabis, MDMA and cocaine.

In order to work with the motivational interviewing with this patient, we proposed five clinical principles: express empathy, create discrepancy, avoid discussion, put a spin on his strength and promote self-efficacy.

The clinical evolution of the proposed patient was positive. As we could see, the motivation for change occurred when the patient perceived a discrepancy between the place where he was and the place he wanted to get. As we saw, the important thing was to define acceptable and accessible targets that represented the progress toward recovery.

In this style, we avoid the persuasion based on the discussion with the patient, instead we assume the validity of the experiences and the subjective perspectives of the patient. The motivational interview represents an alternative to unleash the change, instead of direct persuasion and aggressive confrontation.

* Corresponding author.

Background The Humanitarian Assistance Programmes UK and Ireland (HAP) work in partnership with mental health professionals in Bosnia-Herzegovina (BH), the country affected by war 1992–1995, providing knowledge and expertise in the treatment of trauma, and specifically in the use of EMDR (eye movement desensitisation and reprocessing).

Aim In this way, we aim to build a body of qualified and experienced professionals who can establish and sustain their own EMDR training and professional associations in BH.

Method Authors described educational process considering the history of idea and its realization through training levels and process of supervision which was provided from the Humanitarian Assistance Program (HAP) of UK and Ireland with non profit, humanitarian approach in sharing skills of EMDR to mental health therapists in BH.

Results HAP UK and Ireland started its Bosnia Project in 2009. This is a long-term project, aiming ultimately to bring BiH to the point where its trauma professionals can continue the training themselves, with their own national EMDR organisation. Since 2009, HAP UK and Ireland has trained over 100 professionals with EMDR. In 2015, the newly founded EMDR Association of Bosnia-Herzegovina became a full member of EMDR Europe. HAP UK and Ireland is continuing to provide training and supervision support in Bosnia and several clinicians are now EMDR Accredited Practitioners.

Conclusion Four training of Bosnia-Herzegovina mental health workers to effectively use EMDR with enthusiastic help of EMDR trainers from HAP UK and Ireland resulted with foundation of Bosnia-Herzegovina EMDR Association, which became a full member of EMDR Europe.

Family therapy preventing the recurrent major depression with alcohol dependence patient against recurrent episode: A case study of three cases

H.C. Hsu*, F.Y. Lee, Y.C. Chen

Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Department of Psychiatry, Chia-yi county, Taiwan

* Corresponding author.

Major depressive disorder with alcohol dependence is an easily recurrent disorder, and its dysfunction has increased risk of recurrence. The main purpose of the family therapy model at issue is to prevent the recurrent major depression with alcoholism patient against recurrent episode.

All three patients have had more than 10 relapses and hospitalizations during the past 5 years. Focuses of the therapy are on the apples drawn by the patient (DDAA), the patient, the couple, and the patient-child relationship. Keywords are gathered from every participant during the therapy session. Besides, the subjects to have verbalized meaningful ideas or successful experiences are immediately, intensely praised by applause. DAILY DRAW AN APPLE (DDAA) homework is that the patient has drawn an apple on a calendar everyday and shares with family members about the apple as well as the patient's feelings of the day. The participants of the therapy are the patient, wife/husband, children and the therapists (psychiatrist, social worker). The frequency of the model is from once weekly to twice monthly. Each session consists of the 10 minutes pre-session, the 40 minutes therapeutic session, the 10 minutes post-session. All patients have never been relapsed over the past 18 months after receiving our family therapy under medications.

Finally, with the aid of the family therapy, they have been almost free from affective symptoms and the ambivalence, guilty feeling

toward family, frustrations have been steadily gradually improved. To prevent the recurrent major depression with alcohol dependence patient against recurrent episode has been achieved in family therapy presented here.

Influence of art therapy in complex treatment on the quality of remission in patients with recurrent depressive disorder

V. Korostiy*, S. Hmain

Kharkivnational medical university, Psychiatry-narcology and medical psychology, Kharkov, Ukraine

* Corresponding author.

Introduction According to studies done in recent years regarding the treatment of patients with recurrent depressive disorder, a shift of interest from studies evaluating the effectiveness of therapy to the study of remission is seen. According to the literature, complete remission occurs in only 40–50% of patients, in other cases there is residual symptoms.

Aims Evaluating the effectiveness of art therapy in treatment in patients with recurrent depressive disorder on the quality of remission.

Methods The study involved 135 patients: 60 male and 75 female patients aged from 18 to 30 years old. The main group of patients apart the combined treatment also participated in group art therapy with the use of drawing techniques, while the control group – statutory standard therapy. We used clinical, psychopathological, psychodiagnostic and statistical methods.

Results The results of the effectiveness of art therapy in complex treatment in patients with recurrent depressive disorder is detected primarily in reducing of the level of anxiety at the early stages of treatment, as well as in reducing of the severity of anhedonia and improving the quality of life in remission period.

Conclusion These results support the use of art therapy in treatment in patients with recurrent depressive disorder during period of active treatment, and after achieving clinical remission contributes to achieving and maintaining high-quality and stable remission with full restoration of quality of life and social functioning.

The effectiveness of mindfulness on motivation and academic achievement and increase confidence in students of Azad University of Kerman City, Iran, 2015

A. Mehdizadeh Zare Anari*, Z. Shafiei

Islamic Azad university of Kerman, psychology, Kerman, Iran

* Corresponding author.

Motivations have a significant impact on the level of academic achievement. Academic achievement and self-confidence have mutual relationship. Mindfulness is attention firmly to the expectations of time that we have considered otherwise. People with conscious mind have a great ability to deal with a wide range of thoughts, emotions and experiences.

Materials and methods The present research is of quasi-experiment type with pretest-posttest design together with control group. The sample consisted of 40 students were studying at the

Azad University of Kerman city and then they were placed in two groups of 20 people (experiment and control) through random assignment and completing the questionnaire academic motivation and self-esteem scale Cooper: the mindfulness approach was trained only in experiment group. For data analysis software SPSS version 20 was used.

Findings The results showed that in the experiment group between the pre-test and post-test scores are confident there is a significant difference ($P=0.0001$), this means that increased confidence in the post-test period. The results showed that the experimental group between pre-test and post-test scores of motivation is also a significant difference ($P=0.002$), this means that motivation has increased during post approach. In this study, individuals with different ages of 18–35 years old and married and single, mindfulness therapy were equally affected.

Discussion and conclusion According to the findings, mindfulness has significant role in academic achievement and increased confidence.

Establishing a therapeutic alliance, can negotiation theory help?

U. Merlone*, A. Caldarera, E. Gerino, L. Rolle', P. Brustia
University of Torino, Psychology, Torino, Italy

* Corresponding author.

Introduction Thompson (2012) defines *negotiation* as “an inter-personal decision-making process, necessary whenever we cannot achieve our objectives single-handedly”. Recent contributions in the psychiatric literature discuss the role of negotiation styles in psychiatric practice (see, for instance, Chaplin et al., 2007).

Aims In this contribution, we explore further how negotiation theory can be useful to mental health professionals when trying to establish a therapeutic alliance with patients.

Methods After providing an introduction to negotiation theory we examine how the integrative negotiation approach can be applied. Specifically we will consider the steps suggested in the seminal contribution by Fisher and Ury (1981) and discuss potentialities and possible shortcomings when applying this approach to psychotherapy.

Results Although applying business negotiation techniques seems, at first sight, a bold step, the approach proposed by Fisher and Ury (1981), being based on “negotiating on principles instead of positions”, offers some interesting suggestions that may expand the relation tools mental health professionals need to use in their practice.

Conclusion Applying business and law negotiation techniques to psychiatric practices presents challenges but, at the same time, may offer new approaches when dealing with patients. In particular some concepts seem to be directly applicable to the psychiatric and psychotherapeutic practice.

² Opsta bolnica, Psihijatrija, Dobo, Bosnia and Herzegovina

* Corresponding author.

Introduction ICD-10 classifies trichotillomania (TTM) as one of the habit and impulse disorders. It is characterized by noticeable hair-loss due to a recurrent failure to resist impulses to pull out hairs. The hair pulling is usually preceded by mounting tension and is followed by a sense of relief or gratification. Persons suffering from TTM often hide it. TTM is often unrecognised by doctors, treated by dermatologists or untreated, causing a lot of suffering.

Objective To present treatment of trichotillomania.

Aim To present one case report of trichotillomania treated online.

Methods This is case report of female patient with TTM untreated 13 years. She had earlier been treated for depression and had multiple traumatic experiences. Patient both self-diagnosed TTM and asked for treatment online. During two months, there were 7 sessions and 2 follow-ups. Sessions were online and based on Habit Reversal Training (HRT) and Rational Emotional Behavioural Therapy (REBT). The following issues were addressed: hair pulling, shame, guilt, low self-confidence, assertiveness, low frustration tolerance, panic attacks, sadness. No medications were used.

Results Hair pulling has almost completely stopped. Social functioning and self-acceptance were improved. Guilt and shame have reduced, self-confidence and frustration tolerance have increased.

Conclusion HRT and REBT online treatments have reduced hair pulling and the associated emotional problems.

* Corresponding author.

Introduction In the past six decades, extensive research has been done on family therapy from different areas of knowledge such as psychology, psychiatry and social work. Leading to development of different intervention techniques and optimal clinical evaluation with families.

Aims The systemic perspective focus on the study of the dimensions that contribute to the stability and consistency of the members of the family system. The family is an interrelated system, dependent on each other, where there is an influence of the group over the individual, which is why each of its members plays a pivotal role in family therapy. Throughout all these years of evolution of systemic family therapy, many different concepts and techniques have been used, including the ones currently used today.

Methods Knowing the evolution of the different techniques allows us to understand the functioning of families, for example, their links and the elements that constitute it: their roles, the functions performed by each member in the family, communication, standards and power relations.

Conclusions The descriptive diagnosis of family ties, help us implement intervention strategies that could improve clinical care and diagnostic approach.

Introduction Low level of ability to endure discomfort, hardship and distress, which are integral parts of adverse life events, may lead to loss of mental stability and maintenance of psychological disorder.

Method Review of literature and case descriptions.

Results The patient often tries to cope with their suffering through avoidance and compensatory behavior which may relieve his suffering immediately; however, in the long term, it leads to the deterioration in the quality of his life and the persistence of suffering. Cognitive behavioral approaches focused on increasing the ability to endure unpleasant and distressful life experiences, allow the patient to better bear the inevitable losses in life, which he is exposed to, endure his anxiety, sadness, and the urge to impulsive action or escape; so the patient have more possibilities to

act more freely, functionally and purposefully. Modern cognitive behavioral approaches, such as Dialectic Behavioral Therapy, Mindfulness Based Cognitive Therapy, Acceptance and Commitment Therapy and Compassion Focused Therapy developed and applied therapeutic methods designed to increase the patient's resistance to suffering and his ability to cope it better. These approaches are applied not only in patients with chronic psychiatric disorders, but also in patients with chronic physical illnesses and permanent disability.

Conclusions The modern CBT strategies can help patients to increase his/her resistance to the distress, discomfort and suffering.

* Corresponding author.

Functional somatic symptoms and syndromes are a major health issue. They are common, costly, persistent and may be disabling. From Mentalization Based Treatment perspective, mentalizing impairments are a key factor in these issues. In that sense, many times, emotional suffering is rendered into physical pain, and it is the body that conveys affects and moods while the patients search frantically for an objective diagnosis and a biological cause for their symptoms and complaints. Taking this premise as a starting point, this poster analyses the importance of working on affects, connecting to them, naming them, and thinking about them. Linking symptoms to emotions, to attachment strategies, and interpersonal issues in order to achieve the recovery of mentalization. Considering this as the main goal to release the body from pain and suffering, we specify a proposal of group psychotherapy developed throughout the last eight years in an outpatient setting.

Definitely, one (therapy) does not fit all (depressions): Mentalization based treatment for resentful self-critical depressive patients who abuse of attachment deactivating strategies

J. Ramos^{1,*}, E. Alonso², N. Tur³, P. Sanz-Correcher¹

¹ Unidad de Psicoterapia, Hospital 12 de Octubre, Madrid, Spain

² Servicio de Psiquiatría, Hospital de Fuenlabrada, Madrid, Spain

³ Servicio de Psiquiatría, Hospital Clínico San Carlos, Madrid, Spain

* Corresponding author.

Depression is one of the most prevalent mental disorders and a notably heterogeneous condition with regard to etiology, symptom expression, course, and treatment response. This is why it is extremely unlikely that a “one size fits all” approach to the treatment of depression will be particularly effective. Quite the contrary, it is clear that the future of the treatment of depression may lie in a combined disorder- and person-centred, tailored-made approach, which takes into account the broader interpersonal context and life

history of the individual. Depressed patients with a characteristic cognitive-affective schema of self-critical perfectionism are prone to typical dysfunctional transactional cycles or dominant interpersonal narratives in which rage, distrust and ambivalence are apparent. In addition to this, in these subtype of depressed patients is common to find the overuse of attachment deactivating strategies, in response to threats to attachment relationships specially, and the inhibition of mentalizing as a defensive response to the feelings of rage, emptiness and sadness that are developmentally linked to attachment experiences. The implications of these findings for treatment, particularly with regard to the nature of the therapeutic relationship, are readily important. In this poster we take several cases in order to detail the main psychodynamics and the dominant interpersonal narratives of this subtype of depressed patients and to specify a therapeutic proposal tailored for them.

False memory syndrome: A review and emerging issues, following a clinical report

G. Santos*, V. Costa

Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal

* Corresponding author.

False Memory Syndrome (FMS) is caused by memories of a traumatic episode, most commonly childhood sexual abuse, which are objectively false, but in which the person strongly believes. These pseudomemories usually arise in the context of adult psychotherapy and are often quite vivid and emotionally charged. FMS is rare and sometimes could be confused with psychotic disorder and malingering. The infrequency with which it is encountered makes this syndrome a diagnostic challenge. Failure to diagnose can lead to significant morbidity.

We studied a 26-year-old female with no prior Psychiatric history who started to recall vivid memories of sexual abuse perpetrated by her father, following few sessions of clinical hypnosis. She presented a low mood, disorganized behaviour and aggressivity towards her father when she was admitted to our ward. After a normal CT brain scan and lab tests and a meticulous clinical history, the clinical diagnosis was made. She was successfully managed with supportive psychotherapy combined with mood stabilizer medications.

This case illustrates the unknown field between memory and confabulation and the value of a complete history. Physicians should be alert and keep an open mind about this iatrogenic disorder. Research is needed on the identification of memory mechanisms, specific situations and personality factors involved in this syndrome.

Entering the therapists's world: Experiences of psychotherapists in India

V. Sharma^{1,*}, R. Gupta²

¹ New Delhi, India

² All India Institute of Medical Sciences, Department of Psychiatry, New Delhi, India

* Corresponding author.

Introduction The arena of therapist's perspectives and experiences has been inadequately represented in psychotherapy

research. Along their professional journey, practitioners often have a myriad of experiences in the therapeutic process that influence their therapeutic interactions.

Aim The present study aims to discuss the personal and clinical experiences of trained psychotherapists that influence their choice of the profession and psychotherapy practice.

Methods Snowball sampling technique was used to recruit 10 trained psychotherapists for the purpose of the study. Audio-recorded interviews were held individually with each of the participant using a semi-structured interview schedule developed for the study. The interview schedule was reviewed by 2 experts with more than 10 years of experience in psychotherapy. Qualitative data was subjected to thematic analysis.

Results All psychotherapists identified an integral relationship between their individual belief systems and psychotherapy practice. Role of training, influence of mentors, significant experiences with family members and peers, significant childhood experiences, client characteristics, therapists' emotional responses to clients and the therapist's own beliefs about mechanisms of change were important factors in the psychotherapy process and were seen as significant internal experiences that underlie the psychotherapy process.

Psychotherapeutic interventions in Tinnitus

M. Silva*, A.R. Figueiredo, A. Fornelos, P. Macedo, S. Nunes
CHTMAD, Psychiatry, Vila Real, Portugal

* Corresponding author.

Introduction Tinnitus is defined as the subjective or objective perception of a hearing sensation in the absence of a corresponding external stimulus. It is a very common medical symptom, and some studies show that 5 to 15% of adults had tinnitus in life. It is a condition that could be chronic and for some patients could be very debilitating. Anxiety and depression are common findings in patients with tinnitus. Tinnitus can also interfere with sleep and concentration and affect the quality of life of patients. The heterogeneity of the etiology, pathophysiology and clinical features of tinnitus probably exacerbate the variability of response to treatment of the population and the decision on the best treatment option could be complex.

Objectives The purpose of this study is try to understand how the psychotherapeutic interventions may be useful in the treatment of tinnitus.

Methods Bibliographic research in Pubmed.

Results Currently there are no available effective pharmacological treatments. In some cases, surgical interventions may be effective with respect to ear pathology, but not to tinnitus. Most studies show that psychological interventions are needed to reduce the distress and the impact caused by tinnitus in patients' lives and the cognitive-behavioral therapy is the primary therapeutic intervention in chronic tinnitus.

Conclusion Although cognitive-behavioral techniques demonstrated to be effective in the treatment of the distress and impact caused by tinnitus, little is known about the mechanisms by which this technique achieves this effect, therefore most authors suggest that further studies should be conducted in this area.

EV1096

Treating trauma with EMDR in adults with autism spectrum disorders (ASD) – A literature review

B. Sizoo*, E. Lobregt

Dimence, Center for Developmental Disorders, Deventer, Netherlands

* Corresponding author.

Introduction Little is known about trauma or treatment of trauma with Eye Movement Desensitization and Reprocessing (EMDR), in adults with ASD. Neither is it clear on how ASD influences the expression of posttraumatic stress.

Objectives (1) To increase knowledge about treatment of trauma, and trauma related symptoms in adults with ASD. (2) To provide directions for research into the effects of EMDR on the expression of autistic and trauma related symptoms in adults with ASD.

Methods Review of the literature using Cochrane Collaboration Centre, Embase, Medline, PsychINFO, PubMed and Web of Science.

Results Clinicians often overlook trauma related symptoms in people with a severe mental illness like ASD, due to diagnostic overshadowing (Grubaugh, Cusack and Zinzow, 2008), caused by the overlap between Post Traumatic Stress Disorder (PTSD) and ASD. In the case of diagnostic overshadowing, symptoms like avoidance, hyperarousal and reduced ability to mentalize (Plana, Lavoie, Battaglia and Achim, 2014) are attributed to ASD, while in actual fact they are manifestations of stress reactions related to perceived traumatic events. However, when symptoms are correctly attributed to negative experiences, clinicians tend to withhold treatment because of fear of aggravating symptoms (Frueh, Cusack, Grubaugh, Sauvageot and Wells, 2006). The literature suggests that trauma in adults with ASD is undertreated.

Conclusion To our knowledge, the effects of EMDR in adults with ASD have not yet been studied, except at case level. A study protocol will be presented to assess the efficacy of EMDR treatment for trauma related symptoms in adults with ASD.

EV1097

The birth of Athena – Psychodynamic formulation and case report

M. Skokou*, K. Assimakopoulos, P. Gourzis

University Hospital of Patras, Psychiatry, Patras, Greece

* Corresponding author.

Introduction Athena possesses a special place among the Greek Gods, as she was born from her father, according to an extreme patriarchal model with a marked depreciation of the maternal role. Zeus had swallowed and absorbed the mother of Athena, Mites, because of an oracle that if Mites gave birth to a boy, the boy would take his throne. When the time comes, Zeus commands Hephaestus to cleave his forehead with an axe, and then Athena leaps fully armed and shouting her cry of war, in front of the astonished Gods. The next moment she puts her weapons down, as a token of obedience and devotion. The exceptionally close bond between father and daughter is evident through their uniquely confidential relationship. The ancient myth is paralleled, from a psychodynamic aspect, with the case of a narcissistic patient receiving psychodynamic psychotherapy.

Methods Case report.

Results A case of a woman with narcissistic personality features and depressive symptoms is described, presenting with the complaints of withdrawal, self-depreciation, passivity, and agoraphobia. Psychodynamic factors defining her pathology are her narcissistic and sexualized relationship with her father, whereas the relationship with her mother has been depreciated. The patient experiences an intrapsychic conflict of reciprocal idealization,

against her anger and fear for her father, resulting in the symptoms of agoraphobia and passivity.

Conclusion Like Athena, who puts her weapons down, the patient resigns from her will for autonomy and moves to a passive position, as a result of her entrapment in her idealized relationship with the father.

Emotional avoidance process in patients with schizophrenia and bipolar disorder. New module: Emotional body's sensations and meta-cognitive work on the interpretation of delusional thinking

A. Suchocka Capuano^{1,*}, A. Karar¹, A. Ponseti Gaillochon¹, A. Georjin¹, C. Bungener², G. Dorard², S. Bouyakoub¹

¹ *Centre hospitalier intercommunal de Villeneuve-Saint-Georges, consultations de psychiatrie, Villeneuve-Saint-Georges, France*

² *Université Paris Descartes, institut de psychologie, Boulogne-Billancourt, France*

* Corresponding author.

Introduction Psychological processes play a mediating role in the development of psycho-pathological disorders depending on the Kinderman's model. Excessive use of emotional avoidance becomes, following the model of Barlow and Allen, the booster of emotional distress at long term. Dysfunctional meta-cognitive processes in turn influence the inadequate interpretations of life experiences.

Objective To improve identification, expression and emotional management in patients with schizophrenia (PWS) and patients with bipolar disorder (PWBD).

Aims Introduction of exposition for the emotional body's sensations. This work on emotional awareness by images and sounds prepare to role-playing and to exposure in real life.

Methods Groups of psychotherapy for adults PWS and PWBD was implemented. The techniques used are those of cognitive behavioral therapy CBT (Beck) and emotional therapies (Barlow): columns Beck tailored, role-playing, psycho-emotional and breathing. Four groups of four patients participated in six therapy sessions.

Results An increase in emotional flexibility is observed two weeks after the group work (Wilcoxon $P=0.025$). Work on emotional identification facilitates the relaxation of the avoidance process while promoting social skills. The new format includes nine sessions three additional sessions on the emotional body sensations. Meta-cognitive work on the interpretation of the delusional thinking has been inserted.

Conclusion The experience of this pilot study provides encouraging results. The transdiagnostic approach referring to the alterations of this common psychological process finds use with PWS and PWBD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Significant weight loss related to Briquet syndrome: A case report

C.A. Welte-Santana^{1,*}, F. Trombini Nunes², L. Carvalho de Toledo¹, L. Oliveira¹

¹ *Hospital Municipal Jurandyr Manfredini, Ambulatório de Psiquiatria, Rio de Janeiro, Brazil*

² Instituto Municipal Philippe Pinel, Psiquiatria, Rio de Janeiro, Brazil
* Corresponding author.

Introduction Somatization Disorder is more prevalent in females and is historically known as Briquet Syndrome. It is characterized by complaints in several systems, has early onset and chronic fluctuating course, but without organic substrate. When the duration of symptoms is less than two years or they are less obvious, it is called Undifferentiated Somatoform Disorder.

Objectives This study reports the case of a female patient, previously healthy and with no psychiatric history, which abruptly presented lush somatic symptoms without organic origin.

Case Presentation Case report of a previously healthy woman of 32 years, followed up for 14 months, by a sudden onset frame of profuse diarrhea, tenesmus, fecal incontinence, vomiting, anorexia and weight loss (18 kilos in 2 months), associated with headache and autonomic signs of anxious origin, without clear physical and/or psychogenic trigger. She had only a mild response to drug therapy and excellent improvement in symptoms after psychotherapy.

Results Unconscious triggers came to light only after psychotherapy starts, justifying that the magnitude of autonomic somatoform symptoms surpasses the time period established by ICD-10 for Somatization Disorder. Therefore, the rapid resolution did not allow a diagnosis of Somatization Disorder, according to ICD-10. So, it was diagnosed as Undifferentiated Somatoform Disorder.

Conclusion It is suggested that the grandeur of clinical symptoms in this case is caused by psychogenic factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The challenge of Vitamin D deficiency in an inpatient ward

I. Adamidou^{1,*}, I. Udo²

¹ A & E, Blackpool, United Kingdom

² Merseycare, Psychiatry, Liverpool, United Kingdom

* Corresponding author.

Aims and hypothesis We set out to determine standards that would enable the identification of persons at risk of Vitamin D (VitD) deficiency in our ward; the prevalence of deficiency in at risk patient group on a 25-bedded ward (Brunswick). Deficiencies were identified, managed according to local guidelines and care plans were updated to reflect this change.

Background Low VitD levels have been associated with depression, psychosis, schizophrenia, suicidality, treatment resistance and poor coping. However, serum VitD levels is not a routine investigation on inpatient psychiatric admissions. Factors associated with VitD deficiency include prolonged stay in inpatient units with limited exposure to sun; Inpatients' diet; Self-neglect and social isolation.

Methods Criteria for identifying patients who may be at increased risk was agreed.

These patients were approached, and consented to screening. Results of the investigation were discussed with patients and actioned according to need. Study period May 2015–July 2015.

Results We were unable to identify any criteria in use for identifying persons at risk in psychiatric services. The following criteria were agreed: Hospital stay for > 2 months and limited opportunities of leaving the ward (Detention); Transfer from another unit with a total of hospital stay > 2 months; Admission from the community with severe depression or history of social isolation.

7 patients (28%) were identified to be at increased risk. Of this, 6 patients (85.7%) were deficient and another 1 (14.3%) had insufficient level. Management was instituted.

Conclusions If indicated, psychiatrists ought to consider monitoring VitD levels during inpatient stays and managing as appropriate.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Auditing of discharge summaries Contet at Al Amal medical complex

N. Al Solami

Al Amal Medical Complex, Pharmacy, Riyadh, Saudi Arabia

Introduction and aims Patient's records are the most important clinical assets and tools which are required in consultations. Patient records also support the accurate continuity of care when patients return to other health providers.

Objective Understand the extent of Discharge Summaries, which conform to the set best practise guidelines on the Mental Health Service.

Method A cross-section retrospective study on Discharge Summary contents was conducted at Al Amal Medical Complex. Chart review of randomly selected patient files (200 of a total 495), of Discharge Summaries for Psychiatric Patients in 2014 was performed. The data was statistically analysed using descriptive statistics taking into account proportions and frequencies. Pearson chi square and Fisher's test methodologies were used.

Result This study found of the 200 randomly selected Discharge Summaries that documented data of mental health examination 94% ($n=188$), data of discharge date 100% ($n=200$) while data of social investigation and family work up 82% ($n=164$). The above three categories were the only categories to conform to standard discharge guidelines. The other thirteen items studies were found not conforming to the defined standard guidelines.

Conclusion and recommendation There is an active challenge for clinicians to introduce good clinical practice in Mental Health. Standard guidelines must be followed by clinician's in order to reduce potential areas of concern and achieve a good clinical practise. Regular recurring audits are highly needed & recommended to ensure the alignment with standard guidelines for the writing of Discharge Summaries.

Blackburn with Darwen mental health assessment and treatment team – A service evaluation report

V. Damle*, N. Bhandary

Lancashire Care Mental Health NHS Foundation Trust, Psychiatry, Blackburn, United Kingdom

* Corresponding author.

Introduction Assessment and Treatment Team (ATT) was developed to manage mental health referrals within the borough of Blackburn with Darwen (BwD). The ATT became the main point of initial referral and assessment for adults presenting with mental health needs. It acts as the gateway service for access to specialist mental health services.

Aim To evaluate the effectiveness of ATT against the key performance indicators.

Methods Quantitative data was collected using electronic database from June 2014–May 2015. Feedback was obtained from

GPs and also from patients who attended ATT over a one-week period.

Results The ATT received a total of 2234 referrals. A total of 73% were seen within 10 working days of the referral. Assessment outcome letters were sent to the GPs within 48 h in 47.53% cases. Referral rates to community mental health and Crisis teams were 7% each showing an overall reduction compared to the previous service. GP satisfaction – 70% were 'moderately satisfied' and 30% were 'very satisfied' with ATT. Hundred percent felt the service was easily accessible and 90% felt that the staff were friendly. Patient Satisfaction – 96% of patients rated the team as 'friendly and polite'. Eighty-seven percent reported that they were listened to and 91% felt their concerns were understood. Eighty-three percent felt that ATT involved them in their decision making. Ninety-two percent responded that they were likely/extremely likely to recommend ATT to their friends and family.

Conclusions The establishment of ATT has led to improved satisfaction among GPs and service users and has resulted in reduction in referrals to secondary mental health services.

Factors associated with non-show to first therapeutic appointments in a mental health clinic in Northern Israel

L. Elyashar^{1,2,*}, L. Vadas¹, A. Reshef^{1,2}, B. Bloch^{1,2}

¹ Emek Medical Center, Psychiatry, Afula, Israel

² Technion–Institute of Technology, Faculty of Medicine, Haifa, Israel

* Corresponding author.

Introduction Patient non-show to clinical appointments is a major component of nonadherence, specifically in mental health institutions, being twice that of non-show in other medical specialties, and is associated with a greater risk of morbidity and mortality.

Aims and objectives Our study was conducted to assess the rate and factors associated with missed first appointments in an outpatient mental health clinic, in order to find correlates between the various factors and the probability of non-show among newly referred patients.

Methods This was a retrospective study of 400 consecutive outpatients referred to a single regional mental health clinic in northern Israel during 9 months. Data was collected on sociodemographics, attendance rates, source of referral, the presence of chronic physical illnesses and time elapsed between referral to appointment. The findings were statistically analyzed to identify factors associated with patient non-show rate.

Results Of the 400 patients included in the study, the non-show rate was 39.6%. Patients who missed appointments were significantly more likely to be younger, to belong to the Arab sector and to wait longer for their appointment. They were less likely to be physically ill. Gender, marital status and source of referral were not significantly associated with the non-show rate.

Conclusions Given the problematic potential outcome of non-show to mental health clinics, it is important to identify high-risk factors associated with non-show and unique to the population in question, so that interventions can be targeted at them, thus improving treatment outcome and reducing risk to patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Establishing a physical health monitoring service for patients on depot antipsychotic medication

M. Gill^{1,*}, M. McCauley²

¹ Cavan Monaghan Mental Health Service, Community Rehabilitation Service, Cavan, Ireland

² St Brigid's Hospital, General Adult Psychiatry, Ardee-Co. Louth, Ireland

* Corresponding author.

Introduction Patients with major mental illness are recognised to be at risk of premature death for a multitude of reasons. Those with schizophrenia and bipolar disorder are at highest risk.

Objectives International best practice recommends monitoring of blood tests, physical parameters such as weight, BMI, waist circumference and blood pressure, and side effects of patients prescribed antipsychotic medication. A clinic was established to target these interventions.

Aims This initiative aimed to improve the physical health monitoring of patients prescribed depot antipsychotic medication in a catchment area of approximately 36,000 in Ireland.

Methods A twice-yearly, multidisciplinary monitoring clinic was established. A protocol was drawn up, following a literature review and inspection of current international guidelines, and a proforma assisted as an aide-mémoire. A self-report questionnaire, the Glasgow Antipsychotic Side Effect Scale, was used to enquire about side effects.

Results Evaluation took place in descriptive form with audit used to examine outcomes. Full blood test monitoring improved from 9% of patients to 61% in one year, with 78% of patients having had at least one blood test recorded. Prior to the clinic's establishment, only one patient had had any physical parameters recorded, but this improved to 96% recorded after the clinics were run. Side effect documentation also improved.

Conclusions The clinic was well-received and led to improved teamwork. Future recommendations include organising the clinic so as to include simultaneous blood testing. A similar project is being planned to target all patients attending who are prescribed antipsychotic medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How much longer will a patient stay in acute unit if mechanical restraint is required?

M. Grifell^{1,2,*}, L. Galindo^{1,2}, F.N. Dinamarca¹, V. Chavarría¹, E. Pérez¹, P. Salgado¹, V. Pérez^{1,3}

¹ Parc de salut mar, Institut de neuropsiquiatria i addiccions INAD, Barcelona, Spain

² Hospital del Mar medical research institute IMIM, Grup de recerca en addiccions, Barcelona, Spain

³ Centro de Investigación Biomedica en Red de Salud Mental CIBERSAM G21, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Mechanical restraint is a therapeutic procedure commonly applied in acute units in response to psychomotor agitation. Its frequency is between 21 and 59% of patients admitted. These patients represent a risk to both themselves and for health workers. In order to implement measures to prevent agitation and therefore mechanical restraint, it is important to quantify the

effects and costs of those procedures. The aim of this study is to determine whether the application of mechanical restraint in psychiatry acute unit is related to a longer stay in hospital.

Material and methods We reviewed retrospectively the informatics record of all the mechanical restraints made and the total discharges of the three acute care units and dual disorders of our institution, between 2012 and 2015. For every discharge, the presence of at least one mechanical restraint was coded, resulting in two groups. The length of stay of the groups was then compared performing a *t*-test.

Results The number of discharges analyzed was 4659 from which 838 had an episode of mechanical restraint associated. There are significant differences between the length of stay of admissions with and without episode of mechanical restraint. The episode of mechanical restraint during an admission is associated with 5 to 9 more days of stay in the unit ($P < 0.001$).

Conclusions The performance of a mechanical restraint is associated with a statistically significant and clinically relevant higher length of stay. These results suggest that preventing agitation, and therefore mechanical restraint, would be possible to decrease length of stay, and therefore costs related to hospitalization.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Predictors and rate for one-year inpatient readmission in the psychiatric hospital of Sarajevo Canton

F. Kovac*, M. Ahmic, P. Bilalovic, M. Tahirovic
Psychiatric Hospital of Canton Sarajevo, General, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

Introduction Number of patients who are again unexpectedly admitted to hospital after a previous hospitalization are used to evaluating the quality of hospital care. Readmission can be represented by the total number and by readmission rate.

Objective Understanding the risk factors that can lead to readmission is a factor for the development of interventions that can improve the quality of care.

Aims The purpose of this study was to examine number and predictors of psychiatric readmission within 14 days, 30 days and, 3 and 6 months.

Methods In this retrospective study, analyses were conducted in a sample of 566 discharge adult patients who were admitted to a Psychiatric Hospital of Sarajevo Canton from 1st January to 31st December 2013.

Result Total number of readmission was 14%. The readmission rate within 30 days was 2.8%, number of readmission quarterly was 9.1%, number of readmission within 6 months after discharge was 13%.

In the study, several factors were significantly associated with increased risk of readmission including non-compliance with drug treatment, social problems, aggressiveness, suicidality.

Conclusion Our study suggesting that the prevention of psychiatric readmission requires continuous multidisciplinary work with patients and family members.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Zuoying Branch of Kaohsiung Armed Forces General Hospital, Nursing Department, Kaohsiung, Taiwan

* Corresponding author.

This study is intended to be schizophrenia patients in chronic ward of one southern military hospital. We had based on problem-solving and improvement steps to investigate personal and social function and improve quality of sleep in schizophrenia patients before and after rehabilitation treatment in according with DMAIC. DMAIC is a systematic approach to problem-solving steps and quality improvement, which D represents definitions (Define), M on behalf of measure (Measure), A representative of analysis (Analyze), I on behalf improve (Improve), C representing the control (Control). In this study, first psychiatric professionals completed their PSP in order to identify the severity of psychiatric symptoms in patients. Secondly, we proposed patients in treatment self-administered approach to PSQI to measure and analyze the quality of sleep. In this paper, the subjects respectively accomplished above two assessment scales after they were included in the study and fourth, eight weeks later. Finally, according to problem-solving and improvement steps of DMAIC, we further proposed improvement and solutions of treatment process in chronic psychiatric ward to achieve personal and social function and sleep quality in schizophrenia after series of rehabilitation therapy.

Our study found that sleep quality of most schizophrenia in chronic ward is poor, and often occurs in daytime dysfunction. We should increase gradually the amount of schizophrenia inpatient's physical activity (physical fitness activities, recreation therapy, etc.), and suggest that these patients still need continuous medication and other psychiatric rehabilitation therapy to maintain personal and social function and improve the quality of sleep (Fig. 1).

Quality management and economic downturn. Post-modern topics of community psychiatry

A. Zangrando^{1,*}, F. Babici², E. Pascolo-Fabrizi³, A. Riolo²

¹ University of Trieste, Department of Mental Health, Trieste, Italy

² CSM Domio, Department of Mental Health, Trieste, Italy

³ UCO Clinica Psichiatrica, Department of Mental Health, Trieste, Italy

* Corresponding author.

Introduction The reduction of the budget allocated to community psychiatry is part of financial needs in times of economic crisis. However, the community psychiatry is based on human resources rather than on technological devices and the economic downturn affects the quality of care in a field where the social and relational capital developed by mental health workers is fundamental. Some authors such as Serge Latouche propose to stem the economic decline with the concept of “degrowth”, a constructive idea but difficult to apply.

Objective We would like to analyze whether the economic downturn has consequences only for the organization of psychiatric services or even for people with severe mental disorders. Another issue concerns the possibility that economic downturn increases the social exclusion of vulnerable people.

Results People who live on social welfare or disability pension remain on the margins of society but also those supported by families feel increasingly marginalized with respect to the future.

Conclusions The provision of mental health services may not meet the implicit and explicit wishes in the demand for health by citizens and society. It's therefore necessary to review the quality management within community psychiatry.

Economical and social return of psychosocial rehabilitation model based in needs. The SROI project

S. Benabarre^{1,*}, J. Olivera², C. Pelegrín²

¹ Fundación Agustín Serrate, Centro de Día Arcadia, Huesca, Spain

² Servicio Aragonés de Salud SALUD, Servicio Psiquiatría, Hospital San Jorge de Huesca, Huesca, Spain

* Corresponding author.

Introduction Psychosocial Rehabilitation has demonstrated to be a key factor in the process of deinstitutionalisation, recovery and social inclusion of people affected by a Severe Mental Disorder. Nevertheless, there are few studies about social and economical return of this rehabilitation.

The Fundación Agustín Serrate is a Non-Governmental Organization (NGO), which has been working, since 1995, with psychosocial rehabilitation in Huesca, a small province in the north of Spain.

Objective The aim of this study is to determine and recognize the return and the impact that a rehabilitation and intervention model has in people with a severe mental disorder, on their families and on society.

Methods Three services in its model of rehabilitation: day care centre, integration work centre and supervised houses.

The SROI (Social Return Of Investment) methodology is a tool to make decisions based on the optimization of the social and work

impacts of social projects. The study was done by meetings, workshops, interviews and questionnaires with all groups of interest (patients, families, psychiatrist. . .)

Results A total of 208 users were attended in different services (65% men and 35% women). The age average was 45.8 years. Sixty-eight percent of people had a diagnosis of schizophrenia and schizoaffective disorder. For each euro of investment, the organization returned to society 3.15 euros (social return and economic). The users and their families improved their quality of life (individual and familiar).

Conclusions The principal conclusion is that Psychosocial Rehabilitation is financially profitable for the society and governments; and it is useful for improving the quality of life of patients and their families.

An evaluation of the EOLAS psychoeducation programme for service users: An innovative approach to collaboration between clinicians and ‘experts by experience’

P. Gibbons^{1,*}, A. Higgins², D. Hevey³, M. Monahan², C. O'Connor¹

¹ Health Service Executive, Kildare/West Wicklow Mental Health Service, Celbridge, Ireland

² Trinity College Dublin, School of Nursing and Midwifery, Dublin, Ireland

³ Trinity College Dublin, School of Psychology, Dublin, Ireland

* Corresponding author.

Introduction Psychoeducation for service users has been shown in several recent meta-analyses to improve adherence with treatment, decrease rehospitalization rates and improve various measures of quality of life. The 8-week EOLAS Programme for service users with schizophrenia or bipolar disorder is unique in being designed, co-facilitated and evaluated collaboratively by both clinician and peer representatives. EOLAS forms part of the service plan of the national Health Service in Ireland.

Aims and objectives To evaluate the impact of the EOLAS programme on participants' perceived knowledge, confidence, advocacy, recovery attitudes and hope.

Methodology Anonymised questionnaires were administered to participants before and after completion of the EOLAS Programme. All survey participants were invited to attend for interview to examine qualitatively their experience of the programme. Interviews were recorded and subjected to thematic analysis.

Results Forty-five subjects completed pre- and post-programme questionnaires (participation rate = 55%).

Significant improvements ($P < 0.05$) were identified across each of the 5 domains examined (i.e. perceived knowledge, confidence, advocacy, recovery attitudes, hope). Expressed satisfaction with the programme was high (95%).

At interview, participants ($n = 12$) particularly valued:

- the opportunity to ask questions of the psychiatrist e.g. about medication;
- improving self-care skills e.g. monitoring early warning signs of relapse;
- co-facilitation by a peer, which provided extra credibility and inspired hope;
- sharing experiences with peers.

Conclusions The EOLAS programme succeeds in meeting the needs of the participants across the target domains. This success depends on the unique collaboration between clinicians and peer experts on which EOLAS is based.

Attitude toward medication as a predictor of therapeutic adherence. Importance of psychoeducation on treatment

C. González Soria*, C.I. Fombellida Velasco, L.C. Fernández Martín, L. Sánchez Pernas, L. Al Chaal Marcos, L. Alonso León, R. De La Mata Hidalgo, I. Valriberas Herrero
University Hospital, Psychiatry, Salamanca, Spain

* Corresponding author.

Introduction Between 25–50% of psychiatric patients are non-compliant with their pharmacological treatment. When differences between compliant and non-compliant patients were analyzed, differences were found in relation to their beliefs and feelings about medication. The Drug Attitude Inventory (DAI) was created to measure attitudes towards medication in adults. It predicted adherence in schizophrenia and depression studies.

Objective Determine if psychotherapeutic and psychoeducational activities – during a partial hospitalization at the Psychiatric Day Hospital – can improve aspects related to feelings and thoughts about medication.

Method We gathered retrospectively a sample of 151 patients hospitalized at the Psychiatric Day Hospital, from September 2013 to June 2015. Their thoughts and feelings about medication were measured with the DAI before and after the hospitalization. From the sample of 151 patients, 94 completed both tests, excluding who did not have the final DAI score. Differences between initial and final scores were statistically analyzed with the Wilcoxon test for paired samples.

Results Of the 94 patients who completed the study, 52 showed an improvement in their DAI score, whereas the remaining 27 showed an equal or decreased final DAI compared to initial evaluation. The difference was statistically significant ($P \leq 0.05$).

Conclusion It seems that psychoeducational activities related to medication are important in order to reconsider or modify feelings and thoughts about treatment. Information on medication provided to psychiatric patients (to those who need psychopharmacological treatment), carried out in a group context, which facilitates an open and sincere communication, can be a useful strategy to improve compliance with treatment.

EV1112

Mutual aid program among adults with mental health illness as part of the treatment in a day hospital

M. Guerrero Jiménez^{1,*}, C.M. Carrillo de Albornoz Calahorra¹, J.A. Rodrigo Manzano², B.M. Girela Serrano³

¹ University Hospital San Cecilio, Psychiatry, Granada, Spain

² Santa Ana Hospital, Mental Health, Psychologist, Motril, Spain

³ Santa Ana Hospital, Mental Health Service, Motril, Spain

* Corresponding author.

Introduction/objectives To supervise agents in a mutual aid experience in Motril Mental Health Day Hospital. To perform a supporting role among the agents involved in a mutual aid program to consolidate its operations autonomously.

Methods A multidisciplinary working group, which met every two weeks for 4 months was set. Group sessions were planned. We

selected mutual aid pairs individually and addressed the difficulties in the process. The experiment was performed with 4 agents setting a maximum of 5 interviews. A success criterion of 80% of the meetings planned was established. In between mutual aid group, success criterion was to maintain a 3-month experience held by 5 members. A qualitative analysis of most important issues amongst coordination meetings were also held.

Results Three out of 4 pairs reached 80% of the interviews successfully. The support group was developed weekly during 3 months with an average of 8 participants. The trending topics during coordination meetings were toxic consumption, acute crisis, drug intake and issues to be addressed with the psychiatrist.

Conclusions Mutual aid among users is a way of intervention that needs to be further consolidated. The establishment is still unpretentious and has low weight amongst coordination objectives. The results addressed in number of sessions and satisfaction are favorable, but it is necessary to assess the experience widely and to begin developing specific objectives [1,2].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosocial therapy in schizophrenia

L. Maroto Martín*, P. Hervías Higuera

Hospital Doctor Rodríguez Lafora, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Psychosocial interventions are an essential part of the treatment of schizophrenia and are aimed at promoting the social, family and occupational functioning of the patient and relapse prevention. They are considered proven clinical measures whenever necessary, however they tend to be underused.

Objective Answer the question on psychosocial therapies available today for schizophrenia.

Methods Review through PubMed by entering the following keywords: psychosocial therapy; schizophrenia; cognitive behavioral therapy, and clinical practice guidelines.

Discussion There are several psychosocial therapies used in clinical practice. The main points of approach focus on self-management of the disease, everyday problems, education, crisis intervention, and acquiring insight. The cognitive impairment is an important aspect of schizophrenia to consider. It seems that cognitive remediation therapy has been associated with both neurobiological and cognitive improvement.

Conclusions The combination of different therapies along with psychopharmacological treatment appears to provide better results in the reduction of negative symptoms, positive symptoms and reduced hospital stay.

Voluntary and involuntary admission to a subacute psychiatric hospitalization unit

O. Orejas*, P. Flores Martínez, C. Macías Castellví, M.T. Campillo Sanz, M. Vallvé Elias, A. Casals Arnau, C. Masferrer Herrera

Neuropsychiatry and Addictions Institute INAD, Parc de salut Mar, Psychiatry Hospitalization, Barcelona, Spain

* Corresponding author.

Introduction Involuntary admissions continue to be a controversial topic in psychiatry. However, it is well known that psychosocial rehabilitation treatment is more successful when the patient is involved in it improving awareness and adherence to treatment.

Objectives This study examined admissions patterns, including voluntary, involuntary, and partly voluntary admissions to a subacute psychiatric hospital.

Methods This is a transversal study. All patients admitted for a medium-term psychiatric treatment since 01/06/2014 to 30/11/2015 were included. Patients's basic sociodemographic and clinical data were collected and compiled in a database. Descriptive statistics were performed using SPSS Software.

Results A total of 88 patients (52% men; mean age: 48.6 years) composed the sample. In 58% of cases, schizophrenia and schizoaffective disorder were the diagnoses motivating the admission. Among 88 patients, 44 (50%) had voluntary admissions, 16 (18.2%) had involuntary admissions, 27 (30.7%) had partly voluntary admissions and just one patient (1.1%) had partly involuntary admissions. Seventy-one (80.1%) patients had voluntary admissions at discharge, and only one of them escape from hospital and did not finish the treatment.

Conclusions In the short term involuntary hospitalization has benefits, however also can have adverse long-term consequences for the patient-therapist allegiance, breaking the psychotherapeutic relationship and making the patient abandon treatment. It's important to reassess the condition of admission and work with the patient the need to engage in treatment.

³ Hospital Nuestra Señora del Prado, Family Medicine, 45600 Spain

⁴ Hospital General de Ávila, Psychiatry, Avila, Spain

* Corresponding author.

Introduction The elapsed time since a patients' disease is diagnosed till these patients come to rehabilitation centers is usually long. In this study in our sanitary area, we have checked the average length of time since the patient is diagnosed till they come to the rehabilitation center.

Objectives To calculate and analyze the years of evolution of the disease in patients who come to the rehabilitation center in the Talavera area during year 2014. Classify them by sex.

Methods Retrospective cross-sectional descriptive study. We carried out a register of all the patients who come to the Psychosocial and labor Rehabilitation center in 2014. Classified them by sex, and the time lapsed since they were diagnosed until 2014.

Results From all 135 patients: 92 men (68.15%) and 43 women (31.85%). Less than 2 years of evolution: 1 patient (1%) 1 men, 0 women; between 2 and 5 years of evolution: 7 patients (5%) 5 men, 2 women; between 6 and 10 years evolution: 13 patients (10%) 7 men, 6 women; more than 10 years: 114 patients (84%).

Conclusions It is evident that the number of patients increases proportionally to the number of years since the diagnosis. The majority of patients who come to the center (84%) were diagnosed more than 10 years ago. This leads us to wonder why the patients in our sanitary area with recent diagnosis of diseases such as schizophrenia do not come to the mentioned centers earlier.

The social cognition individualized activities lab: Implementation of a new remediation intervention for social cognition

D. Palumbo*, A. Mucci, G. Piegari, M. Chieffi, A. Mazza, R. Giugliano, F. De Riso, V. D'Alise, S. Galderisi
University of Naples SUN, Department of Psychiatry, Naples, Italy

* Corresponding author.

Introduction People with schizophrenia exhibit deficits in neurocognitive and social cognitive (SC) processes which limit their social reintegration. SC was found to mediate in part the impact of neurocognitive dysfunctions on real-life functioning.

Objective The purpose of this study was to implement a new intervention for patients with schizophrenia, the Social Cognition Individualized Activities Lab (So.C.I.A.L.) which trains both social cognition and neurocognitive functions.

Aims To determine the efficacy of the So.C.I.A.L in improving SC by a comparison with a validated cognitive remediation (CR) intervention: the Social Skills And Neurocognitive Individualized Training (SSANIT).

Methods Nine stabilized patients accepted to participate in this pilot study. Five were randomized to So.C.I.A.L. and 4 to SSANIT. The two programs were matched for the overall treatment duration (20 weeks), as well as frequency and duration of the sessions. Both interventions included individual sessions of neurocognitive individualized training; So.C.I.A.L included group sessions on Emotion Recognition and Theory of Mind, while SSANIT group sessions of Social Skills Individualized Training.

Results No group difference was found for changes in neurocognition, while a significant group effect was observed for changes in SC, due to improvement only in the So.C.I.A.L. group.

Conclusions The study results showed a specific effect of the So.C.I.A.L. on SC, beyond the effect on neurocognition. Further studies are needed to assess the impact of So.C.I.A.L. on real-life functioning in a larger group of subjects.

Advantages and obstacles for community based approach using case management method in the work with users that have psychotic disorders – Case study

G. Racetovic^{1,*}, S. Popovic², B. Rosic², S. Grujic Timarac³

¹ Public Health Institution Health Center, Community Mental Health Center, Prijedor, Bosnia and Herzegovina

² Public Health Institution Health Center, Health Center, Prijedor, Bosnia and Herzegovina

³ Public Health Institution Hospital, Psychiatry Department, Prijedor, Bosnia and Herzegovina

* Corresponding author.

Introduction Case management (CM) is accepted as the most recommended approach for the treatment of people with severe mental illnesses (SMI) in Community Mental Health Centers (CMHC) in whole Bosnia and Herzegovina (BH) in the last 3 years.

Objective All team members of CMHC Prijedor are certificated case managers. Part of our daily activities is work with and for the users included in CM (mostly with schizophrenia or similar disorders) using multidisciplinary approach to find best possible solutions of both treatment and rehabilitation for users that we are in charge. In this moment CMHC cares for 12 mostly younger users involved in the CM.

Aims To show advantages as well as obstacles of the CM.

Methods Case study of young user with schizoaffective disorder included in the CM in the last 2 years.

Results Improvements in user's daily activities and using of the remaining capacities with confrontation of partial or entire poor responses of most other community services.

Conclusions CM has many advantages for the user involved in it, mostly medical and psychological (adequate treatment followed by users wishes, avoidance of hospitalization, improving existing or building new skills, use of remaining capacities, planned activities, minimize of the psychopharmacological treatment, social skills and more new contacts with people, etc.). But, still are existing the obstacles in the community mostly considering employment and social care as an part of the stigmatization of the people with SMI.

Crisis in the psychiatric patient: A structured illness-management-oriented group intervention

G. Fucci, N. Ratti*, R. Gattamorta, R. Godoli, S. Randi, M.P. Riccipetioni

AUSL Romagna, Dipartimento di Salute Mentale, DSMDP, Ravenna, Italy

* Corresponding author.

Introduction Crisis prevention and management of the psychiatric patient have obtained a central role in the policies of Mental Health Services. In this context, Mental Health Centre of Ravenna has launched a "Crisis Center", a rehabilitation group project applied to three types of users: users in an early stage of crisis, users in a post-critical stage and users at high risk of crisis. Intervention was based on the Illness Management and Recovery practice, an evidence-based program which consists in social skills training activities, emotions management, symptom management, coping skills training, psycho-education and, more generally, supporting users in their personal recovery process.

Objective Objectives of this project is to prevent crisis and hospitalization and to provide an alternative to institutionalization for mental health users.

Aims The aims of this study was to analyze and show effects and results of the project, in its first three years of life.

Methods Through the database "Infoclin", we analyzed data of 94 users who took part in the project between January 2012 and December 2014.

Results Analysis showed, primarily, that out of 94 users, 64 (68%) have not needed hospitalization in the following two years after intervention. Furthermore, out of 39 users with a history of one or more hospitalizations at time of entry, 22 (56.4%) have not needed hospitalization in the next two years.

Conclusions Despite the low number of users analyzed, it is believed that this study should be considered a further evidence of the positive effects of the IMR practice within mental health services.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The post-traumatic growth: The wisdom of the mind, its clinical and neuropsychanalytic vicissitudes

I. Rozentsvit

Object Relations Institute for Psychotherapy and Psychoanalysis, Parent-Child Development Program, Fresh Meadows, USA

The purpose of this symposium is to bring awareness about and to promote knowledge of the phenomenon of posttraumatic growth (PTG) and its neurobiological mechanisms. The other purpose is to explore neuro-psycho-education as an important tool in understanding trauma and in promoting PTG.

The idea of PTG was pioneered by Calhoun and Tedeschi (1999), who addressed positive psychological change (as they compared it with the "mind's wisdom"), which occurs in some individuals after trauma. PTG happens in the context of and despite of processing traumatic pain and loss. This phenomenon includes five main factors: relating to others with greater compassion; finding new possibilities, personal strength, spiritual change, and a deeper appreciation of life.

Both neuropsychanalysis and neuro-psycho-education offer us the knowledge of neurobiology and its mechanisms of "action" (such as neuroplasticity, neurointegration, mind-body integration, connectomes, 'triune brain', 'bottom up processing' and 'top-down

regulation', etc.) and help modern mental health practitioners to understand their clients from "inside out": to read the cues of their underlying (and not verbalized) patterns of being; to access their undisclosed, untold, emotional-relational history; to understand how this history shapes the present; to appreciate one's unique personal growth, even in the aftermath of trauma, and to understand mindfulness and mentalization as two powerful healing processes which play significant role in PTG.

Both neuropsychanalysis and neuro-psycho-education also help clinicians to be in touch with and to regulate our own emotions and somatic responses to a "difficult client", while maintaining "benevolent curiosity" and empathic stance.

Sexuality and affectivity: Two themes in a psychosocial intervention for psychotics inpatients

A. Vaccaro*, C. Zoppellaro, V. Fusco
Comunità TESEO, Crest, Milan, Italy

* Corresponding author.

The aim of this project is about valuing these themes, not only in order to increase physiological genres knowledge or the responsible use of contraceptives, but is mainly about growing sexual psychosocial features awareness. Treating these themes in a psychoeducational intervention means: minimize sexually-transmitted diseases, prevent psychotic patients from quitting psychopharmacological treatment and favour the birth and the development of intimate relationships that may help patients leaving an unhelpful isolation condition.

Increase the awareness of different sexual and affection aspects: physiological, anatomic and reproductive, relational and communicative, emotional, social and cultural, playful and pleasant ones. The 18 meetings interventions were done using a psychoeducational model; an active leading group manner (role plays and simulations) was used in order to ease the exchange of views between patients and the group leader.

We did a first round of meetings with ten patients who participated actively; we also submitted to them a questionnaire – before and after the intervention – in which we collected knowledge and opinions about different themes (contraceptives, risk awareness, affective relationships etc.).

From a qualitative analysis of the results we saw a knowledge-improvement about the dealt themes, and also, in some cases, we identified a modification in some problematic behaviours. The sample it's still too small for statistical analysis.

Emotional management training in residential mental health services

A. Vaccaro*, V. Fusco, F. Manfrin, E. Forte, G. Petagine
Comunità TESEO, Crest, Milan, Italy

* Corresponding author.

A core element for the treatment of psychiatric patients in mental health services is the Psychosocial Rehabilitation. In this work we mainly refer to a training whose targets are fundamental components of the Emotional Intelligence (EI), which is, according to the original Salovey and Mayer's definition (1990), "a set of skills hypothesized to contribute to the accurate appraisal and expression of emotion in oneself and in others, the effective regulation of

emotion in self and others, and the use of feelings to motivate, plan, and achieve in one's life".

The purpose of this study is to evaluate the efficacy of Emotional Management Training and to compare our emotional management assessment to standardized emotional intelligence assessment instruments.

Twenty adult inpatients (from 18 to 55 years of age) were enrolled: ten subjects were assigned to a one year lasting emotional management training (clinical target group) and ten subjects were assigned to a clinical control group; furthermore twenty subjects were selected and assigned to a non-clinical control group. Outcome measures were: emotional management assessment, Schutte Emotional Intelligence Scale (SEIS) and Toronto Alexithymia Scale (TAS-20).

Emotional management assessment outcomes confirm the efficacy of emotional management training. Preliminary results also confirm the effectiveness of the assessment compared to standardized emotional intelligence scales.

Emotional management training improves psychiatric patient competence in terms of: emotions definition and acknowledgement, self-emotion identification, self-emotion sharing, management of stressing situation and intense emotions.

The subjective graphic representation as the neural pathway of the information processing: Dyslexia as an example

A. Bernardini
Sinalunga Siena, Italy

Introduction The new theory of the mind by A. Bernardini.

Objective To single out and recover information process's deficits by a new research method.

Aim To demonstrate dyslexia/language can be considered as an answer/neural pathway to what we are able to perceive. This depends on the way in which the C.N.S. elaborates the two aspects of energy of the internal and external space according to the New Theory of the Cognitive Process by A. Bernardini, which underlies her relevant re-educative methodology.

Methods This study was carried out in Italy, in pre-high school education where students with moderate learning abilities and special needs are integrated into mainstream education. The performance of F 81 subjects was examined. They were divided into two groups: the first supported by A. Bernardini's method, the second supported by a remedial teacher (traditional method). The control group being the rest of the class. For five months, tailored programs were followed three times a week, for one hour and a half.

Results At the end of the treatment the second group did not show significant results while the first group showed marked improvement. Among the students of the first group, Tobia was the student who best represented dyslexia; for this reason he has been taken as an example.

Conclusion Dyslexia and disturbances in language learning depend on perceptive deficits and can be recovered by A. Bernardini's method according to her new theory of the Cognitive Process. This last revolutionizes the principles of the current research method.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Does clinical change always means the same? Comparison of different perspectives

S. Egger*, G. Weniger, S. Prinz, S. Vetter, M. Müller
University Hospital for Psychiatry Zurich, ZIP, Rheinau, Zurich, Switzerland

* Corresponding author.

Introduction In psychiatric practice, the assessment of change from pre- to post-treatment is a key approach for monitoring treatment effects and for the prediction of treatment outcomes. The Health of the Nation Outcome Scales (HoNOS) as a clinician-rated measure and the Brief Symptom Inventory (BSI) as a self-report measure are tools (that are) often incorporated in outcome monitoring. Their usefulness, however, has been questioned by two important issues: their psychometric properties and their lack of concordance.

Aims and objectives The aim of the study is to evaluate the responsiveness of HoNOS and BSI as well as their interactions to predict clinical meaningful change according to the Global Clinical Impression (CGI) as quasi-gold standard for treatment outcome.

Methods A consecutive sample of patients admitted to a Swiss psychiatric hospital for either alcohol use disorders, schizophrenic psychoses, mood disorders, anxiety and somatoform disorders, or personality disorders was assessed with Brief Symptom Inventory (BSI) at admission and discharge. The HoNOS and the CGI were rated by the responsible clinicians at admission and discharge. Ordinal logistic regressions will be conducted using the CGI categories as ordered categorical outcome. HoNOS and BSI scores as well as their interaction terms will be used as independent variables.

Results and conclusion Complete data of admission and discharge is available from approximately 600 cases. Graphical presentations will illustrate the resulting associations.

Keywords Clinical Global Impression; Health of the Nation Outcome Scales; Brief Symptom Inventory; Outcome monitoring; Ordinal regression

Descriptive study of the treatment of delusional disorder. Survey study DELIRANDA

B. Girela Serrano^{1,*}, L. Aguado Bailón², P. Calvo Rivera², J.E. Muñoz Negro², J. Cervilla Ballesteros²

¹ Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain

² Hospital Universitario San Cecilio Granada, Psiquiatría, Granada, Spain

* Corresponding author.

Introduction We currently lack clinical guidelines for the treatment of Delusional Disorder (DD) F-22, the low prevalence of the disease coupled with no awareness of illness and poor adherence to prescribed treatment make it difficult to study. The limited evidence available for the treatment is based mainly on clinical series.

Objectives This study evaluates the knowledge and preferences in the treatment of the DD, in order to improve clinical practice and

gain information of the DD to conduct clinical studies of effectiveness of the different treatments.

Material and methods A self-administered survey was conducted on a sample of 80 psychiatrists proceeding on a wide array of mental health care services. Participants provided socio-demographic data and information about clinical details, together with their opinions regarding the, epidemiological aspects, clinical management, diagnosis and therapy. Descriptive statistics were subsequently calculated with SPSS.

Results Most of our sample's of Psychiatrists estimated that the DD prevalence was higher than the one previously established. Ninety-three percent of the sample considered the SGAs as the first treatment option in DD, being Aripiprazol 20.7%, Risperidone 17.4% and Paliperidone 15% the first line treatment chosen by our Psychiatrists.

Conclusions and proposals There is an increasing gap between the old standard DD treatment and the clinical practice of Andalusian Psychiatrists, for this reason we emphasize the need of implementing clinical trials and effectiveness clinical studies.

* Corresponding author.

Introduction Delusional Disorder (DD) F22 is a disease with low prevalence, probably underdiagnosed by clinical specialists due to the high level of functionality, low awareness of disease, low deterioration of patients and poor adherence to prescribed treatment. Adherence to treatment is considered to be one of the major difficulties that stand in the way of the treatment of DD. The present paper assessed psychiatrists' opinion of the adherence to treatment of patients with DD.

Material and methods A self-administered survey was conducted on a sample of psychiatrists proceeding on a wide array of mental health care services. Participants provided their opinions regarding adherence to treatment. Descriptive statistics were subsequently calculated with SPSS.

Results In the opinion of our participants none of the patients have an active compliance of the treatment, 36% consider that the participation is partial or passive. It is also estimated that 57.5% reject the treatment but not totally and 6.5% believe that rejection is absolute.

Conclusions Literature informs of the association of poor adherence to treatment and little or no improvement of patients, suggesting the need to address the lack of compliance and adherence to treatment as a crucial aspect to improve the prognosis of DD. To address this problem Long Acting Injections (LAIs) of Atypical Antipsychotics are postulated to be a plausible solution as a good treatment strategy. In order to improve the clinical practice in DD and obtain information for further effectiveness we emphasize the need of implementing clinical studies.

Internet-based survey applied to experts in schizophrenia: Socio-demographic and professional variables associated to response pattern

G. Guilera¹, M. Barrios¹, O. Pino^{2,*}, D. Salas¹, J. Gómez-Benito¹¹ Faculty of Psychology, University of Barcelona, Department of Behavioural Sciences Methods, Barcelona, Spain² General Hospital of Granollers, Benito Menni CASM, Department of Psychiatry, Granollers, Spain

* Corresponding author.

Introduction In the framework of the development of the International Classification of Functioning, Disability and Health Core Set for schizophrenia, we conducted a cross-sectional, internet-based survey using open-ended questions. An international pool of experts from diverse health care disciplines was surveyed to identify problems in functioning experienced by individuals with schizophrenia.

Objectives The purpose of the study is to explore possible associations between experts' socio-demographic and professional profiles, and whether they answered or not the survey.

Methods Out of 307 invited experts, 189 (61.56%) filled in the survey. However, 37 experts were excluded in the data analysis as they had completed only a part of the questionnaire. Thus, there were 152 of the experts classified as "respondents" and the remaining 155 as "non-respondents". The association between the response pattern and the socio-demographic and professional variables (i.e., gender, World Health Organization region, discipline, and years of experience) was analysed by means of Chi² tests.

Results There was a statistically significant association between the response pattern and the gender of the expert ($\chi^2(1)=4.927$, $P=0.026$; $V=0.127$), showing that 56.3% of female and 43.6% of male experts answered the survey. When comparing the response pattern in terms of discipline, a statistically significant association was also found ($\chi^2(4)=10.101$, $P=0.039$; $V=0.183$), showing that those who tend to answer the survey are occupational therapists (71.4%), followed by psychologists (58.0%), social workers (52.6%), nurses (52.0%), and psychiatrists (41.3%).

Conclusions Females and occupational therapists presented the higher response rate to the expert survey.

Comparing family members' perceptions of the family

M. Kékes Szabó

University of Szeged, Department of Applied Pedagogy and Psychology, Szeged, Hungary

Family organization has arguably a determinative role in our healthy social-emotional and cognitive development, although we may have different perceptions of this system. Its background is in connection with the family members' different experience, knowledge and beliefs about the world. Furthermore, we are also prone to imagine others' mental representations that can help us to understand them better. Sometimes these meta-representations may be more accurate, while other times they may be incorrect. Although theories of mind tasks are well-known tools to explore (meta-) representations, the use of Gehring's (2010) Family System Test (FAST) in this way is less tested. The aim of this study was to compare the family members' perceptions of the family with one another. Children's and parents' family images were explored. In line with Smith, Myron-Wilson and Sutton's (2010) previous findings, my results confirmed the parents' increased ability to assess

the children's perceptions. Finally, growing theory of mind abilities may also be in the background of the results above (Happé, Winner and Bownell, 1998). Subsequent studies have to broaden the focus and involve more methods, age groups in the investigations to know more about human cognitive processes.

EV1129

Facets Mindfulness Questionnaire-10 – A shorter Portuguese version to evaluate mindfulness dimensions in pregnant women

J. Azevedo^{1,*}, E. Bento¹, S. Xavier¹, M. Marques¹, V. Freitas¹, M.J. Soares¹, A.M. Pinto², A. Oliveira³, A. Macedo¹, A.T. Pereira¹¹ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal² Faculty of Psychology and Educational Sciences, University of Coimbra, CINEICC, Coimbra, Portugal³ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Mindfulness refers to the capacity of being present and aware, without feeling the need to react or judge that experience (Kabat Zinn, 1990). This ability is associated with mental health and stress reduction (Baer, 2014; Teasdale et al., 2014). Five Facet Mindfulness Questionnaire (FFMQ) is widely used to measure mindfulness and its relation to psychopathology (Gregorio and Gouveia, 2011).

Objective To analyze the psychometric properties of the Portuguese 15 items FFMQ (Baer; Gregório et al., authors' manuscript) in a Portuguese sample of pregnant women.

Methods A total of 427 pregnant women (Mean age: 32.56 ± 4.785 years) in their second trimester of pregnancy (17.34 ± 4.790 weeks of gestation) completed the Portuguese version of FFMQ-15.

Results The FFMQ-15 Cronbach's alpha was unsatisfactory ($\alpha=0.62$) and five items presented low (<0.20) correlations and had the effect of increasing Cronbach alpha if removed. Without these items, α increased to a satisfactory level (0.72) and all the ten items contributed to internal consistency. The factorial analysis of these ten items resulted in a three factors solution, which explained variance (EV) was of 53.9%. Based on items content, the meaningful three factors were denominated as follows: F1 Nonjudging of experience (EV 27.69%; $\alpha=0.77$), F2 Acting with awareness (18.00%; $\alpha=0.77$) and F3 Observing and describing (8.21%; $\alpha=0.73$).

Conclusions Although the FFMQ-15 has shown good psychometric properties in other samples, in this sample of pregnant women a 10-items FMQ (Facets of Mindfulness Questionnaire) version performed better, presenting good reliability and validity in evaluating three mindfulness facets.

Rosenzweig picture-frustration test modification for a study of emotion regulation strategies among the patients with stress-induced hypertension

E. Pervichko*, Y. Zinchenko

Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

* Corresponding author.

Introduction Emotion regulation (ER) efficiency dwells among the most pressing issues of contemporary psychology and psychiatry. Further development of the methods of reliable assessments for ER makes it the task of current importance.

Objective To modify Rosenzweig Picture-Frustration Test for the study of ER in health and in disease.

Methods In the initial stage of testing participants had to look through a succession of Rosenzweig's pictures, and select potentially traumatizing situations.

In the second stage they answered the following questions:

- what would you say in this particular situation?
- what would you have in mind, saying this?
- could you think of an answer that would taper down the traumatizing character of the situation in your own perception? (Zinchenko, Pervichko, 2014).

A total of 85 patients with stress-induced hypertension (mean age was 45.9 ± 2.8) and 82 healthy subjects (mean age was 44.9 ± 3.1) took part in the study.

Results We came to distinguish among four classes of ER strategies: internal, cognitively non-mediated; internal, cognitively transforming; external, cognitively non-mediated; and external, cognitively transforming (Pervichko, 2015). Hypertensive patients significantly more frequently than healthy subjects reveal wider set of emotionally grave events (19.8% vs 11.2%, $P < 0.001$), they are more prone to rumination, disasterization (19.0% vs 11.1%, $P < 0.001$) and suppression in display of their emotions (31.9% vs 20.2%, $P < 0.001$). The patients will seldom employ the strategy of interactive subject–subject transformations; their capability to actualize new meanings in traumatic situations is diminished.

Conclusions Application of the described modification of Rosenzweig Picture-Frustration Test allows to distinguish and classify various ER strategies, and to demonstrate peculiarities in ER related behaviour of hypertensive patients as opposed to healthy subjects.

New methodologies for faster study of new psychoactive substances: A proposal

P. Quintana Mathé^{1,2,*}, M. Grifell^{1,2,3}

¹ Hospital del Mar Medical Research Institute, Grup de Recerca en Addiccions, Barcelona, Spain

² Associació Benestar i Desenvolupament, Energy Control, Barcelona, Spain

³ Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain

* Corresponding author.

Introduction New psychoactive substances (NPS) are substances that have recently become available, and are not worldwide regulated. They often intend to mimic the effect of controlled drugs, becoming a public health concern. In 2014, 101 substances were reported for the first time in the EU, which may require to be studied and risk-assessed by the scientific community. The EMCDDA recognizes it as an emerging topic where research is most needed, as the scientific community is struggling to keep pace with the speed at which new substances appear. On the one hand, case reports and internet-based surveys are quickly published but do not provide enough evidence to guide clinical decisions. On the other hand, classical high-reliability methodologies such as Cohort and Clinical studies take too long and their cost is too high to be of much use for the study of NPS. We propose an intermediate methodology to tackle this unmet need.

Rationale González and colleagues described a set of highly educated, experimental users of NPS with extensive knowledge and consumption of substances. These users usually look for drug

checking of the substances they intend to consume. We suggest we could benefit from the collaboration of such users, and the possibility of obtaining analytical confirmation, to retrieve information about NPS in a quick and reliable fashion.

Outline of methodology Recruiting of subjects that submit NPS to a drug checking facility. Analysis of the samples for analytical confirmation. Check inclusion criteria and propose inclusion in the study. Give structured forms for reporting effects and adverse events.

* Corresponding author.

Disorders of the self, such as the “loss of continuity” of the self in time, are a core symptom of schizophrenia, but one, which is still poorly understood. In the present study, we investigated two complementary aspects of self-continuity, namely phenomenological and narrative continuity, in 27 patients with schizophrenia, and compared them with 27 control participants. Participants were asked to identify 7 important past events and to narrate a story taken from their life that included these events. They were then asked to imagine 3 important events that might happen in their personal future and to build a narrative of their future life. The memory vividness of these important life-events and the proportion of self-event connections in the narratives were used as a measure of phenomenological and narrative continuity, respectively. Our results showed that the difficulty for patients to construct vivid representations of personally significant events was observed in both temporal directions, past and future. Patients' ability to establish explicit connections between personal events and attributes of self in life narratives was also impaired, but only in the case of past narratives. Our results yield a fresh understanding of the cognitive mechanisms of self-disorders in schizophrenia. The clinical and therapeutic implications of these findings are discussed.

² Laboratorios Farmacéuticos Rovi-S.A., R&D, Madrid, Spain

³ SGS Exprimio NV, Exprimio, Mechelen, Belgium

* Corresponding author.

Introduction Risperidone-ISM is a new long-acting intramuscular formulation intended to achieve sustained plasma concentrations over 4 weeks without oral supplementation. The clinical efficacy to risperidone has been associated with 65–80% occupancy of dopamine D2 receptor (D2RO) and a mean C_{max} between 7.5 ng/mL and 80 ng/mL.

Aim Use a population PK/PD model to predict the PK and the D2RO for Risperidone-ISM in schizophrenic patients and to characterize the relationship among doses, in order to guide dose selection for a future Phase-III trial.

Methods A population PK/PD analysis for Risperidone-ISM using Monolix software was conducted based on 6641 plasma samples from two Phase-I studies (17 healthy subjects and 31 schizophrenic subjects, respectively) and 1 Phase-II study (60 schizophrenic subjects). Simulations were subsequently undertaken predicting the steady state PK and D2RO after multiple Risperidone-ISM doses administered every 28 days for 12 weeks.

Results Doses of 75 and 100 mg, administered either in gluteal or deltoid muscle, were predicted to result in median C_{max} and C_{trough} that stayed between 7.5 ng/mL and 80 ng/mL. At steady state 75 mg and 100 mg dose (gluteal) achieved a D2RO average [min–max] of 70.8% [61.4–80.4] and 74.3% [66.2–82.1], respectively; a 75-mg and 100-mg dose (deltoid) achieved a D2RO average [min–max] of 69.3% [56.5–80.3] and 73.0% [61.8–82.1], respectively. The model estimated that the 65% D2RO occurs within first 8 h after treatment.

Conclusions Simulations were carried out supporting doses of 75 mg and 100 mg Risperidone-ISM to show the greatest efficacy and safety potential to be assessed in the future Phase-III trial.

Electroconvulsive treatment in Parkinson's disease and psychosis:

A case report

T. Aparicio Reinoso*, S. Gonzalez Parra
Hospital Dr. R Lafora, Psychiatry, Madrid, Spain

* Corresponding author.

Background Drug induced parkinsonism is a common side effect. **Objective** The present report describes the case of a schizophrenic patient who developed a parkinsonism after receiving antipsychotic drugs and who had improved his schizophrenia and parkinsonism after electroconvulsive therapy.

Case summary We report the case of a man, who is 35 years old and was admitted to a psychiatric ward, due to decompensated schizophrenia with psychotic features. The patient developed pronounced parkinsonian features, which did not improve with discontinuation of the drug or with carbidopa/levodopa. After several unsuccessful treatments, the patient was treated with ECT and showed improvement in both diseases.

Results The patient's response to this treatment justifies the use of ECT in patients with both syndromes: a psychosis productive and Parkinson's disease. Even the maintenance therapy can establish the initial response achieved and keep it through time. We should keep in mind that the management of these patients, can be extremely difficult because the medications used to both disorders are antagonistic.

Conclusion ECT can be considered in patients with a psychiatric illness associated with parkinsonism.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Intramuscular maintenance treatment with ultra-high-dose long-acting injectable aripiprazole in an elderly patient suffering from chronic refractory schizophrenia:

A case report

L. Bartova*, M. Dold, N. Praschak-Rieder, A. Naderi-Heiden, S. Kasper

Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

* Corresponding author.

Long-acting injectable (LAI) aripiprazole is increasingly appreciated in the course of a maintenance treatment of schizophrenia due to efficacy in delaying – and decreasing relapse, and low rates of feared side effects. In line with the prescribing information, the maximal starting – as well as maintenance dose was restricted to 400 mg following a 26-day interval between the single doses.

We present a 72-year-old female inpatient (66 kg) with an acute exacerbation of chronic refractory schizophrenia, exhibiting primarily positive symptoms including excessive persecutory delusions, self-care deficit, poor insight and insufficient adherence to continuous intake of oral medication. Since she developed a post-injection syndrome after an accidental intravascular administration of olanzapine LAI 405 mg, the antipsychotic treatment was switched to aripiprazole LAI 300 mg once monthly. Due to insufficient clinical response, aripiprazole LAI was gradually increased up to 1200 mg per month under continuous plasma level monitoring. Here, 2 single injections of aripiprazole LAI 300 mg were delivered into both gluteal muscles concurrently, every 14 days.

Consequently, we observed a clinically meaningful improvement (a total-score reduction from 111 to 75 on the Positive and Negative Syndrome Scale), as well as no objectifiable side effects, assessed by "The Dosage Record Treatment Emergent Symptom Scale" and "The Barnes Akathisia Rating Scale", despite multi-morbidity and rather advanced age of the patient.

Our safe experience with applying the almost threefold higher monthly dose over 12 weeks may encourage researchers to further investigate the efficacy, tolerability as well as handling of highly dosed aripiprazole LAI in refractory schizophrenia.

* Corresponding author.

Introduction Patients with epilepsy and schizophrenia could present atypical clinical presentations with neurological symptoms that are not frequently presented in schizophrenia.

Case Report We report the case of a 41-year-old male who was diagnosed of schizophrenia and was admitted into a long-stay psychiatric unit. He started at 33 years old with a depressive disorder. After prescribing venlafaxine, symptoms did not remit and the patient started to present apathy, anhedony, impoverished speech, social isolation and blunted affect. Then, the patient started to present behavioral disturbances consisted in regressive behavior, aggressive behavior, inappropriate language, echolalia, sexual disinhibition, impulsivity, worsening of executive functions and soliloquies. A neurological study was made with CT scan and electroencephalography, and no evidences of neurological abnormalities were found. After that, clozapine was prescribed, with an improvement of some symptoms like apathy, anhedony and aggressive behavior, but persisting the impulsivity, regressive behavior, inappropriate language, sexual disinhibition and echolalia.

Discussion Patients with schizophrenia and epilepsy could not respond appropriately to antipsychotic drugs. In this patient, the psychiatric symptoms more frequently seen in schizophrenia responded well to clozapine, but neurological symptoms did not improve with the standard treatment, causing a severe disability to the patient that was the main reason for his prolonged admission.

Conclusions It is recommended to make a detailed neurological exploration in all psychiatric patients, in order to explore atypical symptoms and comorbidities that could reveal new diagnosis and therapeutic objectives.

R. Jiménez Rico³

¹ Hospital Universitario 12 de Octubre, Psychiatry, Madrid, Spain

² Hospital Dr. Rodríguez Lafora, Psychiatry, Madrid, Spain

³ Centro San Juan de Dios Ciempozuelos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Schizophrenia could be presented with obsessive thoughts or an obsessive-compulsive disorder. It is known that some antipsychotics like clozapine could cause obsessive symptoms or worsen them.

Case Report We report the case of a 53-year-old male who was diagnosed of schizophrenia. The patient was admitted into a long-stay psychiatric unit due to the impossibility of outpatient treatment. He presented a chronic psychosis consisted in delusions of reference, grandiose religious delusions, and auditory pseudohallucinations. He often presented behavioral disturbances

consisted in auto and heteroaggressive behavior, being needed the physical restraint. Various treatments were used, including clozapine, but obsessive and ruminative thoughts went worse. Because of that, clozapine dose was lowered, and it was prescribed sertraline and clomipramine. With this treatment the patient presented a considerable improvement of his symptoms, ceasing the auto and heteroaggressive behavior, presenting a better mood state, and being possible the coexistence with other patients. Psychotic symptoms did not disappear, but the emotional and behavioral impact caused by them was lower.

Discussion This case report shows how a patient with schizophrenia could present severe behavioral disturbances due to obsessive symptoms. If obsessive symptoms are presented, clozapine must be at the minimum effective dose and antidepressants with a good antiobsessive profile.

Conclusions Obsessive symptoms could be presented as a part of schizophrenia. Clozapine could worsen this symptoms and it is necessary to adjust its dose to the minimum effective dose.

⁴ Bristol-Myers Squibb, Oslo, Norway

* Corresponding author.

Introduction The goals with modern treatment of schizophrenia are to achieve remission of clinical symptoms, prevent relapse, and to restore the patients' functions.

Objectives/aims The objective of this study was to investigate the impact of treatment with the partial dopamine agonist aripiprazole on functions, measured as time spent for work or studies, in patients with schizophrenia or schizoaffective disorder.

Methods Retrospective data on employment and study activities were collected for all patients between 18–65 years with schizophrenia or schizoaffective disorder at an open care psychosis clinic in Sweden ($n = 104$). Possible impact of treatment with aripiprazole and of other variables, such as age, gender, and disease severity, was analysed.

Results Among patients who worked or studied at Day of admission ($n = 36$), the probability of maintaining or increasing time for work or studies was significantly higher in patients treated with aripiprazole compared with patients who were not (88% versus 53%; $P = 0.020$). This difference remained significant after controlling for severity of symptoms, age and sex. A secondary analysis, including all patients (independent of work or study status at Day of admission) also showed a significant difference in favour of aripiprazole (53% versus 26%, $P = 0.005$).

Conclusions The results indicate that patients treated with aripiprazole (monotherapy or add-on) have higher probability of maintaining functional capacity. A plausible explanation might be aripiprazole's favourable effect on cognitive functions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Cannabis use is frequently observed in schizophrenia. Several medical and organic factors can lead to this comorbidity. These include depressive symptoms.

Objective Assessing the prevalence of depressive symptoms within a population of schizophrenic inpatients and the association with cannabis use.

Method A group of 403 patients diagnosed with schizophrenia according to Diagnostic and Statistical Manual of Mental Disorders, 4th Edition (DSM-IV), were assessed by The Calgary Depression Scale for Schizophrenia (CDSS) scale measure depressive symptom in schizophrenia. Socio-demographic, clinic, and urine toxicology screens testing data were collected.

Results The Schizophrenic patients included in this study have an average age of 33 years. The majority of them are males (90%), single (76%) and unemployed (72%). A total of 38 patients (9.4%) have depressive symptoms (scored 6 or more on the CDSS). Among this group, 16 patients (42.1%) were tested positive for cannabis used. Although there is a high proportion of cannabis use among patients with depression symptoms, there was no significant correlation between the CDSS total score and cannabis use among schizophrenic patients.

Conclusion Depression is well known to occur during the course of schizophrenia in many patients and contributes substantially to the morbidity. Studies are needed that include correlation analyses between depression and cannabis use in schizophrenia.

* Corresponding author.

Introduction Difficult access and low quality of health care are recognized as factors that may account for the excess deaths widely reported in patients with schizophrenia. As a matter of fact, psychiatrists not always possess adequate competences in the assessment of physical health, while non-psychiatric physicians receive little training in psychiatry and are not prepared to take care of subjects with severe mental illnesses.

Objectives We present a comprehensive and systematic algorithm for screening medical comorbidities, conceived to be easy to use for psychiatrists, after a brief training.

Aims The study is aimed to implement an instrument for proper detection and management of physical illnesses in people with schizophrenia.

Methods The screening protocol, developed by internal medicine specialists, was applied to 15 subjects in two independent assessments, one performed by trainees in psychiatry, after a brief training, and one carried out by one specialist and two trainees in internal medicine. The analysis of the inter-rater reliability was carried out by calculating the Cohen's kappa coefficient and the intraclass correlation coefficient as appropriate.

Results The agreement among raters resulted excellent for 61% of items, good for 17%, moderate for 18% and scarce for 4%. The few items showing scarce inter-rater reliability were excluded. The final algorithm is being tested for feasibility in psychiatric settings.

Conclusions The proposed screening protocol resulted in a suitable tool, showing moderate to excellent inter-rater reliability, that can be used in clinical practice by psychiatrists after a brief training.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1141

Depot aripiprazole as an alternative to the oral formula

M.R. Calero Fernandez

Hospital Gutierrez Ortega, Unidad de Salud Mental, Valdepenas, Spain

Background Aripiprazole depot was launched in Spain in March 2015. American double blind studies with placebo showed a significant delay in relapse and a good tolerance profile with injectable aripiprazole, with similar results to those obtained in studies comparing placebo and paliperidone depot.

Objective To compare the self-perceived changes after de substitution of oral paliperidone to depot formula.

Type of study Descriptive, case series.

Sample Ten patients. Age range: 22–62 years (mean age: 41.2 years). Seven men + 3 women. Inclusion criteria: diagnosis of schizophrenia or schizoaffective disorder, no acute psychotic symptoms. Prior treatment with oral aripiprazole (average dose: 17.5 mg) 20% on monotherapy of aripiprazol Oral aripiprazol was switched to the depot formula; 60% received a dose of 400 mg/28 days and 40% received 300 mg/28 days intramuscularly.

Results One patient abandoned the treatment after the first injection. Instrument for Assessment: IAQ scale: consists of 10 items; we did not consider the items "prolactin level" and "akathisia" (no patient showed neither before or after the treatment). The items were rated by the patient: 1 (much better than with oral treatment), 2 (somewhat better), 3 (equal), 4 (worse) and 5 (much worse) averages scores: Positive symptoms: 1.25 Negative Symptoms: 1.75 Drowsiness: 1.875 Weight gain: 1.625 extrapyramidalism: 1.875 Cognition: 1.625 Energy: 1.5 mood: 1.625 total score media: 13.25 out of 40 (corresponding to the worst maximum score), 1.65 average per item.

Conclusion Depot aripiprazole can be an alternative to the oral formula. The sample showed a self perceived improvement of their general state from "much better" to "somewhat better" than with oral treatment.

Internalized stigma, negative symptoms and global functioning in schizophrenia

O.O. Capatina*, I.V. Miclutia

University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj-Napoca, Neuroscience Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction Negative symptoms (NS) of schizophrenia were usually described as a unitary construct and as a separable domain of pathology; however recent studies suggest, that they encompass 2 separable domains: Diminished Expression (DE) and Avolition-Apathy (AA). Research into the relationship between internalized stigma and NS have yielded mixed results up to present.

Objective The objectives of this study was to assess the factor structure of NS and to examine the relationship between these factors and internalized stigma, global functioning and sociodemographic characteristics.

Aims The broad aim of this study was to gather greater understanding of the relationship between internalized stigma, NS and global functioning.

Methods A sample of 50 consecutive subjects were recruited from outpatient psychiatric hospitals meeting the criteria for schizophrenia according to ICD-10. The patients were evaluated using the Positive and Negative Symptoms Scale (PANSS), Negative Symptoms Assessment-16 items (NSA-16), Global Assessment of Functioning (GAF), Clinical Global Impression-Severity Scale (CGI-s), Internalized Stigma of Mental Illness Scale (ISMI) and were interviewed to assess sociodemographic characteristics.

Results A two-factor structure for the domain of NS was found: an AA and DE profile group. AA and DE subgroups significantly differed on clinically relevant external validators and greater resistance to stigma is related to both fewer AA and DE symptoms in people with schizophrenia.

Conclusions Our findings suggest that the different subdomains of NS can be identified within the broader diagnosis of schizophrenia and that they should be analyzed as distinct domains and that stigma resistance can be a possible intervention target to ameliorate NS.

Hypergraphia: Illustrating clinical pictures

L. Carvalhão Gil*, A. Ponte, J. Gama Marques

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Hypergraphia is an extensive writing tendency sometimes coupled with hyperreligiosity and atypical sexuality, completing a syndrome described by Waxman and Geschwind in 1975 during interictal phases of patients with temporal lobe epilepsy. Nevertheless, it may arise from any temporolimbic lesion, usually in the right hemisphere, in contrast to the schizophreniform psychosis more often seen in left-sided lesions.

Objective A review on the lateralizing significance of temporolimbic lesions, highlighting the (un)specificity of hypergraphia, after a case report concerning a patient with both hypergraphia and schizophreniform psychosis.

Methods Analyse patient's clinical records and PubMed review, using hypergraphia, epilepsy and psychosis as keywords.

Results We report a 74-year-old male admitted due to aggressiveness. The patient had a traumatic brain injury in his 20s with secondary left temporal epilepsy. He lived in a psychiatric asylum, for almost 40 years, with the diagnosis of

schizophrenia, showing fluctuant atypical sexual behavior. After being transinstitutionalized to community nursing-home he developed meningoencephalitis, leading to medication change and behavior relapse. He showed viscosity, circumstantiality, soliloquy, euthymic mood and normal cognition. He wrote profusely, e.g. lists of various categories and letters to eminent clerics and politics. His diary was scanned for illustrative purpose.

Conclusions Hypergraphia is an uncommon but easy to find symptom that deserves the full attention of the clinician, especially in the differential diagnosis between schizophreniform psychosis and temporal epilepsy.

Schizencephaly and psychosis: A case report

L. Carvalhão Gil*, A. Ponte

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Schizencephaly is a rare malformation of the central nervous system, a congenital disorder of cerebral cortical development resulting in the formation of abnormal unilateral or bilateral clefts in the cerebral hemispheres that extends from the pial surface to the ventricle. It often manifests with partial seizures, mental retardation and hemiparesis.

Objective To illustrate a rare case of association between psychosis and schizencephaly and the implication of this association for understanding the biology of the psychosis.

Methods A literature search was performed on PubMed database using the key words schizencephaly, psychosis, brain diseases and retrieved papers were selected according to their relevance. The patient clinical record was reviewed.

Results The authors report a case of a 59-year-old male admitted into a psychiatric hospital with insomnia, disorganized behavior probably secondary to auditory hallucinations and mystic delusions. He also reported epilepsy and strabismus in his right eye since his childhood and right facial paresis. A head CT scan revealed a left deep cortico-ventricular parieto-occipital communication corresponding to schizencephaly.

Conclusions Considering the theory that schizophrenia is associated with abnormal brain development, this case report may provide an example of a neurodevelopment abnormality that manifests as psychosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The evolution of emotional intelligence in schizophrenia: A comparative study of two groups at different times of the disorder

E. Chapela^{1,*}, J. Quintero^{1,2,3}, I. Morales³, M. Félix-Alcántara¹, J. Correas^{2,4}, J. Gómez-Arnau⁴

¹ Hospital Universitario Infanta Leonor, Psychiatry, Madrid, Spain

² Fundación Psiformación, Psychiatry, Madrid, Spain

³ Psikids, Psychiatry, Madrid, Spain

⁴ Hospital del Henares, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction People with schizophrenia show changes in the skills related to emotional intelligence, but little is known about the clinical course of these deficits. Few studies have examined the evolution of emotional intelligence in schizophrenia patients.

Objective To increase knowledge about emotional intelligence deficits in schizophrenia and to study its clinical course and factors related, with particular interest in neurocognitive deficits.

Aims To compare emotional intelligence and other clinical and neurocognitive data in patients with schizophrenia in a different moment of evolution.

Methods Twenty-five patients with schizophrenia for up to 5 years of evolution were compared to 24 patients with schizophrenia for more than 5 years of evolution. The assessment protocol consisted of a questionnaire on socio-demographic and clinical-care data, and a battery of assessment scales, including MSCEIT for emotional intelligence.

Results Both groups show a deterioration of emotional intelligence. Schizophrenia patients over 5 years of evolution have worse performance in emotional intelligence test than schizophrenic lower evolution. In the schizophrenia group of up to 5 years of evolution, none variables correlate with emotional intelligence. In the schizophrenia group of more than 5 years of evolution, there were moderate negative correlations with the severity of symptoms and depressive symptoms, and moderate correlation of positive sign with functionality, but none of the neurocognitive assessment scales.

Conclusions There are arguments for the existence of a progressive deterioration of emotional intelligence in schizophrenia. This deficit in emotional intelligence in schizophrenia appears to be present from the first years of the disease.

Typological characteristics of affective disorders in cases of paranoid schizophrenia

A. Kim, E. Cherapkin*

Kyrgyz-Russian Slavic University named after B.N. Yeltsin, Medical Faculty, Bishkek, Kyrgyz Republic

* Corresponding author.

Introduction There are affective disturbances at any stage of schizophrenia and at any form of its progression. Serious difficulties in diagnostics and treatment are represented by existence of depressive affect against the expressed negative symptomatology.

Objective Studying structure of a rehospitalization phenomenon and its clinical psychological features at paranoid schizophrenia.

Methods Retrospective analysis of frequency of hospitalization by information from epirisis, semiformalized interview, the Positive And Negative Syndrome Scale, the Beck Hopelessness Scale, the Life Style Index, the Zung Self-Rating Depression Scale, the State-Trait Anxiety Inventory.

Results and conclusions The statistical data obtained as a result of research, depression level on a scale of Zung 55.3 ± 0.73 ; 0.71 ($P < 0.01$) testify to interrelation of a negative and depressive symptomatology, existence of depressive affect confirms the high level of hopelessness 14.76 ± 0.35 ; 0.65 ($P < 0.01$). Thus it is possible to note an overlap phenomenon of a depressive and negative symptomatology (Fig. 1). The PANSS-scale is the tool of a multidimensional clinical assessment of schizofrom symptom-complexes, forms at the clinical psychopathological level the register of autistic signs in the form of a secondary negative symptomatology considered by us as personal response to a mental disorder. Allocation of such phenomena as rehospitalization and self-stigmatization with the prevailing negative symptomatology allows diagnosing for patients indirectly a depressive syndrome and promotes optimization of therapy in each separate case.

In clinical practice application of psychometric scales is important for identification of depressive symptoms and expression of positive and negative symptoms.

Integrated treatment in schizophrenia: A psychodynamic approach

M. Cianciulli¹, L. Ciampa^{2,*}, F. Gucci²

¹ ASL Napoli 1centro, Psychiatrist Department of Mental Health, Naples, Italy

² Villa Camaldoli Alma Mater s.p.a., Psychodynamic Integrated Psychiatry Department, Napoli, Italy

* Corresponding author.

Introduction The severe disability of schizophrenia and its impairment in real-life functioning can improve with a treatment that stimulates personal resources such as peer-support by psychologist according to Cordiale and Montinari psychoanalytic model (2012) in a multidisciplinary team.

Objectives Supportive and narcissistic relationships sharing real life experience, according to the cohesion of Self (Kohut 1971), promotes identification processes and improves pharmacological and psychiatrist treatment.

Methods Study participants were recruited for one year, according to diagnostic criteria of DSM V, from schizophrenic patients ($n = 12$) of a Mental Health Department and of a private psychiatric department (DH) in an age between 23 and 36 years, tested by SAT-P and GAF scale.

Results All patients were treated with second generation antipsychotic and an integrated treatment with peer-support, (Galderisi et al., 2014).

Conclusions The valiance of real-life functioning in patients with schizophrenia depends on an integrated intervention that assures a function of flexible and not coercive restraint, allowing to stable relationship with territorial agency (network) (Chiesa, 2008).

Folie à deux

C. Cocho*, M. Baquero, I. Vera, J. Alvarez-arenas

Hospital Universitario Infanta Cristina, Unidad de Psiquiatría, Parla, Spain

* Corresponding author.

Introduction The induced delusional disorder or *folie à deux*, is a rare condition characterized by psychotic symptoms at least in two individuals in close association.

Objectives We report a case of shared psychotic disorder between mother and daughter. We briefly review both classical and current literature.

Methods We summarized the results from articles identified via MEDLINE/PubMed using “induced delusional/shared psychotic disorder” as keywords. We report a case of a woman who develops psychotic symptoms characterized by delusions of persecution. Her daughter started, during the first high school grade with referring sexual threats and having delusions of persecution lived by her mother like a fact. They have very symbiotic relationship. Seven years later, the mother has required hospitalization for chronic delusions.

Results The term *folie à deux* was first coined by Lasègue and Falret, they assume the transmission of delusions was possible when an individual dominated the other and existed relative isolation. Recent studies found no significant differences in age and sex, although described higher comorbidity with other psychiatric diseases. Relative to treatment, separation by itself is insufficient; an effective neuroleptic treatment is required.

Conclusions Our case meets criteria for shared psychotic disorder. The daughter, with a ruling attitude who dominates the relationship, was the inducer. The mother showed no resistance in accepting delusions and remains them active after separation. This leads us to consider the possible predisposition to psychotic illness by both patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Headache and schizophrenia – A cross-sectional cohort study on prevalence, characteristics and management

J. Connaughton*, B. Wand

The University of Notre Dame Australia, Physiotherapy, Fremantle, Australia

* Corresponding author.

Introduction Headache is the most common pain reported by people with schizophrenia. Little research has been conducted into the characteristics and management of headaches in this population.

Objectives Determine the prevalence, type and management of headache in people with schizophrenia.

Aims Identify if best practice treatment of headache occurs and if changes are required to assure people receive appropriate management.

Methods One hundred consecutive people with schizophrenia and schizoaffective disorder completed an extensive, reliable and valid headache questionnaire. Based on the questionnaire responses two clinicians independently classified each person's headache as either migraine headache (MH), tension type headache (TTH), cervicogenic headache (CGH) or other headache type (OH). Any discrepancies were resolved by consensus agreement.

Results Twelve-month prevalence of headache (57%) was higher than the general population (46%) with no evidence of relationship between psychiatric clinical characteristics and presence of headache. Prevalence of CGH (5%) and MH (18%) were comparable to the general population. TTH (16%) had a lower prevalence. Nineteen percent of participant's headache was classified as OH type. No participant with MH was prescribed migraine specific medication. Only 1 of the 5 people whose headache was classified as CGH received manual therapy and none had been prescribed exercises.

No people with TTH received manual therapy, exercise prescription or postural review.

Conclusions It is recommended that education is required for patients and mental health workers about headache classification and the appropriate care pathways for different headache types.

Disclosure of interest The authors have not supplied their declaration of competing interest.

15 years and counting – How are schizophrenic patients with long hospitalization time?

M.A. Duarte^{1,*}, B. Lourenço², A. Ponte¹, A. Caixeiro³

¹ Centro Hospitalar Psiquiátrico de Lisboa, CP 6, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, CP 5, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Reabilitation, Lisbon, Portugal

* Corresponding author.

Introduction Centro Hospitalar Psiquiátrico de Lisboa (C.H.P.L.), in Lisbon, Portugal, is the biggest psychiatric hospital in Portugal and one of the oldest still working. Along with acute inpatient clinics it has long duration inpatient units with 226 patients.

Objectives/aims Characterize and improve the therapeutic approaches in patients committed to the long duration inpatient unit with long hospitalization times and the diagnose of schizophrenia.

Methods During the month of September 2015 all patients, committed before 2000 who fulfilled the diagnosis criteria ICD 10, F20.X (Schizophrenia) were characterized regarding age, gender, time of hospitalization and were evaluated using the Positive and Negative Symptom Scale (PANSS).

Results From the original sample ($n=226$), 31 patients were included in the study. The mean age was 64.4 years (min 50–max 91) and the majority were male (67.7%; $n=21$). The mean years of hospitalization were 28.7 years (min 15–max 60). The average total PANSS score was 99.8 (positive symptoms: 25.4; negative symptoms: 29.9; general symptoms: 44.4).

Conclusions Although in last decades many psychiatric hospitals were closed and community approaches to treatment of the mentally ill were the direction preconized by several international organizations, some patients still “live” in the hospital. Mostly, as we found in our study, have a severe, refractory disease, sometimes with behaviour changes that unable them to be discharged. With the continuous evolution of psychopharmacological drug treatment, this paradigm may change. Meanwhile other therapeutic approaches should be used to improve the disease symptoms.

³ “Victor Babes” University of Medicine and Pharmacy Timisoara, Department of Neonatology and Puericulture, Timisoara, Romania

* Corresponding author.

Introduction Early diagnosis of schizophrenia is often delayed in first-episode psychosis and this could be viewed as an obstacle for a proper therapeutic approach and optimal clinical management.

Objective Our main objective was to identify baseline socio-demographic variables in first-episode psychosis which are associated with an increased likelihood of diagnosing schizophrenia in the second episode of psychosis. As a secondary objective we aimed to assess the diagnostic stability between first and second episode psychosis.

Material and methods Data belonging to 100 patients that were twice admitted in Timisoara Psychiatric Clinic, between 2010 and 2015, for two distinct and consequent episodes of psychosis, were analyzed. The first admittance had to coincide with first episode psychosis.

Results Logistic binary regression showed that a younger mean age (OR=0.90; 95% CI=0.85–0.95), a more unfavorable professional status (OR=3.75; 95% CI=1.10–12.74) and a lesser quality of social support (OR=3.47; 95% CI=1.11–10.82) at the onset of the first episode of psychosis were associated with an increased likelihood for a subsequent diagnosis of schizophrenia.

Conclusions Identifying an initial socio-demographical profile with a high predictive value for a subsequent outcome towards schizophrenia should encourage using this diagnosis starting with the first episode of psychosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Severe mental health disorders lead to low functionality.

Aim Searching factors that help us to improve functionality in psychosis.

Objective Establish whether there is a connection between different components of functionality and the level of insight in chronic schizophrenic patients.

Methods Forty patients diagnosis of psychosis, attending two day centres where transversally assessed with the scale for unawareness of mental disorders (SUMD) and the personal and social performance scale (PSP). Scores of every of the PSP subscales were compared with the global SUMD score.

Results Global score SUMD was higher in patients scoring more than 50 in PSP. There were no significant differences on the SUM scores between the group of patients with low score (good functionality) and higher score (>4, higher impairment) with the exception of the self-care subscale: PSP self-care <4 (n=21): SUMD 10.43 (3.23) and PSP self-care >4 (n=19): SUMD 6.11 (3.07).

Conclusions Patients with higher impairment in self-care (higher score in PSP A) were more aware of their illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment with antipsychotics and sexual dysfunction in a sample of schizophrenic inpatients

M.D.C. García Mahía^{1,*}, Á. Fernández Quintana¹, M. Vidal Millares¹, R. Castro Calvo²

¹ CHU A CORUÑA, Psychiatry, A Coruña, Spain

² CHUS Santiago de Compostela, Admission, Santiago de Compostela, Spain

* Corresponding author.

Introduction Previous studies show association between sexual dysfunction and antipsychotic treatment.

Objectives To study the prevalence and clinical correlates of sexual dysfunction in schizophrenic inpatients treated with antipsychotics. To analyze the influence of sexual complaints in treatment adherence.

Methods Retrospective descriptive study of psychiatric inpatients diagnosed of schizophrenia following DSM-IV-TR criteria and treated in an acute care unit of Psychiatry in a university hospital in a 12-month period. Patients treated with combination of antipsychotics (typical and atypical) were excluded from the analysis (n=60). Sexual side effects were evaluated with Udvalg for Kliniske Undersogelser (UKU) Side Effect Rating Scale and evaluated in two treatment groups: conventional antipsychotics, and atypical antipsychotics. Patients were asked about subjective experience with other treatments.

Results The mean age of subjects was 32.4 (SD=8.7). From the whole sample 38 (63.3%) were men and 22 (36.7%) women. Sexual dysfunction related to treatment was present in 78% of patients. Men were more affected than women and 69% of them related that sexual dysfunction had influenced the decision of treatment withdrawal previous to income. Amenorrhea was more common on risperidone and amisulpride. Analysis of different antipsychotics and its relationship with sexual dysfunction are presented.

Conclusions Sexual dysfunction is a frequent side effect associated with antipsychotics in schizophrenic patients. The sexual side effects may reduce the quality of life and may increase non-compliance that is usually associated to readmissions and worse prognosis of severe mental illness.

The theme of DAECH in delirium of the first psychotic episode

F. Ghali^{1,*}, L. Mnif², F. Medini², A. Tounsi², W. Melki²

¹ Ariana, Tunisia

² Razi Hospital, Psychiatry, Mannouba, Tunisia

* Corresponding author.

Introduction The mediatization of the Islamic State of Iraq and Sham (DAECH), the distribution of its videos of beheading in the social networks and also after the various attacks, which struck in Tunisia and around the world, we noticed an increase of the number of patients whose theme of delirium revolves around the subject of DAECH.

Objectives and methods The objective of our work consists in studying sociodemographic, clinical and therapeutic particularities among patients presenting an acute delirium about the Islamic state, the caliphate and the Jihad, who were hospitalized in our department of psychiatry "D" since March 2015 after the attempt of BARDO MUSEUM.

Results Our sample included 15 patients with an average age of 25.4 years, hospitalized for the first time in a psychiatric institution. They were predominantly male (11 patients). We noted the use of psychoactive substances within 7 patients. The topic of DAECH has

been included in a delirium of persecution in 13 patients, delirium of bewitchment (7 patients), mystical religious ($n=4$) and finally in apart of delusions of greatness ($n=6$) so as to follow a single assignment: to fight terrorism.

Conclusion Delusions focused on the topic of DAECH were observed frequently among young patients and formed an integral part of especially persecution delirium, reflecting the collective fear of this phenomenon.

Analysis of the duration of untreated illness (DUI) in the first episode psychosis Program (FEP) in AGS South Granada

B. Girela Serrano*, M. Guerrero Jiménez, C.M. Carrillo de Albornoz Calahorro, J.A. Rodrigo Manzano, O.B. Martínez García

Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain

* Corresponding author.

Introduction Duration of untreated illness (DUI) has been considered as a relevant variable used to measure the degree of disabilities that are associated with psychotic disorders. In this paper we describe a cluster of patients with a DUI superior to 1 year according to their symptoms and sociofamiliar functioning.

Methods We compare a group with a DUI superior to 1 year ($n=7$) against a group with a DUI inferior to 1 year ($n=17$).

Results The group with a DUI superior to 1 year showed an average age of 4 years younger (21) as the duration of untreated psychosis (DUP) of 1 to 3 months in the 80% of cases and higher percentage of unemployed or without occupation. The 60% were derived from primary care, compared to the 17% of the other group. Although the consumption of toxic substances was similar in both groups, no toxic psychosis were found in comparison with the 35% present in the group with a DUI inferior to 1 year. PANSS' profile scored more positive and less negative symptoms. Both have similar general psychopathology. There were group differences in the Social Functioning Scale (SFS) with lower scores in the superior to 1 year DUI, in the following scales: Prosocial, Autonomy, Execution and Employment. The Global Assessment of Functioning (GAF) gives an average of almost 8 points higher.

Discussion While the SFS shows significant differences in several areas of social functioning, both PANSS' profile and the family questionnaire do not support greater deterioration, as evidenced in the GAF's average score.

Psychosis-related polydipsia and chronic hyponatremia – A case report

F. Gonçalves Godinho*, A.L. Melo, S. Marques, D. Barrocas
Hospital Espírito Santo de Évora, Psychiatry and mental health, Évora, Portugal

* Corresponding author.

Introduction Psychogenic polydipsia has an estimated prevalence of 6–20% in psychiatric population. Although first described in the 1930s, there are few studies addressing this problem and its management. The high water intake can lead to severe hyponatremia with a mortality rate high enough to merit clinical concern.

Aims Report a case of a schizophrenic patient with psychogenic polydipsia and hyponatremia.

Methods Retrospective review of the clinical file and literature research on this topic.

Results A 41-year-old man with a long-term schizophrenia presented to the emergency room (ER) with exacerbation of psychotic symptoms. In the prior 24 months, he had stopped medication and began excessive water intake (5 to 10 L/day). He presented with auditory hallucinations, passivity phenomena and persecutory and other delusional thoughts that justified this behavior – “The water will end; I have to stock it, like camels do”. Presently he had an asymptomatic hyponatremia (128 mg/dL), but 6 months before he had been admitted in the ER with vomiting, altered state of consciousness and convulsions secondary to severe hyponatremia (108 mg/dL). During the present hospitalization, organic causes of hyponatremia were excluded and he was started on behavioral measures and antipsychotics. The psychotic symptoms improved and there was no need for water restriction after the first week, with restored natremia values on discharge.

Conclusions With this case report we intended to raise awareness on this potentially fatal condition that despite its prevalence has no defined diagnostic criteria, nor established controlled trials concerning the effectiveness of treatments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Schizophrenia spectrum disorders: Focus on social cognition and empathy

C. Gramaglia^{1,*}, E. Gattoni¹, G. Giovanna¹, S. Gili¹, A. Feggi¹, V. Binda², P. Prosperini², P. Zeppego¹

¹ University of Eastern Piedmont, Traslational Medicine, Novara, Italy

² AOU “Maggiore della Carità”, S.C. Psichiatria, Novara, Italy

* Corresponding author.

Background Schizophrenic patients show deficits in social cognition, functioning and in interpreting facial expressions. These disabilities contribute to global impairment in social and relational skills. Data started being collected in the context of the Italian Network of Research on Psychosis headed by Prof. Maj and Prof. Galderisi (Galderisi S et al. The influence of illness-related variables, personal resources and context-related factors on real-life functioning of people with schizophrenia. *World Psychiatry* 2014;275–87. Mucci A et al. The Specific Level of Functioning Scale: Construct validity, internal consistency and factor structure in a large Italian sample of people with schizophrenia living in the community. *Schizophr Res* 2014;159(1):144–50); collection in our centre went on also after the conclusion of the national project.

Aims To identify the correlations among social inference, facial emotion identification and clinical history and therapies in schizophrenic patients.

Material and methods We recruited patients with Schizophrenia referring to our Psychiatry Ward, AOU Maggiore della Carità, Novara, Italy. Socio-demographic characteristics were gathered; assessment of patients included The Awareness of Social Inference Test (TASIT), the Facial Emotion Identification Test (FEIT), the Positive and Negative Syndrome Scale (PANSS) and the Brief Negative Symptom Scale (BNSS).

Results Data collection is still ongoing. In a previous study we pointed out that schizophrenic patients showed social skills deficits and difficulties in identifying facial emotions. These features underlie poor and limited social relationships proper to schizophrenia. Our preliminary results revealed that identification of facial emotions is influenced by psychopathological symptoms especially by avolition, blunted affect and alogia. Implication will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background It is becoming well established that CBT is both effective and cost efficient in the treatment of positive and negative symptoms of schizophrenia. However, there is a need to adapt CBT to the cultural, linguistic, and socioeconomic context of diverse cultural groups. We aimed to establish the feasibility of culturally adaptive cognitive behavior therapy for treatment of psychosis in a low-income country.

Methods This is a rater-blind, randomized, controlled trial of the use of CBT in patients with psychosis from a low-income country. Patients with a DSM-IV diagnosis of schizophreniform disorder were assessed using Positive and Negative Syndrome Scale for Schizophrenia (PANSS), PSYRATS (Psychotic Symptom Rating Scales), and the Insight Scale. Participants were randomized into the intervention group ($n = 18$) and TAU group ($n = 18$). The intervention group received 12 weekly sessions of culturally adapted CBT for psychosis (CaCBTp).

Results There were no significant differences between the two groups at baseline. At three months follow-up, there was a statistically significant improvement in the CaCBTp group on PANSS general Psychopathology subscale, PANSS overall score and Insight

scale, as compared to the TAU group. The CaCBTp group had lower scores on PANSS positive, PANSS negative sub-scales, and the two subscales of Psychotic Symptom Rating Scale, but differences were not statistically significant.

Conclusion Culturally adapted CBT added to pharmacological treatment as usual was acceptable to patients and was helpful in reduction of severity of psychotic symptoms. Adjunctive culturally adapted CBT should be further investigated in this population.

* Corresponding author.

Introduction Patients with schizophrenia requiring long-term institutionalization represent cases with poor outcome, often leading to high costs for patients and family and constituting a huge economical burden for society if patients are young.

Aims The aims were the evaluation of patient hospitalized for long period in a psychiatric hospital for chronic patients.

Objectives The objectives of the study were identification of characteristics and predictors of institutionalization in schizophrenia.

Methods Retrospective study of all institutionalized patients with schizophrenia in Brasov County, Romania, with a DSM-IV-TR lifetime diagnosis of schizophrenia institutionalized between 1995 and 2014.

Results Institutionalized patients between 2005 and 2014 ($n = 172$) had lower age (51.15 vs. 57.08, $P < 0.05$) and lower age at institutionalization compared with patients admitted between 1995 and 2004. Lower education level (8.23 vs. 13.22, $P < 0.05$), only one parent, multiple antipsychotics treatments and suboptimal response under first generation long acting antipsychotics are predictors for institutionalization. Haloperidol is the main treatment option (42.54%) followed by olanzapine 17.1% and clozapine 10.24%.

Conclusions Our study showed a tendency to institutionalize patients with schizophrenia at the younger age compared with past decades. Early intervention in psychosis, controlled treatment with SGAs should be solutions to avoid institutionalization of young patients with schizophrenia.

Neurorehabilitation in patients with Schizophrenia is a SET of activities capable of maximizing recovery capabilities through the development of it in their family, work and social sphere, and minimize the effects that arise from the chronicity and the natural

course of this disease. This process emphasizes all the cognitive as both individual capacities as motor through an approach to vocational, residential, recreational, social and educational support, tailored to the unique demands of the patient, in every situation and custom mode.

For this, working through concepts such as social cognition and insight, interdisciplinary way, so to SET goals and accomplish them with a specific planning.

Schizophrenia is a chronic disease that occurs in 1 to 2% of the world population, and causes social marginalization and stigmatization in patients who have it. Be treated, then, since the integration of multidimensional therapeutic resources.

In this paper, descriptively explains the techniques and activities developed individually for each professional and interdisciplinary area of building situational and individual patient diagnosis, potential and limitations as well as the specific treatment that may lead to improved cognitive and motor skills of the patient, and from it an improvement in their social inclusion and quality of life.

Effect of switching to long-acting injectable (LAI) aripiprazole on long-lasting antipsychotic-induced hyperprolactinemia: A report of two cases

M. Juncal Ruiz*, B. Fernández-Abascal Puente, R. Landera Rodríguez

Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction Antipsychotic-induced hyperprolactinemia (> 29 ng/ml in women) is associated with relevant side-effects.

Aim We describe the case of two women aged 50 and 54 years, respectively, diagnosed with schizophrenia who were receiving outpatient treatment with paliperidone depot 100 mg/month and risperidone depot 50 mg/2 weeks, respectively and complained of oligoamenorrhoea and amenorrhoea for at least 6 months.

Methods Routine blood tests showed hyperprolactinemia of 203.5 ng/ml and 306.2 ng/ml, respectively. The patients were evaluated by the Endocrinology unit and an MRI was performed discarding the presence of any primary brain condition. Both patients were switched to LAI aripiprazole due to its partial agonism of D2-brain receptors. At the time of switching both patients were stable in terms of psychopathology.

Results Changes in prolactin levels 3 months after switching are shown in the Fig. 1. Two months after switching, both patients regained cyclic menstrual function. After 6 months, they still showed psychopathological stability.

Conclusions Several studies have described an improvement of drug-induced hyperprolactinemia after switching to or adding oral aripiprazole. In these two cases, the normalization of prolactin levels and the resolution of oligoamenorrhoea/amenorrhoea were observed as soon as 2–3 months after switching to LAI aripiprazole. These findings suggest that switching to LAI aripiprazole may be an effective alternative for managing antipsychotic-induced hyperprolactinemia.

Capgras-delusion in a female patient with schizophrenia: A case report and study of the literature

P. Kolarov^{1,*}, P. Chumpalova¹, G. Georgiev¹, A. Todorov², M. Stoimenova¹

¹ Medical University, Pleven, Bulgaria, Department of Psychiatry and Medical Psychology, Pleven, Bulgaria

² University Hospital, Pleven, Bulgaria, Psychiatry Clinic, Pleven, Bulgaria

* Corresponding author.

Background The Capgras syndrome is a rarely observed condition in patients with different psychiatric diseases, which is characterized with delusional misidentification of people, places, objects, etc.

Objective In this case report we aim to describe the clinical characteristics and manifestation of Capgras syndrome in a female patient with schizophrenia, perform a literature search on the topic and compare our report to literature findings.

Results and discussion A 50-year-old female patient was verbally and physically aggressive to her family members upon admission to our center. The onset of disease was marked 2 years ago when she first started feeling deserted and isolated and had a prescribed therapy for her condition which she did not follow. During the current admission a psychiatric assessment was performed. Delusional misidentification of her family members was observed and consequent food and sleep self-deprivation due to psychosis was noted. The patient denied being suicidal but was intense and psychotic, and reported different objects to have started disappearing mysteriously from her home. The patient was diagnosed with schizophrenia and was treated with haloperidol, olanzapine, chlorpromazine, and biperiden. The patient was discharged in an improved condition, without episodes of obsessive delusions and improved communication with her relatives.

Conclusion Although according to the literature organic substrate may be found in some patients with Capgras syndrome, in the case presented here it is the dominant psychotic theme, which determined the content of the disease.

EV1164

The cremation of care ritual: Burning of effigies or human sacrifice murder? The importance of differentiating complex trauma from schizophrenia in extreme abuse settings

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction This session explores Human Sacrifice killings in extreme abuse cult settings disclosure of which often leads to a misdiagnosis of 'Schizophrenia'.

Objectives The purpose of the paper is to raise awareness and signpost professional development resources regarding extreme abuse 'Death Cults' that operate largely with impunity across the world.

Aims Case study materials and documentary evidence will be utilised to illustrate criminal practices and the impact on survivors.

Method Accounts of extreme abuse and ritual violence were identified in the context of an adult survivor assessment intervention.

Results There are supporters of abuse survivors who bore witness to and believe disclosures of extreme abuse and ritual violence, and 'False Memory' adherents who consider Ritual Abuse an unfounded 'moral panic'. Survivors provide chilling accounts of ritual killings in Scott (2001), Becker, Karriker, Overkamp and Rutz (2008) and Epstein, Schwartz and Schwartz (2011). In the wake of institutional abuse enquiries and the 'unbelievable' child abuse perpetrated by celebrities like Jimmy Saville and Ian Watkins, a 'new reality' is setting in that child abuse is pervasive and knows no limits. Reports of elaborate rituals with 'mock' human sacrifices at the highly secretive annual 'Bohemian Grove' summer festival point towards a pervasive interest in the occult in high society.

Conclusion Mental health professionals have a 'duty of care' towards their service users. Unless clear and irrefutable counter-evidence is available it is inappropriate to claim that disclosures of extreme abuse and/or human sacrifice rituals are 'delusions' and indicative of Schizophrenia.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Autoimmunity in mental disorders: An association known pending development

Y. Lazaro^{1,*}, I. Mesian², A. Perez³, R. Baena¹¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain² Hospital Universitario Infantil Niño Jesús, Psychiatry, Madrid, Spain³ Centro de Atención Integral al Drogodependiente Mostoles, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction In the last century, several studies have confirmed the association between schizophrenia and autoimmunity in the patients as well as in their family. This fact has important implications because of the high prevalence of immune disorders in the population, which has been estimated to be about 20%.

Objectives Analyze a clinical case which suggests autoimmunity as a potential cause for developing schizophrenia.

Aims To point out the need to conduct further research in the field of neurobiology of mental diseases to possibly find a new line of treatment.

Methods A 28-year-old woman with no previous history of mental illness, diagnosed at age eight with celiac disorder. Mother affected by Grave's disease. Paternal uncle diagnosed with bipolar

disorder. The first contact with psychiatry took place in 2005 in the emergency room, being diagnosed with a psychotic episode. Due to her family history of autoimmunity she had regular follow-up, which enabled the control of three later new psychotic episodes (2008, 2009, 2012) on an outpatient basis. Diagnosed with paranoid schizophrenia in 2014, she is currently stable with antipsychotic drugs.

Results This case illustrates the importance of keeping in mind autoimmunity history in development and prognosis of mental disorders.

Conclusions Although symptoms of schizophrenia are well known, there is still a great deal to be discovered in its entirety. Progress in the knowledge of pathophysiology may open new lines of treatment, which can provide a better one and thus, a better prognosis [1].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Paraphrenia: Claiming for its diagnosis

Y. Lazaro^{1,*}, R. Baena¹, L. Olivares¹, A. Perez², I. Mesian³¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain² Centro de Atención Integral al Drogodependiente Mostoles, Psychiatry, Madrid, Spain³ Hospital Universitario Infantil Niño Jesús, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Paraphrenia is currently considered as historical disorder. Sometimes included as paranoid schizophrenia and in many other cases as other persistent delusional disorders, its diagnosis is out of the current code list, such as ICD or DSM. Nevertheless it has unique peculiarities, already objectified by Krapelin.

Objectives Claiming the concept of paraphrenia as a clinical entity with its own phenomenological characteristics included in chronic psychotic disorders.

Aims To keep in mind classic psychopathology, not included in current code list, such as ICD and DSM.

Methods A 40-year-old woman with good premorbid adaptation, no previous history of mental disorder. Her first psychotic symptoms appeared at 30, not because drug effect. Father diagnosed with paranoid schizophrenia. Among her first internment, her mood was persistently elevated, expansive and easily irritable. She had bizarre megalomaniac delusions of grandeur, which combined with erotomanic ideas felt as ego-syntonic, supported by auditive hallucinations. There were no other symptoms found in manic episodes in previous historical of affective descompensations.

Results Antipsychotics only had effect in mood, which turned euthymic. Active psychoticism has continually been present for 10 years although different treatment. No major affective descompensations has taken place among this period. Cognitively conserved, without defectual symptoms, is currently working in supported employment.

Conclusions Clinical symptoms of paraphrenia lied between schizophrenia and persistent delusional disorders. Specifically in this case we had to do the differential diagnosis with bipolar disorder, which was ruled out attending to the longitudinal course.

Risk-taking and self-medicating contribute to the association between psychometric risk for schizophrenia and smoking

M. Verwey, C. Ruzibiza, R. Linscott*

University of Otago, Department of Psychology, Dunedin, New Zealand

* Corresponding author.

Background There is a robust association between positive symptoms of schizophrenia and smoking. This relationship extends to psychometric risk for schizophrenia (schizotypy). We sought to determine whether smoking in schizotypy is best understood in terms of self-medicating or risk-taking behaviour. The self-medication perspective holds that individuals with schizophrenia smoke to relieve stress. By smoking, cortisol levels increase, stimulating negative feedback circuits that reduce the hypothalamic-pituitary-adrenal (HPA) axis stress response. Increased HPA activation also stimulates dopamine release, promoting the expression of positive schizotypal experiences. In contrast, the risk-taking perspective holds that elevated dopamine promotes risk-taking behaviour, including substance misuse, by reducing reward sensitivity and increasing sensation-seeking.

Method Undergraduates ($n=230$) reported current and past nicotine use and completed the Schizotypal Personality Questionnaire and a self-report measure of stress sensitivity.

Results Consistent with risk-taking, positive features of schizotypy predicted having ever smoked ($OR=1.02$, $P<0.05$) but did not distinguish current smoking from non-smoking ($OR=0.99$). The self-medication hypothesis was examined in two ways. When smoking status was regressed onto positive schizotypy and stress, stress was found to predict current smoking ($OR=1.08$, $P<0.05$) but not having ever smoked ($OR=1.09$). Secondly, stress and current smoking interacted to predict positive schizotypy ($\beta=0.31$, $P<0.05$).

Conclusions Risk-taking and self-medicating each contributed to the relation between smoking and schizotypy, but in different ways. Risk-taking seems to contribute to having ever smoked whereas current smoking seems to reflect self-medicating behaviour.

Clinical effectiveness of Paliperidone Palmitate in schizophrenia

E. Lyubov

Moscow Research Institute of Psychiatry, Moscow, Russia

Introduction Along with numerous randomized controlled trials, little is known about the clinical effectiveness of Paliperidone Palmitate (PP).

Aims to evaluate long-term clinical outcomes of PP treatment in schizophrenia, to assess the reasons of PP treatment, and PP usage patterns.

Methods Retrospective analysis of 152 outpatients with ≥ 1 PP (in total, 1446) injections for 10.2 (9.2–11.1) months.

Results The average maintenance PP dose was 82 ± 1.25 (median 75) mg. PP appointed due to the following reasons: partial instable remissions in “typical” (i.e., with oral antipsychotics and long-acting forms of typical ones) therapy (93.4%), full or partial noncompliance (44.7%), intolerability (27.6%). Doctors take into account the patient preferences (38.1%). Only 7.2% of the cohort discontinued treatment, and 4.2% patients by the doctor decision as “resistant” at PP doses of 75 mg (< recommended maximum). PP reduced the frequency of total adverse action (AEs), especially extrapyramidal ones (p

Specifics of communication with schizophrenic patient

S. Manojlovic*, J. Nikolic-Popovic

University of Nis, Faculty of Medicine, Psychiatry, Nis, Serbia

* Corresponding author.

The precondition of communication with schizophrenics is knowing and understanding of their fragmented and chaotic world. Communication with the schizophrenics should respect their fear of fusion and disintegration, as well as the fear of abandoning. In communication with the schizophrenic two facts are important: the real support is accepting the bizarre existence of the patient, and the other side of the support is the capacity of the psychiatrist to understand and withstand the patient. This capacity is determined through the consistency of therapist's behavior, possibility to accept the patient's right on regression, but also the ability to offer the constancy of himself, too. The therapist is the representative of the reality whose consequence and constant presence enables him to grow up from the internal mixture of the mental presentations into an authentic, independent person, dedicated to the patient. The therapist is expected to tolerate the patient's alienation due to the fears from fusion or disintegration. A constant activity of reestablishing of contact and respect of a specific cognitive style are needed. Communication with the schizophrenics implies an explicit calling to a verbal communication that has to be understandable, and searching for the conceptual framework, which provides understanding. Basic characteristics of the adequate communication are persistence, consequence and simplicity of instructions with the norm of behavior control, as well as the clarity of the “here-and-now” situation. The therapist's understanding of the schizophrenics justifies his actions and allows taking the psychotherapeutic attitude.

Psychogenic polydipsia and schizophrenia

L. Maroto Martín*, P. Hervías Higuera

Hospital Doctor Rodríguez Lafora, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Psychogenic Polydipsia is defined as the desire to drink liquid in big quantities with an inappropriate activation of the mechanisms of thirst without loss of liquid for urine. This disorder is frequent enough and can derive in a water poisoning, a clinical presentation of high mortality.

Objective Review of the Psychogenic Polydipsia in patients with schizophrenia and theoretical discussion of a case report.

Methods A case report of a 58-year-old male, admitted in hospital with a clinical presentation of hyponatremia with severe low serum osmolarity secondary to Psychogenic Polydipsia. As psychiatric history he has a diagnosis of Paranoid Schizophrenia for forty years in treatment with Paliperidone 6 mg: 1-0-0, Haloperidol 10 mg: 0-0-0.5, Quetiapina 300 mg: 0-0-1, Trazodona 100 mg: 0-0-1, Ketazolam 30 mg: 0-0-1, Diazepam 10 mg: 0-0-1.

Discussion Psychogenic Polydipsia is not included in any section of current psychiatric classifications as specific diagnosis. There are several psychiatric disorders that may present with psychogenic polydipsia; however, the most common cause appears to be schizophrenia.

Conclusions Mechanisms of hyponatremia in patients with schizophrenia are not well clarified; nevertheless, dopamine seems to be the common link between psychogenic polydipsia and schizophrenia.

Keywords Psychogenic Polydipsia; Hyponatremia; Schizophrenia

Treatment with intramuscular paliperidone palmitate in schizoaffective disorder

L. Maroto Martin*, P. Hervías Higuera

Hospital Doctor Rodríguez Lafora, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Injectable formulations of long acting antipsychotic are a valuable treatment option for patients with psychotic disorders. Schizoaffective Disorder (SAD) is a complex disease; the optimal treatment is not well established yet.

Objective Answer the question about the effectiveness offered by intramuscular Paliperidone Palmitate in SAD versus other injectable antipsychotics. **Keywords:** schizoaffective disorder; paliperidone palmitate injection.

Methods A case report of a 35-year-old male diagnosed with Schizoaffective Disorder six years ago and with personal history of multiple manic decompensation after treatment discontinuation. Throughout his life he has been treated with intramuscular Risperidone 87.5 mg (50+37.5) every 14 days, Olanzapine 20 mg/day, Risperidone 3 mg, Amisulpride 600 mg/day, Valproic acid 1500 mg/day Clonazepam 2 mg/day and Lormetazepam 1 mg. In the last admission one year ago, he started treatment with intramuscular paliperidone palmitate up to 200 mg a month. Currently he receives a monthly dose of 100 mg and concomitant lithium 800 mg/day.

Discussion The use of intramuscular paliperidone palmitate in SAD and its effectiveness against other injectable antipsychotic is discussed.

Conclusions The use of intramuscular paliperidone palmitate appears to constitute an employment opportunity in the treatment of intramuscular maintenance in SAD. It could be effective in stabilizing episodes of acute exacerbation and remissions of psychotic, manic and depressive symptoms.

Characteristics of violent schizophrenic inpatients

R. Masmoudi*, F. Charfeddine, L. Aribi, F. Smaoui, E. Elleuch, J. Aloulou, O. Amami

Hédi Chaker University Hospital, Psychiatry "B", Sfax, Tunisia

* Corresponding author.

Introduction Hetero-aggressive behavior is a frequent reason for psychiatric hospitalization in patients with schizophrenia.

Aim To describe the clinical and socio-demographic characteristics of schizophrenic patients hospitalized following a violent behavior.

Methods It was a cross-sectional and descriptive study. It was conducted in 32 patients diagnosed with schizophrenia, and hospitalized in the psychiatry department "B" at the Hedi Chaker University Hospital of Sfax in Tunisia during the month of August 2014. The reason for hospitalization was hetero aggressiveness.

Results The average age of our patients was 36.19 years with a male predominance (71.9%). Violent schizophrenic patients were single (71.9%) and without occupation (68.8%). They have lived in family in 81.3% of cases. They had a family history of psychiatric disorders in 34.4% of cases, a criminal record in 25% of cases and addictive behaviors in 71.9% of cases. Violent schizophrenics had more than three psychiatric admissions in 50% of cases. They had bad adherence to treatment (62.5%) and poor insight (87.5%). The majority (90.6%) had a previous history of violent behavior. The victim was a member of the patient's family in 90%. At the time of the incident, delusional syndrome was present in 78.1% of cases and a mental automatism syndrome in 21.9% of cases.

Conclusion Violence in patients with schizophrenia depends on several factors such as poor insight, medication non-adherence and a past history of violence. It is essential to assess the risk of violent behavior and act on the associated factors in order to prevent recurrence of violence.

Battery of scales for comprehensive assessment of social cognition, neurocognition and motivation in patients with schizophrenia

M. Minyaycheva*, K. Kiselnikova, O. Papsuev

Moscow Research Institute of Psychiatry, Outpatient Psychiatry and Organization of Psychiatric Care, Moscow, Russia

* Corresponding author.

Introduction There has been a special interest in roles of neurocognition, social cognition and motivation impairments in patients with schizophrenia and possible approaches to remediating these deficits. Clinical practice lacks a comprehensive tool to measure those deficits.

Objective To build a comprehensive assessment battery to measure neurocognitive, social cognitive and motivational deficits in order to form targets for remediation programs and assess their efficiency.

Aims Translation and adaptation for Russian speaking subjects (if needed) of identified assessments upon authors' agreement.

Methods By consensus decision of 5 professionals in the field of clinical psychiatry, psychology and neuroscience a number of assessments were selected with the following criteria: 1. Relevance to domain assessed, 2. Appropriateness for Russian social context, 3. Reference rates in scientific papers, 4. Time consumed by each assessment.

Results Six measures reflecting main domains (neurocognition, Theory of Mind, attributional style, social perception, emotion processing, motivation) were selected: 1. BACS (Brief Assessment of Cognition in Schizophrenia) (R.S. Keefe et al., 2008), 2. Hinting Task (R. Corcoran 1995), 3. AIHQ (Ambiguous Intentions Hostility Questionnaire) (D.R. Combs et al., 2007), 4. RAD-15 (Relationships Across Domains) (M. Sergi et al., 2004), 5. Ekman-60 (P. Ekman et al., 1976), 6. AES (Apathy Evaluation Scale) (R.S. Marin et al., 1991).

Conclusions The battery built encompasses all targeted domains of neurocognition, social cognition and motivation. Time consumed by the battery estimates 130 ± 15 minutes, which is appropriate for clinical practice in a rehabilitation centre. Future research will focus on patients profiling and shaping of rehabilitation programs accordingly.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aripiprazole once-monthly efficacy in patients with schizophrenia. ReviewM.F. Molina López^{1,*}, M.C. Cancino Botello², A. Peña Serrano², M.D.L.A. Canseco Navarro²¹ Valencia, Spain² Hospital General Universitario de Valencia, Psiquiatría, Valencia, Spain

* Corresponding author.

Introduction long acting injectable formulations of antipsychotics are a valuable option for patients with schizophrenia, offering continuous medication delivery and stable dosage levels. Aripiprazole once-monthly is the first dopamine partial agonist available in long acting formulation approved in Europe for Schizophrenia with excellent results so far.

Aims to conduct a current review of articles related to the use and efficacy of Aripiprazole once monthly in patients with Schizophrenia.

Methods systematic review of the literature in English using the following keywords: “aripiprazole once-monthly”, “aripiprazole long acting formulation”, “schizophrenia”. PubMed database.

Results Aripiprazole once-monthly (AOM) formulation efficacy has been proven in many studies. The importance of maintaining an oral overlap during 14 days is highlighted in all studies that have been reviewed in order to reach therapeutic level; therefore, it can be used in patients with acute decompensations. Recent studies comparing AOM versus Paliperidone Palmitate once monthly (PP) have shown that patients with AOM had greater clinical improvement and, even though both drugs were well tolerated, when Quality of Life Style Scale was analyzed an important improvement in empathy, sense of purpose, emotional interaction and curiosity in the AOM group was observed.

Conclusions long acting injectable antipsychotics increase long-term adherence treatment and reduce risk of relapse. Because of its unique mechanism of action, Aripiprazole once-monthly improves positive and negative symptoms, giving the patient an opportunity to have a better quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pharmacological wash out for clozapine induced tics: A case reportA. Morales-Rivero^{1,*}, M. Chavarria-Medina², C.L. Avina-Cervantes¹¹ Instituto1 Nacional de neurología y neurocirugía, psiquiatry, Mexico City, Mexico² Instituto1 Nacional de neurología y neurocirugía, Neurology, Mexico City, Mexico

* Corresponding author.

Introduction Clozapine has been long used for the treatment-resistant schizophrenia. Its effectiveness in the vast schizophrenia symptoms is well established. However, its wide range of adverse effects has limited its use.

Objectives/aims To present a new strategy in order to continue with clozapine treatment despite extrapyramidal adverse effects.

Methods/case report Extrapyramidal symptoms are rarely reported with clozapine. Although, cases of patients with clozapine-induced tics have been described. We report the case of a 28 year-old patient with history of refractory schizophrenia that developed motor tics with clozapine 150 mg total dose. Tics consisted on eye blinking, eyebrow elevation, mouth twitching, facial grimacing, lip licking, tongue protrusion and shoulder shrugging. Reduction of clozapine dose to 50 mg qd was indicated to decrease the motor tics, however exacerbation of psychosis occurred.

We added amisulpride and titrated it up to 600mg qd without response. By using the same principle of levodopa's washout in Parkinson disease and in order to establish a therapeutic threshold, we conducted a one-week clozapine washout.

Results After this therapeutic manoeuvre, tics disappeared and no relapse was observed after clozapine reinitiation along with remission of psychotic symptoms.

Conclusions Wash out might be a new strategy for treatment reinitiation after clozapine induced extrapyramidal side effects in patients with treatment-resistant schizophrenia. To our knowledge no previous report of this strategy has been reported, however further studies are needed to support its effectiveness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Correlation between childhood trauma and cognitive impairment in patients with schizophrenia

J. Mrizak*, R. Trabelsi, A. Arous, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction Abusive childhood experiences are claimed to be more prevalent in people with schizophrenia (SCZ) than in the general population. The exposure to childhood trauma can have adverse effects on cognitive function.

Objectives To investigate whether there is a relationship between childhood trauma (CT) and cognitive functioning in patients with SCZ.

Methods Fifty-eight outpatients with stable SCZ were recruited. The participants completed the Childhood Trauma Questionnaire retrospectively assessing five types of childhood trauma (emotional, physical and sexual abuse, and emotional and physical neglect). They also completed a neurocognitive battery comprising the following tests: the Hopkins Verbal Learning Test-Revised (HVLT-R), the Letter Digit Substitution Test (LDST), the Stroop Test (ST), the “Double Barrage” of Zazzo (DBZ), the Modified Card Sorting Test (MCST), the Verbal Fluency (VF), the Trail Making Test-Part A (TMT-A) and the Digit Span (DS).

Results The patients with a history of physical abuse ($P=0.03$) or emotional neglect ($P=0.07$) performed worse at the delayed recall of the HVLT-R. A history of emotional neglect was also correlated to a significantly worse performance in the TMT-A ($P<0.0001$), while physical abuse was correlated to worse DS ($P=0.015$). High emotional abuse scores were significantly correlated to poorer efficiency in DBZ ($P=0.025$).

Conclusions The results need replication, but underline the necessity of investigating biological and psychosocial mechanisms underlying these subjects' cognitive impairment.

Schizophrenia and sexual desinhibitionM. Palomo Monge^{1,*}, G.M. David¹, D.D. Arántzazu², A.L. Maria Fernanda³, T.G. Maria Fernanda¹, M.M. Gemma³, D.C. Sandra⁴¹ Hospital Nuestra Señora del Prado, Psychiatry, 45600 Spain² Hospital General de Avila, Psychiatry, Avila, Spain³ Hospital Nuestra Señora del Prado, Family Medicine, Talavera de la Reina, Spain

⁴ *Centro de Rehabilitación Psicosocial y Laboral, Psychology, Talavera de la Reina, Spain*

* *Corresponding author.*

Introduction Sexual disinhibition is uncommon in patients with schizophrenia and are included within the behavioral disorders along with others such as agitation, aggression, sleep disorders and circadian rhythm, due to multiple reasons: isolation, rejection, difficulty in personal relationships.

Objectives We report the case of a male patient aged 58 with multiple previous admissions for behavioral alteration symptoms, including exhibitionism. He is referred as irritable, uninhibited and sleeping disorders. There is a risk of flight as he is difficult to be held so it is feared that he can be run over by a car. He shows a marked self-referentiality.

Methodology The patient is admitted. He properly gets used to the rules of the Ward. Pharmacological adjustment is performed. During his admittance he shows no behavior disorders neither episodes of self or hetero aggression and poor impulse. He properly makes comments of what happened during his stay. He responds well to treatment prescribed. Sleep pattern is restored.

Results Schizophrenia (undifferentiated) 295.90 (F.20.3); intellectual disability mild 317 (F70); neurocognitive disorder (possible).

Conclusions This is unusual case because it is normal that the sexual function of such patients is adversely affected, not finding numerous cases of disinhibition in our medical consultation. This is due to the different aspects that are affected, biological (drugs), psychological and social levels. We have different therapeutic alternatives to address this problem. However, they may hinder sociability and patient rehabilitation.

Implications of immunity and inflammation in schizophrenia and related psychotic disorders

J. Perestrelo*, D. Mota, A. Coutinho, M. Santos, G. Lapa
Centro Hospitalar de Vila Nova de Gaia/Espinho, Psychiatry, Porto, Portugal

* *Corresponding author.*

Introduction Intricate interactions between the immune system and the brain might have important etiological and therapeutic implications for neuropsychiatric brain disorders. A probable association between schizophrenia and the immune system was postulated over a century ago, and is supported by epidemiological and genetic studies pointing to links with infection and inflammation.

Objective To describe some important areas of research regarding immune response in schizophrenia and related psychotic disorders and discuss potential mechanisms and therapeutic implications of these findings.

Aims Associations between immune response, inflammation and schizophrenia and related psychotic disorders are reviewed.

Methods A literature review of the theme is surveyed. Several articles were search on MEDLINE with the keywords: schizophrenia, psychosis, inflammation, immunity, infection.

Results Schizophrenia is a multifactorial disease. It is associated with multiple genetic loci that confer risk, in addition to developmental and postnatal risk factors. Antipsychotic-naïve first-episode psychosis and acute psychotic relapse seems to be associated with increased serum concentrations of interleukin 6 and other proinflammatory cytokines, which are normalized after remission of symptoms with antipsychotic treatment.

Conclusions Inflammation and immune dysfunction might contribute to cognitive, negative, and positive symptoms in

schizophrenia. Identification of specific inflammatory pathways for neuropsychiatric symptoms would provide novel targets for therapeutic intervention.

EV1179

Psychosocial interventions for schizophrenia

A. Pestana Santos*, J. Amílcar Teixeira
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* *Corresponding author.*

Introduction Schizophrenia is a stress-related neurobiological disorder characterized by disturbances in the form and content of an individual's thought and perceptual processes. People with schizophrenia are faced with social impairment, which affects their global functioning.

Aims The authors aim to clarify the role of psychosocial interventions for the treatment and recovery of people with schizophrenia.

Methods The authors conducted a literature search in MEDLINE, PsycINFO, and Cochrane Library using the following words "psychosocial practices", "illness management and recovery", "rehabilitation" and "schizophrenia".

Results In schizophrenia as in other psychiatric diseases, a multimodal approach will increase the success of the intervention. On psychosocial point of view, the interventions take into consideration three factors: the characteristics of the individuals, the community requirements and the supportiveness of the environment. According to literature psychosocial treatments for schizophrenia is based on the recovery model of mental health and the expanded stress-vulnerability model. Psychosocial evidence-based practices include social skills training which help individuals to practice and acquire behavioral skills in social interactions; cognitive behavior therapy targets maladaptive thoughts and behaviors; cognitive remediation approaches impairment in information processing skills to indirectly improve social functioning. Other psychosocial practices are family psychoeducation, supported employment and assertive community treatment. Although the later improves daily living skills, it has little impact on psychosocial functioning.

Conclusions Psychosocial interventions are important for treatment and recovery of people with schizophrenia. Depending on the used practices, it reduces the number of relapses as well as it improves social functioning of people with schizophrenia.

LAI versus oral antipsychotic maintenance treatment of schizophrenia: A case-control study on subjective experience of treatment

F. Pietrini^{1,*}, M. Spadafora¹, L. Tatini¹, G.A. Talamba¹, E. Burchi¹, E. Calderani¹, S. Gemignani¹, L. Mallardo¹, C. Andrisano², G. Boncompagni³, M. Manetti⁴, A. Ballerini¹, V. Ricca¹

⁴ *Campo del Vescovo Union, Therapeutic Psychiatric Community, La Spezia, Italy*

* *Corresponding author.*

Introduction Limited research has been devoted to the subjective impact of switching antipsychotic maintenance treatment (AMT) from oral to LAI formulation in schizophrenia.

Objective To compare LAI AMT with oral AMT in terms of subjective experience of treatment, taking into account the effects on psychopathology.

Methods Twenty outpatients (7 males, mean age 40.55 ± 11.00 years) with remitted schizophrenia treated with either olanzapine or paliperidone and switching from oral to LAI AMT were recruited before the switch (LAI-AMT group). A group of 20 remitted schizophrenic subjects with oral AMT and matched for the main socio-demographic, clinical and treatment variables made up the controls (oral-AMT group). All participants were assessed by means of the PANSS and of the SWN-K at baseline (T0) and after 6 months (T1).

Results Between T0 and T1, general psychopathology of the PANSS and all but one of the SWN-K dimensions (except for “social integration”), showed significantly higher percent improvements in the LAI-AMT group compared to the oral-AMT group. After 6 months (T1), the LAI-AMT group showed significantly lower PANSS total and general psychopathology scores, as well as higher mean score of perceived “mental functioning” compared to the oral-AMT group. Item analysis of the general PANSS at T1 showed significant differences between the two groups in anxiety, tension, depression, guilt feelings, poor attention, and active social avoidance.

Conclusions Our data on switching from oral to LAI AMT in remitted schizophrenia suggest a better efficacy of the latter in terms of improvement of general psychopathology and subjective experience of treatment.

LAI versus oral antipsychotic treatment of schizophrenia: A 12-month prospective study on patient's attitude towards treatment and quality of life

F. Pietrini*, A. Ballerini, I. Burian, B. Campone, F. Chiarello, E. Ciampi, E. Corsi, N. Ferruccio, M. Moneglia, L. Poli, A. Santangelo, S. Spitoni, V. Ricca

University of Florence, Department of Neuroscience, Psychology, Drug Research and Child Health, section of Neuroscience, Florence, Italy

* *Corresponding author.*

Introduction It is still a matter of debate whether LAI antipsychotics are able to significantly improve patient's attitude towards treatment.

Objective The aim of this 12-month observational study was to investigate the impact of switching antipsychotic treatment from oral to LAI formulation on patient's attitude towards treatment and quality of life.

Methods A total of 41 schizophrenic patients (25 males, mean age 42.10 ± 11.88 years) were recruited. Patients were expected not to need significant changes in concomitant treatments. All patients were under a stabilized therapy with a single oral antipsychotic (either olanzapine or paliperidone) and were switched to the equivalent maintenance regimen with the long-acting formulation of the same antipsychotic (olanzapine pamoate or paliperidone palmitate). Patients were assessed before the switch (T0), and after 6 (T1) and 12 months (T2) of LAI antipsychotic treatment by means of the YMRS, MADRS, PANSS, DAI-10 and SF-36.

Results Our data evidenced an overall significant improvement of psychopathology, adherence and quality of life over the 12-month period (T0 vs. T2). In particular, while all of the measures significantly improved in the first semester (T0 vs. T1), only YMRS, positive PANSS and DAI-10 improved both in the first and in the second semester (T1 vs. T2), indicating an additional advantage of a prolonged LAI treatment on these clinical dimensions.

Conclusions The switch from oral to long-acting antipsychotic treatment may provide considerable advantages in improving patient's attitude towards (and therefore adherence to) treatment. Part of this improvement could be related with a better efficacy on psychopathology and quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depot medication and compulsory treatment

A. Poças^{1,*}, S. Azenha²

¹ *Centro Hospital de Leiria, Serviço de Psiquiatria, Braga, Portugal*

² *Hospital de Braga, Serviço de Psiquiatria, Braga, Portugal*

* *Corresponding author.*

Introduction It is estimated that 90% of patients with schizophrenia only adhere partially to the treatment. The use of depot medication is an option for patients with schizophrenia rather using it in voluntary or compulsory treatment.

Objectives and aims We tried to check on differences in the outpatient treatment of schizophrenia among patients receiving compulsory (involuntary outpatient commitment [IOC]) and voluntary treatment and analyzed the outcomes in patients in IOC taking oral versus depot antipsychotics.

Method We assessed and compared socio-demographic and clinical features, therapeutics likelihood of medication adherence (with Medication adherence rating scale [MARS]), personal and social performance (PSP) scale and predominant kind of symptoms (with Positive and Negative Syndrome Scale [PANSS]).

Results and conclusion All patients were taking antipsychotics, and 63% of compulsive and 33% of volunteers were taking oral and injectable antipsychotics simultaneously. We observed that 21% of compulsive and 30% of the volunteers were simultaneously doing typical and atypical antipsychotics. Depot medication was being taken by 84% of patients in IOC and in just 54% of volunteers. We do not find statistically significant differences in outcomes of patients in IOC with injectable medication ($n=16$) compared to those who were only with oral medication ($n=3$), in terms of probability of adherence to medication, functionality or predominant symptomatic type. Compulsive patients had higher use of typical antipsychotics, perhaps in order to have a more sedative effect in patients with more severe disease. The prevalence of atypical antipsychotics in volunteers focuses on the need of a better cognitive performance and functionality.

Catatonic schizophrenia vs anti-NMDA receptor encephalitis – A video case report

A. Ponte^{1,*}, J. Gama Marques¹, L. Carvalhão Gil¹, C. Nobrega², S. Pinheiro³, A. Brito³

¹ *Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal*

² *Centro Hospitalar Psiquiátrico de Lisboa, Neurology, Lisbon, Portugal*

³ Hospital de Santo António dos Capuchos, Internal Medicine, Lisbon, Portugal

* Corresponding author.

Introduction Anti-N-methyl-D-aspartate receptor (anti-NMDAR) encephalitis is a treatable autoimmune disease of the CNS with prominent neuropsychiatric features that primarily affects young adults and children.

Objective To present the diagnosis course of a case of anti-NMDAR encephalitis in a patient with previous diagnosis of Schizophrenia.

Methods Analysis of the patient's clinical records and of a PubMed database review, using "anti-NMDAR encephalitis" as keywords.

Results We report a single case of a 33-year-old man diagnosed with Paranoid Schizophrenia in 2009 that after 1 year of treatment abandoned follow-up. Six years later, the patient presented to the psychiatric emergency department with persistent headaches, abnormal behavior and loss of motor skill. He was admitted to the psychiatric ward with a presumptive diagnosis of "Catatonic Schizophrenia" and began to manifest fluctuating catatonic symptoms (captured in video). Neuroleptics and benzodiazepines were tried without success. There was a clinical deterioration with autonomic dysfunction, breathing instability and seizures. Complementary exams revealed: EEG with slow base activity; brain MRI with right temporal pole and right frontobasal lesions compatible with head trauma; CSF with pleocytosis; and positive anti-NMDAR antibodies. Occult neoplasm was excluded. Treatment with high-dose steroids, intravenous immunoglobulins, followed by cyclophosphamide resulted in relevant clinical improvement.

Conclusions As early detection of antibodies may allow for earlier treatment of anti-NMDAR encephalitis, which is associated with better outcomes, we believe the present case underscores the importance of clinicians maintaining vigilance for neuropsychiatric symptoms that have not adequately responded to therapy.

* Corresponding author.

Introduction Schizophrenia is a developmental disorder that includes non-psychiatric abnormalities [2]. Metabolic abnormalities prior to antipsychotic treatment exist. The clozapine metabolic profile causes clozapine underuse in resistant schizophrenia [1].

Objectives To correlate metabolic profile with psychiatric severity and compare the correlations between clozapine/non-clozapine patients.

Aims To determine possible contributory factors to metabolic abnormalities in schizophrenia.

Methods We cross-sectionally analyzed all patients from a Spanish long-term mental care facility ($n=139$). Schizophrenic/schizoaffective patients were selected ($n=118$). $N=31$ used clozapine. We paired clozapine and non-clozapine patients by sex and age and assessed metabolic and psychopathological variables.

We compared psychopathologic variables between patients with/without cardiometabolic treatment and the differences between clozapine/non-clozapine groups.

Results We analyzed: 27 clozapine/29 non-clozapine patients. A total of 67.9% males with a mean age of 51.3 (SD 9.6) years. In the whole sample TG negatively correlated with Negative-CGI ($r: -0.470, P: 0.049$) and HDL-cholesterol correlates with Global-CGI ($r: 0.505, P: 0.046$). Prolactin correlated with the number of antipsychotics ($r: 0.581, P: 0.023$) and IMC ($r: 0.575, P: 0.025$). Clozapine group took less antipsychotics [Fisher ($P: 0.045$)] and had higher scores in total BRPS scale [t -Student ($P: 0.036$)]. They did not use more cardiometabolic treatment. There were no psychopathological differences between cardiometabolic treated/non-treated patients. In the non-cardiometabolic treated group ($n=35/62,5\%$), IMC negatively correlated with positive and total BPRS, positive, cognitive and global-CGI. We found negative correlations between metabolic parameters and psychopathology in clozapine (40%) and non-clozapine subgroups (60%). In the cardiometabolic treated group ($n=21/37,5\%$), we did not find these correlations in either of clozapine (61.9%) or non-clozapine (38.1%) subgroups.

Conclusions Severity [2], prolactine [3] and treatment [1] could play a role in metabolic parameters. In our sample we found negative correlations between psychopathological and metabolic parameters.

* Corresponding author.

Introduction One of the characteristics of Karl Jaspers approach to clinical practice was the importance he gave to the subjective experience by the patient. Patient's self-observation is one of the most important sources of knowledge of the psychic life of the patient. The lack of awareness of illness is quite common in psychotic spectrum.

Aim The aim of this paper was to examine and compare a group of patients diagnosed with psychosis disorder with another group with other mental disorders, in relation to their mental and emotional suffering,

Sample The sample was composed by 118 subjects with both sexes. It was divided into two groups: patients with a diagnosis of psychotic disorder and another one with other mental disorders.

Instrument Inventory SCL-90-R, which evaluating a wide range of psychological and psychopathological symptoms was used.

Statistics analysis Two groups were compared with respect to perceived psychopathological symptoms.

Results Statistically significant differences were observed between both groups. Patients with psychotic disorders showed lower scores in most clinical scales. It reflects less emotional suffering and psychological distress perceived in this group against the other. It could be related to the lack of awareness of illness by psychotic patient.

EV1186

A pilot early psychosis intervention programme in Bolivia

G. Rivera Arroyo

Hospital Universitario Japonés, Mental Health, Santa Cruz, Bolivia

The problem Less than half of the more than 250 adolescents and young adults who are estimated to experience a first episode of psychosis in the city of Santa Cruz each year are ever diagnosed and receive treatment.

Of those patients who are eventually diagnosed, the average duration of their symptoms of psychosis prior to receiving treatment is estimated to be over 2 years.

The opportunity Multiple psychosocial variables, such as the reaction of patients and their families to symptoms of psychosis, which play a vital role in determining long-term outcomes, demonstrate their highest degree of flexibility during the period of early psychosis. Psychological, social and evidence-based pharmacological interventions undertaken during this time frame can have a profound impact on the life-course of an individual with psychosis.

Our solution We propose to establish a pilot early psychosis intervention program that will provide age appropriate biopsychosocial treatment and support for 15–25 years old with first episode psychosis and their families in Santa Cruz. This will improve short and long-term outcomes for those with psychosis, increase speed of recovery, decrease the need for hospitalization, reduce family disruption and decrease rates of relapse.

By utilizing a mobile, multidisciplinary treatment team that emphasizes the roles of trained case managers focused on providing intensive individual and family support in the home, this program will provide culturally appropriate care that will leverage contributions from a limited supply of psychiatrists and shift dependence away from a fragmented medical system.

Disclosure of interest The author has not supplied his declaration of competing interest.

EV1187

Impact of vulnerability to stress in the development and course of first psychotic episodeL. Rossini Gajsak^{1,*}, M. Celic Ruzic¹, M. Rojnic Kuzman²¹ *Neuropsychiatric Hospital Dr. Ivan Barbot, Department of Biological Psychiatry, Popovaca, Croatia*² *University Hospital Centre Zagreb, Department of Psychiatry, Zagreb, Croatia** *Corresponding author.*

Introduction The stress diathesis hypothesis is one of the leading models of etiology of psychotic disorders. Cortisol is one of the most researched stress hormone; yet its role in first psychotic episode is currently subject of many researches. Psychotic disorder occurs when “enough” stress attacks vulnerable personality. Stress response activates HPA axis that results in cascade effects on several body systems (immune, neuroendocrine and inflammatory). Dysregulation of the HPA axis and increased cortisol levels have been implicated in psychotic as well as in other psychiatric disorders.

Objective To follow treatment response through changes in clinical status and stress biomarkers evaluation in longitudinal 18 months research in drug naive FEP.

Aim To assess endocrine and autonomic responses to acute psychosocial stress, their associations with onset of the first psychotic episode and their subsequent remission.

Methods We studied 17 subjects with FEP and age and gender matched controls who were exposed to the Trier Social Stress Test. Other materials have explored clinical status through standardized clinical psychiatric interview and validated psychiatry scales as well as measured laboratory biomarkers (cortisol, prolactin, insulin).

Results Our preliminary findings on a sample of 40 participants indicate a differences between patients and controls in terms of response to stress measured by TSST.

Conclusion In our continued longitudinal research, we plan to further explore the role of hypothalamic-pituitary-adrenal activity in onset and course of psychotic disorder and its relation with other biomarkers.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1188

A case of rare allele T 126, 30,32 base pairs in a schizophrenic patient: A study caseA.I. Sabau^{1,*}, P. Cristina², B. Valerica², P. Delia Marina³¹ *Vasile Goldi, Western University of Arad, Arad, Romania*² *Vasile Goldi, Western University of Arad, the Institute of Life Science, Arad, Romania*³ *Vasile Goldi, Western University of Arad, Psychiatry Department, Emergency County clinical Hospital of Arad, Arad, Romania** *Corresponding author.*

Introduction Schizophrenia is a severe and complex disease clinically characterized by disturbed thought processes, delusions, hallucinations and reduced social skills. Gene coding for neregulin 1 (NRG1) located in 8 p21 chromosome and single nucleotide polymorphism (SNPs) have been identified strongly supporting NRG1 gene as a susceptibility gene for schizophrenia.

Objective The present preliminary study, determines the relationship between polymorphism nucleotide sites (SNPs2) of NRG1 gene and schizophrenia.

Aims Identifying rare allele T of neregulin 1 gene in schizophrenic patients.

Method We analyzed the polymorphism (SNPs2) of NRG1 gene in 20 patients recruited from Psychiatry Department of Emergency Clinical Hospital of Arad diagnosed with schizophrenia according to DSM-5-TM and ICD-10 criteria and 10 healthy controls. From all subjects, we obtained 2 mL of peripheral blood samples. Genomic DNA was extracted using the phenol-chloroform method. Genotyping was performed by PCR-based RFLP analysis for all subjects. The obtained PCR product mixture was completely digested with restriction enzyme, separated on SNP1 and SNP2 agarose gel. We present the case of a 31 years old, male, schizophrenic patient with the SNPs2 polymorphism and rare allele T 126.

Results In both groups, common allele G 127 and 60 base pairs was identified but only 2 schizophrenic patients presented rare allele T 126 and 30,32 base pairs.

Conclusions The polymorphism SNPs2 of NRG1 gene with rare allele T 126 and 30,32 base pairs, may play a role in predisposing an individual to schizophrenia. Further and extended replicating studies with multiple sequencing of NRG1 gene are necessary.

Keywords Schizophrenia; Neregulin 1 (NRG1) gene; Allele T 126

EV1189

Role of specialized hospital units in integrative treatment of first and early course psychosis – 10-year experience of Zagreb first psychosis unitA. Savic^{*}, D. Ostojic, A. Silic, A. Bacekovic, V. Jukic
*University Psychiatric Hospital Vrapce, Department of Diagnostics and Intensive Care, First Psychosis Unit, Zagreb, Croatia** *Corresponding author.*

Introduction As programs for prodromal states of psychosis emerge, part of our focus naturally shifts from first psychotic episodes and early course psychotic disorders. Clinical practice will, however, always confront us primarily with psychosis after its onset, and ample evidence still confirms specificity and importance of early stages of psychosis.

Aim Authors aim to present experience and data from Zagreb First Psychosis Unit, only such unit in Croatia and one of rare units of that type in the region, discussing wider role of stationary units in integrative care of first and early psychoses.

Methods Ten-year data from the unit is analyzed. Demographics and illness specificities are presented, along with duration of hospitalization, involuntary treatment rates, diagnoses, rehospitalization rates, subsequent treatment and other variables. Examples of organic causes and specific clinical presentations are presented in the context of necessary first psychotic episodes differential diagnostic process.

Results In the 10-year period Zagreb First Psychosis Unit had over 2000 hospitalizations, 61% of which were first psychotic episodes and the rest cases in early stages of psychosis; 6.8% of first episode cases required involuntary hospitalization; 71.4% of first psychotic episode cases were not re-hospitalized following the diagnostic process and treatment.

Conclusion First psychotic episodes present especially vulnerable periods that might determine following stages of illness and functioning. It is vital to consider role of specialized first psychosis units that initiate structured specific diagnostic, evaluation, and treatment protocols for first episode patients requiring hospitalization, and present a bridge towards equally specialized and congruent outpatient programs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ University of Oulu and Oulu University Hospital, Research Unit of Clinical Neuroscience, Department of Psychiatry, Oulu, Finland

⁴ University of Helsinki and Helsinki University Hospital, Psychiatry, Helsinki, Finland

⁵ South-Savo Hospital District, Department of Psychiatry, Mikkeli, Finland

* Corresponding author.

Introduction Treatment-resistant schizophrenia (TRS) is a severe form of schizophrenia. From one fifth to one third of all patients with schizophrenia are resistant to treatment.

Objective To determine the knowledge on TRS and to find out the extent and the quality of research on TRS.

Aims To conduct a systematic review of the current literature on TRS.

Methods Original studies and reviews on TRS were systematically collected from PubMed and Scopus databases. The following search strategy was used as a title search; (“ultra-resistant” OR “treatment-refractory” OR “treatment-resistant”) AND (schizophrenia). The search was restricted to English language articles.

Results The literature search identified 403 studies. After abstract and title review, 324 studies were included. The included studies considered medication (*n* 213), electroconvulsive therapy and

repetitive transcranial magnetic stimulation (15), prognosis (15), genetics (15), studies on neurobiology (15), definitions (14), psychotherapy (12), brain structures and functioning (10), cognition (7) and other miscellaneous studies (6) on TRS. Definitions of TRS varied notably and in most of the non-pharmacological studies, the samples were fairly small. Regarding treatments, clozapine, ECT, and cognitive-behavioral therapy have shown effectiveness, though the quality of research on interventions is limited. Very little is known about risk factors and predictors of outcome in TRS.

Conclusions Our findings suggest TRS is poorly studied and understood condition contrasted to its high prevalence, clinical importance and poor prognosis. There is a lack of studies on epidemiology, for example risk factors of TRS, as well as on outcomes and longitudinal course. Most of the studies considered medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric social work intervention program for “high expressed emotion” among the caregivers of persons with schizophrenia in India – a feasibility study

K. Setty^{1,*}, J. Navaneetham¹, S. Bada Math², P. Marimuthu³

¹ National Institute of Mental Health & Neurosciences, Psychiatric social work, Bangalore, India

² National Institute of Mental Health & Neurosciences, Psychiatry, Bangalore, India

³ National Institute of Mental Health & Neurosciences, Department of Biostatistics, Bangalore, India

* Corresponding author.

Introduction Schizophrenia is a severe mental illness that creates various psychosocial problems among family members. In addition, the family also contributes to psychosocial issues such as, expressed emotion. Expressed emotion (EE) has been found to predict relapse. Literature indicated that psychosocial interventions along with medicines would help in mainstreaming the persons with illness. However, there is paucity of culturally sensitive interventions for EE in India.

Methodology The objective of the study is to test the feasibility of cultural sensitive psychiatric social work intervention package to reduce expressed emotion among the caregivers of persons with schizophrenia in India. Ten caregivers of inpatients with schizophrenia from National Institute of Mental Health and Neurosciences, India, participated in the study. MINI 6.0 was used as screening tool. Socio-demographic profile collected. The Family Emotional Involvement and Criticism Scale was used to elicit the expressed emotion. A standardized 10 session spread over 10 days psychiatric social work package was given to the caregivers. Intervention package included methods of Social work and various techniques.

Results and conclusion Mean score of family income (*M*=3200, *SD*=1.98), onset of illness (*M*=26.0, *SD*=6.56), illness duration (*M*=3.10, *SD*=1.41), duration of care giving (*M*=2.3, *SD*=1.56). Overall ill individual's perception of expressed emotion on their caregivers was found to be decreased in post-assessment (*M*=29.60, *SD*=2.9) when compared to the pre-assessment (*M*=50.0, *SD*=1.9). It was found to be statistically significant (0.000* = *P*<0.05). The standardized psychiatric social work intervention was found to be effective to the caregivers of schizophrenia in India.

EV1192

Preventable schizophrenia

C.F. Silvia*, A. Gómez Peinado, P. Cano Ruiz
HNSPS, Psiquiatria, Albacete, Spain

* Corresponding author.

Introduction Schizophrenia is a psychiatric disorder with multiple causes, including genetic, immune, environmental causes of various kinds, which all increase the vulnerability and predisposition to the disorder. Among them stand out prenatal infections, thus being a preventable risk potential factor in our daily clinical practice.

Objectives To analyze the relation between prenatal infections and schizophrenia.

Methods Review of the subject and recent articles on schizophrenia in psychiatric guides and magazines.

Results After analyzing several studies, it has been shown that prenatal infections, where the nervous system is not yet fully developed, may be a risk factor for the development of schizophrenia in adults, in relation with genetically predisposed individuals. Infections such as influenza, especially during the first quarter of gestation; rubella, toxoplasma and herpes simplex virus-type 2 are related to potentially increase risk of suffer schizophrenia.

Conclusions Prenatal infections, especially in the first quarter and the periconceptional period, constitute a risk factor in individuals with vulnerability to develop schizophrenia. Awareness and prevention is important in the pregnant population of the influence of these infections on the possible origin of psychotic episodes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Medication adherence in schizophrenia

F. Fatma, I. Baati, S. Omri, R. Sallemi*, J. Masmoudi
Hédi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

* Corresponding author.

Introduction Compliance is a major issue in the treatment of schizophrenia. Many studies have attempted to identify factors that influence it.

Objective To assess treatment adherence in patients with schizophrenia. To identify factors correlated with poor adherence.

Methods It was a cross-sectional, descriptive and analytical study, involving 37 outpatients with DSM-IV diagnosis of schizophrenia, followed in the psychiatry department at the Hédi Chaker University Hospital of Sfax (Tunisia). The questionnaire included socio-demographic, clinical and therapeutic data. We also used the Medication Adherence Rating Scale “MARS”, the Insight Scale “IS” and the Stigma Scale (9 items).

Results The average age was 36.4 years. The majority of patients was male (68.8%), did not exceed the level of secondary education (89.2%) and had a low socioeconomic level (84.4%).

Paranoid schizophrenia was the most frequent type of schizophrenia (54.1%). Atypical antipsychotic were prescribed in 40.5% of cases.

Patients were non-adherent to treatment in 56.8% of cases. The factors correlated with poor adherence were: psychoactive substance use ($P=0.036$), sexual dysfunction ($P=0.036$), complexity of treatment ($P=0.036$), poor insight according to the subscale “awareness

of the need for treatment” of the IS ($P=0.047$) and high score on the subscale “discrimination” of the Stigma Scale ($P=0.008$).

Conclusion Tunisian schizophrenic patients have a poor adherence to treatment. Acting on risk factors (such as substance use, sexual side effects, poor insight and discrimination perception) would improve patient compliance and management of schizophrenia.

EV1194

Rehospitalization rate of first episode and chronic schizophrenia patients one year after discharge

R. Softic*, E. Becirovic, M. Mirkovic Hajdukovic
University Clinical Center Tuzla, Psychiatry Clinic, Tuzla, Bosnia and Herzegovina

* Corresponding author.

Introduction Relapse rate among patients with schizophrenia can determine outcome of illness. Up to 40% of patients with first psychosis responds well to treatment. Despite this fact relapse rate is still high, in particular if treatment is discontinued. Frequent use of first generation antipsychotics (FGA) in underdeveloped countries can be one of possible reasons for treatment discontinuation and consequent relapse.

Aims To analyse rehospitalisation rate in patients with first and multiple episodes of schizophrenia, and compare it with medication choice.

Methods Retrospective analysis of medical records of patients with schizophrenia hospitalised in Psychiatry Clinic of University Clinical Center Tuzla in period from year 2011 to 2013.

Results During the two-year period, 37 patients with first episode of schizophrenia were hospitalised. Second generation antipsychotics (SGA) were used in 40.5%, and first generation in 13.5%, long acting injectibles - first generation (LAI) were used in 8.1%, and combination of FGA's and SGA's in 5.4% of cases. In the same period, 121 patients with multiple episodes of schizophrenia were hospitalised. SGA were used in 21.4%, FGA in 33%, LAI's in 47.1%, and combination FGA's and SGA's in 35.5% of cases. Relapse rate in the first year after discharge was 16.2% in group with first psychotic episode, and 33% in the group with multiple episodes of schizophrenia.

Conclusion High relapse rate in group with multiple episodes can be explained with nonadherence regarding the side effects of too frequent use of FGA's.

Keywords Schizophrenia; Relapse rate; Adherence; Antipsychotics

Substance abuse in first episode psychosis: Baseline characteristics and clinical outcome

A. Toll*, A. Mané, D. Bergé, V. Pérez-Solà
Hospital del Mar, Institut de Neuropsiquiatria i Addiccions (INAD), Barcelona, Spain

* Corresponding author.

Introduction There are high rates of substance use disorders (SUD) amongst first episode psychosis (FEP). SUD have been linked to better premorbid adjustment, more severe positive and negative symptoms at presentation and poorer symptomatic and functional outcome [1]. Moreover, shorter duration of untreated psychosis

(DUP) has been described as an important predictor of outcome in FEP [2].

Aims With this study, we want to know which baseline characteristics and clinical outcomes differ between FEP patients with and without substance use.

Methods One hundred and seventy-five FEP were consecutively admitted to Hospital del Mar since January 2008 to September 2014 and entered the FEP programme of the institution. The included evaluation was socio-demographic and clinical data at baseline and 1 year follow-up. We studied differences in age, gender, DUP, GAF scores at baseline and 1 year follow-up and PANSS subscale scores at base and 1 year follow-up between substance users and non-users.

Results Cannabis: we found that users were significant younger ($P < 0.01$), had a higher proportion of males ($P < 0.01$) and a significant shorter DUP in users ($P = 0.008$).

Alcohol: we found that users were significant younger ($P < 0.009$), had a higher proportion of males ($P < 0.003$) and a significant lower PANSS negative scores at baseline ($P = 0.01$) and 1 year follow-up ($P = 0.03$).

Conclusions In our sample of first episode psychosis, cannabis and alcohol use is linked with a younger age and a high proportion of males. Moreover, it seems that cannabis use could be associated with a shorter DUP.

Factors associated with schizophrenic evolution after a first episode psychosis

M. Turki*, N. Halouani, R. Naoui, I. Gassara, N. Hamza, J. Aloulou, O. Amami

Hédi Chaker university hospital, psychiatry department, Sfax, Tunisia

* Corresponding author.

Introduction The evolution of a first episode psychosis is a fundamental question, despite its unpredictability. It affects the type of management and drug treatment. In this context, schizophrenia, a disabling psychiatric disease, remains the most formidable evolution.

Objective Assess the frequency and factors associated with schizophrenic evolution after a first episode psychosis.

Methods We conducted a retrospective, descriptive and analytic study including 55 patients hospitalized in psychiatry department, Hédi Chaker Hospital, Sfax, Tunisia, during 7 years (from 2007 to 2013), then managed in the outpatient department. We collected socio-demographic, clinical and evolutive data from clinical observations.

Results The mean age was 26.5 years. Sex ratio (M/F) was 2.9. Among our patients, 74.5% were single and 49.1% had no profession. A trigger factor of this episode was noted in 43.6% and a break with the previous functioning in 63.6% of cases. A schizoid personality was reported in 74.5% of the population. All patients presented positive symptoms, 96.4% had negative symptoms and 61.8% presented mood symptoms.

Schizophrenic evolution was reported in 38.2% of patients. Factors associated with this evolution were: masculine gender ($P = 0.004$), social isolation ($P = 0.009$); absence of mood symptoms ($P < 0.001$) and mental automatism ($P = 0.043$).

Conclusion Our study shows some factors associated with schizophrenic evolution after a first episode psychosis. The identification of these factors, as well as other factors reported in the literature is essential to allow early and adequate support, and ensure a better social integration.

² Mount Carmel Hospital, Department of Psychiatry, Attard, Malta

* Corresponding author.

Introduction The development of treatment-resistant schizophrenia in a 16-year-old Maltese girl was analyzed in terms of its biopsychosocial model of disease.

Objectives To highlight the presentation of treatment-resistant schizophrenia.

To investigate the etiology of treatment-resistant schizophrenia.

Aims To utilize the biopsychosocial model of disease in order to investigate the aetiology of treatment-resistant schizophrenia.

To highlight the treatment modalities utilized in this case of treatment-resistant schizophrenia.

Methods Interviewing the patient.

Analyzing all investigations and documentation made during her admission in an acute psychiatric hospital.

Evaluating the response to various treatment modalities.

Carrying out literature reviews.

Results Image attached.

Conclusions Although the aetiology of treatment-resistant schizophrenia remains somewhat unclear even after many years of study, the biopsychosocial model is nevertheless useful in understanding the development of this condition. The treatment modalities to which the patient was resistant were also identified. Figure not available.

Clozapine and aripiprazole combination

M.M. Vera*, C. Garay Bravo, S. Alonso Gutierrez,

M.D.L.D. Descalzo Cabadés

Hospital universitario general de Valencia, Valencia, Spain

* Corresponding author.

A 32 years old female with paranoid schizophrenia diagnosed at 20 years old, admitted for psychotic decompensation although treatment compliance. She had delusional ideas focused on her family with suicidal behaviour and functional impairment, refractory to different antipsychotic treatments so clozapine was initiated. Valproic acid was initiated too because of seizure risk. Clinically, improvement was accomplish at these treatment doses: valproic acid 1000 mg per day; clozapine 300 mg per day; and aripiprazole 150 mg IM per month.

Discussion The use of clozapine in resistant schizophrenia patients improves functionality at the long-term and it is specially indicated for suicidal behaviour. Recent studies show that rehospitalization rates for patients treated with clozapine raised 13%.

Other studies show that aripiprazole can be off label used as combination therapy in these situations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Institute for Frontier Areas of Psychology and Mental Health, Freiburg, Germany

* Corresponding author.

Background The ability to encode time intervals underlies various cognitive processes. In the light of compromised cognitive functions in schizophrenia patients, it is noteworthy that there are numerous reports indicating impaired timing abilities of these patients. The aim of the present study was to investigate if such timing disruptions are similarly present in patients with first episode of schizophrenia spectrum disorders (SSD).

Methods Time reproduction paradigm was administered in patients with first episode psychoses with the diagnoses of paranoid schizophrenia ($n=43$); schizoaffective disorder ($n=33$); schizotypal disorder ($n=31$) and healthy individuals ($n=94$). Participants reproduced time durations of 10, 20, 15 and 25 s. by pressing the mouse's button at the beginning and at the end of the interval with the supposed duration. The ratio between the real time interval duration and produced time interval duration was estimated ($= 1$ -norm, > 1 -overestimation, < 1 -underestimation).

Results All participants used counting as a strategy for reproduction of the intervals. In healthy individuals, we observed an increasing accuracy (values close to 1) with each trial. The performance of patients differed significantly from controls [$F(12, 508.28) = 3.46, P = 0.013$]. While patients with schizophrenia significantly overestimated the time durations, patients with schizotypal disorder demonstrated marked underestimation (Fig. 1). Patients with schizoaffective disorder performed close to norm.

Conclusions Our results suggest that patients with first episode of schizophrenia and SSD are less accurate at estimating time durations but in a various ways, possibly underlying distinct neurobiological mechanisms of timing disruptions.

A case of somatopsychic depersonalization in schizotypal disorder: A multimodal approach

Y. Zaytseva^{1,*}, M. Wittmann²

¹ National Institute of Mental Health, National IT System of Mental Health and Brain Monitoring, Klecany/Prague, Czech Republic

² Institute for Frontier Areas of Psychology and Mental Health, Freiburg, Germany

* Corresponding author.

Background In the general concept of self-disturbances in schizophrenia and schizophrenia spectrum disorders, somatopsychic depersonalization (SPD) occupies a special place, as it constitutes a syndrome that comprises feelings of detachment from one's own body and mental processes. However, apart from

clinical descriptions, to date the pathophysiology of SPD is not fully understood due to the rareness of the syndrome and a lack of experimental studies.

Methods In a case study of one patient with schizotypal disorder (M.M., male, 29 y.o.), we applied a multimodal evaluation (phenomenological, neuropsychological, behavioural, application of fMRI paradigm) in order to understand the SPD phenomena.

Results The patient's clinical profile was identified as disruption of implicit bodily function, accompanied by depressive symptoms. On a neuropsychological level, the patient exhibited impairment in executive functioning, intact tactile perception and kinesthetic praxis. Behavioral tests revealed an altered sense of time but unimpaired self-agency. Furthermore, the patient exhibited a lack of empathy and he had autistic traits, although with a sufficient ability to verbalize his feelings. On the neurobiological level using an active and passive touch paradigm during functional magnetic resonance imaging (fMRI), we found a hyperconnectivity of the default-mode network and salience network and a hypoconnectivity of the central executive brain networks in the performance of the touch task as well as intact perceptual touch processing emerging from the direct comparisons of the touch conditions.

Conclusions Our data provide evidence for the important role of altered large-brain network functioning in SPD that corresponds to the specific behavioral and neurocognitive phenomena.

EV1201

A journey across perversions history – from Middle Age to DSM

A. Amaral*, I. Ferraz, M. Mota

Centro Hospitalar de São João, Psychiatry and Mental Health Clinic, Porto, Portugal

* Corresponding author.

Introduction Psychiatry's viewpoint of sexual deviance has waned between the normal and the pathological. "Normal" is not determined by nature but by the values of a specific society.

Aims To review the main landmarks in paraphilias history and the importance of social and cultural dimensions to it.

Methods PubMed database was searched using the keywords perversion, sexual deviance, paraphilia, culture and society.

Results Throughout Middle Age and Renaissance any sexual act that differed from the natural/divine law was considered a vice. Unnatural vices (masturbation, sodomy, bestiality) were the most severely punished, as they could not result in conception. In 1886, Krafft-Ebing stated perversions were functional diseases of the sexual instinct caused by "hereditary taintedness" in the family pedigree and worsened by excessive masturbation. Proper perversions were sadism, masochism, antipathic sexuality (homosexuality, transvestism, transsexuality) and fetishism. Later, Havelock Ellis and Hirschfeld claimed sexual interest in the population followed a statistical norm, opposed the idea that masturbation led to diseases and demanded the decriminalization of homosexuality. Freud believed the "perverse disposition" to be universal in the childhood giving rise to healthy and pathological adult behaviors. In 1950's, Albert Kinsey surprised America when he proved many supposedly deviant sexual practices were quite common. The first *Diagnostic and Statistical Manual* (1952) was mainly psychoanalytic. Later, by 1973, homosexuality was removed from

classifications. Recently, DSM-5 distinguishes between paraphilias and paraphilic disorders.

Conclusion A progress in the paraphilic instincts' acceptance has occurred. We hypothesize, in the future, paraphilias will follow homosexuality out of the diseases' classifications.

Socio-demographic features of gender dysphoria in a Sardinian adult population

C. Bandecchi^{1,*}, V. Deiana¹, F. Pinna¹, E. Corda¹, R. Puscaddu¹, S. Pintore¹, A. Oppo², S. Mariotti², A. Argiolas¹, B. Carpinello¹

¹ University of Cagliari, Department of Public Health, Clinical and Molecular Medicine, Section of Psychiatry, Cagliari, Italy

² University Hospital of Cagliari, Multispecialty Department of Endocrinology and Diabetology, Cagliari, Italy

* Corresponding author.

Gender dysphoria (GD) is a rare entity in psychiatry; there are a lot of studies about its clinical aspects, but only few investigations considering the socio-demographic characteristics of these patients, especially concerning Italian population.

The aim of this study is to evaluate socio-demographic characteristics of GD individuals seeking assistance for gender transition and to assess possible differences between MtFs and FtMs.

A consecutive series of 25 patients (56% MtF and 44% FtM), from 17 to 49 years old (mean age: 29.6 ± 9.52), were evaluated for gender dysphoria from June 2011 to May 2015. All subjects met the criteria for gender identity disorder (GID), based on DSM-IV-TR.

The results have shown that FtMs refer for psychiatric help in younger age than MtFs (21–25 years vs. 36–50 years, $P = .038$); most of the patients are unemployed (48%; $P = .014$) and live with their parents (68%; $P = .001$), without statistically significant gender differences. Regarding sexual orientation, 84% of the sample report to feel attracted by individuals of the same-genotypic sex ($P < .001$); 81.8% of FtMs have a stable relationship instead of 21.4% of MtFs ($P = .007$). Moreover, a significant statistical difference was found between the two groups in the "real-life experience"; all FtMs live as males, while only 50% of MtFs show themselves as females in the daily life and activities ($P = .008$).

This is a preliminary study comparing the socio-demographic features of a MtF and FtM GD population in Sardinia. Although the limitation of a small sample, our results do not differ from the literature data; in particular, FtMs display significantly better global functioning and less problems in social integration.

³ Centro de Salud Santa Marta de Tormes, Atención Primaria, Salamanca, Spain

⁴ Hospital Universitario Salamanca, Unidad de Hipertensión, Salamanca, Spain

* Corresponding author.

Background Hypertension is one of today's main health problems around the world. This illness can be prevented and treated with antihypertensives (AHT) medicines, which, besides helping to control vascular circulation, can also have other, secondary, non-beneficial effects.

Objective To evaluate the frequency and intensity of sexual dysfunction (SD), measured against the PRSexDQ-SALEX scale, in patients diagnosed with AHT currently undergoing treatment. To assess differences between the main groups of AHT (mono-therapy and combined therapy). To determine statistically meaningful differences between other significant variables.

Methods Epidemiological, cross-sectional, multi-centric study of an exploratory nature. The study interviewed 256 subjects treated for hypertension (26.6% women and 73.4% men). By clinical interview and through the PRSexDQ-SALEX, the existence, or not, of SD caused by the AHT medication was evaluated.

Results/conclusions SD caused by AHT is a common problem. The percentage of iatrogenic SD was very high for all groups of antihypertensive medicines/pharmaceuticals, with percentages between 53.3 and 83.9% (measured with PRSexDQ-SALEX).

The percentage of patients who reported this problem voluntarily was very low (14.8%).

The treatments most harmful to sexual function were: diuretic+ARB (83.9% of SD) and ACE inhibitors (77.8% of SD). According to statistical models, subjects who take diuretic+ARB have a probability of suffering SD in 83.87% of cases.

Various risk situations might be detected due to the greater probability of suffering SD: patients with poor general health, subjects over 60 with coronary disease, mood disorders or muscular-skeletal disease and patients who take the diuretic + ARB combination.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Challenges faced by gender-variant people in receiving appropriate care and ways to improve their care and lives – A UK study

N. Clementi^{1,*}, E. Dobrzynska²

¹ Royal Cornhill Hospital, General Adult Psychiatry, Aberdeen, United Kingdom

² Cygnet Hospital Kewstoke, General Adult Psychiatry, Weston Super Mare, United Kingdom

* Corresponding author.

Introduction It is only in the last decade that trans people have been accorded rights and give protection in law from discrimination. A survey of 10,000 people undertaken by the Equality and Human Right Commission showed that 1% of the population was gender-variant to some extent. Gender-variant people continue to suffer restricted opportunities, discrimination and harassment at work despite the existence of anti-discrimination and equalities legislation. It is estimated that up to 40% of people with gender dysphoria may not be receiving appropriate help.

Objective Review of UK policies, guidelines, legislation and research on challenges faced by gender-variant people and ways to improve their care and lives.

Aims To improve gender-variant people access to care and ways to fight inequalities.

Methods MEDLINE, PsycINFO databases were searched for articles published between 2005–2015 containing the keywords “gender dysphoria”, “gender-variant people” and “transgender people”. Relevant policies, guidelines and legislations were also reviewed.

Results Transgender people still face major health inequalities and discrimination. National statistics show that 80% have experienced harassment, 62% suffered discrimination at work or home and 54% reported being denied access to NHS care due to lack of cultural competency from staff. Guidelines, research, policies and equality legislation have begun to be implemented to protect transgender people from discrimination and accord rights.

Conclusions Many areas need attention and improvement including not only healthcare but also employment, education, housing and media perception. Promotion of equality in the general population with the aim of achieving cultural change and improvement of cultural competency of health professionals is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Flibanserin: The first drug approved for the treatment of hypoactive sexual desire disorder in pre-menopausal women

N. Couto^{1,*}, R. Ribeiro Silva²

¹ Centro Hospitalar Vila Nova de Gaia/Espinho, EPE, Psychiatry and Mental Health, Braga, Portugal

² Centro Hospitalar Vila Nova de Gaia/Espinho, EPE, Psychiatry and Mental Health, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Hypoactive sexual desire disorder (HSDD) is characterized by persistent or recurrent deficiency or absence of sexual fantasies and desire for sexual activity, causing marked biopsychosocial dysfunction. The etiology of HSDD involves a wide range of biological and psychosocial factors. One of the biological factors is the balance between excitatory and inhibitory neurotransmitter pathways that regulate the sexual response in the central nervous system. Flibanserin is a compound discovered in 1995, agonist of the 5-HT_{1A} antagonist and the 5-HT_{2A} receptors, which became August 2015 in the first drug approved for the treatment of HSDD. **Objectives** Describe the main pharmacokinetic and pharmacodynamic characteristics of flibanserin, as well as the results and conclusions of the phase three clinical trials that led to its approval by the US regulatory authority.

Aims To understand the potential benefits and risks of the clinical use of flibanserin.

Methods Search online titles and abstracts related to flibanserin. **Results** Flibanserin is a multifunctional serotonin agent who is both a serotonin 1A agonist and a serotonin 2A antagonist. Theoretically, flibanserin improves sexual activity by increasing dopamine and norepinephrine release as it reduces serotonin release in brain circuits that mediate the symptoms of interest/female sexual arousal. Flibanserin showed a statistically significant increase in the number of improvements and satisfactory sexual events in several other validated scales. The main side effects include dizziness, sleepiness, nausea and (rarely) syncope.

Conclusions Despite the efficacy of flibanserin not produce statistically powerful results, although statistically significant, this may be important for a particular woman's profile, including those in which other psychotherapeutic approaches have failed.

Personality traits and personality disorders in gender dysphoria

V. Deiana^{1,*}, E. Corda¹, C. Bandecchi¹, S. Pintore¹, F. Pinna¹, R. Pusceddu¹, A. Oppo², S. Mariotti², A. Argiolas¹, B. Carpiniello¹

¹ University of Cagliari, Clinica Psichiatrica, Cagliari, Italy

² AOU Cagliari, Unità Operativa di Endocrinologia, Monserrato, Italy

* Corresponding author.

Investigations in the field of gender dysphoria (GD) have been mostly related to psychiatric comorbidity and severe psychiatric disorders, but have focused less on personality traits and personality disorders (PDs).

We aimed to assess personality and the presence of PDs in a sample of 25 persons with GD attending the Psychiatric Clinic or the Department of Endocrinology of the University of Cagliari requesting sex reassignment therapy. They were assessed through the Minnesota Multiphasic Personality Inventory-2 (MMPI-2) and the Structured Clinical Interview for DSM-IV Axis II (SCID-II).

The sample consisted of 14 MtF and 11 FtM, with a mean age of 29.6 ± 9.5. Overall, 39.1% of the sample met the criteria for at least one PD, more frequently cluster-B PD (21.7%). MtF met a higher number of SCID-II criteria than FtM, especially regarding histrionic personality traits ($P=0.001$). A total of 20 persons (9 MtF and 11 FtM) completed the MMPI-2. Mean T scores did not differ from the general population, except for the Psychopathic Deviate (Pd) scale (mean T = 66.2 ± 11.2). The Masculinity-Femininity (Mf) scale was slightly increased, and its score reduced after correction for perceived sex ($P=0.037$). MtF scored significantly higher at the Family Problems (FAM) scale ($P=0.052$) and lower at the Social Discomfort (SOD) scale ($P=0.005$) compared to FtM.

The high prevalence of PDs confirms that this kind of assessment in GD is of great importance, as a key part of personalized treatment plan tailoring. The high scores on the Pd scale suggest misidentification with societal standards.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Body image and gender role perceived in gender dysphoria: Cross-sex hormone therapy effects

E. Corda¹, C. Bandecchi¹, V. Deiana^{1,*}, S. Pintore¹, F. Pinna¹, R. Pusceddu¹, A. Oppo², S. Mariotti², A. Argiolas¹, B. Carpiniello¹

¹ University of Cagliari, Clinica Psichiatrica, Cagliari, Italy

² AOU Cagliari, Unità Operativa di Endocrinologia, Monserrato, Italy

* Corresponding author.

The gender dysphoria (GD) refers to the distress caused by the incongruence between gender identity and biological sex. This occurs, especially in pre-treatment cross-sex hormone therapy (CHT), with a marked dissatisfaction with their body image.

The purpose of this study is to evaluate the role of perceived gender in a total of 20 subjects (9 MtFs and 11 FtMs), presented for initiation of CHT at the Psychiatric Clinic or Department of Endocrinology of University Hospital of Cagliari and deemed appropriate to take the transition path aimed at sex reassignment. On a subsample of 7 patients (2 MtFs and 5 FtMs) were then evaluated changes, in terms of improving the acceptance of body image, at 2 months after initiation of CHT, using the Minnesota Multiphasic Personality Inventory-2 (MMPI-2) (focusing on MF, Gm and Gf scale), the Bem Sex Role Inventory (BSRI), and the Body Uneasiness Test (BUT). The MF scale shows a moderate elevation, which is reduced significantly as a result of correction for perceived gender rather than biological sex. MtFs get higher scores on the Gf scale and lower

scores on the Gm scale than FtMs. This trend is confirmed by the average scores of BSRI: MtFs are more “feminine”; while the FtMs are less “masculine”. This denotes an excessive identification by MtFs with the female gender role. Before initiating the CHT, the BUT score was indicative of clinically significant distress, which decreased during the CHT.

In conclusion, CHT reduces evidently body discomfort, due to the progressive reduction of the discrepancy between biological and desired gender.

Clinical characteristics of gender identity disorder

R. Pusceddu¹, C. Bandecchi¹, F. Pinna¹, S. Pintore¹, E. Corda¹, V. Deiana^{1,*}, A. Oppo², S. Mariotti², A. Argiolas¹, B. Carpiniello¹
¹ University of Cagliari, Clinica Psichiatrica, Cagliari, Italy
² AOU Cagliari, Unità Operativa di Endocrinologia, Monserrato, Italy
 * Corresponding author.

Traditionally, gender identity disorder (GID) is associated with high level of psychiatric comorbidity, particularly psychotic and affective disorders. The aim of this study is to evaluate clinical aspect of GID in a sample of patients in charge of the Operative Unit for Diagnosis and Therapy of GID, Psychiatric Clinic and the Department of Endocrinology, University of Cagliari.

Assessment was made by SCID-I, for Axis I comorbidity, GAF, for global functioning, BUT for body discomfort (BUT-A measures different aspects of body image, BUT-B looks at worries about particular body parts).

The sample comprised 14 MtF (56%) and 11 FtM (44%), of age between 17–49 years; a diagnosed psychiatric disorder was reported in 32%: 16% mood disorders, 12% anxiety disorders, 4% psychotic disorders. Among subject with GAF < 85, 58.3% were identify to have a Axis I disorder compare to 7.7% patients with GAF ≥ 85 ($P=.011$), especially for mood disorders ($P=.039$). Main score of Global Severity Index (GSI) for BUT-A was 2.45 ± 883 ; all subjects had a score GSI > 1.2 (clinically relevant discomfort index).

Regarding BUT-B, MtF have higher scores in PSDI global scale ($3.37 \pm .577$; $P=0.019$) and subscale VI (4.38 ± 1.496 vs. $.81 \pm 1.864$; $P=0.006$): there are not significant gender differences in the others subscales, although discomfort regards different aspects of both sexes.

According to literature, we observed a slightly higher prevalence of Axis I psychiatric disorders compare to general population, with functioning level statistically significant.

Generally, GID was not associated with higher level of psychopathology, appearing as specific diagnostic aspect, where the main origin of discomfort is dissatisfaction toward self-body image.

Insights on asexuality – defining the fourth sexual orientation

D. Durães*, J. Martins, R. Borralho
 Centro Hospitalar Barreiro-Montijo, Mental Health and Psychiatry Department, Barreiro, Portugal
 * Corresponding author.

Introduction Although the phenomenon of asexuality is not new – it was first mentioned in the 1950s, in the works of Kinsey et al. – it remained ignored and unstudied by the scientific community until Bogaert ignited new interest in this topic. In 2004, the author

published his findings regarding the prevalence of asexuality and reported that 1.05% of the British population was asexual.

Human asexuality is defined as a lack of sexual attraction to anyone or anything, either hetero or homosexual, although this definition is not consensual.

Objectives/aims This work aims to review the conceptualization of human asexuality, and the social, biologic and psychologic factors associated.

Methods A review of relevant literature was conducted alongside online database research (PubMed and Medscape), using the keywords “human” and “asexuality”.

Results Despite the fact that many approaches have been proposed to define asexuality (lack of sexual behavior, lack of sexual attraction, self-identification as asexual or a combination of the previous) there is growing evidence supporting the conceptualization of asexuality as a unique sexual orientation, thus representing a fourth category.

It appears to be more frequent in women and associated to religiosity, lower education level, lower socioeconomic status, and poor health.

Conclusions Despite the increased interest of the scientific community in the study of asexuality, many questions remain unanswered. Additional studies are crucial in order to provide a clear understanding and acceptance of asexuality in this highly sexualized and voyeuristic society we live in, and also to allow for a better understanding of the complexity of human sexuality.

Adolescent hypersexuality: Is it a distinct disorder?

Y. Efrati (Counselor Education)^{1,*}, M. Mikulincer²
¹ Beit-Berl Academic Collage, Beit-Berl, Israel
² Interdisciplinary Center IDC Herzliya, Psychology, Herzliya, Israel
 * Corresponding author.

Adolescent hypersexuality, and its position within personality dispositions, is the subject of this presentation. The personality dispositions examined were attachment style, temperament, gender, religiosity, and psychopathology. To do so, 311 high school adolescents (184 boys, 127 girls) between the ages 16–18 ($M=16.94$, $SD=.65$), enrolled in the eleventh ($n=135$, 43.4%) and twelfth ($n=176$, 56.6%) grades, most of whom (95.8%) were native Israelis. By religiosity, 22.2% defined themselves as secular, 77.8% reported various degrees of religiosity. Five possible empirical models were examined, all based on current theory and research on hypersexuality. The fourth model was found to be compatible with the data, indicating that psychopathology and hypersexuality are independent disorders and are not related by a mediating process. In addition, religiosity and gender are predictors, but the relationship between temperament and attachment is independent of them – the process is identical in religious and non-religious adolescents, both boy and girl. Additionally, the hormone oxytocin may be related to hypersexuality, with implications that could affect the therapeutic meaning of understanding the location of adolescent hypersexuality as a disorder in and of itself.

EV1211

Military culture and sexual issues: The sex-stress phenomenon

L. French
 Webster, USA

Introduction Sex abuse within the military has long been an open-secret afflicting both male and female veterans whose etiology is often attributed to character deficits (personality disorders or paraphilic disorders). Few studies look at the sex-stress phenomenon as a feature of military life itself and the role this plays in sex abuse within the military milieu. While much attention is focused on US forces, this problem is endemic within military cultures per se. The recent sex abuse scandal involving the French military in the Central African Republic illustrates the pervasiveness of the problem.

Objectives/aims To explore the psycho-cultural mechanisms of stress and its sexual expression and how certain scenarios within the military milieu exacerbates this impulse-control reaction. To address the relationship of the availability of sex-release options – without and/or without the military population (and how increased enlistment of women has changed the nature of the target population in today's military).

Methods Look at the problem historically (from WWII – present) with particular illustrations. Evaluate common (often failed) approaches to addressing the problem, including the fallacy that superior officer know best how to handle these cases. Explain the psycho/physiology of the sex-stress phenomenon – mechanism of the hypothalamic-pituitary-adrenal-gonad axis. Look at the relationship between sex-trauma and suicides among veterans.

Results/conclusions Offer a viable assessment/diagnostic of sexual problems within the military culture along with a treatment model that offers both psychotherapeutic (cognitive-behavioral protocols...) as well as identifying acute clinical symptoms that may respond to psychotropic medications.

Disclosure of interest The author has not supplied his declaration of competing interest.

Introduction Lack of adherence for side effects of treatment is one of the main causes of discontinuation therapy and readmission in the acute care setting.

The elevation prolactin, capable of generating amenorrhea, osteoporosis and sexual dysfunction, can be one of the main causes of treatment discontinuation.

Objectives Our objective was the study of prolactin in blood with three different patient who presented adverse effects that motivate the change in treatment, with better adherence and normalization of prolactin.

Method Clinical series of three patients.

Results Treatment was changed by oral aripiprazolo the first 4 days.

After verifying the tolerabilidad was administered Abilify Maintena, associating an oral dose of aripiprazole between 10–30 by status clinic.

We get rapid normalization of prolactinamia with side effects disappearance.

Conclusions In patient who principal problem a lack of adherence for sexual secondary effects, aripiprazole may be a good therapeutic option.

At the same time, it has demonstrated that depot formulation guaranty better adherence with respect to the oral treatment.

Premature ejaculation in Spanish men

H. Guillen Rodrigo*, S. Fuentes Márquez, R. Alonso Díaz

Hospital Juan Ramon Jimenez, Salud Mental, Huelva, Spain

* Corresponding author.

The vast majority of men experience premature ejaculation at some point in their sexual life. It is the most common sexual problem in men, affecting between 25–40% of them. This disease has both organic and psychological causes so it is important to search an organic disorder in order to dismiss the organic causes.

The following case is about a 56-year-old male, married and retired. He went to the USMC in Huelva relating a premature ejaculation problem from approximately two years ago. He relates feeling a great discomfort due to the inability to maintain a satisfactory sexual relationship with his partner.

The patient was diverted from the Department of Urology at the Juan Ramon Jimenez hospital, so we dismissed an organic or physical disorder.

He refers an intervention of a herniated disc, which made him staying in bed during a long season, as a precipitating event. After that appears a first episode of premature ejaculation, what produced him a great discomfort, presenting anticipatory anxiety symptoms to the sexual experience from then. These anticipatory anxiety symptoms were characterized by negative thoughts about the own sexual performance and the capability to satisfy the partner. After this first episode more episodes of the same type occurred, increasing the described anxiety and worsening his sexual performance. During the treatment, the basilar compression technique was practiced in addition a restructuration of the negative thoughts of the patient regarding to his sexual performance was made. Lastly, we worked together with his partner strengthening the relationship and the communication between them.

Introduction Gender dysphoria is incoherence between the sex a person feels or expresses and the biological.

Objective Revise the inclusion criteria for hormone therapy and sex reassignment surgery in gender dysphoria. Expose the multidisciplinary approach. Make differential diagnosis with other psychological disorders.

Methodology A 45 years old male patient (biological female), who was sent from Endocrinology Unit for a psychiatric evaluation before restart a hormonal treatment. Since his childhood, he has presented dissatisfaction with his sexual characteristics; he has had fantasies and dreams, in which he belonged to the other sex.

He has always chosen male activities and male stereotypes companies. He has presented preference for cross-dressing from 9 years. Always felt the sexual attraction for women. He first consulted for this reason in 1995.

Results It reported favorably to start hormone treatment after completing the eligibility criteria: > 18 years old; knowledge of the effects of hormones; and more 3 months documented real-life experience. The hormone therapy caused the growth of microprolactinoma, which was treated with dopamine agonists until it disappeared and the cessation of galactorrhoea. Testosterone treatment is restarted. Laboratory tests are done every 3 months during the first year and then, every 6 months.

Conclusions Is the gender dysphoria a pathology? The EU recommends a reclassification as no pathological disorders in ICD-11. The treatment of gender dysphoria is necessary, and there is no reason to postpone it. The main difficulty is the differential diagnosis; there may be comorbidity with others mental disorders which are not exclusive (psychotic disorder, OCD, personality disorders and other disorders of gender identity).

Primary and secondary transsexualism, really?

F. Jurysta^{1,2,*}, G. Hladki²

¹ Centres Hospitaliers Jolimont Asbl, Psychiatrie, Haine-Saint-Paul, Belgium

² ULB, Hôpital Erasme, Centre de Sexologie et des Troubles de l'Identité du Genre CESTIG, Brussels, Belgium

* Corresponding author.

Introduction Transsexualism suffers from several definitions that evolve across time. Therefore, some discrepancies appear progressively in regard of evidence-based medicine and psychological approaches as sexo-analysis.

Objectives In our present study, we test if “primary” or “secondary” transsexualism defines in accordance with sexo-analysis definitions will be reliable with the pathology course.

Aims Clarify the definition of transsexualism to obtain a better understanding of this trouble and perhaps to change psychological approaches of gender disorders.

Methods Nine transsexual male-to-female (MtF) aged between 25 to 65 were voluntary recruited. They were diagnosed by a psychiatrist. We adapted the GID scale to measure the lifetime process. Descriptive statistics were reported. Results are expressed as mean ± standard deviation.

Results Age of the group is 41 ± 12. All subjects were treated by hormone therapy. One of them was surgical reassigned. All subjects reported a persistent feeling to be a woman across their entire life. None showed a decreased female feeling during a part of their life or a brutal apparition of this trouble during the adult period.

Conclusions In regards of our preliminary results, we concluded that secondary transsexualism should be redefined and was probably induced by sociocultural aspects. Our results are limited by amount of subjects and should be confirmed by a large population included MtF and FtM people.

Sex, drugs and enhanced libido

B. Macías*, N. Serrano, M. Díaz

Hospital Dr. Rodríguez Lafora, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Twenty-eight years old male, admitted into a long-stay unit diagnosed of schizoaffective disorder, who has presented behavioural disturbances consisted in sexual disinhibition.

Case report Since the patient was 15 years old, he has presented several behavioural disturbances and erotomanic and reference delusions, which have not ended even after beginning treatment with clozapine. Nowadays treatment consists of clozapine 600 mg/day, haloperidol 20 mg/day, amisulpiride 2000 mg/day, olanzapine 30 mg/day, ciproterone 50 mg/day, valproic acid 2300 mg/day, clorazepate dipotassium 15 mg/day, lorazepam 7.5 mg/day, nevertheless the patient still presents sexual disinhibition against other patients and staff members (masturbation, exhibitionism, frotteurism, coprolalia). During treatment, he has suffered from hyperprolactinaemia, but this entity did not decrease the patient's sexual desire.

Discussion Although this patient has been treated with a wide pharmacologic strategy, it has not been effective, so it should be highlighted how a mixed approach including also psychotherapy, could be more useful in controlling the libido.

Conclusions This case is an example of variability among patients and how antipsychotic drugs and chemical castration are not always useful for decreasing enhanced sex drive.

⁷ Centro de Salud Mieres Sur, Nursing, Mieres del Camino, Spain

* Corresponding author.

Introduction The side effects of the various antidepressant drugs on the sexual field (with very few exceptions) are well known, and they affect the quality of life in important manners. The incidence rate, communicated spontaneously by the patient, has been estimated around 10–15%, and can reach amounts of 50–60% with SSRIs when studied specifically. It has been suggested that these effects compromise treatment adherence.

Objectives To estimate the incidence and intensity of the side effects on the sexual field with different antidepressants, as well as its relationship with treatment adherence.

Methodology Transversal study on 50 patients assisted in medical consultation. Collection of data in office (October 2014–October 2015).

Administration of survey PRSexDQ-SALSEX. In order to research the relationship with treatment adherence, one question surveyed the patient whether he/she had thought about finishing treatment for this reason.

Results Twenty-nine patients (58% of the sample) presented some degree of sexual dysfunction. Five individuals (17.2%) communicated it spontaneously. Nine individuals (31%) responded that they did not accept positively the changes in their sexual field, and they had thought about withdrawing treatment for this reason.

They were given the test of self-compliance statement (Haynes-Sackett), with a result of four non-compliant (44.4%). The most frequently involved drugs were fluoxetine ($n = 5$, 10% of the sample total) and paroxetine ($n = 4$, 8%).

Conclusions The high impact of sexual side effects with a low rate of spontaneous communication coincides with previous existent studies.

Limitation when estimating adhesion due to methodological difficulties in the design of the study. However, high impression by using the selected method of determination.

Paraphilic disorder in the 21st century

A.R. Caldeano*, J. Nunes, P. da Costa

Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital, ULS Guarda, Guarda, Portugal

* Corresponding author.

The term paraphilia refers to the sexual preferences and conducts that divert from what is generally accepted for a certain society in a given historic and cultural period. It demonstrates the practices that involve the use of non-human objects, mandatory humiliation and sexual suffering or non-consensual involvement of sexual partners. A paraphilic disorder is a paraphilia, which, presently, causes uneasiness and damages not only the patient but also others, as these behaviours exclude or damage the other affecting the patient's social relationships.

Paraphilias are only practiced by a small percentage of the world's population. However, the causes are only reported if there is a search for treatment or if there are any legal complications. By which is believed that the prevalence is higher than the number of diagnosed cases.

Although there are already a few paraphilia types registered, new forms of practice of this disturbance are emerging, mainly associated to the use of new technologies, as the Internet.

The authors propose to produce a bibliographic review concerning the concept of paraphilic disorders and its exhibition forms; identify therapeutic strategies; perform a time frame regarding paraphilias and analyze the influence that the new technologies have in paraphilic disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Controversy diagnosing sex addition

M. Palomo Monge^{1,*}, G.M. David¹, D.D. Arántzazu², D.C. Sandra³, T.G. María Fernanda¹, S.D.L.P. Silvia⁴, A.L. Maria Fernanda⁴, O.B. Rubén¹

¹ Hospital Nuestra Señora del Prado, Psychiatry, 45600, Spain

² Hospital General de Avila, Psychiatry, Avila, Spain

³ Centro de Rehabilitación Psicosocial y Laboral, Psychology, Talavera de la Reina, Spain

⁴ Hospital Nuestra Señora del Prado, Family Medicine, 45600, Spain

* Corresponding author.

Introduction The sexual compulsive behavior also known as sex addition is the repetitive and intense sexual behavior of the individual. Although the few studies carried out, the prevailing rates vary between the 2% and the 20%.

Objectives We present the case of a 46-year-old male with psychiatric treatment records since he was 17 and a personality disorder group B diagnosis and depressive reactions reactive to

environmental frustrations. Several short-, medium- and long-term hospitalizations. Currently he is admitted after having expressed some autolytic ideas.

Methodology The patient started a treatment in the Unit of Addictive Behaviors. He says he started to frequent the brothels 10 years ago to satisfy his sexual needs, but gradually increased the frequency. Later, he started to have sex online, also in fee-paying web pages. This has had a negative influence in the different aspects of his life, leading him to economic stress and endless debts.

Results Borderline personality disorder. 301.83 (F60.3).

Other specified disruptive, impulse-control, and conduct disorder (sex). 312.89 (F91.8).

Pathological gambling. 312.31 (F63.0).

Persistent depressive disorder. 300.4 (F34.1).

Conclusions It is clear that the compulsive sexual behavior is a disorder that includes repetitive, intrusive and distressing thoughts and leads to behaviors that affect negatively several aspects of the lives of people suffering such disorder, so that is why it is associated with other psychiatric disorders. Even though it has been described and discussed for years in literature, it is difficult to classify within psychiatric nosology and nowadays its categorization is still a challenge within the mental health.

Sexology population characterization – a two years' experience at a Lisbon specialized centre

M.I. Varregoso^{1,*}, G. Borges¹, R. Xavier²

¹ Hospital Garcia de Orta, Psychiatry, Almada, Portugal

² Hospital Santa Maria, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Within psychiatry, sexology is a very particular area of expertise both by the nature and specificity of its diagnosis, as by the various difficulties and challenges their patients place. Sexology is a sub-specialty niche, but also a vast universe that covers such diverse conditions as paraphilia, gender dysphoria or sexual dysfunction. The sexology consultation of Santa Maria Hospital (HSM) is one of the biggest centers specialized in sexual disorders in the country. Consultations depend on the collaboration of a sexologist psychiatrist and psychiatry residents in close connection with endocrinology, urology and plastic surgery services.

Objective We intend to conduct a characterization of the population observed in the HSM sexology consultation, in a period of 2 years, from the analyses of different general and diagnosis-specific relevant variables.

Methods We intent to make a descriptive analysis of the population that attended the sexology consultation over the last 2 years. The sample study refers to all patients who have been specifically referred to sexology department or that directly requested access to this consultation. Data will be collected from medical computer records.

Results Through systematic evaluation of different variables we can possibly conclude by some putative associations. A comprehensive characterization of this particular population is a possible method for a better and deeper insight on the diagnosis itself.

Conclusions The purpose of this work is to increase peers' sensitivity both to sexology and to the patients sexology serves.

Disclosure of interest The authors have not supplied their declaration of competing interest.

From hero to zero: The manifestation of addictive problematic sexual behaviour

R. Vella Baldacchino*, J. Vella Baldacchino
Mount Carmel Hospital, Psychiatry, Attard, Malta
* Corresponding author.

Introduction Addiction refers to a pattern of:

- loss of control, as shown by unsuccessful efforts to stop the behaviour;
- continuation of the behaviour despite adverse consequences – such as marriage breakdown;
- an obsession with obtaining, using or recovering from the behaviour.

To date, DSM-5 does not recognize sex addiction as a disorder, however when problematic sexual behaviours fulfil these same three criteria, the process is considered to be an addiction.

This case report describes the development of problematic addictive sexual behaviour, possibly as a result of other psychiatric comorbidities including obsessive-compulsive disorder (OCD), alvinophilia, and obsessional fetishism. The presence of the Madonna-Puttana syndrome is also explored.

Aims To use the biopsychosocial model to investigate the aetiology of addictive problematic sexual behaviour. To explore the role of psychiatric comorbidities in the expression of such behaviour. To examine the holistic impact of sexual addictions. To examine the treatment modalities of addictive problematic sexual behaviour.

Methods A 25 year old happily-married nurse who confessed to serial extramarital affairs was interviewed. Underlying psychiatric comorbidities were identified. Family members were also interviewed for a collateral history. The above objectives were explored and the response to various treatment modalities were evaluated. Literature reviews were carried out.

Conclusions This case illustrates a form of OCD which manifested as addictive problematic sexual behaviour. The message portrayed is that hope exists for such couples once various treatment modalities are put into action.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexual dysfunction as a side effect of psychopharmacology: What to do now?

A. Hugo*, J. Gomes, G. Lima
Centro Hospitalar Barreiro-Montijo, Psychiatry and Mental Health,
Barreiro, Portugal
* Corresponding author.

Introduction Sexual dysfunction is a side effect caused by many of the psychiatric drugs commonly used in clinical practice. Both antidepressants and antipsychotics have the potential to cause this side effect, which can lead to therapeutic nonadherence. Considering this problem and their adverse consequences to the patient and the treatment adherence, we can conclude that it is important to better understand this problem and the ways to deal with it.

Aims and objectives The objective of this work was to better comprehend this problem, its consequences and the ways to avoid, minimize and revert it.

Methods We reviewed the literature related to this theme through a search for papers indexed in PubMed and Science direct.
Results Both antidepressants and antipsychotics have the potential to induce sexual side effects although this potential seems to differ from drug to drug. In order to avoid or minimize this, some management options are described in literature. Nevertheless, this problem still seems to be neglected by doctors and under-reported by patients and, because there is still a lack of knowledge about which is the best management option when the problem appears, the decision about what to do when it appears is still left to the doctors.

Conclusions Sexual dysfunction caused by psychiatric drugs is a real problem, still under-reported, and affects in a hazardous way our patients lives and possibly leading to therapeutic nonadherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexuality in mental health: Brazilian science production review (2001–2014)

R. Boaes^{1,*}, M.B.B. Silva², J.A. Russi²

¹ Federal University of Rio de Janeiro, Health Sciences Centre, Rio de Janeiro, Brazil

² Rio de Janeiro State University, Institute of Social Medicine, Rio de Janeiro, Brazil

* Corresponding author.

Aiming at analyzing mental health and sexuality studies, specifically in papers published in Brazil, this dissertation brings a review of the literature carried out in two databases. It can be noticed that studies on sex, gender and sexuality show the complexity of the understanding of human sexual life going from essentialist to constructivist perspectives, conceiving sexuality in several manners. However, studies on madness, mental health and psychosocial care point to different conceptions of mental sickening process, mental health being at the same time a science field and a psychological well-being value to be achieved. Surveys in nursery homes show that institution agents represent the sexuality of a mentally suffering person (MSP) as abnormal or non-existing. The review of academic production on the subject, has put together 685 publications, 43 of them in both, with only 109 from Brazil, these ones having been systematized by title and abstract, only eleven were selected and studied thoroughly. Results show that the analyzed science production is scarce, being the theme just at its beginning in collective health, with the predominance of biomedical approaches focusing in on sexual behavior, with special attention to the vulnerability to IST/HIV/AIDS, the absence of sexual education and gaps in the training to work with sexuality. The conclusion is that the studied Brazilian science production on sexuality in the field of mental health is not centered on sexual and reproductive rights of MSP, while user sexual practices and the representations of professionals come to the fore in the analyses.

Radiotherapy and treatment of cervical cancer – sexuality implications

A. Fornelos*, P. Macedo, S. Nunes, A. Figueiredo, M. Silva, M. Viseu

Centro Hospitalar Trás-os-Montes e Alto Douro, Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction Cancer of the uterine cervix represents 10% of malignant tumors affecting women. Despite occupying fifth place in the global mortality rate it is described with the highest healing potential. One of the most used treatments is radiotherapy, which has a particularly significant impact on women's quality of life, especially in their sexuality. Biological and psychic factors are suggested as possible etiologies for sexual dysfunction situations. Changes in body image may arouse feelings of shame and low self-esteem. In what concerns biology, vaginal stenosis is referred as a cause of vaginism and vaginal bleeding, with consequent decrease in libido and pleasure.

Objective Describe the implications in the sexuality of women with cancer of the uterine cervix after radiotherapy.

Methods A literature search using the PubMed and Scielo databases of scientific articles published in the last 10 years.

Results In the literature, there are significant changes in sexual behavior in women with cervical cancer in the period after radiotherapy. A large percentage reveals sexual abstinence and an equally significant part presents sexual dysfunction caused by lack of lubrication, arousal and orgasm. Moreover, it is reported decreased libido and sexual pleasure, vaginal bleeding and vaginism. On the other hand, there is a small account of cases in which it is mentioned increase libido and pleasure.

Conclusion Despite the high probability of healing this disease, the patients' quality of life after advanced stages of radiotherapy, should be a source of concern, especially with regard to sexuality.

Premature ejaculation – how to treat?

A. Fornelos*, P. Macedo, F. Veríssimo, M. Viseu

Centro Hospitalar Trás-os-Montes e Alto Douro, Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction Premature ejaculation (PE) corresponds to “a persistent or recurring ejaculation pattern that occurs during sexual activity with a partner approximately 1 minute after vaginal penetration and before the person wishes to”. It affects 5–20% of men, having its origin in psychological factors and with important biological contribution. It is considered generalised, when not confined to certain patterns of stimulation, situations, or partners, or may be situational. It may occur soon after the onset of sexual activity (primary) or after a normal sexual functioning (acquired). Primary EP is associated with the hyposensitivity 5-HT_{2C} receptors and/or hypersensitivity 5-HT_{1A} receptors. High performance anxiety levels are related to acquired EP. Increasing this physiological knowledge has enabled significant advances in treatment.

Objective Approach the therapeutic options of EP and its peculiarities.

Methods Literature review of articles published in the last five years, using the PubMed and Scielo databases.

Results At present, the approaches include psychosexual counseling, behavioral and pharmacotherapy. Among the most

popular drugs, antidepressants stand out, particularly dapoxetine, the first medication specifically approved. Local anesthetics, phosphodiesterase-5 inhibitors and tramadol are also used. Acupuncture is suggested as a useful therapeutic, but needs more research.

Conclusion The behavioral therapies are referred to as first-line treatment in the long-term, associated or not with medication. Dapoxetine is the preferred symptomatic treatment. However, a holistic approach, including psychotherapy and sex therapy, is the most beneficial modality for sexual and marital relationship.

EV1226

Sexual function in schizophrenia

D. Lin

Napa, CA, USA

Objective This study surveys patients with schizophrenia or schizoaffective disorder, to understand the relationship between sexual function and treatment with antipsychotic medication. The study compares patients on single versus multiple antipsychotics as well differences between first and second-generation agents.

Design and methods Patients diagnosed with schizophrenia or schizoaffective disorder are eligible. Once patients are evaluated to ensure they meet enrollment criteria and are consented, they are administered the Positive and Negative Syndrome Scale (PANSS), Abnormal Involuntary Movement Scale (AIMS), and either the International Index of Erectile Function for men, or the Female Sexual Function Index for women. Inclusion criteria include age 18–65, able to participate in a structured interview, fulfill DSM-IV criteria for Schizophrenia or Schizoaffective disorder, and on stable doses of one or more antipsychotic medications for at least six weeks. Exclusion criteria include patients taking Selective Serotonin Reuptake Inhibitors (SSRIs), and inability to provide informed consent.

Results Patients taking typical antipsychotic had marginally worse score on sexual function scale. Patients taking multiple antipsychotics scored better on the sexual function scales. Those on prolactin-sparing agents tended to rate sexual function as higher. Clozapine was associated with more sexual dysfunction compared to other antipsychotics. No trend noticed between PANSS scores and sexual dysfunction. No trend noticed related to AIMS scores.

Conclusions There is high prevalence of sexual dysfunction in schizophrenic patients. Prolactin-sparing agents are associated with less sexual dysfunction. There is an advantage to the use of atypical antipsychotics.

EV1227

Sex addiction: Myth or reality

D. Lin

Napa, CA, USA

Objective Since the concept of sexual addiction was first introduced in the 1970's, two schools of thought have emerged amongst sexologists and mental health providers regarding whether hypersexual behavior should be characterized as an addiction, or if it is part of a co-existing psychiatric disorder. The objective of this study is to help clarify this debate.

Method A literature review was conducted to explore these opposing viewpoints. Articles published from the year 2000 to present relating to the topic of sex addiction, hypersexuality, sexual compulsivity/impulsivity were reviewed to determine whether or not hypersexual behavior can be characterized as an addiction or if it can only co-exist with a current psychiatric disorder.

Result The activities of sexual behavior are pleasurable due to the release of endorphins and enkephalins, and the receptors in the brain that bind these neuropeptides are the same ones that bind exogenous chemicals that produce the euphoric feelings described in addiction. Some proponents of sex addiction have even advised a 12-step treatment program because it is an addiction characterized by patterns of compulsive sexual behavior despite adverse consequences-relationship difficulties, neglect of work obligations and social/family responsibilities to pursue or participate in sexual behaviors, and excessive amounts of time seeking these opportunities.

Conclusion Despite standard and even increasing use of the term “sex addiction” in media and popular culture, mental health professionals remain divided in regards to this subject. The notion of hypersexual behavior as an addiction warrants further exploration, especially since how it is defined may dictate treatment modality.

⁴ Iran University of Medical Sciences IUMS, Faculty of Management, Tehran, Iran

* Corresponding author.

Sexual satisfaction decreases during postmenopause life and may improve by various methods of complementary therapy such as use of herbal medicine.

Aim To assess the effect of oral capsule of mixed *Tribulus Terrestris*, *Zingiber Officinale*, *Crocus Sativus* and *Cinnamomum Verum* on postmenopausal women’s sexual satisfaction.

Methods In this triple blind randomized control clinical trial, 80 healthy volunteer postmenopause women with age 50–60 years old in one of clinics of west of Tehran had been involved (year 2013–2014). Participants were randomly assigned to intervention and placebo group and received one month same shape capsules two times in a day. Tools of this study had two main parts of personal characteristics and sexual satisfaction. All ethical points were considered and approved by Ethics committee of Research Institute for Islamic & Complementary Medicine (RICM, IUMS).

Results After a month intervention, there is significant increase in the mean score of sexual satisfaction between two groups ($P=0.01$), but when sexual satisfaction compared with pre-menopausal time in two groups, t -test results showed no significant difference ($P=0.16$).

Conclusions Use of oral capsule of mixed *Tribulus Terrestris*, *Zingiber Officinale*, *Crocus Sativus* and *Cinnamomum Verum* two times a day for a month could improve sexual satisfaction in postmenopausal women. Referring to no significant change with comparing premenopause time, it sounds they have same satisfaction as premenopause time. There were no side effects during study and one month follow-up. It is suggested to do same

research on sexual satisfaction and function with more month intervention.

About an exhibitionism clinical case: Entity’s review and state of the art exposure

M.I. Varregoso^{1,*}, S. Coelho¹, G. Borges¹, R. Xavier²

¹ Hospital Garcia de Orta, Psychiatry, Almada, Portugal

² Hospital Santa Maria, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Exhibitionistic disorder may be present when there is sexual arousal from the exposure of one’s genitals to an unsuspecting and nonconsenting person. This disorder prevalence is unknown but we know it is highly unusual in females. It generally starts at adolescence and its course is likely to vary with age. There are temperamental and environmental risk factors.

Most of what we know about exhibitionistic disorder is largely based on research with individuals convicted for criminal acts involving genital exposure, and this may represent an important bias. From a clinical case of exhibitionism, the authors intend to review this type of paraphilia from an historical, conceptual and etiologic point of view.

Objective To review the concept behind this diagnosis and its evolution, the comprehensive theories that attempt to justify and frame it, as well as the type of intervention currently considered to be the state of the art.

Methods Patient’s observation and assessment, along with an extensive review of the relevant literature.

Conclusions Starting from a real clinical case, the authors present a general theoretical review on the subject.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emerging treatments options for narcolepsy throughout a case

A. Alvarez Astorga*, L. Gallardo Borge, H. de la Red Gallego, A. Alonso Sánchez, S. Gómez Sánchez, C. Noval Canga, E. Mayor Toranzo, S. Cepedello Pérez, L. Rodriguez Andrés, T. Ballesta Casanova

HCU Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Background Narcolepsy is a neurological disorder characterized by disturbances in REM sleep. The symptoms that the patient could present are excessive daytime sleepiness, cataplexy, sleep paralysis, hypnagogic hallucinations and disrupted nocturnal sleep. Its etiology is unknown. Currently, there is established pharmacotherapy for symptomatic treatment, which are often unsatisfactory.

Objective Review of new treatments for narcolepsy based on recent advances about its ethiopathogenesis.

Method Seventy-five year-old female with a personal history of arterial hypertension and obstructive sleep apnea syndrome. The patient presented several episodes of abrupt muscular weakness, nightmares, sleep paralysis and excessive daytime sleepiness.

Diagnosed of narcolepsy and treated with methylphenidate immediate-release (IR) 10 mg, alprazolam 1 mg, and trazodone 100 mg with good response.

Results Due to persistent symptoms, treatment was modified to osmotic-release oral system (OROS) – methylphenidate resulting on a substantial weight loss (12 kg) and persistence of symptoms. Another methylphenidate preparations were unsuccessfully tested. Currently she continues treatment based on methylphenidate release-release and she improved significantly though she sometimes presented daytime sleepiness.

Discussion Recent studies have shown that a loss of the hypothalamic neuropeptide hypocretin causes Narcolepsy with cataplexy and that an autoimmune mechanism may be responsible for this loss (related to HLA DQB*0602). Pathophysiology of narcolepsy without cataplexy is less understood.

Although amphetamines and its derivatives are the mainstay of management, therapies that involve hypocretine seems to be hopeful (intranasal, peripheral or hypocretin cell transplantation). Monotherapy with GHB, H3 antagonist receptors, TRH analogs and immunotherapy are also being studied.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sleep quality among medical students

I. Gassara*, R. Ennaoui, N. Halwani, M. Turki, J. Aloulou, O. Amami

Hédi Chaker Hospital, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction College students seem to be a population group that is increasingly recognized to be at risk of having sleep difficulties. Some studies revealed that medical students, in particular, are believed to be more stressed and sleep deprived than their non-medical peers.

Aim The present work aimed at investigating the quality of sleep among medical students at the University College of Medicine in Sfax, Tunisia.

Methods The study consisted of an anonymous, voluntary survey for a sample of 74 students. A two-part questionnaire was used, including demographic criteria and the Pittsburgh Sleep Quality Index (PSQI), a self-rated instrument that measures sleep habits for a month (a total score of 5 or greater is indicative of poor sleep quality).

Results The average age was 24 years (range 19–33) with a sex ratio almost equal to 1. In 47.3% of cases, students were married. These latter had at least one child in 34.2% of cases. A total of 39.4% of the students reported being smokers, while 25.6% of them admitted having regular alcohol consumption.

Poor sleep quality was reported by 63.5% of students with a PSQI average score of 9.32 ± 3.64 .

The most correlated factors with poor sleep quality were parenthood ($P=0.031$), alcohol consumption ($P=0.004$) and stressful studies ($P=0.02$).

Conclusion Poor sleep quality was pervasive among surveyed medical students and this seemed to be in relationship with some factors. This study points to the need for further evaluation of medical students' sleep problems in order to improve their performance and their quality of life as well.

How much does depressive mood affect sleep for high school students?

S. Kim*, J. Park, H. Kim, T.K. Kim, Y. Min, J. Kim, J. Lee, J. Yang
Korea International High School KIS, Jeju, Bioscience research,
Seogwipo-si-Je-ju do, Republic of Korea

* Corresponding author.

Background This research examined gender variations in depressive mood for high school students affected by emotional upset and how such depressive mood affect their sleep quality.

Methods Research was conducted from September 2015 to October 2015. Both males and females were divided into normal group and depressive group by Zung Self-rating Depression Scale (ZSDS). Each group adopted the Pittsburgh Sleep Quality Index (PSQI) to measure sleep quality.

Results Analysis was made on a total of 155 students, which were 83 male students and 72 female. The average ZSDS for all high school students was 43.38 and the average PSQI was 5.39. The number of male students in the normal and depressive group who were diagnosed with sleep disorder were 2 (3.8%) and 9 (29.0%), respectively ($P<0.05$). But the number of female students in the normal and depressive group who were diagnosed with sleep disorder were 11 (32.4%) and 33 (86.8%), respectively ($P<0.05$). Both males and females shared a meaningful result over sleep latency, sleep disturbance, use of sleep medication, and daytime functional disturbance among 7 items of PSQI for sleep quality, and female students had a significantly meaningful result over sleep duration, habitual sleep effects ($P<0.05$).

Conclusion This research showed that sleep quality of all high school students was not too bad but it can be problematic for those with depressive mood. Especially, female students were diagnosed with sleep disorder more than male students.

Studying the dreaming content in the patients with methadone maintenance therapy who were admitted to the drug rehabilitation centers in the city of Kerman in 2014

A. Mehdizadeh Zare Anari*, A. Ghaffari Nejad, A. Sabahi, D. Rashid Farokhi

Kerman university of medical sciences, Psychiatry, Kerman, Iran

* Corresponding author.

Introduction Drug addiction and relapse are a social destructive phenomenon. The identification of factors associated with relapse can help predict the relapse in the addicts. One of the important factors for the people's psychological dynamics analysis is the study of dreams.

Methods and materials This scientific-comparative study is cross-sectional. Among the addicts with methadone maintenance therapy and their relatives who have referred to the private addiction treatment centers and Shahid Beheshti Hospital in Kerman, in 2014, a random sample of 110 patients (55 patients treated with Methadone and 55 in control group) was selected and they answered to the Hall/Van de Castle test and questionnaire of demographic characteristics. Data analysis was performed by SPSS18 software.

Findings The patients with methadone maintenance therapy reported more non-verbal activities related to drug abuse and its related activities than the control group in their dreams ($P=0/001$). Patients with methadone maintenance therapy saw more unknown places in their dreams ($P=0/001$).

The patients without the relapse history saw the content of greater success in their dreams ($P=0/02$). The group with a history of relapse reported more non-verbal activity content including the drug abuse and its related activities in their dreams ($P=0/003$) and reported more drug-related recreational facilities such as Vafoor (a pipe for opium smoking) in their dreams ($P=0/03$).

Conclusion Our study showed that the frequency of non-verbal activities that is associated with the drug abuse and related issues reports a warning to relapse the drug abuse.

EV1234

Comparative effects of ziprasidone and quetiapine on sleep physiology measures in patients with major depressive disorder

A. Miljatovic

Clinical Hospital Center "Zvezdara", Psychiatric hospital, Belgrade, Serbia

Background Sleep complaints are reported in a large percentage of patients with major depressive disorder (MDD). While subjective complaints of insomnia (problems falling asleep, frequent awakenings during the night, early morning awakening or nonrestorative sleep) represent the most common form of sleep disorder, a subset of depressed patients report hypersomnia, typically associated with anergy, lethargy and fatigue. Quetiapine is an atypical antipsychotic approved for the treatment of schizophrenia, bipolar disorder and along with an antidepressant to treat major depressive disorder. Ziprasidone was the fifth atypical antipsychotic to gain approval (February 2001) in the United States.

Method Patients ($n=35$) received initial baseline polysomnography evaluations over 2 consecutive nights. Subjects were randomly assigned to either quetiapine (50–100 mg/day) or ziprasidone (60–100 mg/day) treatment. For an 8 week double-blind, double-dummy treatment trial.

Enrolled patients were required to meet the following criteria: 19–67 years of age with a DSM-IV diagnosis of MDD based on a semistructured clinical interview, a score of ≥ 18 on the 21 item Hamilton Rating scale for depression, and a score of >4 on the 3-HAM-D sleep items. Single-night polysomnograms were conducted at weeks 1, 2, and 8 with depression ratings assessed at baseline and weeks 1, 2, 3, 4, 6 and 8.

Conclusion In particular, the prominent effects of quetiapine in shortening sleep latency and increasing total sleep time suggest that this medicament compound may be of particular benefit in the treatment of depression associated with prominent insomnia. The present findings demonstrating beneficial effects of quetiapine on sleep physiology parameters in MDD patients with insomnia. . .

Recurrent hypersomnia: Kleine-Levin syndrome

L. Rodríguez Andrés*, A. Rodríguez Campos, L. Gallardo Borge, G. Isidro García, E. Mayor Toranzo

Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction Kleine-Levin syndrome was first described by Kleine in 1925 and elaborated on by Levi in 1936. It is an infrequent

syndrome that predominantly affects teenagers, and boys are four times more likely to be affected than girls. It is rare for patients over 30 years although some cases have been reported. Kleine-Levin syndrome is a recurrent hypersomnia characterized by episodes of hypersomnia lasting for 2 days to 4 weeks associated with symptoms of hyperphagia, hypersexuality and cognitive impairment. It can be accompanied by other abnormal behavior such as aggression, personality changes and irritability. Deficits are resolved between episodes.

Case report It is presented the case report of a patient that suffers from recurrent episodes of hypersomnia associated with hyperphagia and abnormal behavior.

Electroencephalography EEG demonstrates slowing of drowsiness and a decrease in REM sleep. The test of multiple sleep latency is abnormal and the rest of complementary test are normal.

Diagnosis F51.1 Recurrent hypersomnia (Kleine-Levin syndrome) [307.44].

Discussion Kleine-Levin syndrome is an intriguing, severe and homogenous disease with no obvious cause or treatment. Treatment is generally supportive. It should be considered in any teenager presenting with recurrent episodes of hypersomnia concurrent with cognitive changes or disinhibition.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1236

The relation between sleep quality and mental health in students of Kashan University of Medical Sciences

Z. Sepehrmanesh

Kashan University of Medical Sciences, Kashan, Iran

Introduction Sleep is one of the most essential biological cycles, which have complex pattern. Sleep disorders have adverse effect on social performance and mental health. Prevalence of sleep disorders is increasing specially in young adult. Some groups like University students have more sleep disorders. This study investigates relation between mental health and sleep quality in the students.

Methods This case-control study was conducted on dormitory students of Kashan University of Medical Science from 2013 to 2014. Two hundred students were selected by randomized sampling that included 100 cases (50%) with sleep disorder and 100 cases without sleep disorder. Three questionnaires were used, include: demographic variables, Pittsburgh and GHQ questionnaires.

Results The mean age of students with sleep disorder and without sleep disorder was 22.61 and 22.35, respectively, which have not significant difference. There was a significant relation between general mental health, physical symptoms, anxiety and depression scales with sleep quality ($P<0.01$). GHQ score was 31.52 in cases with sleep disorder and 18.49 in cases without sleep disorder. Thirty-five percent of students with sleep disorder and 7% of students without sleep disorder had suicidal thoughts. Suicidal attempt ideas were 32% and 7% in people with sleep disorder and without sleep disorder, respectively. There was significance relation between sleep disorder and suicidal thought and attempt (P value <0.001).

Conclusion Sleep quality have important role on different aspects of mental health. Attention to improve sleep quality of dormitory students is necessary for better mental health. Education about sleep hygiene have essential role to improve mental health for University students in dormitories.

Background In the last few years, there has been a growing attention to sleep and related disorders. Numerous studies conducted within the past decade have analyzed the deleterious effects of sleep deprivation on medical students and medical staff in various specialties, but only few studies have been conducted in the Middle East.

Aim of the study This study intends to explore the quality of sleep in different academic classes of medical undergraduate students of two Egyptian Universities.

Subject and methods This is a cross-sectional, questionnaire based, observational study carried out during the period of April to June, 2015 among 1182 undergraduate medical students enrolled at Assiut and Mansoura Universities, Egypt.

The data were gathered using socio-demographic questionnaire and Pittsburgh Sleep Quality Index (PSQI) and were analyzed using SPSS software.

Results Mean PSQI score was 6.01 (SD = 2.73), according to PSQI interpretation 46.7% of subjects had good sleep quality and 53.3% had poor sleep quality. Poor sleep quality was mostly prevalent among early years of medical education, caffeine consumers, cigarette smokers, students with fair academic achievement, those with fairly bad and very bad subjective sleep quality, sleep latency above 30 minutes, sleep duration less than 7 hours, fairly bad and very bad daytime functioning, those taking sleep medications, those with sleep disturbance, and sleep efficiency below 85%.

Conclusion Poor sleep quality is highly prevalent in the medical students in Egypt.

Depression and suicide ideation in medical students

A. Alonso Sanchez, A. Alvarez Astorga, H. De la Red Gallego*, R. Hernandez Antón, S. Gómez Sanchez, C. Noval Canga, I. Sevillano Benitez, G. Isidro García, M. Hernandez García, F. De Uribe Ladrón de Cegama

HCU Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Background Medical students have higher levels of depressive symptoms than the general population. Additionally, depressed students are more likely to commit suicide. Recent studies find up to 10% of medical students experience depression and suicidal

ideation, which is meaningfully higher than general population of similar age (5–8%). However, little is known about depression and suicidal ideation in medical students in Spain.

Objective This study aims to create a self-administered questionnaire to investigate the prevalence and factors involved in depression and suicidal behaviour in medical students from a Spanish University.

Methods We evaluated the main risk factors leading to suicide in students. In addition, we selected an appropriate scale to assess depression among the existing ones. The evaluated items included demographic reports, academic information (academic course, unfinished subjects and accomplishment) and sanitary data (psychiatric family history, psychiatric personal history, psychotropic drug consumption, distress emotional events in the last twelve months and drugs consumption). Furthermore, we selected the 9-item Patient Health Questionnaire (PHQ-9) because of its rapid implementation and proven efficacy.

Conclusions Rates of depression and suicidal ideation are high in medical students. Currently, there is no program to detect and prevent depression neither suicide in students. For that reason, we consider that creating a new instrument to evaluate mental health in student is useful in order to offer early detection and treatment at medical school.

* Corresponding author.

Objective The objective of the study is the analysis and the description of patients who committed autolitic acts and were attended in a mental health hospital unit in 2014.

Method We analyze the patient registry for the attended emergencies in our mental health hospital unit, extracting the following variables: gender distribution, age range, type of method applied in the attempt and diagnosis based on DSM-IV TR.

Results The study reveals a larger share of autolitic acts in the feminine population between 14 and 69 years old. A total of 31 patients needed to be attended in an emergency hospital unit (11.74%). The most common method is the medical substance abuse (23 patients, 74.19% from the admitted patients in our Mental Health Hospitalary Unit). The diagnoses in order of frequency were: affective disorders (13 patients, 41.93%), personality disorders (8 patients, 25.80%), adaptive disorders (7 patients, 22.58%) and psychotic disorders (3 patients, 9.68%).

Conclusion Our population-based sample confirms the epidemiologic data found in the consulted literature as well as in other population groups.

* Corresponding author.

Facial expression is an independent and objective marker of affect. Basic emotions (fear, sadness, joy, anger, disgust and surprise) have been shown to be universal across human cultures. Techniques such as the Facial Action Coding System can capture emotion with good reliability. Such techniques visually process the changes in different assemblies of facial muscles that produce the facial expression of affect.

Recent groundbreaking advances in computing and facial expression analysis software now allow real-time and objective measurement of emotional states. In particular, a recently developed software package and equipment, the Imotion Attention Tool™, allows capturing information on discreet emotional states based on facial expressions while a subject is participating in a behavioural task.

Extending preliminary work by further experimentation and analysis, the present findings suggests a link between facial affect data to already established peripheral arousal measures such as event related potentials (ERP), heart rate variability (HRV) and galvanic skin response (GSR) using disruptively innovative, noninvasive and clinically applicable technology in patients reporting suicidal ideation and intent compared to controls. Our results hold promise for the establishment of a computerized diagnostic battery that can be utilized by clinicians to improve the evaluation of suicide risk.

Introduction Scientific research indicates that accessibility of suicide means has a significant influence on the choice of method. Since the choice of suicide method largely depends on availability of suicide means, the lethality of method at hand plays a crucial role in a period of suicidal crisis.

Aims We aimed to reveal the associations between accessibility and availability of medications and toxic substances and suicidal behavior of teenage girls in Armenia.

Objective Our objectives were to determine whether accessibility and availability of medications and toxic substances have any impact on development of suicidal behavior among teenage girls in Armenia and whether toxicity and quantity of medications and toxic substances at hand or purchased by attempters are associated with severity of outcome.

Methods A qualitative analysis of patient histories of 26 teenage girls, hospitalized in the ICU, Toxicology Center "Muratsan", Yerevan, RA, diagnosed as having acute deliberate self-poisoning was performed.

Results In majority of cases, conflict situation preceded suicidal behavior and decision on attempting suicide was impulsive. Being emotionally distressed teenage girls reached for medications and toxic substances readily available in the household or bought medications from a pharmacy.

Conclusion The vast majority of teenage girls attempted suicide by medications and toxic substances at hand. Admittedly, both, type of medication and quantity of pills or amount of toxic substances utilized, affected the severity of outcome. Hence, the availability and accessibility of medications and toxic substances played a crucial role in development of suicidal behavior and severity of outcome.

Mental health and suicidal risk in lesbian, gay and bisexual population

P. Azevedo*, J. Vitória, A. Norton

Magalhães Lemos Hospital, Inpatient Unit C, Porto, Portugal

* Corresponding author.

Introduction Nowadays, the lesbian, gay and bisexual (LGB) community still suffers from prejudice and social stigma, including from medical professionals.

Thus, it is urgent to draw attention to this population since these individuals have an increased risk of mental disorders, substance abuse and dependence, suicidal ideation and suicide attempt or complete suicide.

Aims To underline the prevalence of mental disorders and increased suicide risk in the LGB population.

Objectives To summarize the latest literature about this field.

Methods A brief review of the latest literature was performed on PubMed using the keywords "mental health", "suicidal risk", "LGB population".

Results LGB individuals appear to be at increased risk of mental disorders and suicidal behavior than heterosexuals. According to Meyer, they are exposed to what is called the minority stress: proximal, depending on the subject and related to fear of rejection and internalized homophobia and distal, regardless of the individual including prejudice, social stress, social exclusion (including their own families) and violence.

The odds of attempting suicide are approximately 2 to 7 times higher for lesbians, gay men and bisexuals (LGBs) than for heterosexuals.

Conclusions Minority stress related to prejudice and stigma against LGB people has a significant risk that can be related to suicide ideation and attempt.

The higher rate of many psychiatric conditions noted in this community underscores the need for clinicians to provide nonjudgmental care and approachable environment.

EV1243

Relationship of suicide ideation with depression and hopelessness

R. Alsalmán*, B. Alansari

Kuwait University, Department of Psychology, Kuwait, Kuwait

* Corresponding author.

Introduction The association between suicide ideation, depression, and hopelessness is relatively ignored in the literature of the Arab World, particularly using suicide ideation, Beck Depression, and hopelessness inventories.

Objective The specific research questions related to this model are as follows: does the relationship between suicide ideation, depression, and hopelessness, postulate the latent factor?

Methods The participants were 200 girls, first year Kuwait University students. The mean age (18.18 ± 0.38) and BMI (23.50 ± 4.85). The Arabic versions of the Beck Scale for Suicide Ideation (BSI), Beck Depression Inventory-II (BDI-II), the Beck Hopelessness Scale (BHS), and demographic surveys were administered to participants in the class. All participants read and signed a consent form before test administration. The correlation matrices, exploratory factor analysis, and reliability analysis are used in this study.

Results Internal consistency of scores were satisfactory for the BSI, BDI-II, & BHS inventories respectively (Cronbach's alpha = .91, .89, .85). A correlation of ($r = .53$) between the BSI and BDI-II and ($r = .43$) with BHS. Meanwhile, a correlation of ($r = .58$) between BDI-II & BHS. A principal-axis factor analysis with oblique rotation suggested one factor accounting for 67.73% of the common variance.

Conclusion This trend indicates there is a strong relationship of suicide ideation with depression and hopelessness. The results of the present study suggest that targeting depression may be as important in adolescents as in adults to reduce suicidal ideation and prevent suicidal attempts.

EV1244

Gender differences in suicide ideation among college students in Kuwait

R. Alsalmán

Kuwait University, Department of Psychology, Kuwait, Kuwait

Introduction The Beck Scale for Suicide ideation (BSS) has consistently been regarded as a strong tool for measuring cognitive and somatic aspects of suicide ideation symptomatology in both clinical and non-clinical population. There is no study until this date that examines the BSS within Kuwaiti College students.

Objective The present study aims at identifying impact of gender (male/female) on suicide ideation.

Methods The sample was consisted of (584) undergraduates students (284 of males and 300 females). The study applies Beck Scale for Suicide ideation (BSS) and suicide Ideation Questionnaire (SIQ). **Results** Table 1 descriptive statistics for two standardized self-report measures means and standard deviations for these measures were within the expected ranges for college samples. The mean (BSS) score was 5.2 for males and 7.0 for females. The mean (SIQ) score was 11.3 for males and 13.7 for females.

Conclusion BSS revealed significant gender differences in score indicated that females obtained higher scores than males on suicide Ideation although the magnitude of the difference was small.

Table not available.

EV1245

The influence of the Foehn wind (Halny) on the occurrence of suicide in the Tatra Mountains, 1999–2014I. Koszewska¹, E. Walawender², A. Baran^{3,*}, J. Zieliński⁴, Z. Ustrnul⁵¹ Cumulus Foundation, Cumulus Foundation, Warsaw, Poland² Jagiellonian University, Department of Climatology, Cracow, Poland³ Mid-Sweden Network of Suicide Prevention, Mid-Sweden Network of Suicide Prevention, Nyköping, Sweden⁴ Medical University of Warsaw, Department of Biophysics and Human Physiology, Warsaw, Poland⁵ Institute of Meteorology and Water Management, Institute of Meteorology and Water Management, Cracow, Poland

* Corresponding author.

Introduction In the dawn of increasing interest in climate changes, including extreme weather events, e.g. the Foehn winds, and their influence on public health, it is of great importance to understand their role in suicide.

Objectives The association between suicides in the Tatra Mountains, Poland from 1999 to 2014 and the Foehn wind (called Halny in this region) was examined. The belief that suicides are affected by Halny seems to be firmly rooted in local language and culture.

Aims The purpose of the study was to assess the Halny wind as a suicide risk factor.

Method Data concerning all suicides in the region were included. Meteorological data were derived every three hours during the period of the study. Halny was defined as a complex of interacting meteorological conditions. The two days preceding and following the wind were recognized as the period of the Foehn influence (FI). The probability of suicide in the presence of Halny and during the FI period was calculated.

Results From 1st January 1999 to 31 December 2014 (5844 days), 210 consecutive suicides were registered. The number of suicides in men was markedly higher than in women. Halny did not change the overall probability of suicide. However, the presence of Halny modified the suicide risk according to the season ($P = 0.00095$, two-way ANOVA test). The FI periods appeared to increase suicide risk in summer and autumn.

Conclusion Halny may contribute to the increased suicide risk in summer and autumn. It should be taken into account in suicide preventive interventions in this region.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction According to Durkheim's theory, suicide attempts increase during periods of rapid economic changes and decrease again when stability is achieved, due to the social integration in the community guaranteed by occupational status. Since 2009 in Europe, it was observed an increase in the suicide rates, in line

with the increase of unemployment. Although unemployment is considered a risk factor for suicide, it was observed a noticeable increase in suicide rates among Italian employed men during the last years, probably related to the specific economic scenario and to emerging difficulties in keeping an income to adequately maintain one's own family standard of living.

Aim To study attempted suicides with a specific focus and attention on the current Italian economic scenario.

Methods Determinants of emergency room visits for psychiatric reasons in patients aged > 16 years were studied prospectively from 2008 to 2015 at the AOU Maggiore della Carità Hospital, Novara, Italy. Each patient was assessed by an experienced psychiatrist with a clinical interview and socio-demographic and clinical features were gathered. Statistical significance was set at $P \leq 0.05$.

Results Preliminary results suggest an increase in suicide attempts according to the rise of the unemployment rate in Novara. Although in absolute figures most attempters are unemployed, it seems that suicide attempts are more frequent in the group of employed subjects, which includes also people under redundancy fund. This subgroup may be considered halfway between employed and unemployed attempters.

Conclusions Data collection and statistical analyses are still ongoing. Implications for clinical practice will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Università del Molise, Medicine and Health Science, Campobasso, Italy

* Corresponding author.

Background Mental disorders are considered a risk factor for suicide: for example, the lifetime risk of suicide is estimated to be 4%–8% in people with mood disorders. The literature suggests that a history of suicide attempts is significantly related to electrodermal hyporeactivity and that patients with violent suicide attempters exhibit faster habituation of the electrodermal response to repeated neutral tones than patients with non-violent attempts. The impact of depressive symptoms on suicidal ideation may be moderated by resilience. Resilience refers to the ability to maintain or regain mental health despite experiencing adversity. In bipolar and depressive disorders, resilience may influence severity of episodes, frequency of relapse and response to treatment.

Aim The objective of our study was to assess the possible correlation among attempted suicide, resilience and dermal reactivity in a sample of depressed patients.

Methods We recruited patients with depressive disorders and bipolar depression; data about socio-demographic, clinical features, severity of attempted suicide and suicidal risk were gathered. Patients filled in the Resilience Scale for Adult (RSA). Moreover, for each patient we performed the Edor test in order to assess dermal reactivity.

Results Data collection is still ongoing. We expect to find lower levels of resilience in those patients who are hyporeactive and attempted suicide. Moreover, we hypothesize that suicide attempts

in the group of hyporeactive patients would be characterized by planning and greater severity. Clinical implications will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1248

How does someone who weighs so little feel like a burden to everyone?

F. Coutinho*, I. Brandão, E. Pereira

Centro Hospitalar de São João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction Anorexia nervosa (AN) is one of the most lethal psychiatric disorders, which is explained partially by starvation related health problems, but also because of high suicide rates. One of the proposed theories to explain a suicide attempt is the interpersonal theory of suicide (IPTS), with its three essential variables: feelings of thwarted belongingness, perceived burdensomeness and the acquired capacity for suicide.

Objective To review the literature about suicidality in AN and to present a case report of a patient with restrictive AN who has committed suicide.

Methods To review of the literature using the database Medline, through PubMed, with the keywords “anorexia nervosa”, “eating disorders” and “suicide”.

Results Suicide attempts and completed suicide are highly prevalent among patients with AN, and some authors suggest that 20–40% of deaths in AN are due to suicide. Recently, the IPTS has been proposed as a mean to explain increased suicidality in AN patients.

Conclusion We present a case report about a patient with a long standing AN who has committed suicide after leaving a goodbye note describing strong feelings of perceived burdensomeness directed to her family. It is of utmost importance to continue the study about the phenomenon of suicide in AN to be able to prevent this tragic outcome.

Psychiatric consultations in the emergency room: Focus on suicide attempters with and without longitudinal psychiatric disorders

C. Delicato*, S. Di Marco, E. Gattoni, I. Coppola, A. Venesia, D. Marangon, G. Avanzi, L.M. Castello, C. Gramaglia, P. Zeppego

Università degli Studi del Piemonte Orientale “A. Avogadro”, Translational Medicine, Novara, Italy

* Corresponding author.

Introduction The role of mental illness in the pathway leading to suicide is widely discussed in the literature. Nonetheless, the debate about this issue is open, both from a clinical and philosophical point of view.

Aims The purpose of the present study was to compare suicide attempters with and without a history of psychiatric disorder, in order to highlight the possible differences between the two groups, with a specific focus on intent to die and methods of the attempt.

Methods Data from all ER referrals undergoing a psychiatric consultation in the period 2008–2015 at the Maggiore della Carità Hospital, Novara, Italy, were gathered. Comparison of qualitative

data was performed by means of the Chi² test. Statistical significance was set at $P \leq 0.05$.

Results We have already gathered data from more than 2000 ER psychiatric consultations, including 495 suicide attempters. Preliminary results suggest that these kinds of behaviours are more common in subjects without psychiatric disorders but with clinical history of previous contact with mental health services and in psychopharmacological therapy. Reasons for self-harming are associated with relational problems rather than psychiatric symptoms. Among Axis II diagnoses, almost half of cases are affected by histrionic personality disorder.

Conclusions The results described above should be considered as preliminary, as data collection and statistical analyses are still ongoing. Anyway, the observed correlation between previous contact with mental health services, socio-relational issues and suicide attempt, and the significant frequency of attempts in histrionic personality disorders seem to be particularly interesting. Implications will be discussed.

³ SC Medicina d'Urgenza, UPO, Università degli Studi del Piemonte Orientale, Dipartimento di Medicina Clinica e Sperimentale, Novara, Italy

* Corresponding author.

Introduction The effects of psychotropic drugs and alcohol acute intoxication are important risk factors for attempted suicide among individuals with and without substance use disorder (SUD).

Aims The first aim of this study is describing the socio-demographic features and clinical history of subjects who were acutely intoxicated when attempting suicide. The second aim is to compare their features with those of subjects without acute alcohol and substances intoxication at suicide attempt time.

Methods Determinants of ER psychiatric consultations were studied prospectively during the period 2008–2014 at the “Maggiore della Carità” Hospital in Novara, Italy. For each patient, a data sheet was filled in by experienced psychiatrists, in order to gather demographic features, psychiatric history and present clinical issues like blood and urine dosage of amphetamine and methamphetamine, cannabinoid, cocaine and alcohol. Comparison of qualitative data was performed by means of the Chi² test. Statistical significance was set at $P \leq 0.05$.

Results We collected a sample of 495 suicide attempters who referred to our ER. Statistical analysis of demographic and clinical data is still ongoing.

Conclusions Preliminary results point out that acute alcohol and drugs intoxication at suicide attempt time is much more frequent in subjects without a SUD. Implications will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1251

Suicide attempt in alcohol use disorder and Wernicke encephalopathy: A case report

L. Espinosa*, A. Fortea, G. Oriolo, M. Balcels, C. Oliveras
Hospital Clinic, Psychiatry, Barcelona, Spain

* Corresponding author.

Background The relation between alcohol dependence and suicidal behavior is well known and alcohol consumption is a risk factor to take in consideration in order to prevent suicidal attempts. Wernicke encephalopathy (WE) is a common acute neurological disorder caused by thiamine deficiency frequently associated with alcohol use disorder and often infra-diagnosed. Just few cases are reported about the possible correlation between suicidal behaviour and Wernicke encephalopathy.

Objective To describe the possible association between suicidal attempts and Wernicke encephalopathy.

Methods We report the case of a 57 year old man, with past diagnosis of dysthymia and amphetamine abuse disorder, and a history of bariatric surgery, who was hospitalized in the intensive care unit (ICU) of hospital clinic for a suicidal attempt by mean of metro railway precipitation. He presented two episodes of psychomotor agitation in the context of an abstinence syndrome that reverted with midazolam continuous perfusion and clonazepam 8 mg per day. Consequently to medical improvement, he was moved to Psychiatry Unit of Addictive Behavior and finally diagnosed with alcohol use disorder.

Results In the physical exam, bilateral nystagmus and cerebellar ataxia were observed. Signs of malnutrition were detected in the blood analysis. In a brain magnetic resonance image, volume deficits in the mammillary bodies, thalamus, cortex and corpus callosum, as well as peri-aqueductal altered signal were observed, all signs compatible with Wernicke encephalopathy diagnoses.

Conclusions Wernicke encephalopathy is a frequent concomitant condition in patients with alcohol use disorder. The consequent cognitive decline could represent an independent added risk factor for suicidal behavior.

EV1252

Forecasting of suicides rate in Russia using time series analysis

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction Mortality forecasting has gained in importance in recent decades. Time series methods are commonly used for long-term mortality forecasting since these methods have the advantage of being stochastic. The difficulty of suicides forecasting is related to the fact that suicide is influenced by a large number of factors, which can be hardly predicted for the long-term future.

Objectives This paper tests the possibility of forecasting the suicides rate in Russia using the analysis of time series data from 1956 to 2010.

Methods Time series analytical modeling techniques autoregressive integrated moving average (ARIMA) were used to forecast the suicides rate in Russia. The data on age-adjusted sex-specific suicides mortality rates per 1,000,000 of the population are taken from the Russian State Statistical Committee (Rosstat).

Results The two time series were well accounted for by a first-order differencing procedure and the specification of a first-order moving average parameter. The results suggest a declining trend in suicides mortality for both sexes.

Conclusions This study is the first attempt to forecast suicides rate in Russia. This study highlighted the limitations associated with forecasting of suicides using extrapolation of time series. Adoption of new anti-alcohol initiatives in 2006 appeared as an intervention which effected the trends in suicides mortality. This suggests that different kinds of social interventions hamper reliable forecasting of suicides rate.

⁵ Camden and Islington NHS Foundation Trust, Psychiatry, London, United Kingdom

⁶ Manchester Metropolitan University, Mental Health, Manchester, United Kingdom

* Corresponding author.

Introduction It has been estimated that the global burden of suicide is a million deaths per year (WHO, 2014). Rates of self-harm in British South Asian (BSA) women are higher compared to their white counterparts. Limited evidence is available on effective preventative strategies and culturally sensitive interventions for these patients.

Objective To understand common perceptions about self-harm, identify any barriers to accessing services and service improvement recommendations including appropriate interventions for BSA women.

Aim To examine the views of health professionals on the culturally adapted problem solving therapy (C-MAP) in BSA women.

Methods The design was a qualitative study using focus group discussion. This is part of a larger exploratory trial, to test a culturally adapted problem solving therapy (C-MAP) in British South Asian women who have a history of self-harm (Husain et al., 2011). Three focus groups were held with Asian lay members of the community, health professionals and service users. The data was analysed using a manual content analysis and indexing technique.

Results Results showed lack of identification of self-harm by health professionals. Common self-harm methods reported were serious overdoses, use of household chemicals, burning and cutting. Lack of trust in GPs was one common reason for non-disclosure of self-harm behaviour. Need for increased awareness, working along with local Imams, better cultural sensitivity among health professionals and non-judgmental support were some solutions offered to address these barriers.

Conclusion The results of this study have provided insight into developing strategies to prevent and manage self-harm in British South Asian women.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1254

Suicide risk assessment and early recognition of risk factors

V. Fricchione Parise*, L. Addeo, G. Balletta

Mental Health Centre Avellino, ASL Avellino, Avellino, Italy

* Corresponding author.

Suicide is a common cause of death in people with mental health problems. No specific patient stereotype nor single risk factor can be used to easily identify which person or patient will attempt suicide. Mental health professionals often have to assess or manage suicide risk and this is challenging by reason of accurate methods of predicting remain elusive. Presence of multiple risk factors often suggest the need for additional evaluation for suicidal ideation, but an impending suicide attempt is not always recognized, even after evaluation by healthcare provider. More half of suicidals have seen a psychiatrist or psychologist or other healthcare provider within one month beforehand. The presentation of possible warning signs can be subtle and experience is required. Service provision for suicidal patients is often substandard, particularly at times of highest need such as after discharge from hospital or emergency department. As many as 75% or more of people who die by suicide have a diagnosable mental health disorder at the time of their death. The most common are bipolar disorder and schizophrenia over major depression. Between 25% and 50% of bipolar patients will attempt suicide at least once, and 5% to 20% will die by suicide. In schizophrenia diagnosis, 20% to 40% of patients will attempt suicide and more than 10% will die by suicide. Additional risk factors: alcohol misuse, family history, illegal substance use. The way in which suicide is broached and discussed with patient plays a significant role. Here, a focus on clinical management of suicide risk.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Suicide attempts related to homelessness in patients with personality disorder

P. García González*, R. Huerta-Ramírez, A. Capllonch Carrión, A. Molina Serrano

Complejo Asistencial Benito Menni, Unidad Hospitalización Breve, Ciempozuelos, Madrid, Spain

* Corresponding author.

Suicide is among the main causes of death in homeless population. In some samples, up to 34% of homeless adults have attempted suicide and psychiatric diagnoses are related to a higher rate of suicidality.

We report here two cases of suicide attempt related to a situation of homelessness. The first case is a young male who was a squatter after being kicked out of the family home, ended up homeless and made a suicide attempt. The second case is a middle-aged female with poor relationship with her family, who was unemployed and ended up penniless. She made a suicide attempt after being unable to pay for the hostel where she stayed. Both were admitted to our Psychiatry Hospitalization Unit, had a previous diagnosis of mixed personality disorder and related clearly the suicide attempt with their social situation.

We review related literature regarding the relationship between homelessness and suicide attempts. Psychosocial factors have a strong relationship with suicide ideation and attempts, specially in patients with personality disorders. Ensuring a place to live is an important part of the stabilization of these patients, so mental health professionals should always take into account this issue when it appears in one of our patients. To this day, it is difficult to

address this problem from our mental health system so it is important to have a good coordination with social services and improve the resources we have to tackle this problem.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Who are the suicide reattempters?

E. Gattoni^{1,*}, C. Gramaglia¹, C. Delicato¹,
S. Di Marco¹, I. Coppola¹, A. Venesia¹, D. Marangon²,
M.L. Castello¹, G.C. Avanzi¹, E. Torre¹, P. Zeppegno¹

¹ Università del Piemonte Orientale, Translational medicine, Novara, Italy

² AOU "Maggiore della Carità", SC Psichiatria, Novara, Italy

* Corresponding author.

Background History of previous suicide attempts is one of the most important risk factors for a subsequent completed suicide. Suicide reattempters (SR) has been long associated with demographic and clinical risk factors for suicide, such as unemployment and psychiatric disorders, however a recent review of the literature has not supported a specific age and gender profile of SR, but rather underscored that, as far as diagnosis is concerned, SR were more likely to have a personality disorder. According to literature, 16%–34% of the subjects repeat a suicide attempt within the first 2 years after the previous one.

Aim The purpose of our study was evaluating clinical and socio-demographic characteristics and the outcome of psychiatric consultation among subjects referring to an emergency room for recommitting a suicide attempt.

Methods We considered a sample of SR aged > 16 years. We extracted data from the database including all patients requiring psychiatric evaluation in the emergency room, and eventually compared the features of SR and patients with a single suicide attempt. For each patient, we gathered socio-demographic features, psychiatric history and current clinical issues, suicidal intent and suicidal behaviors.

Results Data collection and statistical analyses are still ongoing. Preliminary results show that, compared to patients with a single suicide attempt, SR were more frequent female, unmarried, employed, with a low level of instruction; they had a psychiatric disease (axis I – anxiety disorder, somatoform disorder; axis II – histrionic personality disorder); they are under the care of mental health services and under psychopharmacological treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Suicide attempters: Clinical characteristics and management

E. Gattoni^{1,*}, A. Feggi¹, C. Gramaglia¹, P. Bergamasco²,
I. Coppola¹, S. Di Marco¹, C. Delicato¹, A. Venesia¹,
D. Marangon², P. Zeppegno¹

¹ Università del Piemonte Orientale, Translational medicine, Novara, Italy

² AOU "Maggiore della Carità", SC Psichiatria, Novara, Italy

* Corresponding author.

Background Suicide attempts, defined as self-inflicted, potentially injurious behaviors with a nonfatal outcome, and with evidence of intent to die are extremely prevalent. Literature suggests that suicide is more common among males, while attempted suicide is more frequent among females. Depression, mental

disorders, substance use disorders and history of suicidal behavior are important risk factors for suicide: the risk of suicide attempt is 3 to 12 times higher in psychiatric patients than in the general population.

Aim The aim of our study was to compare severity of depressive symptoms in a sample of suicide attempters with a diagnosis of bipolar and related disorders or depressive disorders and in a sample of sex- and diagnosis-matched patients who do not commit a suicide attempt. The severity of attempted suicide and the suicidal risk in the hospital will be assessed as well.

Material and methods We collected a sample of inpatients who committed a suicide attempt during 2015. For each attempter, we selected another sex- and diagnosis-matched patient with no history of attempted suicide. Socio-demographic and clinical characteristics of the sample were gathered. Assessment included: Montgomery-Asberg Depression Rating Scale (MADRS) for severity of depressive symptoms in both groups, Suicide Intent Scale (SIS) for the severity of attempted suicide and the suicidal risk with a nurse assessment for suicide.

Results Data collecting is still ongoing. We expected to find more severe symptoms in patients who attempted suicide. Clinical implication will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1258

Who is a survivor of suicide loss? A systematic review

S. Gili^{*}, C. Delicato¹, A. Feggi¹, C. Gramaglia¹, P. Zeppegno¹

Università del Piemonte Orientale, Translational Medicine, Novara, Italy

* Corresponding author.

Introduction Death by suicide stuns with soul-crushing surprise, leaving family and friends not only grieving the unexpected death, but confused and lost by this haunting loss. The underlying structure of grief for survivors of suicide loss appears complicated.

Aims The purpose of this study consists in reviewing literature data about survivors of suicide, especially exploring the few informations emerged by researches on the role of psychiatrist as "survivor".

Methods A PubMed search was conducted using combinations of the following keywords: survivors suicide or bereavement suicide or suicide psychiatrists and randomized.

The search was conducted through September 10, 2015, and no conference proceedings were included.

Results Bereavement following suicide is complicated by the psychological impact of the act on those close to the victim. It is further complicated by the societal perception that the act of suicide is a failure by the victim and the family to deal with some emotional issue and ultimately society affixes blame for the loss on the survivors. This individual or societal stigma introduces a unique stress on the bereavement process that in some cases requires clinical intervention.

Conclusions Suicide bereavement seems to be different from natural loss. Clinicians may react to a patient's suicide both on a personal and professional level, with emotions such as loss of self-esteem or blame. This grief somehow nullifies the core of a helping relationship and may imply a more conservative management of future patients or even avoiding to accept suicidal patients for treatment. Support interventions have been proposed.

* Corresponding author.

Introduction Suicide is among the ten leading causes of death in the world. According to WHO, the annual suicide mortality rate is 16:100,000. Suicide rate has increased by 45% globally and by 60% in Spain in the last 50 years.

Objective It will be explained:

- scale of the problem;
- suicidal behaviour characteristics;
- risk factors due to Werther effect;
- protective factors;
- presenting the study on autolytic attempts at HCUV from July to December 2013.

Materials and method Data about autolytic attempts treated at the HCUV in the last 6 months were collected. A structured history was compiled for each patient collecting information about age, personal circumstances, cohabitation, studies, employment status, residence (urban, semi-urban or rural), religious beliefs, day of the week, family background, personal organic and psychiatric background, previous autolytic attempts, last three month's events, last week's events, method and medical practice undertaken.

Conclusion The study shows that the average age is 43 years old, 42.2% are married, 41.3% live with their family, 33% have primary studies, 27.3% are unemployed and other data, which will be exposed through diagrams. Compared to a study from 1996/1997, there has been a 27% increase in the suicide attempts rate.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The number of suicides rises in the Netherlands. In 2008, 1435 suicides were recorded; in 2012: 1753 (CBS). Adequate risk assessment with suicidal behaviour (SRA) is essential for prevention. The Health Inspectorate and Insurances seek to have a stronger grip on the way suicide risk is assessed and insist on using questionnaires. This runs counter to the multidisciplinary guidelines in the Netherlands for diagnosis and treatment of suicidal behaviour, which state that "questionnaires or observation instruments cannot replace clinical diagnostic examination."

Objective Do questionnaires rather than 'care as usual' (CAU) in SRA lead to different treatment policies?

Aim To determine whether the use of questionnaires rather than CAU in SRA leads to different treatment policies.

Methods Patients who were seen by staff at the department of Psychiatry at the ETS Hospital, either for in-house consultation or at

the MPU, in connection with attempted suicide, auto-intoxication, or psychological distress with suicidal statements. Patients were examined by conducting a questionnaire, resulting in treatment policy (admission, discharge with an appointment with patient's own practitioner, discharge with referral to a practitioner, discharge without aftercare). Then, the same patient was again examined by another colleague in a free interview (CAU). The colleague was not informed about the outcome of the first assessment. Again, treatment policy was determined as a result. The two outcomes were then compared.

Results Data collection still continues.

Conclusions There are signs that there are no differences in the determined treatment policies following SRA based on the use of questionnaires or CAU.

* Corresponding author.

Introduction Suicide is a serious public health problem in Western countries. In Spain, suicide is the leading cause of unnatural death in front of traffic accidents. The presence of a mental disorder is referred to as a risk factor of great interest both for its presence in suicides and the possibility of being treated and thus to reduce the risk of suicide.

Objective Study the presence of psychiatric diagnoses in subjects entering the treble unit of Huelva for attempted suicide.

Methods We conducted a retrospective study comparing the data obtained with this material in the literature. Statistical analysis was performed using the statistical package SSPs.

Results The age range is between 17 and 86 years, with a mean of 42 years. There are large differences by gender. Only 12% of the sample lived alone. Thirty-nine cases, representing 25% were in active employment at the time of the suicide attempt.

About 80% had a history of mental health and more than half of the sample had a previous suicide attempt.

The diseases most often associated are personality disorders, depressive disorder (unipolar) and alcohol abuse various toxic; followed by anxiety disorders, organic disorders and alcohol.

Conclusions Presence of diagnosis and prevention opportunities. Differences between sexes. Further exploration and increasing the sample compared to suicides.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Suicide is the deliberate act of take off life to itself. According to WHO, more than one million people commit suicide every year.

Goals Compare data of suicide attempts between 1996 and 2014 in the University Hospital of Valladolid. Influence of the economic crisis on suicide data. Expose the risk factors. Provide prevention strategies.

Material and methods We have performed a study of epidemiological surveillance collecting descriptive data of suicide attempts; using the same methodology as in 1996. The variables studied were: sex, age, day, month, residence, method, personal status, education, employment status, religious beliefs, family history of suicide, psychiatric history and family and personal psychiatric history.

Results Increase in the rate of suicide attempts 27%. Distribution by sex is similar, but in 2014, a higher proportion was observed in males. The percentage of women is significantly higher than that of men in the group of teenagers (10–19 years old) (20% women vs. 4.5% of men; $P=0.005$); 83.5% have a psychiatric diagnosis (54.2% of them have a depressive disorder). Unemployment and economic problems stand out as environmental stressors in 2014. The main suicide method used in Valladolid is the hanging, and the second method used is the precipitation.

Conclusions The primary, secondary and tertiary prevention strategies are very important. Suicide is the major cause of mortality in the young age group (15–24 years old). Mortality in the general population has been on a downward trend; but suicide rates per 100,000 population has remained stable over the last decade.

The aim of the study was to identify inpatients due to autolytic behavior in the acute psychiatric hospitalization of Dr. R. Lafora Hospital. It is an observational, descriptive and retrospective study. We collected information about patients aged 18 to 64 who were hospitalized during the month of January of 2015 in the acute psychiatric hospitalization by Selene software. The results were analyzed by SPSS software; 53.3% of patients diagnosed with schizophrenia spectrum and other psychotic disorders were hospitalized for acute exacerbation of paranoid schizophrenia; 57.1% of personality disorders for suicide attempts, 28.6% autolytic ideation; 28.6% of bipolar disorders due to mania, 28.6% depression, 28.6% mixed clinical and 14.29% suicide attempts; 60% of alcohol use disorders for autolytic ideation, 20% intoxication; 100% of substance-related and addictive disorders due to autolytic ideation; 100% of feeding and eating disorders for autolytic ideation; 50% of obsessive-compulsive and related disorders due to autolytic ideation; 100% of adjustment disorders with depressed mood due to drug over-eating; 100% of adjustment disorders with mixed anxiety and depressed mood for mixed clinic; 16.7% of depressive disorders due to dysthymia, 16.7% due to major depressive episode, 16.7% for moderate depressive episode, 16.7% for mild depressive episode with mixed nature, 16.7% for drug over-eating, 16.7% for autolytic ideation. It would be important to focus on patients with a diagnosis of adjustment disorders, personality disorders, alcohol use disorders, obsessive-compulsive and related disorders and bipolar disorders, providing community care and avoiding the risks associated psychiatric hospitalization.

² Dimence Groep, Dimence, Developmental Disorders, Deventer, Netherlands

* Corresponding author.

Introduction There is emerging evidence that suicide and suicidal behavior frequently occur in people with autistic spectrum disorders (ASD), although this topic is largely understudied. We have little understanding of suicidal behavior among individuals with ASD and there are no empirical data to guide practitioners in the treatment of suicidality in persons with ASD. There is a need to investigate risk factors associated with suicidal behavior in persons with ASD, to improve prevention strategies and interventions.

Objectives To get an overview from literature of risk factors for suicidality in individuals with ASD.

Methods Review of the literature using Cochrane Collaboration Centre, Embase, Medline, PsychINFO, PubMed, and Web of Science.

Results In the literature, we found that, among already known risk factors like comorbid depression, an underlying vulnerability in personality may be a risk factor for suicidal behavior. Several studies showed that a high score on the temperament factor 'novelty seeking' and 'harm avoidance' is associated with suicidality. In other studies, where suicidality was not an object of study, adults with ASD showed high scores on 'harm avoidance' and low scores on 'novelty seeking'. This suggests that personality profiles may be of predictive value for suicidality in adults with ASD. A study proposal focused on this possible association be presented.

Methods of suicide in old age in Israel: Age and gender differences

B. Katz

Western Galile College, Criminology, Acre, Israel

Introduction Suicide rates in the western world rise with age among both men and women. However, suicide at older ages gets less consideration in research and prevention strategies compared to younger age groups.

Objective This study examines the differences between men and women in Israel in the method chosen for committing suicide over three decades, focusing on the elderly (younger seniors 65–75, and older seniors 75+) and compares them to younger age groups (15–24; 25–44; 45–64).

Methods Suicide rates by age, gender and the method chosen are calculated based on data from official publications of the Ministry of Health in Israel over the years 1981–2008.

Results The findings of the study show that in all the methods used to commit suicide [hanging, drowning, fire, getting run over by a motor vehicle, jumping from heights, drugs and poisons, the suicide rate of the elderly (age group 75 and up)], followed by ages 65–75 was higher than the suicide rate of younger age groups (15–24; 25–44; 45–64) except for the use of weapons. In all age groups, the male suicide rate was higher than females, with the exception of taking poison for 75 year olds and above. In this age group, the females' rate of suicide was higher than males.

Conclusions These findings reveal the need develop strategies to prevent suicide in the community in general, and especially among seniors. Particular attention should be devoted regarding the use of drugs and various poisonous substances among elderly women.

* Corresponding author.

Background Optimizing psychiatric assessments could help to standardize the use of structured instruments in clinical practice. In recent years, several research groups have applied Computerized Adaptive Tests (CATs) to simplify assessments in depression, anxiety and also suicidal behaviors. We aimed to construct a shortened test to classify suicide attempters using a decision tree methodology that allows the integration of relevant clinical information, namely the history of past suicide attempts, in the construction of the test.

Methods The sample was composed of 902 adult participants in three subsamples: first-time suicide attempters, psychiatric inpatients that never attempted suicide and healthy controls. The performance of a decision tree built using the items of a previously developed scale for suicidal risk was examined. The history of past suicide attempts was used to separate patients in the decision tree. The data was randomly divided in a training set and a test set. The test set, that contained 25% of the data, was used to determine the accuracy of the decision tree. Twenty-five cross-validations of this set up were conducted.

Results The first four items of the decision tree classified correctly 81.4% of the patients.

Conclusion As a result of a methodology based on decision trees that, contrary to CATs, can incorporate relevant information in building the test we were able to create a shortened test capable of separating suicidal and non-suicidal patients. Using all the information that is available improves the precision and utility of instruments adapted for psychiatric assessments.

* Corresponding author.

Introduction Suicide causes 1.4% of deaths worldwide. Twenty times more frequent, suicide attempts entail an important source of disability and of psychosocial and medical resources use.

Objective To describe main socio-demographical and psychiatric risk factors of suicide attempters treated in a general hospital's emergency room basis.

Aims To identify individual features potentially useful to improve both emergency treatments and resource investment.

Methods A descriptive study including data from 2894 patients treated in a general hospital's emergency room after a suicidal attempt between years 2006 and 2014.

Results Sixty-nine percent of the population treated after an attempted suicide were women. Mean age was 38 years old. Sixty-six percent had familiar support; 48.5% had previously attempted a suicide (13% did not answer this point); 72.6% showed a personal history of psychiatric illness. Drug use was present in 38.3% of the patients (20.3% did not answer this question); 23.5% were admitted to an inpatient psychiatric unit. Medium cost of a psychiatric hospitalization was found to be 4900 euros.

Conclusion This study results agree with previously reported data. Further observational studies are needed in order to bear out these findings, rule out potential confounders and thus infer and quantify causality related to each risk factor.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Suicide attempts: Results from data collected in a psychiatric emergency ward in a general hospital

J. Narciso^{1,*}, M. Real²

¹ Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Suicide behavior constitutes a public health problem worldwide. It deserves epidemiological investigation regarding "best clinical practices", and it is fundamental since the patient's first observation at psychiatric emergencies services. These are the ideal practices to start suicide prevention, and prevent further suicidal behavior. The improvement of healthcare quality includes the adoption of clinical guidelines, which support medical care since the emergencies services. The lack of specific instruments to evaluate suicidal risk urges the scientific community to create them.

Aims The authors aim to discuss the advantages and limitations of the application of these kinds of instruments, and the creation of models based in scientific evidence available.

Discussion From multiple available studies, the Modified Sad-Persons Scale (MSPS) seems to be one of the most scientifically used in literature, as well as in epidemiological studies of suicide attempts and their repetition, either by nonfatal or fatal attempts. However, even this scale has been questioned by experts, and the lack of specific and sensible tests towards suicide behavior and risk of suicide attempts raises the importance of the need of further investigation towards this area. This evidence would then help the clinician in his work at emergencies wards and provide better healthcare towards preventing new suicide attempts.

A multidisciplinary model of suicide and suicidal behavior in Korça region, Albania

I. Nikaj

University of Korça, of Education, Korça, Albania

Patterns of suicide and suicidal behavior vary among different cultures. In Albania and in Korça region has a relatively high number of suicides and behavior related to for a long period of time related to the transition, the changes that have occurred and occur in Albania,

the economic, social, psychological and cultural, politics conditions in which we are.

This presenting article explores multidisciplinary explanations for suicide and suicidal behavior in region and in Albania as a whole through data collected from official and public institutions. The interconnection of Durkheimian concepts of social integration and regulation with ecological insights into family relations in change and psychological and psychiatric theories on individual distress are relevant.

Keywords Albania; Ethnicity; Research tradition; Shame culture; Suicide and suicidal behavior

¹ Karolinska Institute, Center for Molecular Medicine, Solna, Sweden

² Lund University, Department of Clinical Sciences, Lund, Sweden

³ Sant'Andrea Hospital, Sapienza University of Rome, Department of Neurosciences, Mental Health and Sensory Organs, Suicide

Prevention Center, Rome, Italy

* Corresponding author.

Introduction There is limited information published on the specific financial costs of completed and/or attempted suicide in bipolar patients. In the last 15 years, only 6 studies were published. Their results vary considerably due to differences in methods used. Also, information on cost for pure manic versus mixed episodes is lacking. This is surprising, since studies have shown that suicidal behaviour is more common among patients with depressive symptoms than with pure mania, and this difference increases considerably when the mixed-features specifier is applied.

Objectives We conducted a registry study with the aim to expand the epidemiological information on suicidal behaviour by episode type in bipolar disorder, and its associated costs.

Methods Health data were retrieved from the Swedish Patient Register. Data covered the period 1990–2014 and included the number of discharged patients with bipolar diagnosis, hospital readmissions, and attempted and/or completed suicides. Moreover, we retrieved data on suicide and cause of death from the Swedish Cause of Death register. Analyses were done for the whole sample and stratified by subtypes (mania, depression and mixed forms).

Results First results will be presented at the EPA meeting.

Conclusions This is a nation-wide Swedish study of completed and attempted suicide in bipolar patients. The hypothesis we will test is that there is a substantial variation between different bipolar disorder subtypes, and that most of the expenditures due to suicidal behaviour in bipolar disorder are linked to mixed forms, mania in combination with depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Profile of Islamic suicide bombers: A literature review

A. Paraschakis^{1,*}, I. Michopoulos², A. Douzenis²

¹ Psychiatric Hospital of Attica, "Dafni", Athens, Greece

² 2nd Department of Psychiatry, Athens University Medical School,

"Attikon" General Hospital, Athens, Greece

* Corresponding author.

Aim To try to define the profile of Islamic suicide bombers.

Methods Literature review of scientific articles (PubMed-Google).

Results According to the very few relevant studies there does not seem to exist a single psychological characteristic that differentiates suicide bombers. However, some profiles have been proposed. Islamic bombers are predominately young men (60–70%), mostly single, originating from all social, economic and educational backgrounds (the more educated ones have increased lately). They appear to possess dependent and/or avoidant traits; other times impulsive and/or emotionally unstable ones. They are described as submissive against authority figures, "inadequate" in handling stressful situations and with a rather "constricted" view of reality. Suicide bombers do not appear to suffer from major psychopathology. Sometimes, they want to take revenge for the injury/killing of (a) loved one(s). The conviction of "ethnic humiliation" and "victimization", the view that the "enemy" is dominant and that the "rules of the game are unjust" appear crucially important: only an unexpected, devastating act of self-sacrifice ("martyrdom") could "turn the tables on". Suicide bombers' families are generously compensated and enjoy high social status. Religion seems to provide "ethical legitimization" to similar acts. Islam condemns suicide except when used to champion Islamic values or fight against "infidel invaders" ("Jihad"). In these cases, there is the promise of absolving all the individual's sins and of after death pleasures.

Conclusions The decision to become an Islamic suicide bomber appears determined by a plethora of personal, social, political and religious factors. This kind of suicide resembles Emile Durkheim's type of "altruistic" suicide.

Physician suicide prevention

A. Poças^{1,*}, S. Pinto Almeida²

¹ Braga, Portugal

² Centro Hospitalar de Leiria, Psiquiatria e Saúde Mental, Leiria, Portugal

* Corresponding author.

Every year there is a medical school full of physicians who commit suicide. Depression is a major risk factor and physicians frequently fail to recognize their own depression and that of their colleagues. Even when they do, many of them avoid treatment. The greater knowledge of lethality of drugs and easy access to means can contribute to the higher suicide rate among physicians.

Some studies say that training physicians are at particularly high risk of suicide, with suicidal ideation increasing more than 4-fold during the first three months of internship year. In Portugal, there are no reliable statistics about resident's suicide. We do not even talk a lot about it and the collective silence only compounds the problem – the refusal to speak perpetuates the stigma that mental health problems are signs of weakness or failure. Assess existing resources and best practices should be the next step to establish training programs to suicide prevention in these professionals, addressing response programs. As primary prevention, we should act in order to prevent healthy medical students or physicians from developing a condition that would lead to suicide. A randomized clinical trial in US with 199 residents from multiple specialties found that a free, easily accessible, brief web-based cognitive behavioural therapy program is associated with reduced likelihood of suicidal ideation among medical residents.

It is also essential too early diagnose and treat after the illness onset. Moreover, it should exist a rehabilitation of suicidal physicians and their return to maximal function with minimal risk for recurrence.

EV1274

Immigration and suicide in Spain: Literature review

S. Rodríguez Vargas
Almería, Spain

Objectives and method Although it is increasingly an immigrant country, we can not forget that for years has been a world leader as a meeting place of many nationalities. It has carried out a review of the literature about the number of suicides that occur in the immigrant population of our country.

Results Cultural factors that influence suicidal behavior are religion, socio-demographic factors (inverse relationship between socioeconomic status and suicide attempts), conflicts, alcohol/drugs, and social and family support as emigration entails fostering emotional and cultural rootlessness isolation and increased risk. Stresses in young Filipinos (20%) and American Indians (19%) than for any other ethnic group. Among the immigrants, I returned to their country of origin, the Germans have a 30% rate of suicides. And if we consider the length of stay, a clear decrease in rates seen since the frequent change of residence results in an increased risk. In the comparison of nationality and gender, it shows that the rate for suicides is very high among Moroccan women aged between 10 and 24 years.

Conclusions and discussion Migration can alter the development and adaptation of people and sometimes increase the risk of suicide especially when migration occurs alone. Attempted suicide is an exceptional crisis that requires special attention. Progress in research will deepen the psychological effects of migration in adults and in children migrated.

Disclosure of interest The author has not supplied his declaration of competing interest.

Sibling death in childhood and self-inflicted injuries in young adults – a national cohort study from Sweden

M. Rostila^{1,*}, L. Berg¹, A. Arat¹, B. Vinnerljung², A. Hjern¹
¹ Centre for Health Equity Studies, Stockholm University, Karolinska Institute, Stockholm, Sweden

² Department of Social Work, Stockholm University, Stockholm, Sweden

* Corresponding author.

Previous studies have shown that sibling death influences health and mortality in bereaved adult siblings. Few studies have so far examined whether exposure to sibling bereavement in childhood is associated with suicidality later in life. The aim of the present research was to investigate whether the loss of a sibling during childhood influences self-inflicted injuries/poisoning in young adulthood. A national cohort born during 1973–1982 ($n=717,723$) was followed prospectively in the National Patient Discharge Register from 18 to 31–40 years of age. Multivariate Cox analyses of proportional hazards with adjustment for socio-demographic confounders and family covariates were used to test hypotheses regarding sibling loss and hospital admission due to self-inflicted injuries/poisoning. Men (HR: 1.28, 95% CI: 1.01–1.62) and women (HR: 1.23, 95% CI: 1.00–1.51) who had lost a sibling during childhood had an higher risk for being admitted to hospital for a self-inflicted injury/poisoning in young adulthood after adjustment for socio-demographic confounders and family risk factors. Losing an infant sibling was most detrimental for men (HR: 1.43, 95% CI: 1.03–1.98) while losing a non-infant sibling was most detrimental for women (HR: 1.38, 95% CI: 1.05–1.81). The risk of hospital admission due to self-inflicted injuries/poisoning was particularly detrimental for both men (HR: 1.40, 95% CI: 0.92–2.13) and women (HR: 1.54, 95% CI: 1.09–2.17) who lost a sibling in adolescence (12–18 years) when compared to loss at younger ages (0–5 years and 6–11 years). It is important to provide support for siblings bereaved in childhood in order to prevent suicides.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Over, but not out-recognition and preventing aircraft-assisted murder-suicide by Aircrew

A. Saxena^{1,*}, V. Sharma (Chief Research Officer)², A. Walia³, P. Sharma⁴

¹ Indian Armed Forces, Department of Psychiatry, Jorhat, India

² Institute of Aerospace Medicine, Indian Air Force, Bangalore, India

³ Indian Armed Forces, Department of Aerospace Medicine, Jalandhar, India

⁴ Indian Armed Forces, Department of Psychiatry, Bangalore, India

* Corresponding author.

Context and introduction The recent crash of Germanwings Flight 4U9525 appears to be the latest act of aircraft-assisted murder-suicide. The psychiatric preventive aspects of the murder-suicide need to be discussed, and effective measures for recognition and prevention of this murder-suicide are needed. Aircrew health is biased towards the physical ailments, and evaluation manuals have not discussed the mental health aspects, especially preventive strategies. These strategies involve multifactorial interventions, their applicability and usefulness are not globally validated.

Objectives and methods Thanatology has since long, focused on early detection of mental distress and elucidating behavioural and psychological factors that predispose towards attempts at self-harm. Aircrew forms a different group from the general population. The recognition and preventive strategies in this special group, must, therefore, be tailored to this group with its special characteristics.

Data sources, study selection and data synthesis publications were identified via electronic searches using multiple search terms related to suicide prevention. The available effective preventive measures were juxtaposed on the current concepts in aerospace psychiatry.

Conclusions Murder-suicide by aircrew is an event that is the culmination of undetected, ignored or even condoned discrete events that gradually progress and insidiously escalate. The importance of psychological factors in this catastrophic event needs to be disseminated amongst psychiatrists, and aircrew medical examiners. Ascertaining which components of suicide prevention programmes are effective in early recognition of aircrew who may attempt or complete the murder-suicide and putting into practice these to optimize the use of limited resources, is therefore essential and necessary.

Clinical morbidity at pregnancy: The role of previous suicidal attempts and repetition

M.J. Soares^{1,*}, S. Bos¹, A.T. Pereira¹, M. Marques¹, B. Maia², A. Macedo¹

¹ Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

² The Catholic University of Portugal, Braga Regional Centre, Faculty of Philosophy, Braga, Portugal

* Corresponding author.

Introduction Previous suicide attempts are a consistent risk factor for suicide. Repetition has been associated with higher future morbidity and suicidality.

Aim To examine the relationship between psychological variables at pregnancy and previous repetition of suicidal attempts, first attempts and absence of attempts.

Methods The sample comprise 568 third trimester pregnant women, mean aged 29.82 years (SD = 4.55; variance = 17–44). Previous suicidal behaviors were assessed with diagnostic interview for genetic studies, depression with PDSS and BDI-II, and affect with POMS. Current suicidal thoughts were assessed with PDSS dimension; hopelessness and helplessness by summing the scores of the POMS items hopeless/gloomy; and lonely/helpless, respectively.

Results Repeaters (R; n = 11, 1.9%) scored higher than non-repeaters (NR; n = 20, 3.5%) in most of the clinical variables, but only significantly in sleeping/eating disturbances (PDSS).

R and NR when compared to women who never attempted suicide (NA; n = 535, 94.5%) both revealed significant higher levels of depressive/hostility affect (POMS), BDI-II total score, suicide ideation, guilt/shame (PDSS) and anxiety/insecurity or anxiety/somatic (PSDD or BDI-II).

In comparison with NA, R also revealed significant higher levels of negative affect (POMS), PDSS total score, loss of self, mental confusion (PDSS), cognitive and affective symptoms, fatigue (BDI-II), hopelessness and helplessness. NR also differs from NA in their higher emotional liability (PDSS).

Conclusion Women with previous suicide attempts are at elevated risk for high depressive symptoms, negative affect and suicide ideation at pregnancy. Compared to never attempters, repeaters revealed high morbidity than first attempters. The intervention in pregnancy must carefully assess previous history of suicide attempts.

* Corresponding author.

Introduction Current research aimed at more in-depth analysis of suicidal behavior caused by alcohol consumption among women and the development of effective and innovative approaches to its prevention and correction.

Objective To identify the main patterns of correlation of clinical, personal, social and environmental components in the genesis of suicidal behavior, as a result of alcohol use among women in the indigenous population of the Russian Far East. Participants in the current study consisted of 50 females with alcohol dependence (ICD-10 criteria).

Aims Identification of clinical, social, ethno-cultural laws of structure formation of suicidal behavior among women of reproductive age due to alcohol consumption in the population of the indigenous peoples of the Far East to the development of effective measures of correction and prevention of suicidal behavior.

Methods Clinical and catamnestic and experimental psychological methods.

Results The study involved 50 females with alcohol dependence, 70% of them had suicidal tendencies, of which 55% had suicidal thoughts, 45% had a history of suicide attempts. The obtained data on suicidal behavior in women caused by alcohol, the representatives of indigenous peoples of the population of the Khabarovsk Territory.

Conclusions On the basis of an integrative approach to the assessment of patients with suicidal behavior, created a model forecast the effectiveness of therapy of this disease to predict the effectiveness of treatment of mental disorders, affective register at admission to the clinic. Develop an optimal algorithm for rehabilitation measures that will improve the quality of life of patients studied groups.

Suicidal behavior in a psychiatric emergency room

J. Teixeira Silva^{*}, M. Gonçalves, D. Rafaela, A. Craveiro
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Recent studies alerted for the increasing number of suicidal patients at emergency rooms. These suicide attempts are not restricted to any age group, ethnicity or socioeconomic status and are not always associated with psychiatric comorbidity.

Objectives Characterize the suicide attempters admitted to a Portuguese emergency room during a 3-month period (July to September 2010).

Aims The aim of the present study was to improve effectiveness of suicidal behavior intervention in the emergency care setting.

Methods A retrospective descriptive study was conducted by consulting hospital records. Socio-demographic and clinical data were collected. Statistics were performed with SPSS.

Results Suicidal behavior were more frequent among females with previous psychiatric history. The most used method was medication overdose. Psychiatric comorbidity like depression and substance abuse were commonly present. The majority of suicide attempt patients were discharged without hospitalization.

Conclusions The emergency room is a vital setting for suicide prevention and may be the only access to healthcare available for some patients. The physicians must be capable to quickly assess the potential lethality of a suicidal behavior and create a safe treatment plan to prevent future suicide attempts.

EV1280

Suicide risk assessment and prevention interventions in military veterans

A. Teo

VA Portland Health Care System, HSR&D, Portland, USA

Introduction Concerns over suicide among military veterans has been as issue of major public and policy concern, particularly by the Veterans Health Administration (VHA), which is the largest integrated health care system in the United States.

Objectives and aims The reasons for suicide risk and means to reduce risk in this population have been under active investigation and implementation. The aim of this presentation is to review recent trends in suicide risk assessment and suicide prevention interventions within the VHA in the United States.

Methods A literature review consisting of an electronic database search of PubMed, “gray literature” search, and manual search for articles related to suicide in military personnel and veterans was conducted.

Results In recent years, annual VHA rates of completed suicide have ranged from approximately 34 to 40 suicides per 100,000 person-years, rates significantly higher than the general US population. Risk assessment methods examined in military veteran populations have primarily included self-report instruments, scales, and checklists. Recently, “big data” approaches to analysis of electronic medical records have shown promise in stratifying veterans into high- and low-risk groups. VHA suicide prevention initiatives have included extensive staff hiring, development of research centers and data-sharing agreements focused on suicide, a national telephone crisis line, routine suicide risk assessment and screening, and suicide safety plans.

Conclusions Military veterans in the US receiving care in the VHA have a variety of risk factors for suicide and continue to be at elevated risk despite implementation of numerous suicide prevention initiatives.

EV1281

A new evidence-based neuropsychological model of suicidal propensity and suicide based in depression

L.-H. Thorell

Linköping University, Linköping, Sweden

Introduction Objectively validated models of the depressed suicide are lacking. Early observations that electrodermal hyporeactivity was strongly related to suicide in depression required an untraditional statistical approach that was applied on materials

from published materials with between themselves totally confirming results.

Objectives A plausible explanation model of the relationship had to be developed.

Aims The aims were to investigate the nature of electrodermal hyporeactivity and its possible causes and connections to other suicide relevant factors and to formulate a coherent model of the depressed suicide.

Methods Published materials with in- and outpatients (in total >900 patients) comprising follow-up of suicide and tests of habituation of the electrodermal response were analysed. Symptomatology, gender, age and other variables were considered and so were knowledge and theories from other scientists.

Results The apparent loss of or considerably reduced specific electrodermal orienting (curiosity) responses in future depressed suicide victims showed clear relationships to and clear independence of considered important suicidal factors.

Conclusions Loss of specific orienting responses indicates loss of hippocampal CA3 plasticity. CA3 areas are early and centrally positioned in the information processing of neocortical sensory input supporting the hypothesis of a particular neuropsychological dysfunction disabling normal cognitive and emotional curiosity reactions to everyday events. It is proposed that this dysfunction may make the depressed person ready to leave the everyday life and fearless of imminent pain – a loss of two important barriers against suicide.

It seems righteous to propose this basically objectively validated model as a plausible explanation of the depressed suicide.

Disclosure of interest The author has not supplied his declaration of competing interest.

EV1282

Attempted suicide among patients attending neuropsychiatry department – a study from tertiary care neuroscience hospital in Bangladesh

M.M.J. Uddin

National Institute of Neurosciences and Hospital, Psychiatry, Dhaka, Bangladesh

Introduction Attempted suicide is a growing problem with significant clinical and public health importance globally as well as developing countries like Bangladesh. Psychiatric disorders are the most common reasons for suicide or suicidal behavior among other causes of such behavior.

Objective The objective of the study was to find out the suicide attempters among the patients with psychiatric disorders attending the neuropsychiatry department of National Institute of Neurosciences and Hospital (NINS&H), Dhaka, Bangladesh.

Methodology This descriptive cross-sectional study was done in NINS&H, Dhaka, Bangladesh from July 2013 to August 2014. Psychiatric diagnoses of the patients were done by the psychiatrist following Diagnostic and Statistical Manual of Mental Disorders – IV-Text Revision (DSM-IV-TR) diagnostic criteria. Ethical issues were maintained strictly.

Results Total 63 patients were found with history of single or more than one suicidal attempt out of 954 patients. Among the suicidal attempters, 34 (53.97%) were male and majority 38 (60.32%) belonged to 20 years to 40 years age group. In this study, the most common methods of suicidal attempt were found taking over dose of sedatives and multiple drugs 22 (34.92%), ingestion of pesticides and other corrosive agents 17 (26.98%) and hanging 14 (22.22%). Psychiatric disorders wise distributions of suicidal attempters were found major depressive disorder 18 (28.57%), borderline personality disorder 14 (22.22%), schizophrenia and related disorders 10 (15.87%).

Conclusion Results of the study indicate that all attempts of suicide should be taken seriously and crisis hot line and emergency services should be ensured for this group.

Predictors of suicidal behaviour persistence and recurrence

I. Untu^{1,*}, N. Cartas², M. Mutică³, B.A. Ciubară⁴, A. Ciubară¹, C. Roxana¹

¹ UMF Iasi, Psychiatry, Iasi, Romania

² Socola, Institute of Psychiatry, Iasi, Romania

³ UMF Craiva, Psychiatry, Iasi, Romania

⁴ UMF Iasi, Iasi, Romania

* Corresponding author.

Introduction Suicidal behaviour represents a global public health issues; personal suicidal history is the most common predictor of the persistence and recurrence of suicidal ideation and behaviour in general.

Objective This paper proposes to elaborate a synthesis of the scientific literature, concerning the main predictive factors of the persistence and recurrence of suicidal behaviour, considering that the current diagnostic criteria available fail to make a distinction and to specify clearly the differences between all psychiatric disorders without self-harming behaviour and the same nosological entity accompanied by suicidal behaviour.

Materials and methods I conducted a literature review, by analyzing the data concerning the predictors of the persistence and recurrence of self-harming behaviour, obtained from articles published between January 2013 and January 2015. I browsed the PubMed website, by keywords such as suicide, suicidal risk, suicide predictor, persistent suicidal ideation, and suicidal behaviour recurrence.

Results The scientific literature underscores that that entrapment and defeat are two elements often neglected; however, they should be a priority criterion, alongside traditional predictive factors, such as the following: gender, age, history of suicide attempts, socio-familial status, etc. All of these factors must be considered within the complex endeavour of assessing suicidal risk. However, there is still only scarce validated data concerning the mechanism that leads to entrapment and the one that determines its relation with self-harming behaviour.

Conclusions This paper proposes to synthesize the current data concerning suicide predictors, in order to obtain new research assumptions. The final purpose is to develop proper preventive and therapeutic approaches.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Risk factors for attempted suicide: A prospective study on psychiatric consultations in the emergency room

A. Venesia^{1,*}, I. Coppola¹, C. Gramaglia¹, D. Marangon¹, S. Di Marco¹, C. Delicato¹, E. Gattoni¹, G.C. Avanzi¹, L. Castello¹, F. Bert², M.R. Gualano², R. Siliquini², E. Torre¹, P. Zeppegno¹

¹ Università del Piemonte Orientale, Translational Medicine, Novara, Italy

² Università degli Studi di Torino, Public Health and Paediatric Sciences, Torino, Italy

* Corresponding author.

Introduction Studies conducted on Italian samples suggested that 70% of self-harms referred to the emergency room (ER) were suicide attempts. Suicide attempts are associated with societal, relationship and individual risk factors, which vary with age and gender, occur in combination, and may change over time. We conducted a previous study on a sample of psychiatric consultations in ER from 2008 to 2011. We observed that female gender, a permanent job and being in the warmer months of the year were risk factors for suicide attempts.

Aim To update knowledge about risk factors for attempted suicide analyzing a larger sample of ER psychiatric consultations.

Methods Determinants of emergency room visits for psychiatric reasons were studied prospectively in a period of 8 years, from 2008 to 2015 at the “Maggiore della Carità” Hospital in Novara. The psychiatric assessment of patients was performed by experienced psychiatrists with a clinical interview. For each patient, a data sheet was filled in order to gather demographic and clinical features. Comparison of qualitative data was performed by means of the Chi² test while differences between groups for continuous variables were assessed through a *t*-test. Statistical significance was set at $P \leq 0.05$. A multivariate analysis was performed using logistic regression in order to assess the potential predictors of attempted suicide. Results are expressed as odds ratio (OR) with 95% confidence intervals (95% CI).

Conclusions We have collected data from more than 500 psychiatric consultations for attempted suicide. Data collection and statistical analyses are still ongoing. Implications will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Substance abuse is common issue in youth and may influence youth's suicide thoughts or actions. It can lead to social isolation, low self-esteem, loss of work or school, estrangement from family and friends – all these may create a core of stresses that may lead to suicidal tendencies.

Analysis addictive factors correlating with occurrence of suicidal thoughts and behaviours among adolescents at the age of 18–20. Study was based on authorial, previously validated questionnaire, included 16 questions about suicidal thoughts. Questionnaires were filled by adolescents (age 18–20) of 21 Secondary Schools in Katowice.

From the group of 965 adolescents, 28.8% had suicidal thoughts. From all respondents: 31.3% smoked, 92.7% drunk alcohol, 16.0% used legal highs and 30.9% – drugs; 35.8% of smoking adolescents had suicidal thoughts. In group of non-smoked adolescents – 25.6%. There was statistical significant difference ($P=0.0012$) between these groups. Among adolescents who drunk alcohol, 28.8% had suicidal thoughts. In the group of non –drinking alcohol adolescents – 27.9%. There was no statistical significant differences ($P=0.88233$) between these groups. There were 43.7% adolescents with suicidal thoughts who used legal highs. In the group of non-users of legal highs, 26.0% adolescents had suicidal thoughts.

Adolescents that are using examined stimulants are in the group risk of suicidal thoughts and autodestructive behaviours. Results show the need of psychiatric and psychotherapeutic support that

is aiming to prevent suicides and autodestructive behaviours in this group. Screening questionnaires that are assessing the problem of addiction within the adolescent may help to identify persons with suicidal tendencies.

EV1286

A salivary biochemical analysis of certain recruits associated with suicidal ideation

W. Xiaomei

Institute for Diseases Prevention and Control, Military Medical Scientific Department, Beijing, China

Objective To explore the biochemical indicators of the persons at high risk of suicide.

Aims To achieve early screening of the persons at high risk of suicide.

Methods Suicide ideation of new recruits was generally investigated with self-rating idea of suicide scale (SIOSS). Twenty-five recruits whose scores were more than 12 were recognized as the suicide ideation group. Another 25 recruits without suicide ideation were randomly selected as the control group. Saliva samples of each group were collected for biochemical analysis after one month and three months. The SIOSS was used again for evaluation of suicide ideation.

Results After one month, the concentrations of Ca, Mg, Amy and SA in saliva were demonstrated to be statistically different between the two groups. After three months, the concentrations of Ca, Mg, Amy and SA in saliva between the two groups showed no significant difference. According to SIOSS results, only 7 persons of the original suicidal ideation group were recognized as suicidal ideation group, the other 18 people's SIOSS scores were less than 12. And the SIOSS scores of the control group (without suicidal ideation group) were also less than 12. There was no statistical difference in the three groups for comparison of salivary Ca, Mg, Amy and SA.

Conclusion The biochemical indicators of saliva lack specificity for suicidal ideation screening.

Online mindfulness as therapy for fibromyalgia patients

N. Garrido-Torres*, A.S. Viedma, A. Rodriguez, M. Reina, S. Fernandez, C. González, I. Prieto

HJRJ, Psychiatry, Huelva, Spain

* Corresponding author.

Introduction Fibromyalgia is a chronic disease. This diagnosis has been controversial in scientific society. However, there is one fact: there are women who feel not only uncontrollable and non-specific body pain, but also psychological symptoms.

Objective To compare the efficacy of online sessions versus onsite sessions. To demonstrate that online mindfulness sessions could help to reduce pain in patients with a diagnosis of fibromyalgia.

Method A website created to give education and advice to women with fibromyalgia related to the disease was used as a platform to offer online mindfulness sessions.

Two hundred and thirty-four patients with fibromyalgia asked to participate in the online sessions, but only 13 were included in the study. Nineteen other women received onsite mindfulness sessions. Patients were evaluated before and after intervention. Two analyses were undertaken: intragroup and intergroup.

Results No differences were found between online mindfulness session and onsite mindfulness session. In both cases, an improvement in the questionnaire scores was demonstrated. Mindfulness as a kind of psychotherapy helped patients to control pain and symptoms of anxiety.

Discussion The new ICTs offer a huge of possibilities in medicine and mental health. With respect to psychiatry, not only intervention, like psychotherapy, can be offered but also psychoeducation. However, there are factors such as age and educational level that make online intervention difficult.

Conclusion In the near future, most people will interact with technology and it would be easier to supply online interventions and psychoeducation e-patients already exist, so e-doctors and e-psychiatrists should be online soon.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1288

Online psychoeducation: E-patients are looking for e-doctors

N. Garrido-Torres^{1,*}, R. María¹, C. González¹, L. Hernandez¹, L. Rodríguez-Santana², S. Torres-Sánchez³, I. Prieto¹

¹ HJRJ, Psychiatry, Huelva, Spain

² Universidad de Sevilla, Sociology, Seville, Spain

³ Universidad Pedagógica, Psychology, Bogotá, Colombia

* Corresponding author.

Method A website was designed to offer psychoeducation and advice to women who demand more information about health after traditional visit to GPs. A total of 564 patients visited the website in three months. Women asked for information and interacted with different topics on the platform. Only the women who completed all the form (age, previous diseases, current treatment) were analyzed. A total of 226 e-patients were included.

Results The most demanded information was about: excess weight, fibromyalgia, depression, anxiety, bipolar disorder and the menopause although other topics related to medicine such as HTA, breast cancer, and pregnancy were part of the website contents.

Discussion Even when many topics about medicine were available on the website, women were more interested in, and showed the need for information about mental health.

Online psychoeducation could help the clinician to save time at the personal consultation and could be especially useful in following the patient for a long time.

However, there are technological barriers and at least one first face-to-face interview is required in complicated cases to determine a correct diagnosis.

Conclusions A high demand for e-mental online health education does exist. It would be useful for professionals to be trained in information technology in order to cover that demand and avoid misinforming patients.

It would be interesting to undertake a meta-analysis with all the studies around the world and determine the profile of the patient that could be helped through online attention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction In the UK, mental illness is a major source of disease burden costing in the region of £105 billion pounds. mHealth is a novel and emerging field in psychiatric and psychological care for the treatment of mental health difficulties such as psychosis.

Objective To develop an intelligent real-time therapy (iRTT) mobile intervention (TechCare) which assesses participant's symptoms in real-time and responds with a personalised self-help based psychological intervention, with the aim of reducing participant's symptoms. The system will utilise intelligence at two levels:

- intelligently increasing the frequency of assessment notifications if low mood/paranoia is detected;
- an intelligent machine learning algorithm which provides interventions in real-time and also provides recommendations on the most popular selected interventions.

Aim The aim of the current project is to develop a mobile phone intervention for people with psychosis, and to conduct a feasibility study of the TechCare App.

Methods The study consists of both qualitative and quantitative components. The study will be run across three strands:

- qualitative work;
- test run and intervention refinement;
- feasibility trial.

Results Preliminary analysis of qualitative data from Strand 2 (test run and intervention refinement) in-depth interviews with service users ($n=2$) and focus group with health professionals ($n=1$), highlighted main themes around security of the device, multimedia and the acceptability of psychological interventions being delivered via the TechCare App.

Conclusions Research in this area can be potentially helpful in addressing the demand on mental health services globally, particularly improving access to psychological interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁷ The University of Manchester, School of Nursing, Midwifery and Social Work, Manchester, United Kingdom

* Corresponding author.

Introduction The early intervention service (EIS) approach is based on therapeutic interactions, which promote service user recovery from first episode psychosis. Collaborative therapeutic work between the service user and case manager depends on good communication. This can be a challenge for people with psychosis as the process of thought can be disrupted or stimulus misinterpreted leading to communication errors.

Objective The objective is to develop an interactive tool that can assist service user's communication of distress, whilst employing a psychoeducational approach to the use of an informal therapeutic measurement scale; subjective units of distress (SUDs) and early warning signs (EWS). The ApTiC mobile intervention will include ten numerically graded emoticons from low to extreme distress. Each emoticon is associated with specific individualised service user descriptors and linked to an individually agreed action plan and level of response to be offered by a staff member.

Aim The aim of the present study will be to examine the feasibility and acceptability of the ApTiC mobile intervention in preparation for a larger randomised controlled trial.

Methods Phase one: qualitative research to inform the development of the complimentary tool and mobile app (qualitative). Phase two: a 12-week rater-blinded randomized control trial of ApTiC compared to routine EIS case management (quantitative).

Results The qualitative data will be presented.

Conclusions It is expected that once validated, the SUDs based ApTiC will enhance rapport and understanding thus improving the recovery approach to well-being and hopefully preventing relapse or the involvement of the crisis team or hospital admissions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Postnatal depression is known to cause disability and suffering in women and negative consequences both for their infants and their families, with huge costs globally. Several studies from low and middle income countries (LAMIC) have demonstrated that effectively delivered psychological interventions are cost effective for improving maternal and child health, but access to these interventions is limited in both the low and high income countries.

Objective The objective of the study is to develop and test a mobile phone-based intervention (TechMotherCare), which will include components of cognitive behavioural therapy (CBT) and child development related psychoeducation.

Aim The aim of the study is to examine the feasibility and acceptability of the TechMotherCare intervention.

Methods A total of 36 participants will be recruited from health centers in Karachi, Pakistan for this 2-arm randomized pilot study. The TechMotherCare App intervention will be based on principles of CBT and learning-through-play (LTP) a parenting intervention and will assess the real-time depressive symptoms of participants and respond, using intelligent real time therapy (iRTT) dependent on symptoms reported by participants.

Results Outcome assessments will be completed after 3 months (end of intervention). In-depth qualitative interviews will also be conducted with participants pre- and post-intervention. The trial is ongoing and we will present both the qualitative and quantitative results.

Conclusions The results of this pilot trial will inform the design of a larger randomised controlled trial using a mobile based technology platform to address the huge treatment gap in LAMICs.

The patient-centered care features quality, affordable, and timely care in a variety of settings – technology is a key part of that – particularly among younger generations and child and adolescent patients. The consumer movement related to new technologies is nearly passing clinicians by, as new ways of communicating with others (text, e-mail, Twitter, Facebook) revolutionizes how we experience life and access healthcare. This paper explores a continuum with healthy, innovative behavior on one end (e.g., social media) and pathological Internet use on the other end – and the range of self-help and e-mental healthcare options being used. Specifically, it focuses on how social media adds to,

yet may complicate healthcare delivery, such that clinicians may need to adjust our approach to maintain therapeutic relationships, interpersonal/clinical boundaries, and privacy/confidentiality. We suggest planning ahead to discuss expectations about online communication between doctors and patients as part of the informed consent process, offer other do's and don't's for patients and clinicians, and review applicable guidelines. More research is needed on consumer and patient use of technology related to healthcare, as is an approach to basic and advanced measurement of outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Telepsychiatry in the opinion of Polish patients and psychiatrists

M. Wojtuszek, J. Kachnic, J. Wutke, K. Krysta*

Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

* Corresponding author.

Background Telepsychiatry takes advantage of modern communication technologies and new forms of patient–doctor and doctor–patient contact.

Objective This research focuses on the knowledge of telepsychiatry and the attitude to it among patients and psychiatrists in Poland. **Subject and methods** An anonymous survey was conducted among 105 psychiatrists aged 26–74, including 74 women and 31 men and 102 patients aged 21–79, including 61 women and 41 men.

Results Research reveals that the majority of patients never met with the concept of “e-psychiatry” and do not know what it means. However, more than 50% of respondents answered positively to every question considering the utility of telepsychiatry. Furthermore according to 18%, it is possible to replace an eye-to-eye conversation by videoconferencing. Only 15% of doctors claim to have an extensive knowledge on telepsychiatry, and 10% do not know what it means. The vast majority of physicians perceive positive aspects of this method of medical care, but 63% would not want any general insertion of telepsychiatry. Doctors are apprehensive of losing personal data and medical confidentiality, and of the necessity of legal changes.

Conclusions The obtained results allow us to conclude that Polish patients and doctors, regardless of their knowledge, age, gender or disease, perceive advantages of telepsychiatry. In connection with this, implementing this method into the Polish medical market makes sense and is in accordance with both patients' and doctors' opinion. Based on our research, we confirmed that there is a necessity of wider popularisation of telepsychiatry among Polish therapists.

MindfulSpot: A mindfulness mobile app for people dealing with infertility

B. Monteiro^{1,*}, A. Galhardo^{1,2}, M. Cunha^{1,2}, M. Couto¹, F. Fonseca³, L. Carvalho⁴

¹ Instituto Superior Miguel Torga, Psychology, Coimbra, Portugal

⁴ Instituto Superior Miguel Torga, Technology and programming of information systems, Coimbra, Portugal

* Corresponding author.

Introduction Infertility is not only a medical condition and its impact in mental health is well established. Although most couples facing fertility problems and the demands of medical treatment are able to adjust, some of them may show psychological difficulties with clinical relevance, such as depression and anxiety. The Mindfulness Based Program for Infertility (MBPI) is a group intervention designed for infertile women and data from its efficacy study revealed impact in depressive symptoms reduction as well as in internal and external shame, entrapment and defeat. Based on the MBPI, a mindfulness app targeting infertile patients was developed – the MindfulSpot.

Aims This study addresses the MindfulSpot development.

Methods The MindfulSpot is a prototype mobile app, which seeks to offer the chance of practicing mindfulness in a comfortable and accessible way. This app covers informative audio and written texts. The audio contents correspond to mindfulness formal practices and suggestions for informal practice, making possible its use throughout different moments of the day. Beyond the practices mentioned above, users are invited to explore the informative menu, including information on the impact that infertility may have in several aspects of the patients' lives.

Results The efficacy of the MindfulSpot is still under analysis and results are expected to be available soon.

Conclusions The MindfulSpot was designed as a medium for training mindfulness skills and it includes useful information regarding specific aspects of the emotional impact of infertility. Additionally to its independent use, it may also be used as a support tool of the MBPI.

Towards a gold standard for internet-delivered programs in behavioural and mental health

D. Richards^{1,2,*}, N. Vigano¹, D.D. O'Callaghan³, E. O'Brien¹, J. Mooney¹, C. Bonner¹

¹ SilverCloud Health, Clinical Research & Innovation, Dublin, Ireland

² Trinity College Dublin, School of Psychology, Dublin, Ireland

³ SilverCloud Health, Chief Security Officer, Dublin, Ireland

* Corresponding author.

Introduction Technological innovation has been pervasive and has touched almost every aspect of modern life, including the delivery of behavioural and mental health care. As telehealth expands, internet interventions are particularly interesting as a medium of delivering effective care. However, standards are required to help inform healthcare policy makers, providers, clinicians and patients. **Objective** Move towards outlining a gold standard for internet-delivered behavioural and mental health interventions.

Aims Contribute and build upon existing standards and guidelines for the practice of telehealth, but to now extend these to include internet-delivered interventions.

Methods Drawing from research, experience and practice, the authors propose a matrix for the evaluation of what might be considered a gold standard for internet-delivered behavioural and mental health interventions.

Results Seven elements are proposed and considered aspects of what would constitute a gold standard and they include, the use of evidence-based and empirically supported content, robust, engaging, secure and responsive technologies, shaped by behavioural health subject matter experts, employ user-centred design and development principles, have a focus on accountable care-achieving clinical outcomes, have research and evaluation that supports its effectiveness, and a well developed implementation science and support.

Conclusion The paper proposes some characteristics that could compose a gold standard for internet-delivered interventions for behavioural and mental health care. The contribution is neither exhaustive nor conclusive, but offers an invitation to the discussion. **Disclosure of interest** The authors have not supplied their declaration of competing interest.

mHealth in mental health: What do the users think about it?

J.M. Sengelen*, I.C. Banea

Centre Hospitalier de Rouffach, pôle 2/3, Rouffach, France

* Corresponding author.

There is currently a major trend for e-health and the first mental health applications for smartphones are now released. Patients and health care professionals are still struggling to position themselves in relation to these new approaches. So, we wanted to know more about the involvement of mental health users and their care providers in mobile health (mHealth) technologies. We needed to understand their expectations and their reluctances. For achieving this purpose, we carried out an online survey for mental health users ($n = 108$). It turns out that people who responded to this survey are well equipped with smartphones and are experienced in using mobile apps. They expect from professionals an advisory role in relation to e-health. The major interest lies in practical, concrete applications and the main reluctance is about management, transit and storage of data. It is necessary to involve mental health users and health care professionals together in order to develop these new tools. To achieve this, health care professionals must continue to invest themselves in the use and understanding of m-Health tools.

Drug-induced tardive dyskinesia: A case report

I. Abida*, I. Baati, S. Omri, R. Sallemi, J. Masmoudi
CHU Hédi Chaker, Sfax, Tunisia

* Corresponding author.

Introduction Tardive dyskinesia (TD) is a serious medical condition that affects a significant proportion of patients treated with antipsychotic agents.

Objective To report a patient who developed tardive dyskinesia after initiation of antipsychotic and antidepressant treatment.

Case report Miss H. is 24-year-old Tunisian woman who had been diagnosed with bipolar disorder 6 years ago. She received various drugs: olanzapine, haloperidol, amisulpride, sertraline, paroxetine, etc. On November 2013, she first complained of hand tremor and then developed severe dystonia of the trunk and chorea. A series of laboratory tests was performed after the onset of these involuntary movements. It included complete blood count, liver, renal, and thyroid function tests, blood prolactin level, blood glucose level, blood copper level and ceruloplasmin level. A brain MRI was also performed. These examinations showed no specific findings. The diagnosis of TD was presumed. The patient was first treated with amisulpride, lorazepam, avlocardyl and piracetam until May 2014. Then, amisulpride was substituted by olanzapine

until August 2015. The lack of improvement led to her admission. We stopped antipsychotic treatments and prescribed her vitamin E (900 mg/day), clonazepam (6 mg/day) and vitamin B6. The follow-up led to the decline of the Abnormal Involuntary Movement Scale (AIMS) score of 7 points over 6 weeks.

Conclusion TD remains a serious side effect that worsens the prognosis and affects the quality of life of patients. Cluster randomised trial should be done in order to develop practice recommendations for prevention and management of TD.

A psychiatrist's poll on their methods to treat schizoaffective disorder

L. Aguado^{1,*}, B. Girela², P. Calvo¹, J.E. Muñoz-Negro¹, J.A. Cervilla¹

¹ San Cecilio University Hospital, Mental Health Unit, Granada, Spain

² Santa Ana Hospital, Mental Health Unit, Motril, Spain

* Corresponding author.

Introduction Schizoaffective disorder (SAD) is the second most frequent psychotic disorder after schizophrenia. There is a relative scarcity of specific studies looking into SAD treatment and evidence on drug treatment of SAD is patchy. We aimed to study naturalistically, interviewing psychiatrists systematically, what do they think is most useful in SAD treatment.

Objectives/aims To know the actual management of SAD in real clinical practice and provided data for effective clinical studies.

Methods We administered an online poll to 65 psychiatrists (52% male, 48% female), 75% of which described themselves as having a holistic background. The poll was completed using a Google doc's questionnaire. The three main questions made were:

- what is your first treatment choice for SAD;
- do you tend to use mono- vs. poly-therapy;
- provide a level of utility for each drug between 1 (little use) to 4 (maximum use).

Results Atypical antipsychotics were considered the most common first choice in the treatment of SAD according to 66.2% of psychiatrists. The second most selected first choice answer was combining drugs and psychotherapy, which was answered by 20% of the sample. Monotherapy was preferred (60%) to polytherapy (40%). Finally, the most useful drug for SAD according to the sample was aripiprazole followed by mood stabilizers, olanzapine and paliperidone.

Conclusions Real practice in SAD treatment may differ grossly to what is advocated for in clinical guidelines and seem to also deviate from officially approved indications of some drugs.

Erotomania: A case and review

A. Almada*, A. Luengo, P. Casquinha, M.J. Heitor
Hospital Beatriz Ângelo, Psychiatry, Loures, Portugal

* Corresponding author.

Introduction Erotomania (“Clérambault’s syndrome”) is a rare syndrome characterized by a delusional belief of being loved by another person, usually of higher social status.

Objective This case report aims to describe and discuss a case of erotomania, providing an updated review on this disorder.

Methods Regular clinical interviews were performed during admission period to collect information about the clinical case and to promote an intervention approach to the patient. A literature review in Science Direct database, with the keyword “erotomania”, was also conducted.

Results A 51-year-old woman was admitted in Beatriz Ângelo Hospital psychiatric ward with delusional beliefs of being loved by the ex-boss. Positive misperceptions and persecutory delusions regarding her husband as the obstacle for the love were manifested. The lack of insight for the situation and the necessity of treatment created some difficulties. A clinical report and a bibliographic review were made to allow a better understanding about the case and to orient the case evidence based.

Conclusions Despite the evidence about the good response of atypical antipsychotics (e.g. risperidone) in erotomania, in our case study, the partial remission was only achieved with high dose of the old typical antipsychotic, pimozide.

Defining therapeutic plans and purposes for psychiatric patients served by a home-visiting program

F. Couto Gomes*, G. Sobreira, I. Capeto Coelho, J. Oliveira
Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction PreTrarCa is a home-visiting program at an inpatient clinic in Lisbon, Portugal, constituted by a team of nurses, social workers and a psychologist, and managed by a psychiatrist.

Objective To describe the criteria and purposes for the home-visiting program, its congruence with therapeutic plans, and patients' service satisfaction.

Aims To help in defining common purposes to patients and professionals, to improve quality of care.

Methods Questionnaires regarding admission criteria and purposes for the home-visiting, individualized therapeutic plans and service satisfaction were applied to patients, family, team members and psychiatrists.

Results As for the individual treatment plan, symptom control and better treatment adherence were frequently mentioned by patients, family members, team members and psychiatrists (respectively, 72.22% and 47.22%, 93.75% and 93.75%, 94.44% and 91.67%, and 68.42% and 33.33%). Team members frequently mentioned control of drug adverse effects (88.89%) and psychiatrists frequently mentioned control of drug adverse effects, social integration and social skills (42.11%, 36.84%, 21.05%). As for the purposes of home-visiting, symptom control and better treatment adherence/administration of long acting injectable drugs were frequently mentioned by the majority of patients, family members, team members and psychiatrists (69.44% and 66.67%, 93.75% and 93.75%, 91.67% and 80.55%, 52.63% and 68.42%).

Conclusions Patients, families, team members and psychiatrists share similar views on the individual therapeutic plans, though team members and psychiatrists give importance to some aspects that patients and their families tend not to mention. Purposes are generally congruent with treatment plans, which may signal satisfactory communication between all these elements.

EV1301

Pregabalin augmentation in the treatment of borderline personality disorder with partial therapeutic response – case report

D. Duisin^{1,*}, S. Milovanovic², B. Batinic³

¹ Institute of Psychiatry Clinical Center of Serbia, Day Hospital, Belgrade, Serbia

² Clinic of Psychiatry, Clinical Centre of Serbia, Serbia School of Medicine, University of Belgrade, Day Hospital, Belgrade, Serbia

³ Clinic of Psychiatry, Clinical Centre of Serbia, Faculty of Philosophy, Department of Psychology, University of Belgrade, Belgrade, Serbia

* Corresponding author.

Introduction Emotional dysregulation is one of the core problems of borderline personality disorder (BPD). Forty-one year-old married female diagnosed with BPD at the age of 21, was admitted to the partial hospitalization unit due to a depressive symptoms and emotional dysregulation and poor overall functioning.

Objective Patient was previously treated with numerous psychotropic agents: antipsychotics (AP) – fluphenazine, levomepromazine, risperidone, clozapine; antidepressants (AD) sertraline, mirtazapine, maprotiline, amitriptyline; psychostabilizers – carbamazepine/valproate) without achieving the full therapeutic response. After switching to combination of clomipramine and aripiprazole, we have reached partial clinical response.

Aim The aim of this treatment was to improve clinical response and achieve emotional stability by augmentation with neuromodulator pregabalin.

Method Augmentation strategy was realized by gradual titration and tapering of pregabalin (300 mg/d) over a two-week period. We started with pregabalin dose of 75 mg/d, followed by gradual increase to the dose of 300 mg/d. The Beck Depression Scale (BDS) and the Emotional Dysregulation Scale–short form (EDS) have been used for efficacy monitoring.

Results Mental state before augmentation therapy: the BDS (score 30–moderate depression) and the EDS–short form (score 127). Parameter status after augmentation with pregabalin: BDS score 16–mild mood disturbance, EDS score 87.

Conclusions Augmentation strategy with pregabalin have improved emotional control, maintained affective and behavioral stability, with significant reduction of feelings of emptiness, as well as the achievement and maintaining of emotional attachment.

Pharmacotherapy of acute psychotic states: The reason for benzodiazepines and valproic acid augmentation

A. Veraksa^{1,*}, A. Egorov²

¹ City Psychiatric Hospital N 3, Inpatient Unit N 24, St. Petersburg, Russia

² IM Sechenov Institute of Evolutionary Physiology and Biochemistry, Laboratory of Behavior Neurophysiology and Pathology, St. Petersburg, Russia

* Corresponding author.

Acute psychotic states (APS) usually are diagnosed as schizophrenia spectrum and affective disorders and make up about 45% of cases. The goal of the study was to elucidate the effect of benzodiazepines (BDZ) and valproic acid augmentation in the APS pharmacotherapy. The study was carried out on 102 inpatients diagnosed up to ICD-10 as schizophrenia ($n=24$), acute and transient psychotic disorders ($n=40$), other mental disorders due to brain damage and dysfunction and to physical disease ($n=17$), schizoaffective disorder

($n=12$), bipolar affective disorder ($n=9$). Patients were randomized into four therapeutic groups:

- benzodiazepines (BDZ);
- one neuroleptic or combination of one neuroleptic and one BDZ (NBDZ);
- combination of valproic acid with BDZ or neuroleptic (VBDZN);
- polypragmasy (PP): from two drugs of one group up to four and more drugs at the same time.

The mental state of the patients was evaluated daily and estimated before, weekly and after APS termination by BPRS and CGI scale. The APS in all groups lasted from 1 to 50 days (mean 11.4). The shortest duration of APS was in BDZ group – 4.7 days; in VBDZN and NBDZ, the duration was 7.0 and 7.4 days ($P<0.05$); in PP group, the treatment lasted 24.5 days ($P<0.001$). Before therapy, average BPRS rate was 43.5 ± 8.1 , CGI – 6.2 ± 0.8 ; after APS, BPRS was 18.9 ± 2.1 , CGI – 1.1 ± 0.3 . All rates did not differ among subgroups. APS therapy by BDZ and its combination with neuroleptics and valproic acid was effective compared to the polypragmasy.

It is possible to change clozapine by another neuroleptic

F.X. Fluvia^{1,*}, R. Pastor²

¹ Home for the chronically mentally ill, Psychiatry, Xabia, Alacant, Spain

² Home for chronically mentally ill Xabia Bella, Psychiatry, Xabia, Alacant, Spain

* Corresponding author.

It is well known that when we have a schizophrenic patient who do not respond to two batches of neuroleptics at full dosage for more than six month, it may be wise to try with clozapine which is believed to be one of the best neuroleptics we have but with two main handicaps: it can produce leucopenia which can be fatal and epileptic seizures as well. We do think that in many cases, clozapine has been used too soon in the treatment of the schizophrenic patient, before we can really talk of a resistant patient. To prove that we have changed the clozapine treatment of four chronically ill schizophrenic patients admitted to a home for the chronically mentally ill. Two patients were changed from clozapine 400 mg/day to paliperidone 15 mg/day along two months time. They both improved in mental clarity and ability of thinking. Another patient were changed from 600 mg/day to 27 mg/day of paliperidone. That patient worsened a little bit mainly with hostility and social avoidance but it was mandatory to change neuroleptic because he had had two seizures and had low levels of platelets and therefore he was at risk of developing leukopenia. The fourth one was taking 300 mg of clozapine and was changed to 12 mg of paliperidone. We got no change in the clinical outcome.

Discussion We discuss the different explanations for the results we got.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prescription profile of antipsychotics in inpatients with psychotic disorders

M.D.C. García Mahía*, Á. Fernández Quintana, M. Vidal Millares
CHU A Coruña, Psychiatry, A Coruña, Spain

* Corresponding author.

Introduction Previous studies of prescribing in psychiatric services have identified the relatively frequent use of combined antipsychotics in schizophrenia.

Aims – To analyze the proportion of patients treated with more than one antipsychotic;

– to study clinical as sociodemographic variables associated with types of prescription.

Methods Retrospective descriptive study of treatment prescribed to psychiatric inpatients treated in an acute care unit of Psychiatry Service in a large teaching hospital during a period of 3 years. Consecutively admitted inpatients receiving concurrent antipsychotics were compared with those treated with a single antipsychotic. Prescription drug records at discharging were revised, $n = 263$.

Results From the total sample, 61% received more than one antipsychotic. The most common types of combinations were atypical plus a typical antipsychotic followed by two atypical antipsychotics, being less frequent combination of three or more antipsychotics. There were 19 different drug combinations. Concurrent antipsychotics were most frequently prescribed in schizophrenia and schizoaffective disorder. Patients with more previous episodes of illness received more frequently concurrent antipsychotics than patients with low number of previous episodes of illness ($P < 0.03$). Patients with longer time of hospitalization, and age between 30 and 50 years were treated more frequently with several antipsychotics. Analysis with other variables is presented in the study.

Conclusions There is a significant difference in the strategies of treatment with antipsychotics depending on diagnosis and number of previous episodes of illness. The concurrent use of multiple antipsychotics in psychiatric inpatients appears to be a response to treatment resistance and is frequent in schizophrenic patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Brief psychotherapy in eating disorders

E. García^{1,*}, M. Leon², F. Polo², R. Martínez³

¹ Ciudad Real, Spain

² Hospital General de Ciudad Real, UTCA, Ciudad Real, Spain

³ Hospital General de Ciudad Real, USMIJ, Ciudad Real, Spain

* Corresponding author.

First time we began to work with eating disorders, we used to hear the chronic course of the illness and the long-term treatment that our patients would need. When you have a team trained in brief psychotherapy, but not in this specific area, it sounds as just the opposite you try to reach with your patients. National guidelines however are full of psycho-educational and cognitive-conduct treatment's models, without any other validated kind of treatment. However, it was our experience that solution focused or problem focused therapy were also two clinical effective approaches to many psychiatric problems. In fact, we had a mature consult, in which as far as two thirds of patients had become, some way chronic. Problem was, as far as we can imagine, if that was a disease's effect or a lack of a deeper intervention, which were wider than those classic. So, we classified our patients in resistant or not resistant, and doing so we add brief therapy to the first group, reevaluating every week each intervention and the course of the illness. By doing so, we found that chronicity was, in some cases, just the result of limited treatments. Here we have analysed some chronic patients with a bad course and the alternatives that let them to recover.

Tech Connect: An innovative pilot intervention to improve treatment adherence for adolescents with mood disorders

R. Gearing^{1,*}, K. Moore², R. Guetta³

¹ University of Houston, GCSW, Houston, USA

² Columbia University, Columbia, New York, USA

³ North Shore Child and Family Guidance Center, Child and Family, New York, USA

* Corresponding author.

Introduction Over a third of adolescents terminate prematurely from mental health treatment. A core underlying assumption of most, if not all, evidence-based psychosocial interventions is that patients will fully and actively engage in the treatment protocol. Poor adherence remains a fundamental challenge in the treatment of mood disorders in adolescents. Tech Connect is a proactive, technology-assisted intervention of manualized between session contacts and structural supports to increase adherence of adolescents with depression who are at high risk of dropout from treatment.

Objective To test Tech Connect in a randomized controlled trial (RCT) with depressed adolescents by:

- assessing feasibility;
- estimating preliminary intervention parameters;
- investigating adherence and mental health outcomes.

Methods An RCT with depressed youths (13–17 years) who were at high-risk for premature dropout were randomized to Tech Connect (treatment condition) or standard community-based care (control condition). Standardized measures assessed mental health symptoms and outcomes, health beliefs, family involvement, adherence, and therapeutic alliance.

Results Results found significant differences between the number of treatment sessions attended by the adolescents assigned to Tech Connect and those of the control group.

Conclusions Tech Connect was designed to increase sessional adherence in the early phase of treatment. All adolescents in the treatment condition attended the first treatment session, with 90% attending the targeted first 8 sessions. In comparison, only 40% of adolescents in the control condition completed the first 8 sessions. The Tech Connect Program is a novel, technologically driven intervention designed to address this gap by improving engagement and adherence to treatment.

¹ Hospital Clínico Universitario de Valladolid, Psiquiatría, Valladolid, Spain

² Complejo Asistencial de Zamora, Psiquiatría, Zamora, Spain

* Corresponding author.

Introduction Over the years, it has been shown that various psychopharmaceuticals cause alterations on thyroid function. The objective of this review is to summarize the most important thyroid side effects associated with them. Special attention is paid to antidepressants, which are widely used and whose side effects are not receiving the attention they deserve.

Clinical cases This review presents three cases of patients who were undergoing treatment with venlafaxine. Before the start of

treatment, we asked for an analytical with thyroid profile in which no change was observed. After establishing treatment, a decrease in total T4 and free T4 was observed, TSH remained unchanged.

Discussion It is important to note the need for systematic evaluation of thyroid function at the beginning of an antidepressant treatment, and perform their monitoring controls. We cannot forget that the clinical of hypothyroidism sometimes presents with depressive symptoms, which could mask the effectiveness of treatment.

Clozapine induced blood dyscrasias and a therapeutic approach

A. Gomez Peinado*, P. Cano Ruiz, S. Cañas Fraile, M. Gonzalez Cano, G.E. Barba Fajardo

Hospital Nuestra Señora del Perpetuo Socorro, Mental Health, Albacete, Spain

* Corresponding author.

Introduction Clozapine is a neuroleptic commonly used in treatments resistant to schizophrenia. However, despite the benefits, clozapine might cause some serious side effects. Hence, it is of the utmost necessity to keep an exacting control of the patients.

Objectives To study some of the therapeutical approaches to the treatment of clozapine induced neutropenia and agranulocytosis.

Methods Review of some articles in Mental Health Journals.

Results The treatment with clozapine, substratum of aminergic and muscarinic receptors, entails a 0.9% risk of causing agranulocytosis, and approximately a 2.7% risk of causing neutropenia. Both occur, over 80% of them, during the first 18 weeks of treatment. Thus, before starting it, it is necessary to draw some blood and analyze the complete blood count (CBC). Also, we must analyze CBCs weekly during the first 18 weeks. Other dyscrasias like leukopenia, leukocytosis, anaemia, eosinophilia, thrombocythaemia or thrombocytopenia can also be observed. When agranulocytosis appears, it can be treated by discontinuing the clozapine treatment, but also using granulocyte-colony stimulating factor or lithium, both separated or combined with clozapine. Lithium produces reversible leukocytosis once plasma levels of > 0.4 mmol/L are reached. Despite the simultaneous treatment with lithium, clozapine can trigger some neurological side effects, it seems that seizure risk remains invariable.

Conclusions Some of the clozapine's side effects, like neutropenia or agranulocytosis, are potentially lethal. Their treatment consists of discontinuing clozapine or initiating granulocyte-colony stimulating factor or lithium. These are good options that can give rise to a later continued treatment with clozapine.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Misuse of trihexyphenidyl: Factors associated to the prescription

K. Hajji^{1,*}, M. Ilyes², F. Soumaya², Y. Samira², N. Mohamed²

¹ Boulogne-Billancourt, France

² Hospital Of Mahdia, of Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Trihexyphenidyl (THP) is an anti-Parkinson and anticholinergic drug. It is essentially prescribed by psychiatrists in order to treat abnormal movements and Parkinsonism induced by antipsychotics. However, in unusual practice, the THP is widely used by patients.

Aims To assess different factors associated to the prescription of trihexyphenidyl in patients treated with neuroleptics.

Methods A cross-sectional, descriptive, comparative and analytical study among 153 patients followed in outpatients clinics and treated by antipsychotics.

Results During a six-month period, 153 patients were interested by the study. In total, 79.73% of them were receiving a treatment by THP. Mean age was 47.79 years old. Almost patients were married (44.1%), having a primary level education (46.7%) and jobless (66.7%). Mean factors associated to THP prescription were: hospitalization in a psychiatry unit ($P=0.025$), good evolution of mental disorder during hospitalization ($P=0.008$), regular follow-up ($P=0.005$), episodic evolution and existence of residual symptoms ($P=0.001$), personality disorder ($P=0.025$) and somatic comorbidities ($P=0.001$). Prescription was crucial in order to indicate necessity of THP. Doses of neuroleptics were a determinant factor ($P=0.0001$). Forty-one percent of patients were receiving more than one treatment ($P=0.0001$). In most cases, prescription consists of classic antipsychotics (67.60%).

Conclusion Prescription of THP should be argued, considering different factors associated to the prescription, in order to prevent misuse of the drug.

Light as an aid for inpatient recovery: A systematic review

J. Henriksen*, N. Okkels

Aarhus University Hospital, Psychiatric Research Academy, Department of Affective Disorders Department Q, Risskov, Denmark

* Corresponding author.

Introduction The indoor light environment of hospital wards may affect functions and symptoms that are central to the process of inpatient recovery, including sleep, anxiety, well-being, and mood. **Objective** To assess whether interventions in light improves recovery in hospitalized patients across all medical specialties.

Methods We systematically searched and reviewed the literature for RCT's on adult inpatients where any light intervention were compared to standard care or placebo. We reviewed effects of light on various outcomes, and compared differences in administration, timing, color, and intensity of the light.

Results We identified 2330 titles, of which 32 met our predefined selection criteria. Choice of administration, timing, wavelengths, and intensity varied. However, most studies investigated bright light therapy with high intensity and short exposure time, others low-intensity light at night filtered of wavelengths in the blue spectrum, and yet others the use of dawn simulation. Comparators were either placebo lamps with low intensity or regular indoor light. Most studies were performed on psychiatric inpatients, showing that bright light therapy is an effective aid in recovery of major depression. Across medical specialties, several studies reported improved sleep quality during the light intervention. Other studies found a lower rate of delirium. In elderly patients with dementia, studies found light interventions to relieve agitation and confusion. **Conclusions** Light may ease a broad range of symptoms and behaviors across inpatient categories. The intervention is inexpensive, well tolerated, and non-invasive. This study underlines intelligent lighting design as an interesting, yet under-explored, non-pharmaceutical treatment.

* Corresponding author.

Introduction The use of long-acting injectable antipsychotics is useful in patients with low therapeutic compliance.

Objective To present the demographic and clinical data of a case series in which long-acting injectable aripiprazole has been prescribed in an ambulatory Mental Health Center.

Methods Systematic review of the related literature and clinical history of patients in which long-acting injectable aripiprazole had been prescribed from January to March 2015 in a Mental Health Center.

Results We found 10 patients, whose diagnosis were schizophrenia (4), non-specified psychosis (2), personality disorder (1), bipolar disorder (1), schizoaffective disorder (2), of whom 7 were men and 3 women, with a mean age of 43.8 years old. The mean of years since diagnosis was 15.1 years. In 7 patients, we found concomitant treatment with another antipsychotic agent (low dose quetiapine in all of them); antidepressants in 1 patient, benzodiazepines in 6; mood stabiliser in 5 and biperidone in 1. In relation to previous antipsychotic drugs, we found: aripiprazole 15 mg/day oral (4); long-acting injectable paliperidone 150 mg/28 days (2) paliperidone 6 mg/day oral (1); combination of paliperidone 6 mg/day oral plus olanzapine 5 mg/day oral (1). Only 4 patients had used long-acting injectable drugs previously in their lifetime. The reason of having initiated treatment with long-acting injectable aripiprazole was sexual disturbance (3); lack of compliance (4); clinical instability (2) and motor side effects (1).

Conclusions In our series, we can observe a chronic patient profile, predominantly men with diagnosis of psychotic spectrum.

Uncommon effects of clozapine

J. Jerónimo*, J. Santos, L. Bastos
Santa Maria's Hospital, CHLN, Psychiatry and Mental Health
Department, Lisboa, Portugal

* Corresponding author.

Introduction Clozapine is the first option for treatment-resistant schizophrenia, affecting about 20–30% of all patients. Weight gain, sedation, hypotension and hypersalivation are common and well-known adverse effects associated with clozapine. However, it is also important to be aware of uncommon adverse effects, like parotitis.

Objective We report a case of clozapine-induced parotitis.

Methods Literature was accessed through Pubmed, using the search terms parotitis and clozapine.

Results A 36-year-old male with paranoid schizophrenia, whose psychotic symptoms have responded only slightly to two antipsychotic trial, with both haloperidol and olanzapine. Therefore, he began treatment with clozapine with the dose titrated to 400 mg/day. At first, the only registered adverse effect was hypersalivation. Eventually, after 3 months of treatment, he developed a unilateral swelling of the left parotid gland. Bacterial and viral parotitis were ruled out and the diagnosis of clozapine-induced parotitis was evoked. Patient scored 5 in the Parotitis-Specific Criteria Modified Naranjo Probability Scale. Symptomatic medication was initiated with paracetamol and a non-steroidal anti-inflammatory with a favorable outcome.

Conclusion There are few reports of clozapine-induced parotitis, a very rare and poorly known adverse effect with an unknown pathophysiology. Early recognition and proper management are essential to reduce morbidity associated with the treatment. There is no consensus how to manage these adverse effect, however, generally it is not necessary to discontinue the treatment.

Development and psychometric testing of a Scale for Evaluating Self-management Needs of Knee Osteoarthritis (SMNKO) in Taiwan

M.H. Kao^{1,*}, Y.F. Tsai²

¹ Mackay Junior College of Medicine, Nursing, and Management, Department of Nursing, New Taipei City, Taiwan

² College of Medicine, Chang Gung University, School of Nursing, Tao-Yuan, Taiwan

* Corresponding author.

Introduction Knee OA is a chronic and multifactorial disease; self-management needs are complex, which requires a multi-dimensional management plan. There is a need for healthcare providers to provide patients with knowledge of knee OA and how to effectively manage the disease.

Objective Self-management-needs scales are one means of determining the management requirements of an individual patient. There is no suitable instrument available for assessing self-management needs of adult patients with knee OA in Taiwan. This study developed an instrument that could assess the self-management needs of knee OA patients using Orem's self-care theory as a theoretical framework.

Aims This study developed and psychometrically tested a new instrument for measuring adult patients' self-management needs of knee OA (SMNKO).

Methods Development of the instrument involved three phases: item generation and scale development; content and face validity of the initial instrument; and evaluation of validity and reliability of the new instrument. Participants ($n = 372$) were purposively sampled from orthopaedic clinics at medical centres in Taiwan.

Results The self-care theory guided the development of the 35-item SMNKO scale. The content validity index was 0.83. Principal components analysis identified a 3-factor solution, accounting for 53.19% of the variance. The divergent validity was -0.67 ; convergent validity was -0.51 . Cronbach's α was 0.95, Pearson correlation coefficient was 0.88, and the intraclass correlation coefficient was 0.95.

Conclusions The SMNKO scale can measure and identify the individual self-management needs of knee OA patients. It will help healthcare providers better evaluate strategies that can help these patients cope with this chronic disease.

Some side effects of antipsychotics

L. Montes Reula^{1,*}, A. Ballesteros Prados²

¹ Red Salud Mental Gobierno de Navarra, CHN Psychiatric, Pamplona, Spain

² Red Salud Mental Gobierno Navarra, Mental Health Center, Estella, Navarra, Spain

* Corresponding author.

Background Pharmacological treatments for chronic diseases cause side effects. It is important to identify which of these effects could be avoided because it is a cause to drop the treatment. In the chronic psychiatric illness, one of the problems is the induction of changes in prolactin (PRL) serum.

Purpose Review of the literature that has been published to assess the association between different types of antipsychotic drugs and prolactin levels.

Method Literature search on PubMed, NCBI literature in the last three years using MeSH terms: “prolactin” and “antipsychotics”.

Conclusions The increase of prolactin is a common effect poorly studied in the past. After several studies have been able to achieve treatments, called “atypical”, which cause less effect on this substance. For example, asenapine, olanzapine and ziprasidone have a slight effect on PRL levels. Aripiprazole could even result in lower levels probably by partial agonism on dopamine receptors. Therefore, we have to make a good clinical practice taking into account the effectiveness and tolerance and interpersonal variation.

The effect of relaxation techniques and trigger points therapy on stress reduction of patients with mental health disorders in a Greek hospital

G. Lyrakos^{1,*}, D. Menti (MSc in Health Psychology)², I. Spyropoulos¹, V. Spinaris¹

¹ General Hospital Nikaia “Ag. Panteleimon”, Psychiatric, Nikaia, Greece

² City Unity College, Department of Psychology, Athens, Greece

* Corresponding author.

Background Patients with mental health disorders usually suffer from high stress levels. Trigger points therapy has been shown to be very effective in providing prompt relief from stress in these patients.

Aim To investigate the effect of the combined use of relaxation techniques and trigger points therapy on stress levels of patients with mental health disorders.

Method Thirty-one patients participated in this study, 14 (45.2%) males and 17 (54.8%) females, with a mean age of 39. Out of them,

10 (32.3%) suffered from anxiety disorders, 6 (19.4%) from obsessive compulsive disorder, 10 (32.3%) from depression and 5 (16.1%) from chronic condition stress. Data analysis was conducted with *t*-test analysis and ANOVA, using the SPSS software.

Results The findings revealed significant differences on stress levels before and after the use of relaxation techniques and trigger points therapy as $t(30)=18.316$, $P<0.0001$. Before the use of relaxation techniques and trigger points therapy, individuals reported higher stress levels ($M=6.129$, $SD=1.087$) compared to after the therapy ($M=1.741$, $SD=.889$). Moreover, significant differences were found in stress reduction with regard to psychiatric illnesses ($F(3,27)=5.027$, $P=0.007$). More specifically, individuals with depression reported lower reductions in their stress levels after the therapy compared to both those with chronic condition stress ($M=-2.1$, $SD=0.61$, $P=0.013$) and anxiety disorders ($M=-1.4$, $SD=0.503$, $P=0.05$).

Conclusion The findings of this study highlight the importance of using trigger points therapy, combined with relaxation techniques, to reduce stress levels of patients with mental health disorders.

Antipsychotic combination strategies in patients with bipolar disorder

R. Molina Ruiz*, M. de Castro Oller, V. Gomez Macías, M. Roncero Rodriguez, F. Montañes Rada

Hospital Universitario Fundación Alcorcón, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Treatment strategies in bipolar disorder (BPD) has changed in the last decades and polypharmacy including antipsychotics has become extremely common compared to monotherapy with mood stabilisers. Clinicians tend to use 2 or more atypical antipsychotics despite the lack of evidence to support safety, tolerability and efficacy of this practice.

Objective To determine most frequently used treatment strategies in a sample of bipolar disorder patients and review of the literature.

Methodology Analysis of a sample of 35 patients with BPD from Madrid and review of recent literature for evidence arising from international guidelines recommendations and meta-analyses.

Results Most frequently used treatment approach in our sample was polytherapy, including at least 1 atypical antipsychotic (31%) and polytherapy, including at least 2 antipsychotics (47%) together with mood stabilisers. Only 11% were in monotherapy with mood stabilisers and another 11% were in monotherapy with one atypical antipsychotic but without mood stabilisers. Aripiprazole and olanzapine were among the most preferred atypical antipsychotics. Efficacy and safety of such combinations have not been systematically compared with monotherapy in the literature. Previous data indicate that polytherapy in BPD may incur in important disadvantages [1].

Conclusions Treatment of BPD remains challenging. Polytherapy seem to have replaced monotherapy due to less relapses and better results in treatment of affective symptoms. However, compliance and secondary long-term effects should be taken into account. Superiority in terms of efficacy in polytherapy needs to be balanced with tolerability issues. More studies on combination therapy, long-term efficacy and safety are needed.

A systematic review on pharmacological treatment in delusional disorder

J.E. Muñoz Negro*, J. Cervilla-Ballesteros
Andalusian Health Service, Mental Health Unit, CIBERSAM.
University of Granada, Granada, Spain

* Corresponding author.

Introduction Pharmacological treatment is the gold standard in DD. None SGA is authorized for the treatment of DD. To date, only one systematic review-addressing treatment of DD has been performed. However, it was only reported data about CBT therapy.

Methods A systematic review on pharmacological treatment of DD was conducted. We selected the best evidence available, mainly searching in online databases. Then, we analyzed them critically, assessing its biases and quality, finally performed a narrative and quantitative synthesis.

Results The quality of the evidence was very low. There were not randomized clinical trials and most of the studies were observational or case series reports. We could collect a good number of cases, ($n = 336$) 137 FGA, 189 SGA and 10 antidepressants. Antipsychotics achieved a good response in a 61.35% of the patients. Moreover, SGA (65.08% good response) were more effective than FGA (56.20% good response) although the difference did not reach statistical significance. ($\text{Chi}^2 = 2.6384$, $P \leq 0.10$). Haloperidol (88.14% good response), risperidone (69.60% good response) and olanzapine (71.64% good response) were the most effective treatments, although the difference in favour of haloperidol it might be biased by the methodology used.

Conclusions Although the quality of the evidence was very low to make strong recommendations, antipsychotics appear to be an effective treatment for DD. We need to develop clinical trials in DD and SGA might be the best candidates to do.

Keywords Paranoia; Delusional disorder; Treatment; First generation antipsychotics; Second generation antipsychotics.

Lamotrigine induced DRESS syndrome in bipolar disorder: Multiple snares behind a potentially life-threatening adverse reaction

G. Oriolo^{1,*}, A. Brugués², J.M. Goikolea¹, L. Pintor¹

¹ Hospital Clínic de Barcelona, Psychiatry, Barcelona, Spain

² Hospital Clínic de Barcelona, Dermatology, Barcelona, Spain

* Corresponding author.

Background Lamotrigine is widely used to prevent bipolar depression. Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) is a rare, potentially life-threatening adverse effect. The long latency between drug exposure and disease onset, added to the high variability of its clinical presentation, can increase the risk of misdiagnosis lamotrigine withdrawal delay.

Objective To highlight potential risk factors that can be related to a worse clinical onset and evolution of lamotrigine-induced DRESS syndrome.

Methods We report the case of a 25-year-old-man, with a type I bipolar disorder, treated with lithium and lamotrigine 50 mg per day during the first 13 days of treatment, progressively increase up to 200 mg. Thirty-five days after the treatment initiation, a pruritic rash appeared in his upper arms, and scabies infestation was diagnosed. After 72 hours, the patient required urgent hospitalization due to hemodynamic instability.

Results On admission, facial edema and erythrodermia were involving 70 to 80% of the body surface. DRESS diagnosis due to lamotrigine was made following RegiSCAR criteria (Table 1). Psychiatric medication was stopped and DRESS treatment established. Complete recovery without recurrence was achieved after 2 months.

Conclusions The lamotrigine up titration faster than recommended may have facilitated the DRESS syndrome reaction. Moreover, the latency between lamotrigine introduction and the rash onset could have increased the possibilities of misdiagnosis. In light of this, physicians need to consider at least the last 3 months treatment history when assessing a rash, as the delay of DRESS syndrome diagnosis can fastly lead to a fatal event. Table not available.

⁵ Hospital Fundación de Jove, Psiquiatría, Gijón, Spain

⁶ Hospital Universitario Central de Asturias, Unidad de Psiquiatría, Oviedo, Spain

* Corresponding author.

Introduction Long-acting injectable antipsychotics (LAIs) were developed in the sixties with the purpose of improving schizophrenia maintenance treatment. The main advantages are: the ability to ensure compliance, maintaining stable plasma concentrations and allowing better clinical management of drug therapy. Long-acting atypical injectable antipsychotics start to develop in the late nineties. Currently, they are the most widely used depot treatment for severe mental illness.

Objective Checking patient profile and diagnosis where we use LAIs.

Methods Review of 217 patients treated with LAIs in CSM El Coto-Gijón.

Results In our sample, the average age of the patients was 48.94 years old. Most of them were men (135 vs. 82). More than half of treated patients were diagnosed with schizophrenia (112), the paranoid subtype was the most repeated (93). Other severe mental illnesses were also treated with LAIs: emotionally unstable personality disorder (31), delusional disorder (19), bipolar disorder (15), schizoaffective disorder (12) and other less frequently. For all groups, paliperidone palmitate was the most used injectable antipsychotic. The new aripiprazole long-acting injectable starts being used in psychotic patients with a significant affective component.

Conclusions The schizophrenic patient remains being the prime candidate for this therapy although other severe mental disorders may also benefit of LAIs treatment. Most classical long-acting injectable antipsychotics have been replaced by new atypical injectable antipsychotics with a more tolerable side effects profile.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Therapeutic attitudes and clinical global impression: A 2-year follow-up study of 33 outpatients with a mental disorder in treatment with paliperidone palmitate

M.D. Perez Lopez*, M. Soto Laguna, J. Prados Gomez, I. Zarranz Herrera Oria, R. Perez Asenjo, S. Bolaño Mendoza, M. Fernandez Torrija Daza, P. Gonzalez Rivera, B. Herrejon Teodoro
Hospital Provincial de Toledo, Psiquiatria, Toledo, Spain
* Corresponding author.

Introduction Maintaining antipsychotic therapy in mental disorder is important in preventing relapse, rehospitalization, and suicide. Lack of awareness of illness may be a leading cause for non-adherence. Long-acting depot can prevent non-adherence and thus potentially contribute to better patient outcomes.

Objective The aim of this prospective, observational, non-interventional 2-year-long study is to assess severity and post-intervention changes and attitudes toward medication of a group of patients treated paliperidone palmitate (PP).

Methods Thirty-three outpatients stabilised with PP during the last 24 months. Inclusion criteria were: patients' age (> 18 years), a diagnosis of schizophrenia, bipolar disorder, schizoaffective disorder stabilised during the last 12 months with PP, without a diagnostics from axis I or II (except for nicotine of caffeine) and able to sign the inform consent. Data collected: general sociodemographic and clinical data (age, sex, level of education, socioeconomic situation, family support, psychiatric diagnosis, years of evolution, use/abuse of substances, treatment, previous and later number of hospitalisations. Evaluations included disease severity (Clinical Global Impression-Severity (CGI-S) and Drug Attitude Inventory, (DAI)).

Results Thirty-three outpatients were followed during 24 months [mean dose 132,58 (44,4) mg], 75,8% were men, age 45,05 years old, 87,8% with a diagnoses of paranoid schizophrenia. Antipsychotic monotherapy increased over the time with PP. Significant improvements were observed on both Clinical Global Impression and Drug Attitude Inventory. The number of rehospitalizations and mean stays decreased from the beginning until the end of these 24 months.

Conclusions Our results suggest an improvement in the patient's clinical vision and attitude towards medication with long-acting depot.

* Corresponding author.

Introduction Shared decision-making denotes a structured process that encourages full participation by patient and provider in making complex medical decisions. There has been extensive and growing interest in its application to long-term illnesses but surprisingly not in severe psychiatric disorders, such as schizophrenia. However, the great majority of schizophrenics are capable of understanding treatment choices and making rational decisions. Although the main justification for shared decision-making is ethical, several randomized controlled trials support its effectiveness in improving the quality of decisions, but robust evidence in objective health outcomes is needed.

Aims and objectives Of the study: to demonstrate the effectiveness, measured as treatment adherence and readmissions at 3, 6 and 12 months, of shared decision making in the choice of antipsychotic treatment at discharge.

Of the oral presentation: to present the study design; to make an interim report of the data obtained at the moment of the congress.

Methods Randomized controlled trial, prospective, two parallel groups, not masked, comparing two interventions (shared decision making and treatment as usual). Study population: Inpatients diagnosed of schizophrenia and schizoaffective disorders (ICD-10/DSM-IV-R: F20 y F25) at Adult Acute Hospitalization Unit at Jerez General Hospital.

Results Currently in the recruiting phase with 55 patients included in the study. An interim analysis of at least half of the target sample size.

Conclusions We will show the study design and decision tools employed. Conclusions in relation to the effectiveness (adherence and readmissions) and subjective perception.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Shared decision-making denotes a structured process that encourages full participation by patient and provider in making complex medical decisions. Although the main justification for shared decision-making is ethical, several randomized controlled trials support its effectiveness in improving the quality of decisions, but robust evidence in objective health outcomes is needed.

Aims Analyze the degree of antipsychotic polytherapy or monotherapy in patients discharged after their inclusion in the study and randomized to Share Decision-Making or Treat as Usual. Present preliminary conclusions after 20 months of follow-up.

Methods Randomized controlled trial, prospective, two parallel groups, not masked, comparing two interventions (shared decision making and treatment as usual). Previous antipsychotic treatment is collected by interviewing patient and family and as included in digital history and health card, discharge and reviews conducted at 3, 6 and 12 months.

Results Interim analysis shows there are no differences between groups (SDM and TaU) before intervention, we note the following results:

– the degree of antipsychotic polytherapy prior to admission for the entire sample decreased at discharge;
 – at discharge, there is a difference between SDM and TaU. Antipsychotic polytherapy in SDM decreases in a higher level.

The utility of omega-3 fatty acids in depression

M.A. Quintanilla*, A. Salas, S. Pedrosa, L. Bosqued, C. Perez, B. Villagrasa, B. Aguado, P. Gracia
 Lozano Blesa Hospital, Psychiatry, Zaragoza, Spain

* Corresponding author.

Introduction Recent studies have reported therapeutic benefit from the use of omega-3 fatty acids (EPA and DHA) as adjunctive treatment of depression.

Objectives The goal of this work is to assess the effectiveness and tolerability of dietary supplementation with omega-3 in the treatment of depressed patients.

Method Prospective, descriptive, observational study in a general psychiatry outpatient clinic. Consecutive inclusion of depressed patients started on dietary supplementation with omega-3 because of partial response to antidepressants and/or intolerance to high doses or combination of antidepressant drugs between January and May 2015. Sociodemographic variables, clinical data and information about tolerability were recorded. Clinical response to treatment over time was assessed at 4–6 months follow up using the 5-item CGI (Clinical Global Impression) scale.

Results We included 30 depressed patients started on omega-3. None of them reported side effects. Seventy-three percent of patients reported clinical improvement (40% much improvement, 33% some improvement). None of them got worse. We did not find association between clinical response and age, sex, type of depression nor duration of illness.

Conclusion Despite the limitations of this study, our work support previous positive results on the use of omega-3 fatty acids (EPA and DHA) as adjunctive treatment of depression. Giving the safety of its use, clinicians might recommend omega-3 as adjunctive treatment of depression in cases with a partial response to antidepressants.

 Complejo Hospitalario de Huelva, Psiquiatria, Huelva, Spain

* Corresponding author.

Objective To demonstrate the therapeutic efficacy of aripiprazole LP by a case of difficult clinical management and that we often find in our daily practice.

Methods Description of a clinical case of a 21-year-old man, recently diagnosed with paranoid schizophrenia with no awareness of disease neither treatment adherence and harmful use of THC and cocaine that are identified as precipitating factors for multiple hospital admissions.

Results Injectable medication with objective clinical improvement is significant, cessation of readmissions, achieving improvement in all parameters measured functionality and proper adherence to treatment as well as outpatient mental health of both devices as of drug dependence.

Conclusion Psychiatry is facing the great challenge of modifying the natural history to the deterioration of schizophrenia, a disease considered one of the leading causes of years lived with disability. The objectives medium and long-term treatment of this disease are centered on the delay-avoidance disability and improving the functioning and quality of life of people with this disease.

Introduction The extended release injectable offers a good alternative for those patients with no or poor adherence to treatment. Numerous studies indicate that decrease the number of relapses in such individuals. Our aim is to check whether a group of our patients diagnosed with dual pathology coincide with these data.

Methods We followed a group of 5 patients diagnosed with paranoid schizophrenia or delusional disorder with drug consumption in the last year. We measured the number of relapses, understood as the number of visits to emergency and outpatient devices Mental Health Hospitals and hospitalizations six months before the start of treatment with aripiprazole injectable extended release and six months after.

Results The preliminary results point to a significant reduction in the number of emergency room visits and hospitalizations after starting sustained release injectable treatment.

Conclusions Our preliminary results are consistent with the literature, we found also reduced consumption of toxic and better adherence to drug addiction devices. The new antipsychotics extended release is a good alternative for patients with dual diagnosis.

Introduction Electroconvulsive therapy (ECT) is an effective depression treatment, but it has potential cognitive side effects. Bitemporal ECT has been traditionally used, but in recent decades, right unilateral (RUL) electrode placement has been proposed to decrease the cognitive side effects of ECT. Ultrabrief pulse (UBP) right unilateral (RUL) ECT is an increasingly used treatment option that can potentially combine efficacy with lesser cognitive side effects.

Objectives To evaluate whether ultrabrief pulse (UBP) right unilateral (RUL) electroconvulsive therapy (ECT) is as effective as brief pulse (BP) RUL ECT in addition to cause lesser cognitive side effects. **Material and methods** A search is performed in the available scientific literature on systematic review and meta-analysis of the subject under study, through the database PubMed.

Results – Current evidence supports the efficacy of right unilateral (RUL) electroconvulsive therapy (ECT) given with an ultrabrief pulse width in the treatment of depression;

– ultrabrief pulse RUL ECT leads to lesser cognitive side effects than traditional forms of ECT;

– ultrabrief pulse RUL ECT may be slightly less effective than traditional forms of ECT.

Conclusions BP compared with UBP RUL ECT was slightly more efficacious in treating depression and required fewer treatment sessions, but led to greater cognitive side effects. The decision of whether to use BP or UBP RUL ECT should be made on an individual patient basis and should be based on a careful weighing of the relative priorities of efficacy versus minimization of cognitive impairment.

Acute pancreatitis and olanzapine–valproate association: A pilot study

M.G. Ravel^{1,*}, E. De Vivo¹, F. Marmo¹, F. Gucci²

¹ Villa Camaldoli Alma Mater SPA, Psychiatrist, Psychodynamic Integrated Psychiatry Department, Napoli, Italy

² Villa Camaldoli Alma Mater SPA, Head Psychiatrist, Psychodynamic Integrated Psychiatry Department, Napoli, Italy

* Corresponding author.

Introduction Drugs are responsible for 0.1–2% of acute pancreatitis incidents, which is characterized by the onset of parenchymal fat necrosis with inflammation in a previously healthy individual (Jones, 2015). Elevation of serum amylase is an effective marker of disease (de Berardinis, 1999). Valproic acid induces acute pancreatitis as a direct toxic effect of free radicals on the pancreatic tissue (Kaurich, 2008). Most cases of pancreatitis occurred within 6 months after the start of therapy with one or more antipsychotic agents (Koller, 2003). The temporal relationship of the onset of pancreatitis with the start of drug therapy further supports a cause-and-effect relationship (Alonso-Alonso, 2006). Some clinical reports noticed sporadic acute pancreatitis in patients taking both valproate and olanzapine.

Methods We selected 50 psychiatric inpatients taking both olanzapine and valproate, presenting acute and aspecific gastroenteric symptomatology. We measured out their serum amylase and the time between drug prescription and start of gastroenteric symptomatology.

Results and conclusions A large part of subjects associated olanzapine and valproate over 6 months before gastroenteric symptoms would start. Elevation of serum amylase rates does not suggest a link between this drug association and acute pancreatitis.

Meanwhile, larger populations surveys could be helpful in early detecting sporadic cases.

Psychiatry heal thyself: a lifestyle intervention targeting mental health staff to enhance uptake of lifestyle interventions for people prescribed antipsychotic medication

S. Rosenbaum^{1,*}, A. Watkins², P.B. Ward¹, D. Pearce², K. Fitzpatrick², J. Curtis²

¹ University of New South Wales, Psychiatry, Sydney, Australia

² South Eastern Sydney Local Health District, Keeping the Body In Mind Programme, Sydney, Australia

* Corresponding author.

Introduction People experiencing severe mental illness (SMI) face a shortened life expectancy of up to 20 years, primarily due to preventable cardiovascular (CV) diseases. Lifestyle interventions are effective in reducing CV risk, yet examples of service-wide interventions are lacking. Staff culture remains a barrier to the successful implementation of lifestyle interventions. The Keeping the Body in Mind (KBIM) program, established by SESLHD (Australia), aims to close the gap in life expectancy through multidisciplinary teams, including clinical nurse consultants, dieticians, exercise physiologists, and peer support workers. Prior to the KBIM rollout, an individualized lifestyle intervention called Keeping Our Staff In Mind (KoSiM) was offered to all district mental health staff.

Objective KoSiM examined the effectiveness of a staff intervention to improve physical health, confidence, knowledge and attitudes of mental health staff.

Methods Mental health staffs were invited to participate in an online survey and a 4-week individualized intervention including personalised health screening and lifestyle advice, with a 16-week follow-up. Outcomes assessed included: attitudes, confidence and knowledge regarding metabolic health, weight, waist circumference (WC), blood pressure, sleep, diet, physical activity and exercise capacity.

Results Of a total of 702 staff, 204 completed the survey (29%). Among those completing the survey, 154 staff (75%) participated in the intervention. A mean decrease in waist circumference of 2 ± 2.7 cm, ($P < 0.001$) was achieved. Among staffs that were overweight or obese at baseline, 75% achieved a decrease in WC.

Conclusion Improving staff culture regarding physical health interventions is an important step in integrating lifestyle interventions into routine care.

Prolactine borderline, a case report

N. Salgado^{1,*}, B. Macias¹, S. Benavente², R. Ruiz¹

¹ Hospital Dr. Rodriguez Lafora, Psiquiatria, Madrid, Spain

² Hospital Universitario 12 de Octubre, Psiquiatria, Madrid, Spain

* Corresponding author.

Introduction It is known that antipsychotic drugs can increase prolactinaemia, we report a case in which the use of aripiprazole after treatment with paliperidone helped regaining normality levels.

Case report During treatment with PALiperidone 12 mg/day the patient, a 27-year-old female diagnosed with borderline personality disorder, developed hyperprolactinaemia with galactorrhoea

and menstrual disorders. During hospitalization, aripiprazole is introduced while paliperidone is progressively decreased. Antipsychotic were prescribed because delusions of reference and auditory pseudo-hallucinations arose suddenly in a woman without history of previous psychotic breaks. Before treatment with aripiprazole, prolactinaemia was 156,96 ng/mL (pregnancy test was negative) and after stopping, paliperidone was 23,60 ng/mL.

Discussion If hyperprolactinaemia symptoms appeared (galactorrhea...), aripiprazole is a good option if antipsychotic treatment is required. In this case, paliperidone was decreased slowly, while aripiprazole was increased, until minimum effective dose was reached.

Conclusions Hyperprolactinaemia is a common side effect in antipsychotic treatments and if symptoms appeared aripiprazole is a good option.

Delirium associated with sertraline, a case report

N. Salgado^{1,*}, S. Benavente², B. Macias¹, M. Duran¹, P. Leganes¹

¹ Hospital Dr. Rodríguez Lafora, Psiquiatria, Madrid, Spain

² Hospital Universitario 12 de Octubre, psiquiatria, Madrid, Spain

* Corresponding author.

Introduction Delirium is a clinical entity consisting of acute loss of consciousness, with attention deficit and fluctuating evolution. Antidepressive medication can cause these symptoms or worsen them.

Case report We report the case of a 84-year-old blind female who was diagnosed of delirium in relation to intoxication with sertraline. The patient was admitted into a short-stay psychiatric unit for three days. She presented behavioural disturbances consisting in auto and heteroaggressive behaviour, altered consciousness and visual hallucinations (rocks, turtles). When dosage of sertraline was doubled from 50 mg/day to 100 mg/day visual hallucinations started. There were not other medical causes found, so sertraline was suspended, achieving clinical improvement.

Discussion This case report shows how a patient with antidepressive treatment can display delirium. The three main causes of delirium that are infections, side effects and metabolic syndrome.

Conclusions In the case of treating a patient with delirium, the presence of previous illness has to be investigated. It is indispensable to describe the presence of previous illness, medication and recent changes of the dosages in the medical history in a patient with Sertraline.

Drug eruption due to bupropion, a case report

N. Salgado^{1,*}, S. Benavente², J.M. Coll³, A. Vives¹

¹ Hospital Dr. Rodríguez Lafora, Psiquiatria, Madrid, Spain

² Hospital Universitario 12 de Octubre, Psiquiatria, Madrid, Spain

³ Hospital Universitario La Paz, Psiquiatria, Madrid, Spain

* Corresponding author.

Introduction We present a clinical case of eruption caused by the use of bupropion. Bupropion is known to cause hypersensitivity reactions.

Case report We report the case of a 48-year-old female who was diagnosed of depressive disorder. She went to emergency because

a few days after prescribing bupropion (150 mg/24 h) scaly skin eruptions were found distributed along the skin. In the present case, after its introduction, bupropion was found to be a probable etiological agent. The patient was successfully treated with corticosteroids. Because of that, bupropion dosage was stopped and replaced with fluoxetine. No remissions and exacerbations were noticed in a month's follow up.

Discussion In this case report, we present a patient with an eruption related to bupropion. The aetiological spectrum of eruption include drugs, infectious agents and food additives. Drugs attributing eruption include nonsteroidal anti-inflammatory drugs, antibiotics, and anti-epileptic drugs, antidepressive medication amongst others.

Conclusions No specific diagnostic criterion exists for eruption and the diagnosis is purely based on clinical presentation. Diagnostic features, which suggest eruption, are the acute onset (or recurrent nature) and skin lesions.

A “Newly Discovered in Romania” atypical antipsychotic prolonged release treatment for patient with schizophrenia. First results of a naturalistic study with recently approved paliperidone palmitate

M. Sarpe^{1,*}, M. Ladea², M. Bran³

¹ Focsani, Romania

² “Obregia” Hospital of Psychiatry, III Ward, Bucharest, Romania

³ “Coltea” Hospital, Outpatient Care Unit, Bucharest, Romania

* Corresponding author.

Introduction Intramuscular paliperidone palmitate is a long-acting atypical antipsychotic, which has only been marketed in Romania from march 2015 as a free of charge medication/subsidized for the acute and maintenance treatment of schizophrenia in adults.

Objectives and aims To determine the efficacy and tolerability of paliperidone palmitate in 12 patients with schizophrenia in an outpatient care unit, taking into account the limited clinical experience with this product in Romania.

Methods The study was performed in an outpatient care unit. Data was collected from medical records of patients started on paliperidone palmitate between March and June 2015. This time period was selected because we wanted to have at least a 6-month period of evaluating these patients. Some of the patients were previously on risperidone long-acting injection (in Romania the advantages of a 1-month injection instead of 2 and the fact that the medication does not need to be held in a refrigerator are 2 important factors that can increase the compliance of the patients). Others were treated with other long-acting antipsychotics (flupentixol). The rest were patients treated before with risperidone, with good response, but with problems of non-compliance.

Results None of the patients treated with paliperidone palmitate relapsed. Some of them had, at maximum dose, minor extrapyramidal symptoms that disappeared when we lowered the dose. Taking into account the lack of insight and the non-compliance of patients with schizophrenia, this treatment seems to be extremely valuable, maybe more in this kind of cases, in outpatient care units.

Integrated treatment for opioid addiction complicated with neuroophthalmic pathology due to codeine and levomycetin abuse narcoassociated phenomenon

I. Sosin*, Y. Chuev, O. Goncharova

Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

* Corresponding author.

Introduction Among drug addicts cohort in Ukrainian population, the phenomenon of codeine narcotic effect intensification and prolongation with antibiotic levomycetin simultaneous combined dose was identified. Current narcology encounters the insufficiently studied problem of drug addicts who lost vision due to levomycetin abuse at chronic codeine intoxication. Continuous levomycetin abuse was proved to cause optic nerve neuritis followed with eyesight loss. This is connected with discrete loss of eyesight pathogenesis in opioid addicts.

Aims and objectives To elaborate integrated method of treatment considering main pathogenic links of this narcotic addiction.

Method It is based on combined therapy at traditional detoxication and includes membrane plasmapheresis 2–5 times at once every 3 days. Everyday 2.0 mL pyridoxin hydrochloride 5% solution for 15 days. Capillary stabilizer L-lysine aescinat in drops once in 24 h for 5–8 days. Transorbital medicinal electrophoresis (thiamine bromide 2.5% solution), 15–20 min exposure, daily, 10–12 procedures. Peroral retinol acetate, 1 capsule 3–4 times daily, for 7–10 days. Enterosorbent atoxil, 10–12 g daily, for 3–5 days.

Results Five codeine addicts with neuro-ophthalmic disorders due to levomycetin abuse as a narco-associated phenomenon were examined. The addicts explained additional levomycetin composition in individual narcotization schemes by the aim to intensify and prolong codeine effects maintaining its stable dose. Combined comprehensive therapy restored the eyesight partially; renewed capacity to move independently, the patients' disability was ceased.

Conclusions Membrane plasmapheresis in the proposed method integrates in therapy the prescribed pharmaceuticals and corresponds numerous tasks of detoxication at continuous combined codein and levomycetin abuse.

Nutrition interventions in people with severe mental illness: Novel strategies for addressing physical health co-morbidity in a high-risk population

S. Teasdale^{1,*}, P. Ward², K. Samaras³, S. Rosenbaum², J. Curtis¹, O. Lederman¹, A. Watkins¹, B. Stubbs⁴

¹ South Eastern Sydney Local Health District, Mental Health, Bondi Junction, Australia

² University of New South Wales, Psychiatry, Sydney, Australia

³ Garvan Institute of Medical Research, Diabetes and Obesity Program, Darlinghurst, Australia

⁴ Kings College, London, Psychosis Studies, London, United Kingdom

* Corresponding author.

Introduction Nutrition interventions are critical for weight management and cardiometabolic risk reduction in people experiencing severe mental illness (SMI). As mental health teams evolve to incorporate nutrition interventions, evidence needs to guide clinical practice.

Aims A systematic review and meta-analysis was performed to assess whether nutrition interventions improve:

- anthropometric and biochemical measures,
- nutritional intake of people experiencing SMI.

To evaluate the effectiveness of a dietician-led nutrition intervention, as part of a broader lifestyle intervention, in the early stages of antipsychotic prescription.

Method An electronic database search was conducted to identify all trials with nutritional components. Included trials were pooled for meta-analysis. Meta-regression analyses were run on potential anthropometric moderators. Weekly individualised dietetic consultations plus group cooking classes were then offered to clients attending a Community Early Psychosis Programme, who had recently commenced antipsychotics for a 12-week period.

Results From pooled trials, nutrition interventions resulted in significant weight loss (19 studies, $g = -0.39$, $P < 0.001$), reduced BMI (17 studies, $g = -0.40$, $P < 0.001$), decreased waist circumference (10 studies, $g = -0.27$, $P < 0.001$) and lower blood glucose levels (5 studies, $g = -0.37$, $P = 0.02$). Dietician-led interventions ($g = -0.90$) and trials focussing on preventing weight gain ($g = -0.61$) were the most effective. The 12-week nutrition intervention resulted in a 47% reduction in discretionary (junk) food intake ($P < 0.001$) and reductions in daily energy ($-24%$, $P < 0.001$) and sodium intakes ($-26%$, $P < 0.001$), while improving diet quality ($P < 0.05$).

Conclusion Evidence supports the inclusion of nutrition interventions as part of standard care for preventing weight gain and metabolic deterioration among people with SMI.

Acute dystonia and dyskinesia progressing in the patient with fibromyalgia upon the use of duloxetine

C. Tüz

Erenköy FTR Hastanesi, Psychiatry, Istanbul, Turkey

Purpose In this article, a case who was prescribed duloxetine (30 mg capsule) upon the fibromyalgia diagnosis by a physical therapist and had acute dystonia and dyskinesia after approximately 1.5 hours from duloxetine intake shall be presented.

Case It was learnt that a married female patient aged 38 consulted a physical therapist with the complaint of back pain and duloxetine (30 mg capsule) was prescribed. It was reported that, the patient applied to our hospital with the complaint of involuntary movements around the mouth, on the lips and neck, spasm, inability to open the mouth completely, spasm in jaw, gritting teeth, mumbling and aphasia after approximately 1.5 hours from her duloxetine intake. The patient was conscious. Her psychomotor activity was natural. As a result of cranial MR, EEG, BT examinations hemogram and the routine biochemistry examinations, any abnormality in zinc and iron levels was not detected. Complaints of the patient regressed after 1 hour from the discontinuance of duloxetine and the administration of biperiden 5 mg/mL ampoule 1000 cm³ in SF. After 72 hours, any symptoms were not found.

Discussion Dopamine neurotransmission can be inhibited through the increase in serotonin and norepinephrine [1]. Additionally, dystonia may originate from the prevailing of noradrenaline as a result of the failure of dopaminergic–noradrenergic balance [2].

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Additive effect of religious activity in the management of patients with schizophrenia: A study from Bangladesh

M.M.J. Uddin

National Institute of Neurosciences and Hospital, Psychiatry, Dhaka, Bangladesh

Introduction Schizophrenia is a chronic psychiatric illness that needs psychological treatment in addition to drug treatment for betterment of the patients. Religious activity is one of the psychological modalities of treatment for schizophrenia patients practiced in some centers in Bangladesh.

Objective – To see the additive effect of religious activity and practices in addition to antipsychotics in the management of schizophrenia;

– to see the socio-demographic characteristics of the of the schizophrenia patients;

– to assess the compliance of the patients taking religious activities.

Methods Fifty-two patients with schizophrenia taking antipsychotics and religious activity comprises group A and 46 age, sex, religion and duration of illness matched patients with schizophrenia taking only antipsychotics comprises group B were selected purposively for the study in National Institute of Mental Health (NIMH), Dhaka, Bangladesh from October 2012 to March 2013. Among the group A, most of them were Muslim. Religious activity and practices started according to their own religion.

Results Patients with schizophrenia who received antipsychotics and religious activity showed reduced relapse rate (17%), increased treatment compliance (89%) and improve quality of life (82%).

Conclusion Religious coping assigns significance to life challenges and provides a sense of meaning and purpose, emotional comfort, personal control, intimacy with others and a higher power. Further broad based study is needed in this regard.

The clinical effect an Nao Wan Merger risperdal on schizophrenia

Y. Zhang

Xi'an mental health center, Xi'an, China

Objective To evaluate the clinical curative effect of risperdal merger An Nao Wan for schizophrenia.

Methods Screening a mental health center in the first half of 2012 hospitalized patients with schizophrenia, which alone give risperdal or merger An Nao Wan give risperdal with 28 days treatment cycle, were as a clinical observation objects. Efficacy was assessed using symptoms scale (PANSS), evaluation of adverse reactions was with side effects scale (TESS). And through collecting the clinical data, related testing results, the daily detailed medical records to record adverse reactions.

Results Fifty cases of screened 427 patients meet the conditions, including 11 cases with risperdal merger An Nao Wan, and 39 cases only used risperdal. All of 50 cases after two weeks treatment, the symptoms were down significantly ($P < 0.01$). The adverse reactions rate of patients only with risperdal was 53.8%, of patients with risperidone merger An Nao Wan was only 27.3%.

Conclusion Risperdal merger An Nao Wan can improve the therapeutic effect of risperidone, short the recovery time of

schizophrenia, prevent the adverse reaction of psychotic drug, also improve the safety and patient drug compliance.

⁵ Hospital Clínico Universitario Lozano Blesa, Department of Psychiatry, Zaragoza, Spain

* Corresponding author.

Introduction Hospitalization is fundamental in the treatment of severe psychiatric disorders, at present and in the past. The Psychiatric Hospital “Ntra. Sra. Del Pilar de Zaragoza”, established in 1425, is one of the most ancient hospitals and with longest history of the country, one of the first centers to start considering as demented persons as another sick patient. This paper describes the sociodemographic and clinical characteristics of the patients admitted to the psychiatric hospital between 1912 and 1915.

Method We developed a descriptive research, using secondary information sources (clinical histories) of patients hospitalized between 1912 and 1915. For data analysis was used software SPSS 10.

Results We reviewed 110 files and the most common diagnoses were senile dementia and manic-depressive psychosis. The mean of age was 42 years, and the predominant marital status was the single status (47%). We documented that in more than 60% of the cases, the precedence of the patients was from rural zone. El 75% of the patients had remained hospitalized during several years until their death. Only the 10% were discharged for improvement.

Conclusion It is important to understand the socio-economic variables of the female patients from a century ago to be aware of the evolution of psychiatry and psychiatric treatment and consequently of the profile of current patients.

Domestic violence against women: The unheard sound

M. Alqahtani

King Khalid University, Mental Health, Riyadh, Kingdom of Saudi Arabia

Objective This study aims to discover women's attitudes toward domestic violence and their determinants, and explores the types of violence among women attending psychology clinic in Riyadh, Saudi Arabia.

Methods A cross-sectional study among married women who visited the psychology clinics. Study was carried out in March 2013. A total of 356 women were interviewed.

Results Our study indicates that descriptive statistics and logistic regression were used to measure relations between attitudes towards domestic violence and several variables. Many women (66%) reported different types of domestic violence against them in the last six months. The most common types of reported violence were verbal abuse (73%) and emotional abuse (47.5%) were the most violence reported, followed with several non-physical violence (35%). Whereas physical violence were reported among (11%) of the sample.

Conclusions The study shows frequent types of domestic violence against women. Increasing women's authorization, mainly providing the proper education about her right, may protect women from such violent behavior in the future.

² Unidade Local de Saúde do Nordeste, Department of Psychiatry and Mental Health, Bragança, Portugal

* Corresponding author.

Introduction Perinatal mental illness is one of the most frequent complications of pregnancy and the postpartum period. During the puerperium, the risk of developing a mental disease, such as a psychotic episode, is higher than in any other time in a woman's life.

Objectives The two main objectives are to describe a case series of 4 patients diagnosed with postpartum psychosis, and to synthesize the most important facets of this mental illness based on a literature review.

Aims The aim is to provide an overview of the clinical and epidemiological aspects of postpartum psychosis.

Methods The four clinical cases are presented by describing the similar as opposed to the differential aspects between all patients, using the information obtained through successive clinical interviews and the case file. Research was accomplished through Clinical Key and PubMed (2005–2015) using the keywords: postpartum psychosis.

Results In all four cases, the patients developed symptoms of sleep disturbance, mood fluctuation, altered thinking process with delusions or obsessions, and bizarre behaviours. This occurred within the first four weeks after labour, which was in all cases an obstructed labour. The data suggests that postpartum psychosis is a presentation of bipolar disorder. Clinical aspects and risk factors related to this perinatal complication all coincide with the cases presented.

Conclusions Postpartum psychosis is a rare presentation of perinatal mental illness. However, it presents itself, as a psychiatric emergency, and the early and correct assessment are crucial to reset the development of the mother–child bond.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Nursing is a job with high level of load, so nurses must have well health to deal with their job challenge. Mental health is easier ignored than physical health, thus, the risk factors of mental health is valued to pay attention.

Objective The objective of this study was to explore the related factors of mental health on female nurses in southern Taiwan.

Methods This is a cross-sectional study design, and all female nurses in two southern Taiwan hospitals are invited. We use structured questionnaires to collect information. Mental health, perceived stress, and job stress were measured with the five-item Mental Health Index (MHI-5; a subscale of the SF-36), Perceived Stress Scale (PSS), and Job Content Questionnaires (JCQ), respectively. All subjects provided informed consent as approved by the Ethics Review Board.

Results A total of 943 female nurses from two hospitals in Taiwan were recruited. Eight hundred and seventeen questionnaires were completed, and the response rate was 86.6%. Major of subjects were 30 or less years old (48.0%), married (67.1%), and university educational level (96.4%). The mean score of MHI-5 and PSS was 56.23 (percentage of full marks is 56.23%) and 20.14 (50.35%). The mean score of job control, mental demand, and social support was 63.5, 35.4, and 23.5, respectively. After adjusting confounders, PSS and social support were significant factors related with mental health.

Conclusions Mental health of nurses was common, thus, the strategies must be developed to reduce the perceived stress and promote social support in the future. (The publication is partial supported by the MOST, ROC).

The effectiveness of first-time-mother parent education for infant interaction and sense of parenting competence in Taiwan

F.F. Chung^{1,*}, H.E. Liu²

¹ Chang Gung University of Science and Technology, Department of Nursing, Taoyuan City, Taiwan

² Chang Gung University, School of Nursing, Taoyuan City, Taiwan

* Corresponding author.

Background This study is designed to investigate the relationship between first-time-mother postpartum parenting education and its effectiveness on the quality of mother–infant interaction and in turn, sense changes of parenting competence.

Methods Eighty-one healthy first-time-mother infant dyads were recruited. The control group ($n = 40$) received normal postpartum care, being the medical and cultural norms practiced in Taiwan. The experimental group ($n = 41$) received extra education by way of a 40-minute videotape on infant states, behaviors, communication cues, and a handout about play practices. Data was collected at five time periods: around first week, followed by the first, second, third and sixth month after birth. Assessment scales used for this study were the Chinese Version of the Parenting Sense of Competence Scale (C-PSOC), the Edinburgh Perinatal Depression Scale (EPDS), and the Nursing Child Assessment Teaching Scale (NCATS), in order to score videotaped mother–infant interactions.

Results The results of the study between these two groups showed that there was an increase in the quality of mother–infant interaction within the experiential group. In addition, it was found that at the five points of assessment, there were no significant sense

changes of parenting competency and no significant differences in postpartum depression. For all subjects, there was a correlation between postpartum depressions, competency in parenting, and quality of mother–infant interaction.

Conclusions Study results prove that first-time-mothers in Taiwan who are provided extra educations about infant abilities, as well as how to effectively play with babies, are likely to witness an improvement in interactional quality.

Characteristics of patients in a new perinatal mental health program

A. Doll

CSM Villa Vallecas, Psychiatry, Alcalá de Henares, Spain

Background Perinatal mental illness is a significant complication of pregnancy and the postpartum period. These disorders include depression, anxiety disorders, and postpartum psychosis. This mental health conditions have the potential to impact negatively on not only the woman but also her partner, infant, and family. Early detection and effective management of perinatal psychiatric disorders are critical for the welfare of women and their offspring.

Objective To evaluate the characteristics of patients who came to the new perinatal mental health program in the last 6 months.

Methods We recruited 13 mothers to take part in the study. Control variables included demographic and sociodemographic variables, pregnancy variables, antenatal and postpartum health behaviours, and birth outcomes. We assessed the improvement with Clinical Global Impressions Scale in the beginning of intervention and 3 months later.

Results Eight mothers were in the antenatal period, three in the postpartum, and one had suffered the pregnancy lost in the 36 week. The mean age was 33.44. The diagnoses were anxiety disorder (4), antenatal depression (2), postpartum depression (2), obsessive-compulsive disorder (1), bulimia nervosa (1), adjustment disorder (2) and complicated grief (1). Nine of them have a previous psychiatric history. All of them have been treated with psychosocial interventions, and in six cases have received psychopharmacological treatment. In all the cases, we observed a clinical improvement (CGI scale)

Conclusions Perinatal mental illness is a significant complication of pregnancy and the postpartum period, and need of specific programs and interventions.

Women, madness and psychiatry: Insane or persuaded?

C. García^{1,*}, M.A. Soriano²

¹ Valle del Guadalhorce Mental Health Center, University Hospital, Málaga, Spain

² University Hospital, Psychiatry, Málaga, Spain

* Corresponding author.

During the nineteenth and early twentieth century, feminist movements proliferated in Europe and USA in order to vindicate the rights of women both in the workplace and political issues, such as women's suffrage and birth policies, among others. At the same time, psychiatry tried to gain a foothold as a medical specialty, which created a positivist discourse where it was important to

measure and quantify mental disorders and their possible causes. As many feminist writers have argued (Chesler, Showalter, Jordanova, and others) this occurs at the same historical moment that a “feminization of madness” was taking place in several ways: madness begins to be described in feminine terms, Freud was developing his research on hysteria; diagnostics, such as puerperal and involuntal psychosis were taking hold; the interest about the influence of hormones in women's mood were raising, and gynaecology was thought as the organic etiology of female madness. The hegemonic psychiatric discourse appeared to have been a catalyst for logical social inclusion and exclusion, notably influencing the design of a new femininity, distant from the danger of feminism that began to gain prominence. The boundaries between insanity and mental health were really diffuse in case of women. The aim of my work is to highlight how attitudes and attributes of women were transformed into psychiatric symptoms, as the feminist theorist support. I will make a retrospective about clinical women reports of the public asylum of Malaga from the beginning of twenty century.

Antipsychotics and women: Yes, prolactin is important

N. Garrido-Torres*, S. Fernandez, A. Rodríguez, M. Reina, I. Prieto, A.S. Viedma, C. González, L. Hernandez
HJRJ, Psychiatry, Huelva, Spain

* Corresponding author.

Introduction The hormonal imbalance produced by antipsychotics can be detected by symptoms, such as: infertility, acne, hirsutism, sexual dysfunction and galactorrhea. We consider especially important the study of women's diseases, which may develop due to hyperprolactinemia, specifically: breast cancer, endometrial cancer and osteoporosis.

Objective To undertake a systematic review about the relationship between hyperprolactinemia as a result of the treatment with antipsychotics and endometrial and breast cancer.

Method An exhaustive search was performed on PUBMED and COCHRANE (from 2006 to 2015).

Fifteen papers were selected including comparative studies, clinical trials and clinical reviews.

Results With respect to endometrial carcinoma, there is no direct relationship with the use of antipsychotics. However, most papers have suggested that the blood prolactin elevation is a risk factor in the development of endometrial engrossment, which could lead to endometrial hyperplasia, polyps and endometrial cancer. Related to the use of antipsychotics as a treatment for schizophrenic women and breast carcinoma, a significant association was found and this association is strengthened through the interaction of other factors like the fact that women with schizophrenia are less worried about going to the clinical screening reviews in their health centre, smoking, and lower physical activity than healthy women.

Conclusions Aripiprazolis associated with a low prevalence of hyperprolactinemia. Menopausal women, the obese, and women who smoke receiving antipsychotics that produce hyperprolactinemia have the greatest risk of developing endometrial pathology. Schizophrenic women with hyperprolactinemia due to antipsychotics and loss of motivation to go to screening activities have a greater risk of breast cancer. Sexual dysfunction could be a non-adherence treatment factor.

EV1347

Codependency in mothers of addicted persons: Cross-cultural differences between Greece and Bulgaria

V. Giannouli^{1,*}, D. Ivanova²

¹ Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

² South-West University Neofit Rilski, Department of Psychology, Blagoevgrad, Bulgaria

* Corresponding author.

Introduction The people who maintain close relationships with relatives suffering from addiction to psychoactive substances may become more sensitive to develop a physical, mental and emotional state, similar to an emotional addiction.

Objective The aim of this study is to give a cross-cultural perspective to codependence and reveal the profile of female relatives of addicted persons in Greece and Bulgaria.

Method Thirty-nine Greek mothers of addicted persons from Greece ($M_{age} = 43.97$, $SD_{age} = 18.34$, all high school graduates), a similar group of forty Greek female participants (32 mothers of non-addicted persons, $M_{age} = 40.97$, $SD_{age} = 17.22$, all high school graduates), and thirty Bulgarian women (all mothers of addicted persons, $M_{age} = 53.55$, $SD_{age} = 5.58$, all high school graduates) were examined with the STAI-state questionnaire, the ZUNG Self Rating Depression Scale and the Questionnaire of Establishment of Codependency.

Results Results indicated that there are statistically significant differences between the Greek and the Bulgarian female relatives of addicted persons on the scores of ZUNG ($M_{Greek} = 51.64$, $SD_{Greek} = 2.07$, $M_{Bulgarian} = 73.63$, $SD_{Bulgarian} = 4.04$) and STAI ($M_{Greek} = 53.89$, $SD_{Greek} = 2.68$, $M_{Bulgarian} = 74.16$, $SD_{Bulgarian} = 4.84$), but not for the Questionnaire of Establishment of Codependency. Statistically significant differences in all three questionnaires were found for the groups of Greek mothers of dependent and non-dependent persons ($P < .005$).

Conclusions This research suggests that although there is more anxiety and depression reported by the Bulgarian mothers of addicted persons, no cross-cultural difference was found for codependence in mothers of addicted persons.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1348

Co-dependency in mothers of addicted persons: Data from Bulgaria

D. Ivanova^{1,*}, V. Giannouli²

¹ South-West University Neofit Rilski, Department of Psychology, Blagoevgrad, Bulgaria

² Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

* Corresponding author.

Introduction Co-dependent relationships are characterized as a type of dysfunctional helping relationship in which there is an excessive reliance on other people for approval and identity. This is very common for female relatives who support/enable another person's addiction, poor mental health, immaturity, and/or irresponsibility.

Objective The aim of the present study is to reveal the codependence profile of mothers of addicted persons in Bulgaria.

Method Four hundred Bulgarian women coming from Blagoevgrad, Sofia and Stara Zagora ($M_{age} = 53.55$, $SD_{age} = 5.58$; level of education: 71% with high school degree, 29% with university degree; all mothers of addicted persons) were examined at the Municipal Council on Drug Addiction Blagoevgrad with the

STAI-state questionnaire, the ZUNG Self Rating Depression Scale and the Questionnaire of Establishment of Codependency.

Results Results indicated that in a scale of scores ranging from 2 = minimum to 4 = maximum of co-dependence, this group of women had high self-reported levels of co-dependence ($M = 3.6375$, $SD = .52610$), a high depressive profile ($M = 49.07$, $SD = 3.23$, and high state anxiety ($M = 66.60$, $SD = 5.58$).

Conclusions The present research suggests that mothers of dependent individuals in Bulgaria show a high level of codependency, anxiety and depression. Future research should clarify the reasons of this overall negative emotional profile.

The meaning of war violence against women and children: Individual, family and social perspective

M. Goldner-Vukov^{1,*}, L. Moore²

¹ Mental Health Unit, Cairns, Australia

² Loma Linda VA, Loma Linda University, Psychiatry, Loma Linda, CA, USA

* Corresponding author.

Introduction Since 1995, more than 70 civil wars resulted in 20 million deaths and the displacement of 67 million people. In WWI civilian casualties accounted for 5% of victims, in WWII 50%, and presently 80% of casualties are women/children.

Objectives – To speak the truth without politics;

- to focus on the psychological dimension;
- to emphasize the dynamics of the abuse of women/children;
- to conceptualize the role of the individual, family and society;
- to emphasize the role of the unconscious in the hatred of women: mythological, psycho-historical, biological, psychological and political.

Aims – To describe the meaning of war violence against women/children on the level of the individual as degradation; on the level of the family as devastation and on the level of society as dehumanization;

- to instill hope that we can move from destruction to happiness;
- to show that embracing the feminine principle and shaping a different parenting is the way forward.

Methods Literature search, trans-cultural focus and unconscious dynamics of the hatred of women/children.

Results No ethnic group/nation is naturally more violent than any other. Violence is a cultural trend. The origins of abuse are on the level of the individual, family and society.

Conclusion There is hope for the future. The way forward is to promote the development of the anima in men and to affirm the feminine principle in women. In child-rearing practice, we recommend positive parenting with “a helping mode”. We believe that epigenetics can help.

Marital violence: Prevalence and risk factors

S. Hentati*, F. Charfeddine, L. Aribi, E. Elleuch, J. Aloulou, O. Amami

CHU Hédi Chaker Sfax, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Marital abuse is a serious social problem that has damaging impact on women's well-being. Therefore, prevention

and intervention efforts require determining the risk factors involved.

Objective Study the prevalence and risk factors of marital violence.

Methods A descriptive cross-sectional and analytical study carried on 50 married women without psychiatric history. Data collection was conducted via a questionnaire exploring socio-demographics characteristics and the marital relationship. Three scales were passed:

- the Conflict Tactics Scales (CTS): to assess verbal domestic violence (six items) and physical domestic violence (nine items);
- Maternity social support scale (MSSS): to evaluate the social and family support;
- Marital satisfaction scale of Azrin: assessing the satisfaction experienced of the wife at the partner's behavior.

Results The average age was 41 ± 11.5 years. Education level did not exceed the primary level in 64% cases. The socio-economic level was judged to be average in 72% of cases. The prevalence of domestic violence in its verbal and physical forms was 72%. More than one third of women (44%) reported that they were victims of physical. Low socio-economic level ($P=0,003$), low partner's educational level ($P=0,049$), parental history of childhood abuse, poor marital satisfaction and poor social and family support were significantly associated with physical violence, parental history of childhood abuse on the one hand, and physical violence on the other hand.

Conclusion Domestic violence against women, in its various forms remains a worldwide phenomenon. Several risk factors inherent to the woman, the husband and their marital relationship seem to be associated with domestic violence in its physical form.

The relation between social support and marital satisfaction and couples' depression after the birth of the first child

S.S. Hoseini Omam^{1,*}, L. Panaghi², M. Habibi Asgarabadi³, J. Davoodi²

¹ Semnan University, Psychology, Tehran, Iran

² Shahid Beheshti University, Family Therapy, Tehran, Iran

³ Shahid Beheshti University, Family Therapy, Tejr, Iran

* Corresponding author.

Aim Child birth can play a major role in parents' mental status and though it is considered as cherished event, it can dramatically jeopardize mental state of parents. Thus, we conducted this paper in order to study the relation between social support and marital satisfaction and couples' depression after the birth of the first child.

Methods Statistical population was consisted of 75 couples (parents). They were assessed via Edinburgh Postnatal Depression scale, marital satisfaction (ENRICH) and Multidimensional Scale of Perceived Social Support.

Results Regression analysis showed that there was a significant and inverse relationship between social support and depression among men and women after childbirth. Furthermore, there was a significant relationship between marital satisfaction and depression among men and women after childbirth. In addition, social support and marital satisfaction can be explained by the predictive role of depression in men after childbirth. But only social support can be predictive for explaining depression in women after childbirth.

Conclusion Thus, inadequate social support and low marital satisfaction can put couples at risk of postpartum depression.

Biofeedback-assisted relaxation training helps women with breast cancer after mastectomy: Effects of EMG-HRV biofeedback on psychological symptoms

S.S. Hoseini Omam^{1,*}, S. Makvand¹, H. Nazemi²

¹ Semnan University, Psychology, Tehran, Iran

² Semnan University, Psychology, Semnan, Iran

* Corresponding author.

Aim The aim of present research was to investigate the effects of EMG-HRV biofeedback-assisted relaxation training on psychological and physiological symptoms of breast cancer women after mastectomy.

Methods About 14 breast cancer women in one of the Tehran hospital's in-patient service were chosen and divided to experimental and control groups. Informed consent was provided from subjects and research design approved in the Ethics' Committee of Semnan University. Measures of DASS scale were gathered from all subjects before any intervention and experimental group were received 8 sessions of biofeedback-assisted relaxation training over 4 weeks interval, whereas no intervention made on control group. All patients were asked again to complete the DASS scale afterwards. Indices of smooth artifact free sEMG and HRV biofeedback were recorded using a Biofeedback 2000^x-PERT system Version 4.

Results Data were extracted and analyzed by GLM statistical analysis.

Conclusions Results were shown significantly differences for depression, anxiety and stress measures after 8 sessions biofeedback treatment. Significantly differences were also observed in the sEMG and HRV measures of two groups during baseline (0) middle phase (4) and termination phase (8) of the training sessions with better results for experimental subjects as well. It was concluded that biofeedback-assisted relaxation training could effectively decrease negative psychological symptoms of the breast cancer patients after mastectomy due to EMG-HRV positive changes.

¹ Semnan University, Psychology, Tehran, Iran

² Shahid Beheshti University, Family Therapy, Tehran, Iran

³ Shahid Beheshti University, Family Therapy, Tehran, Iran

⁴ Azad University Tonekabon Branch, Clinical Psychology, Tonekabon, Iran

* Corresponding author.

Aim In the present study, the psychological morbidity compared with perceived treatment outcomes based on expected outcome of the mastectomy in women with breast cancer.

Methods In the current study, 300 female patients with breast cancer were studied before and after mastectomy using the

General Expectancy Outcome Incongruence and General Health questionnaire-12.

Results The finding yielded that there was significant difference between patients with the high and low expected outcome of the mastectomy based on the psychological morbidity and perceived outcome of surgery. Similarly there is significant difference between the age, level of education, occupational status based on the psychological morbidity and perceived outcome of surgery. There was significant difference between elderly and non-elderly women psychological morbidity.

Conclusions Results show the higher level of expectation of the surgery outcome can be useful in establishing primary social adjustment but lead to underestimate the negative effects of surgery and may disturb psychological adjustment. Thus, high expectancy of outcome of treatment indirectly plays a significant role in increasing problems after mastectomy and can be affect on patients' psychological morbidity and perceived treatment outcomes.

⁴ University of Pedagogy in Bialystok, Department of Psychology, Bialystok, Poland

⁵ Medical University of Lublin, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland

* Corresponding author.

Introduction There is an evidence indicating that women experiencing intimate partner violence (IPV) quite common suffer from anxiety and depression, but predictors and protective factors are not well known in this group of patients.

Aim The aim of the study was to try to find factor that are connected with higher rates of anxiety and depressive symptoms in the group of female patients experiencing IPV.

Method The study was conducted in six randomly selected centers of primary health care (PHCs) in Lublin province. One hundred and two female patients experiencing IPV were administered a structured questionnaire and the Hospital Anxiety and Depression Scale (HADS). The sequential models were created with using backward stepwise multiple regression to investigate potential risk and protective factors connected with higher rates of anxiety and depression symptom in the group.

Results In a study group, 68% in Anxiety Subscale(A) and 56% in Depression Subscale of HADS (D) had positive scores. Living in the country ($P=0.003$) was connected with higher scores in HADS-A ($P=0.003$) but not in HADS-D. Experiencing physical violence was connected with higher score in HADS-D ($P=0.005$), but not in HADS-A. Chronic physical illness ($A P=0.013$; $D P=0.015$), being unemployed ($A P=0.024$; $B P=0.008$), and experiencing economic violence ($A P<0.001$; $D P=0.001$) were connected with higher stores in both Subscales of HADS. Taking financial support ($A P=0.002$, $D P=0.003$) was the protective factor for both kinds of symptoms.

Conclusions Socio-economic factors have stronger influence on anxiety and depressive symptoms in women experiencing IPV than demographic factors.

* Corresponding author.

Background This research aimed to identify the effects of depressive mood of female high school students on dysmenorrhea and sleep quality.

Methods This research was conducted for 2 months from September 2015 to October 2015. A total of 3 types of self-reported questionnaire were adopted for the research. Control group was separated by Zung Self-rating Depression Scale (ZSDS). Each group adopted a self-made questionnaire for research on menstruation and Pittsburgh Sleep Quality Index (PSQI) for research on sleep. Chi² test and AVOVA analysis through SPSS-21 were used as statistics methods.

Results Analysis was made on 72 female students who submitted clear answers to the questionnaire. There were 34 students from normal mood group and 38 from depressive mood group. Depressive group presented meaningful results on regularity, pain severity, and drug treatment history of menstruation. Particularly, depressive group had 51.4% among subjects having severe menstrual pain of grade 3 by VMS (verbal multidimensional scoring system), way higher than 27.6% among subjects in the normal group. PSQI for sleep showed a meaningful result that 20.8% of those in the normal group were diagnosed with sleep disorder compared to 86.8% for the depressive group. A meaningful difference was seen in sleep latency, sleep duration, sleep disturbance, use of sleep medication, daytime functional disturbance among 7 items of PSQI.

Conclusion This research showed that female high school students with depressive mood had high frequency and severity in dysmenorrhea and sleep quality disturbance.

Women coping strategies to infertility stress can impact IVF outcome

B. Kitanovic^{1,*}, L. Tulic²

¹ "Zvezdara", PHC, Belgrade, Serbia

² Clinic of Obstetric and Gynecology Clinical Center of Serbia University of Belgrade, In vitro Fertilization Unit, Belgrade, Serbia

* Corresponding author.

Infertility is defined as a failure to achieve a pregnancy after a woman has attempted to get pregnant for more than 12 months. The impact of psychosocial factors on IVF outcome is a growing field of research. This is the first study estimating the impact of psychosocial stress and women coping on IVF outcome in Serbia. The aim of this pilot investigation was to assess the influence of psychological factors on the outcome of in vitro fertilization in Serbian

women. Psychometric tests were administered at the first visit to 100 women undergoing IVF treatment at Clinic of Gynecology and Obstetrics, Clinical centre of Serbia, University of Belgrade, Serbia. We used questionnaire that covered key demographic and obstetric information and Serbian version of COMPI test, specially designed test measuring stress in infertility, as well as, Zung Depression Self-Rating Scale and Beck Anxiety Inventory. Results of pregnant and non-pregnant group were compared. In the cohort of Serbian women, it has been remarked that they predominantly use active confronting coping style. We found statistically significant differences ways of coping styles between pregnant and non-pregnant group. Women from the pregnant group had significantly lower scores of marital distress, and significantly higher use of meaning-based coping styles. It is found that the use of active avoidance coping correlates negatively with the level of depression and personal, marital and social distress. Clinicians should be aware that infertility is a stressor itself and that coping strategies can influence IVF outcome. Therefore, psychosocial assessment should be a part of an IVF unit.

Examining the person X situation interactions of internalized traits, state body affect and upward comparison behaviour

A. Rogers¹, V. Lewis², I. Krug^{3,*}, M. Fuller-Tyszkiewicz⁴

¹ Deakin University, Psychology, Melbourne, Australia

² University of Canberra, Psychology, Canberra, Australia

³ University of Melbourne, Psychology, Melbourne, Australia

⁴ Deakin University, Deakin University, Melbourne, Australia

* Corresponding author.

Objective Although the influence of trait internalization and state body satisfaction on appearance comparisons has been well documented, their interactive influence on comparison behaviours is unknown. Therefore, the present study thus tested a person X situation model in which both mood state and trait internalization interacted to predict engagement in upward comparisons.

Method One hundred and forty-eight women aged 18 to 40 completed baseline measures of trait internalization, and then completed via iPhone app an experience sampling phase in which they reported momentary experiences of mood and comparison behaviours at up to 6 random times daily for 7 days.

Results Multilevel analyses revealed that although upward comparisons were more likely for individuals who internalized the thin ideal ($t = 3.27, P < .001$), this effect was minimized in instances when a participant was satisfied with her appearance ($t = -1.90, P = .031$). Further exploratory analyses showed that state body satisfaction was a stronger predictor than trait internalization of comparison behaviours ($R^2 = .14$ vs. $R^2 = .11$) when the time lag between state body satisfaction and comparison event was less than 2 hours, but this pattern reversed as the time lag between state level predictor and outcome increased beyond 2 hours ($R^2 = .09$ vs. $R^2 = .12$).

Conclusions Present findings suggest that bolstering one's body satisfaction in the moment may be as clinically important as reducing a client's interest in the thin ideal for alleviating occurrence of unhealthy body comparisons.

Post-partum psychosis

F. Leite^{1,*}, O. Campos², H. Salgado³, P. Carvalho³

¹ Matosinhos, Portugal

² Hospital de Magalhães Lemos, Departamento de Psiquiatria, Matosinhos, Portugal

³ Hospital de Magalhães Lemos, Departamento de Psiquiatria, Porto, Portugal

* Corresponding author.

Introduction Postpartum psychosis (or puerperal psychosis) is a term that covers a group of mental illnesses with the sudden onset of psychotic symptoms following childbirth. A typical example occurs when after childbirth, a woman becomes irritable, has extreme mood swings and hallucinations with the possibility of needing psychiatric hospitalization. Often, out of fear of stigma or misunderstanding, women hide their condition.

Aims and objectives To review the evidence regarding prophylactic treatment and acute management of postpartum psychosis and affective disorders in the puerperium.

Methods Online search/review of the literature has been carried out, using Medline/Pubmed, concerning "postpartum psychosis", "postpartum", "mental disorders", "mania" and "depression".

Results Postpartum psychosis is a rare and severe psychiatric condition requiring rapid restoration of health in view of significant risks to both mother and the infant. The known risk factors and negative consequences of postpartum psychosis point to the importance of preventive and acute treatment measures. The majority of patients who develop psychosis immediately following childbirth suffer from bipolar disorder.

Conclusions Understanding the relationship between postpartum psychosis and affective disorders has implications for perinatal and long-term treatment. The rapid and accurate diagnosis of postpartum psychosis is essential to expedite appropriate treatment.

Pregnant patients admitted to an inpatient psychiatric unit: An 18-months' experience

A. Ozdemir^{1,*}, D. Bulanik¹, C. Aksoy-Poyraz², E. Cirakoglu¹, S. Enginkaya¹, N.B. Tomruk¹

¹ Bakırköy Mazhar Osman Research and Training Hospital for Psychiatry, Neurology A, Psychiatry, Istanbul, Turkey

² Cerrahpasa Faculty of Medicine, Istanbul University, Psychiatry Department, Istanbul, Turkey

* Corresponding author.

Objective Our aim was to describe demographic data of pregnant patients admitted to an inpatient psychiatric unit and analyze treatment preferences for acutely ill pregnant patients.

Methods A prospective chart review was carried out to identify pregnant patients who admitted to the inpatient unit during the period April 2014–September 2015. Details regarding their sociodemographic, clinical, and treatment data were obtained from these records for the study.

Results The total number of pregnant patients, admitted to our psychiatry inpatient clinic during the survey period was 15. The mean age of the patients was 30.33 (with a range of 21–38 years). Two thirds of the patients were hospitalized in the 1st trimester. Bipolar disorder (46.6%) was the most common diagnosis, followed by psychotic disorder (33%), and unipolar severe depression (20%). Eleven patients (67%) out of 15 had a psychiatric illness before getting pregnant. It was found that premenstrual syndrome was reported by 60% of patients. Haloperidol was the most frequently used psychotropic drug for the treatment of psychotic disorders and bipolar manic episodes.

Conclusion The information regarding the course of bipolar disorder in pregnancy is controversial. While some studies support the opinion that pregnancy appeared to have a protective effect against an increase in symptoms, others stress that the risk for relapse in the pregnancy period is high. It is noteworthy that the majority of our patients are bipolar patients in the 1st trimester. The abrupt cease of mood stabilizer use may lead to recurrence in bipolar disorder.

The role of mindfulness in lifetime history of depression: A study in Portuguese pregnant women

J. Azevedo^{1,*}, E. Bento¹, S. Xavier¹, M. Marques^{1,2}, V. Freitas¹, M.J. Soares¹, A.M. Pinto^{1,3}, M. Bajouco^{1,2}, A. Macedo^{1,2}, A.T. Pereira¹

¹ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

³ Faculty of Psychology and Educational Sciences, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Despite the empirical support for the effects of mindfulness based interventions for recurrent depression (Velden et al., 2015), the literature on the relation between Mindfulness and Lifetime History of Depression/LTHD are scarce.

Objective To compare Mindfulness levels between women with vs. without LTHD and to analyze if mindfulness dimensions are significant predictors of LTHD.

Methods One hundred and twenty-seven pregnant women (mean age: 32.56 ± 4.785 years) in their second trimester of pregnancy (17.34 ± 4.790 weeks of gestation) completed: Facets of Mindfulness Questionnaire-10 (FMQ10; Azevedo et al. 2015) assessing the dimensions non-judgement of inner experience/NJ, ACT with awareness/AA and observe and describe/OD; a new self-report questionnaire developed to evaluate the presence of LTHD, with several “Yes/No” questions, based on DSM-5 criteria for depression.

Results Ninety-seven (23.0%) women had LTHD. Bisserial Spearman correlations between LTHD and FMQ scores were significant, negative and moderate ($> .30, P < .01$); only OD did not significantly correlated with LTHD. Independent sample *T*-test revealed that women with vs. without LTHD had significantly higher levels of total FMQ-10, NJ and AA (all $P < .001$). Logistic regression analysis showed that the model containing FMQ-10 explained 12.7–18.8% of the LTHD variance and correctly classified 77.9%; the OR was of 1.19 (95% CI .801–.886; Wald = 44.504; $P < .001$). The model composed by NJ and AA explained 15.5–23% and correctly classified 76.5%. NJ OR was of 1.23 (CI .734–.884; Wald = 20.806; $P < .001$) and AA OR was of 1.41 (CI .708–.903; Wald = 13.004; $P < .001$).

Conclusions Our research discloses that less mindfulness abilities enhances the probability of having lifetime history of depression.

The lack of psychopathological studies and available records concerning the prevalence of mental disorders in African countries, namely in Mozambique lead our attention to the study of the prisoner population due to the large number of mental disorders usually identified among it. According to this, we designed a study with the primary objective of detecting various mental conditions in the inmates of Maputo (Mozambique) prisons. In Maputo (Mozambique) prisons, a large number of individuals with mental disorders identifiable by the instruments used (MINI), is about 80% of the sample, with a larger prevalence in the male population (52.3%). In regards to the type of crimes committed, those against property are the most prevalent, theft specially and mostly committed by men. Crimes against people, particularly homicide (61% of these) were mostly committed by women. Concerning to the relationship between crime and mental disorder, manic episodes were statistically associated with crimes against people and alcohol abuse with other crimes (drug traffic, coin and document forgery, illegal possession of guns and illegal migration).

Psychosis due to traumatic brain injury – controversies and diagnoses difficulties

A. Amorim

São João da Madeira, Portugal

Introduction A traumatic brain injury (TBI) can cause numerous psychiatric complications. Humor and anxious disorders, personality disorders and psychoses are some of those possible problems. The diagnosis of psychosis due to traumatic brain injury (PDTBI), although controversial, has been subject of crescent debate and the idea that a TBI could cause a psychosis is gaining credibility. Diagnosing a PDTBI can be difficult. DSM-5 criteria are rather vague and there are many potential confounding factors due to similarities with other etiological psychosis.

Objectives and aims Alert clinicians to the diagnosis of PDTBI, clarify this clinical entity and define features that may allow them to do the differential diagnosis with other etiologic psychotic disorders.

Methods The authors performed a research in PubMed using the keywords psychosis and traumatic brain injury and selected the adequate articles to meet the objectives proposed.

Results Differential diagnosis of PDTBI should be done with schizophrenia, schizoaffective psychosis, delusional disorder, substance-induced psychosis, psychosis due to other medical condition and with posttraumatic stress disorder. Differentiating PDTBI and schizophrenia can be particularly difficult. Some features have been proposed in the literature as potentially differentiating, namely the presence of negative symptoms (more common in schizophrenia), findings in MRI/CT and EEG.

Conclusions Establishing PDTBI diagnosis can be difficult. While awaiting new studies, clinicians should, in cases of TBI related psychosis, achieve a meticulous clinical history and mental exam, in order to ensure a correct diagnosis and, therefore, determine an appropriate intervention.

Steroid treatment has been widely used for immunologic and inflammatory disorders. Psychiatric symptoms are not uncommon complications of the corticosteroid treatment. Correlations between the hypothalamic-pituitary-adrenal (HPA) axis and various psychoses have been already established in the specialty

literature (modified HPA activity by drugs or not, glucocorticoid receptors downregulation, reduced hippocampal volume). The prevalence of corticosteroid-induced psychotic disorders varies around 5–6%. Most corticosteroid-induced symptoms start during the first few weeks after treatment initiation, but their onset can also be in the first 3–4 days. We would like to report the case of a 30-year-old woman who was taken to the psychiatry emergency room for psychomotor agitation, auditory and visual hallucinations, and bizarre delusions, disorganized thinking and modified behavior. The patient had no personal or family history of psychiatric illness. One month earlier, she was admitted in a neurosurgery ward and underwent lumbar surgery for L4–L5 disc protrusion; at discharge, eight days later, she began treatment with methylprednisolone 80 mg/day for three days. One week later, psychotic symptoms emerged that resulted in her hospitalization in our ward for apparent steroid-induced psychosis. Treatment with risperidone (up to 6 mg/day) and diazepam (10 mg/day, rapidly discontinued) was initiated. The endocrinology examination revealed modified plasmatic cortisol. The psychosis resolved several weeks later and the patient was discharged. Psychiatric complications induced by steroids underline the role of physicians that have to educate the patients and their families about these side effects and their early recognition.

Predictors of aggressive behavior among acute psychiatric patients: 5 years clinical study

T. Aparicio Reinoso^{*}, S. Gonzalez Parra

Hospital Dr. Rodriguez Lafora, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction The problem of violence and aggressive behaviour among patients with psychiatric disorders need careful assessment to improve the quality of psychiatric care.

Objective The aim of this paper is to describe the characteristics of repeated episodes of violence among patients admitted to a Psychiatric Ward, which is a total of 66 beds at Doctor Rodriguez Lafora Hospital from January 2009 to December 2014.

Methods We designed a retrospective, longitudinal and observational study over a 5-year period in two brief hospitalization units of Doctor Rodriguez Lafora Hospital in Madrid. The main variables studied were: type of admission, diagnosis, age, trigger and shift.

Results In our study, we analyzed the prototypical person who carries out these episodes of aggression: a male between 31–40 years, diagnosed with psychotic disorder or personality disorder, involuntary admitted. This episode is associated as a main trigger to mood disturbances, lack of acceptance of standards and psychotic symptoms. These episodes occur more frequently in the afternoon shift one business day and often processed without injuries or minor bruises to other patients and/or nursing assistants. In our practice, we have observed that in most cases adequate verbal restraint in the beginning is sufficient to prevent the episode of aggression.

Conclusions Understand the aggressive factors can influence the production of violent behavior and the use of appropriate containment techniques may be considered a therapeutic option to prevent and address violent behavior in psychiatric patients hospitalized in brief hospitalization units.

Introduction Travel might represent a stressful adventure that can influence mental state to a considerable extent. Some of the travellers experience psychiatric emergencies that require medical attention, during the course of their travel, leading to admission to psychiatric hospital and then repatriation.

Aims Identify the number and clinical characteristics of foreign patients needing medical repatriation due to psychiatric disorders.

Methods This is a retrospective and descriptive study on patients with nationalities other than Tunisian that were admitted to Razi Psychiatric Hospital in Tunis/Tunisia for a psychiatric condition from January 2000 to January 2015. Medical records were analyzed and patients requiring medical repatriation were identified.

Results A total number of 157 hospitalizations of patients with foreign nationalities were recorded during the last fifteen years. Among those hospital admissions, 100 patient files were examined. Twenty-nine percent of patients were repatriated to their home countries, most of them to Europe (72.4%, $n = 21$). The majority of patients were female and single. Fifteen out of these 29 patients (51.7%) were diagnosed with bipolar disorder, 34.4% with chronic psychotic disorders, and 6.8% with acute transient psychotic disorders. The majority of patients were visiting Tunisia as part of a pathological journey (55.1%, $n = 16$), 24.1% of patients ($n = 7$) were tourists and 13.7% ($n = 4$) were resident in Tunisia.

Conclusion The majority of repatriated patients was diagnosed with bipolar disorder and was visiting Tunisia in the context of a pathological journey. Other patients could have been repatriated without being hospitalized. Further studies must be conducted to refine results.

Résumé

Objective A growing number of travellers in Tunisia are being hospitalized for a psychiatric condition. This study aimed at characterizing pathological travellers, a population seldom studied in psychiatry.

Methods This is a retrospective and descriptive study on patients with nationalities other than Tunisian that were admitted to the only psychiatric hospital in Tunisia from January 2000 to January 2015. Patients were identified on the basis of administrative data. Their medical records were then analyzed and pathological travellers were identified.

Results A total number of 157 hospitalizations of patients with foreign nationalities were recorded during the last fifteen years. Among those hospital admissions, 80 patient files were examined. 28.7% of patients ($n = 23$) were hospitalized for a pathological journey. Fifteen out of these 23 patients were diagnosed with bipolar disorder, five with schizophrenia and three with schizoaffective disorder. Pathological travellers came from European and African

countries. The majority of patients were male and single. Average age was 41 years with extremes going from 23 to 73 years. Most of them travelled alone.

Conclusion In the context of globalization, international travel is on the increase, which may lead to a rise in pathological journeys. In our study, the majority of pathological travellers were diagnosed with bipolar disorder. Their choice to travel to Tunisia could be explained by the relatively easy accessibility from Europe or Africa, by the nature of the climate, as well as by cultural and religious specificities of the country.

Introduction Alcohol intoxication is often involved in the commission of criminal behaviors that are risky and involve personal confrontation. Individuals who reported having three or more drinks before driving exhibited greater impulsivity when under the influence of alcohol than did those who did not report heavy drinking before driving.

Objectives The present study utilized the Minnesota Multiphasic Personality Inventory-2 (MMPI-2) to compare the characteristics of individuals with a single driving while intoxicated (DWI) offense with individuals who were multiple DWI offenders and to identify whether there was a typical profile for multiple offenders.

Methods The charts of patients were examined in terms of demographic characteristics including age, sex, employment, and education; the MMPI scores of the two groups were compared using an independent *t*-test, and we identified the typical profile of multiple DWI offenders by using hierarchical cluster analysis with Ward's method.

Results Scores on the F and the depression (D) scales of the MMPI-2 were significantly higher among multiple offenders than among first offenders. The multiple offenders-I group obtained relatively high scores on the D and psychopathic deviate (Pd) scales, and the multiple offenders-II group had low scores on both the hypomania (Ma) and social introversion (Si) scales. Thus, some multiple offenders may have poorer emotional adjustment, characterized by tendencies toward psychopathic deviance, mania, and depression, as well as psychopathological characteristics associated with patients with alcohol-use disorders.

Conclusion The present findings suggest that multiple offenders should be considered a high-risk group for alcohol-use disorders and recurrent drunken driving.

Burden of disease in treatment resistant schizophrenia

S. Bandali^{1,*}, V. Bisht^{1,2},D. Ho (Consultant Forensic Psychiatrist)¹,A. Kotze (Psychiatric trainee)¹, J. Asubiaro¹,R. Aigbogun (Staff Grade Psychiatrist)¹¹ Psychiatric Trainee, South Essex NHS Partnership Trust SEPT, Wickford, United Kingdom² South Essex NHS Partnership Trust SEPT, Consultant Forensic Psychiatrist, United Kingdom

* Corresponding author.

Background Treatment resistant schizophrenia (TRS) accounts for up to 20% of cases diagnosed with schizophrenia [1]. This represents a large proportion of disease burden and nowhere is this more so true than in forensic services where there is not only a larger presence of such cases but often it is closely linked with their offending behaviour and risk of future offending.

Aim and objectives Building on our service evaluation on treatment resistant schizophrenia in 2014, we are aiming to compare the burden of disease encountered by patients suffering from treatment resistant schizophrenia to a matched cohort of non-resistant patients suffering from schizophrenia within South Essex Partnership Trust (SEPT) secure services. Specifically we will also be looking to compare burden of disease between our male and female patients.

Methodology A list of eligible patients suffering from TRS and non-TRS patients will be identified from the SEPT Mobius System (Live electronic Patient Records). The cohorts will be matched for age, gender, and diagnosis. Data with regards to length of hospital admission and number of violent incidents will be extracted from the electronic notes. Each patient will be administered the Positive and Negative Syndrome Scale (PANNS) in addition to the Clinical and Global Impression scale (CGI) by a medically trained doctor. The results will then be collated and analysed for statistical significance. They will initially be published in a poster format and subsequently submitted as a journal article.

Results To Follow.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Excerpt from the history of the “Hochschulpsychiatrie Erlangen” (1818–2016): On the history of a connection between University and Institutional Psychiatry, Unique in Germany (1903–1974)

B. Braun^{1,*}, J. Kornhuber²¹ Psychiatry and Psychotherapy, Erlangen, Germany² Psychiatry and Psychotherapy, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany

* Corresponding author.

Objective To examine the more than 70-year history of a connection between University and Institutional Psychiatry.

Method Relevant archival material as well as primary and secondary literature were examined.

Results As early as 1818 Johann Michael Leupoldt (1794–1874) held a seminar on “madness” as an assistant professor in Erlangen. But the University Psychiatric Clinic did not begin until 1903

within the association of the mental asylum founded on a contract agreement between the Friedrich-Alexander, University Erlangen and the County Senate of Middle-Franconia. The history of the “Hochschulpsychiatrie Erlangen” reflects part of the history of German psychiatry. The plans to accomplish independence were doomed to impracticability by the social-political situation before, during and after the First and also Second World Wars. Clinic patients were registered as “Institutional residents”, the Clinic had no income of its own, the Head of Department and Director of the Clinic was formally considered as the “senior doctor of the asylum”. **Discussion** The complicated duty dependence of the Head of Department on the Director of the asylum undoubtedly contributed to their decades spanning “mésalliance tradition”. A public scandal arose in 1978 from an accusation of dereliction of duty to the government of Middle-Franconia because of lacking protection of patient documentation and medications during the relocation of the former institution departments to the newly constructed Regional Hospital on the Europakanal.

Outlook Cooperation between the University Clinic and the Regional Hospital exists in altered form today. The Psychiatric Clinic can thus include patients from the Regional Hospital in scientific studies.

ADHD, one of the most challenging mental disorders in adult psychopathology

M.C. Cancino Botello*, J.M. Hernández Sánchez, F. Molina López, M.D.L.A. Canseco Navarro, A. Peña Serrano

Consorcio Hospital General Universitario, Psychiatry, Valencia, Spain

* Corresponding author.

Introduction In 40 to 60% of children with ADHD, the disorder persists into adulthood. Nevertheless, diagnosis in adulthood sometimes becomes a challenge because, even the etiology is not very clear yet, ADHD shares several clinical features or may coexist with other psychiatric disorders. This issue leads to confusion and also to a delayed treatment or a wrong treatment, causing negative effects on patient outcomes.

Objective To highlight the importance of making an accurate differential diagnosis and to consider the coexistence of other mental disorders, in the diagnosis of a patient with ADHD.

Methods Systematic review of the literature in English (Pubmed). Keywords: “adult ADHD”; “bipolar disorder”; “substance abuse”; “personality disorders”.

Results Adult ADHD has a prevalence in Europe of 3,4% and it seems to appear more frequently in developed countries. In adults, the clinical presentation differs from children. There often are symptoms of impulsivity, attention deficit, restlessness, and emotional dysregulation and risk behavior, causing difficulties in everyday functioning. The coexistence of substance abuse and the similarity between bipolar disorder and personality disorders with ADHD, translate in a difficult diagnosis, especially for patients with mild presentations.

Conclusions So far, the authors conclude that a detailed clinic history plus the validated scales for adult ADHD are the most reliable tools for diagnosis. Neuroimaging and EEG studies do not provide conclusive data to consider them as diagnostic methods.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Leganés Psychiatric Hospital in the early twentieth century (1900–1931): An approach to healthcare activity

R. Candela Ramírez^{1,*}, A. Consejieri Gámez², P. Vázquez de la Torre Escalera¹

¹ Fuenlabrada Hospital, Psychiatry, Fuenlabrada, Madrid, Spain

² Parla Hospital, Psychiatry, Parla, Madrid, Spain

* Corresponding author.

Introduction Leganés Psychiatric Hospital has been the subject of several studies about its institutional history and clinical activity. The first decades of the twentieth century are the less explored years; however, important events for the development and establishment of the discipline of psychiatry happened in Spain during this period.

Objectives/aims To describe the clinical and therapeutic management of inpatients admitted to Leganés National Asylum between 1900 and 1931.

Material and methods This is a retrospective case series study. We reviewed medical records found in the Historical Archives of Psychiatric Institute, Germany ($n = 1043$) of inpatients admitted between 1900 and 1931. We analyzed clinical care variables, mainly related to diagnosis and treatment, of the patients who were admitted during this period ($n = 1043$) with SPSS v21. We consulted bibliography, such as asylum documents and diverse primary and secondary literature.

Results The diagnosis of mania was very common in the early twentieth century. Lypemania nearly disappeared after 1910 and monomania was not observed in any patient. Delusions decreased after 1905. The first patient diagnosed with schizophrenia was admitted on 19th November 1921. From that moment, the use of this term increased significantly. Only 4.4% of patients admitted underwent treatment.

Conclusions We confirmed the predominance of French nosology in the early twentieth century. From 1920, an increase in German nosography was observed. The application of treatments was rare.

¹ Fuenlabrada Hospital, Psychiatry, Fuenlabrada, Madrid, Spain

² Parla Hospital, Psychiatry, Parla, Madrid, Spain

* Corresponding author.

Introduction Leganés Psychiatric Hospital has been the subject of several studies about its institutional history, clinical activity and demography of its institutionalized population. The first decades of the twentieth century are the less explored years; however, important events for the development and establishment of the discipline of psychiatry happened in Spain during this period.

Objectives/aims To describe the sociodemographic and hospitalization characteristics of the patients who were admitted to Leganés National Asylum between 1900 and 1931.

Methods This is a retrospective case series study. We reviewed medical records found in the Historical Archives of Psychiatric Institute Germain ($n = 1043$) of inpatients admitted between 1900 and 1931. We analyzed sociodemographic and hospitalization related variables of medical records with SPSS v21. We consulted bibliography, such as asylum documents and diverse primary and secondary literature.

Results Most inpatients were male, single, with an average age of 38 years, came from home and were admitted as fee-paying boarders. Circa 64% of them remained in the institution until death and the average stay was 7.92 years.

Conclusions Even though the Leganés Asylum was born amidst debate on the asylum model, it did not meet the expectations. Among other reasons, it presented serious architectural deficiencies and was unable to classify inpatients according to the French tradition (agitated, dirty, quiet) or to separate populations, such as minors or criminal inpatients, thus becoming a charity institution asylum instead of a therapeutic mental hospital.

Cyclic vomiting syndrome

P. Cano Ruiz^{*}, S. Cañas Fraile, A. Gómez Peinado, M.D. Sánchez García

HNSPS, Psiquiatría, Albacete, Spain

* Corresponding author.

Introduction Cyclic vomiting syndrome (SVC) is a functional gastrointestinal disorder characterized by paroxysmal episodes of vomiting, recurrent and cyclical presentation. Although this disorder was first described in children, recently it has increasingly been recognized in adults.

Objective To know the pathogenesis of the syndrome and the optimum approach.

Method Theoretical review and cyclic vomiting syndrome brief statement of a case. This is a man of 51 years for 7 months has repeated episodes of vomiting often than 1 episode per week, with vomiting every 10–15 minutes. The patient is admitted to the neurology department for endless instability and multidirectional nystagmus and right hemispheric deficiency symptoms, with acute renal failure prerenal rehydration and study. While entering data semiotic Wernicke disease are objectified. With replacement therapy meeting evolves favorably at the time of discharge from hospital asymptomatic.

Discussion CVS, in conclusion, is a rare disease in adults whose diagnosis is one of exclusion. The adult presentation usually presents more durable, less frequent episodes. The pathogenesis remains unknown. The optimal treatment is to establish prophylactic migraine medications like amitriptyline. In the prodromal phase, it could be used ketorolaco or sumatriptan and in the acute phase, ondansetron or lorazepam. Because of the morbidity associated with CVS, in particular the severity of symptoms, it is necessary to conduct more studies in adults.

Borderline versus personality

C. Cotta^{1,*}, G. Jesus², V. Vila Nova¹, C. Moreira²

¹ *Centro Hospitalar Barreiro, Montijo*

² *Centro Hospitalar Psiquiátrico de Lisboa*

* *Corresponding author.*

Introduction Latest classifications led to an inflamed debate urging for change or validation in the way personality disorders are classified. The placement in psychiatric classifications of several personality disorders, particularly Borderline Personality Disorder (BPD), is also a matter of discussion.

Objectives and aims The present work aims to question BPDs place in classification alongside with other personality disorders, rather than focusing on the algorithms used to classify it. The authors review updated literature on core features of the disorder collected from online scientific databases.

Results Studies reveal that the stability of the diagnosis of BPD over the longer term is less than what standard general definitions of personality disorders would appear to require. It is a chronic and debilitating syndrome with severe functional and psychosocial impairment that remain relevant when comparing to other personality disorders. Additionally, these measures show further declines over time in spite of improvement in psychopathology, in contrast to what happens with other personality disorders. Several misconceptions may have led to the placement of BPD on former axis II, namely being a direct consequence of trauma and merely explained by environmental factors. However, recent research on heritability shows the contrary and several neurobiological markers suggest it has got a nature of its own.

Conclusion BPD is probably the most studied and validated personality disorder and has substantially greater empirical basis, clinical significance and public health implications, being both enduring and distinct from other personality disorders. We suggest the placement of BPD as major psychiatric disorder in classifications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction In prospective and controlled studies followed up until adult age of patients diagnosed with ADHD in their childhood, the most frequent comorbid disorders were major depressive disorder, personality disorder (borderline and antisocial), substance use disorder and, less frequently, panic disorder and obsessive compulsive disorder.

Objectives We report the case of a male patient aged 60, diagnosed with obsessive-compulsive disorder from his adolescence. His psychopathological progress has become aggravated over the years. Nowadays, he presents an important restlessness, which has led him to social isolation and family claudication.

Methodology Our patient is admitted to the Psychiatric Day Hospital with an appropriated treatment for his OCD (sertraline and aripiprazole). After several days under observation, we used the scales ASRS-V1.1 y WURS finding results that suggested adult ADHD. Extended release methylphenidate was prescribed, with a fast improving of our patient's symptoms of restlessness, insecurity and impulsion phobia. He was discharged from the Centre for Psychosocial Rehabilitation showing a good evolution.

Results – Anankastic personality disorder (F60.5);

– Dependent personality disorder (F60.7);

– Hyperkinetic disorders (F90).

Conclusions Seventy-five percent of adults diagnosed with ADHD have comorbid disorders that should be used as severity rates, since they may cover up the ADHD symptoms or complicate the response to treatment. Adults with ADHD present high score on the scales “social maladjustment” and an often concomitant and polymorphic psychiatric pathology, object of varied diagnoses.

Introduction Description of the most relevant data found in a Psychiatric Day Hospital opened ten months ago in the hospital complex of Ávila.

Objectives The goal is to evaluate clinical and management data in patients of the Psychiatric Day Hospital.

Methods Retrospective cross-sectional descriptive study. A data collection form where each patient is classified into: sex, age, average stay, first admission or readmission, origin, reason for discharge, destination on discharge and diagnoses (classification ICD-10) was used.

Results From the opening of the Psychiatric Day Hospital ten months ago, 58 patients have been admitted: 70.7% women and

29.3% men. Readmissions: 1.7%. Their origin was: psychiatric hospitalization (53.5%), outpatient department (31%), emergency room (13.8%) and Centre for Psychosocial Rehabilitation (1.7%). 41 out of 58 patients have been discharged. Reasons for discharge: improvement (78%), referral to other units (7.4%), voluntary discharge (4.8%) and others (9.8%). The destination on discharge was: outpatient department (90.4%), Centre for Psychosocial Rehabilitation (4.8%), and Inpatient Rehabilitation Unit (4.8%). The most frequent diagnoses on discharge were: bipolar affective disorder, adaptation, emotionally unstable personality disorder, dysthymia, persistent delusional disorders, specific personality disorders and severe depressive episode with psychotic symptoms.

Conclusions The Psychiatric Day Hospital is an intensive treatment unit with a partial hospitalization system, which is distinguished by the variety of patients it is able to admit, as well as the clinical and management benefits the dynamic of these units can provide.

Psychoses of epilepsy – “Acute attacks of insanity”. What literature says and how we act

N. Echeverría Hernández*, M.D.M. Lázaro Redondo, F. de la Torre Brasas, A. Duque Domínguez, A. Mas Villaseñor, C. García Montero, L. Martín Díaz, M. Otorra Navarro
Complejo Asistencial de Ávila, Servicio de Psiquiatría, Ávila, Spain

* Corresponding author.

Introduction Patients with epilepsy seem particularly liable to certain major psychiatric disorders. Prevalence of schizophrenia within an epileptic population varies between 3% and 7% (1% in general population). The aetiology is possibly multifactorial (drugs and neurosurgery).

Objectives To study comorbidity between psychoses and epilepsy and management in the literature and in our patients.

Aims To analyze factors that might influence the onset of psychoses within an epileptic population and how this potential association could influence our practice.

Methods PubMed search was conducted with interest in psychoses of epilepsy, pharmacology, and comorbidity. Up to 10 variables related with factors influencing psychotic episodes that required hospital admission in three patients with epilepsy were studied.

Results Unlike published data, our patients did not have postictal psychoses. All cases had early onset temporal lobe epilepsy with no seizure activity since diagnosis (more than 20 years). No family history of either epilepsy or psychoses. Management included lamotrigine, oxcarbazepine, carbamazepine, zonisamide, and levetiracetam in conventional doses. The psychosis, which comprised affective, schizophrenic, and confusional elements, lasted longer and was more troublesome than psychosis in non-epileptic patients. Response to neuroleptics was poorer than in non-epileptic patients with psychoses. Consultation with Neurology Unit resulted in end of treatment with zonisamide and levetiracetam.

Conclusions Less than perfect evidence suggests the association between psychosis and epilepsy. In our patients, no postictal cases were recorded. Management showed poorer effect of neuroleptics when compared with non-epileptics, and zonisamide and levetiracetam were changed for other drugs with presumably lower association with psychoses.

The examination of psychiatry clinics in terms of therapeutic milieu in Turkey

G. Ergün^{1,*}, I. Işık², G. Dikeç³

¹ Mehmet Akif Ersoy University, Department of Emergency Aid and Disaster Management, Burdur, Turkey

² Yeditepe University, Nursing, Istanbul, Turkey

³ Izmir University, Nursing, Izmir, Turkey

* Corresponding author.

Psychiatry clinics have a high importance for treatment of psychological problems. In some cases, individuals can stay in the inpatient treatment units after having being diagnosed a mental illness. Only Ergün [1] gives information about the physical status of psychiatry clinics, educational status and the number of the healthcare personnel in Turkey in her master thesis. For that reason, obtaining data for therapeutic milieu of the psychiatry clinics in Turkey will contribute to the development of contemporary psychiatry approach. This research is cross-sectional and definitive. Survey form of 42 questions has been prepared in the research. The data has been collected between the dates of 15th July–25th June by the researcher. The sampling involves all hospitals having psychiatry clinics in Turkey ($n = 195$). As a result of the research, it is found that psychiatry clinics in Turkey are not sufficient in terms of some of the therapeutic milieu features and sufficient for some. The nurses actively participate in the clinic activities. The interview room, dining hall and recreational rooms in the clinics are not sufficient. The group therapy, sweet day activities and sport activities are not conducted sufficiently. The researchers suggest developing the psychiatry clinics in terms of therapeutic milieu.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Knowing conversion disorder is the key to understand the complex human's unconsciousness at the beginning of psychoanalysis. In conversion disorder, a mental trauma is repressed to an individual's unconsciousness, and then displays itself as some neurological symptoms. Here, we introduce the case of a young girl who experienced a minor car accident without any organ injury. She did not have any problem for a week after the accident. However, she started to have stuttering when she met with her mother. The noteworthy point is that her mother had the experience of a sexual abuse in a car, which caused her to start stuttering afterwards. We will discuss here whether this is a type of conversion by proxy.

Neurosyphilis and early-onset major neurocognitive disorder – Case reports

A.M. Exergian*, M. Ladea, R. Hagi

“Prof. Dr. Al. Obregia” Psychiatric Hospital, 3rd department, Bucharest, Romania

* Corresponding author.

Introduction Neurosyphilis has been called “the great imitator” because of its atypical clinical presentation ranging from motor dysfunctions to psychotic episodes to dementia. This, and the fact that it has become a rare disease, makes diagnosis challenging.

Objective This work will present three early onset Major Neurocognitive Disorder cases for which neurosyphilis was considered as a possible cause.

Aims In this presentation, we underline clinical characteristics that should raise the suspicion of neurosyphilis and the importance of an adequate diagnosis.

Methods The three patients presented as case-reports were admitted to an acute psychiatric ward, presenting with psychomotor agitation and aggression. The initial clinical evaluation (including the patient’s medical history) did not suggest the presence of syphilis. Subsequent blood-tests were performed, including RPR (Rapid Plasma Reagin) or VDRL (Venereal Disease Research Laboratory) which were positive in all three cases. Other tests were performed in order to confirm the presence of neurosyphilis.

Results All three patients had positive treponemal and nontreponemal test results. For only one of the three patients, imagistic abnormalities of the brain were present. For two of the patients, a positive diagnosis of Major Neurocognitive Disorder due to neurosyphilis was established.

Conclusions Neurosyphilis can be a cause for Major Neurocognitive Disorder. The diagnosis of this pathology is important because cognitive function can be improved by adequate treatment.

* Corresponding author.

Introduction Attention Deficit Hyperactivity Disorder (ADHD) prevalence in the general adult population is estimated to be between 2–4%. Despite the high prevalence, until recently there was only one validated semi-structured interview available for the accurate diagnostic assessment of ADHD within the adult population: the Conners Adult ADHD Diagnostic Interview for DSM-IV (CAADID).

Objectives To examine the concurrent validity of the DIVA 2.0 interview comparing the diagnostic rate with the CAADID interview. To analyse the criterion validity of the DIVA 2.0 in the Spanish language in an adult sample.

Aims The aim of this is to study was to evaluate criterion validity of the DIVA 2.0 in an adult sample comparing with the CAADID and other ADHD severity scales.

Methods A transversal study was performed to check the criteria and concurrent validity of the DIVA 2.0 compared to the CAADID.

Results Forty patients were recruited in an adult ADHD program at a university hospital. The DIVA 2.0 interview showed a diagnostic accuracy of 100% when compared with the diagnoses obtained with the CAADID interview and goods correlations with three self-reported rating scales: the WURS, the ADHD Rating Scale and Sheehan’s Dysfunction Inventory.

Conclusions The DIVA 2.0 has good psychometric properties and is a reliable tool for the assessment of ADHD in adults.

Compare among hope, life quality, and distress resistance in nurses in internal department and ICU to normal persons

N. Farrokhi Namini^{1,*}, N.N. Maryam²

¹ Payame Noor University, Qazvin, Psychology, Tehran, Iran

² Islamic Azad University Tonkabon Branch, Clinical Psychology, Qaemshahr, Iran

* Corresponding author.

Introduction Power promising an important role in healing various diseases and increase physical and mental quality of life and people’s distress tolerance.

Aim The object of research is to compare among hope, life quality, and distress resistance in nurses in internal department and ICU to normal persons.

Methods The object of research is to compare among hope, life quality, and distress resistance in nurses in internal department and ICU to normal persons. Statistical society includes all employees in Rouhani hospital in 2014–2015. Statistical sample and the method of sampling have been sampled randomly and the volumes of sample have been selected by Kerjesy table and Morgan and are about 108 persons.

Results The findings shows the mean of value difference of nurses in ICU department is equal to 29/94 on distress resistance, hope and life quality and in comparing to this amount in normal person responding is equal to 36/3 and shows internal department nurses and ICU does have less mean in distress resistance to respondents.

Conclusions According to research findings, the relation among hope, life quality and distress resistance is multi-directional relation. Hopeful persons do have lesser bodily and psych problems and are more adaptive in society and are more hopeful than those who have lesser level of hope in life.

Keywords Hope; Life quality; Nurse’ distress resistance; Normal person

Group therapy for university students with autism spectrum disorders

Y. Furuhashi^{1,*}, F. Shusuke²

¹ Shizuoka University, Shizuoka, Japan

² The National Printing Bureau, Clinic, Tokyo, Japan

* Corresponding author.

Introduction Autism spectrum disorders (ASD) are a group of neurodevelopmental syndromes characterized by deficits in communication, social interaction and imagination. These symptoms are present in the early developmental period, but may not be fully obvious until social demands exceed the child’s limited capacities. In spite of its early presenting, this condition is not diagnosed until adult stage. In Japan, many patients with ASD were diagnosed after

entering university, however, few treatment options are available. The aim of this study is to investigate the effectiveness of group therapy in university students with ASD.

Methods A one-group, pre-intervention-post-intervention design was adapted for this study. All patients with ASD were recruited from Shizuoka University. The group therapy programs consisted of cognitive behavioral therapy and recreational activity. Outcome measures were Beck Depression Inventory-Second Edition, Quality of Life Inventory, State Trait Anxiety Inventory and Rosenberg Self-Esteem Scale.

Results There were 14 participants, 7 males and 7 females. Their ages were from 19-years-old to 23-years-old. All participants had over 80% of attendance in the six-month group therapy.

Conclusions These preliminary results suggest that the group therapy can improve symptoms of depression and anxiety for some students with ASD. More research is needed to draw more sturdy conclusions, especially with respect to improvements in quality of life.

Disruptive behaviour's treatment with paliperidone in autistic disorder: Review and case report

M. García Moreno^{1,*}, A. De Cós Milas², L. Beatobe Carreño², B. Poza Cano³

¹ Hospital Universitario Puerta de Hierro Majadahonda, CSM Majadahonda, Madrid, Spain

² Hospital Universitario de Móstoles, CSM Móstoles, Madrid, Spain

³ Hospital Universitario El Escorial, CE San Carlos El Escorial, Madrid, Spain

* Corresponding author.

Introduction Autistic disorder (AD) is a neuropsychiatric disorder that often presents significant disruptive symptoms such as irritability, aggression and self-injury in addition to impairment of social skills and communication. These symptoms interfere both individuals with AD and their families and social environment.

Objective Show paliperidone effect in behavioural symptoms in AD.

Methods Literature review about behavioural symptoms in AD and paliperidone effect in its treatment, followed by a case report of clinical improvement after treatment with paliperidone in a patient with autism. Agitation subscale Aberrant Behavior Checklist (ABC-I) scores was compared prior and 4 weeks after paliperidone treatment, and clinical improvement was assessed with Clinical Global Impression-Improvement Scale (CGI-I).

Results Although risperidone has been one of the most studied atypical antipsychotic to treat this symptoms, its use should be limited in order to avoid extrapyramidal and metabolic symptoms. Paliperidone – the major metabolite of risperidone – has shown effectiveness in the treatment of behavioral symptoms in patients with autism, even in subjects with a prior ineffective trial of risperidone. Our patient, 21-years-old male with AD and significant disruptive symptoms was treated with paliperidone 9 mg/day. We observed a 20-points reduction in ABC-I scores 4 weeks later, with most significant improvement in items like auto-aggression, heteroaggressivity, irritability and slams. CGI-I scores showed a much better improvement, and no significant adverse effects appeared.

Conclusions Paliperidone is an effective and safe treatment in behavioral symptoms associated to AD, with reduction in ABC-I subscale scores. More studies are needed to confirm our data.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does community care works? Evaluate the effectiveness of mental health services

M. Giacomini

Psychiatrist Director of Semiresidential Day Center in Mental Health Center of Villorba (Tv), Italy

Introduction Improving quality require the capability to evaluate clinical and operational processes and improve patients outcomes. Just in the view of evidence-based practise (EBP) it's used HONOS rating Scale, adopted since May 2012, by Mental Health Center of Villorba (Treviso-Italy) There are 3 package treatments: rehabilitative, territorial and clinical.

Objectives To identify which variables are positively correlated to HONOS improvement in patients group who frequented Mental Health Centre along 36 months. All patients present severe mental illness.

Aims Evaluate the effectiveness of interventions and correlate to treatment package and individual feature. Analyze treatment process for quality improvement.

Method A psychiatric team (4 nurses, 1 psychiatrist) administered Honos Rating Scale along 3 years: on starting point and 6, 12 and 36 months later: T 0,1,2,3,4. Patients are also described by diagnosis, mental, social and autonomy skill, time, utilization of MHC and anagraphic information.

Results All 15 groups' patients realize lower scoring, after 36 months' treatment. Seven have got reliable improvement (i.e. => 8-point lowering T3–T4) and positively correlate with: (1) 36 months' treatment, at 12 months in rehabilitative Package; (2) days in residential/semi-residential community from 82 to 311 days. Related tables are included in paper.

Discussion and conclusion HONOS score correlates directly with clinical and riabilitation improvement, i.e. mental, social capacity, and personal autonomy. It needs more investigation to clear which other factors are involved with improvement.

Diagnosis and treatment of ADHD in young adults

C. Glod

Merrimack College, Academic Affairs, North Andover, USA

Introduction ADHD is one of the most common psychiatric disorders, affecting 6–10% of children. Recent studies have shown that the illness persists into adolescence and adulthood.

Objectives The purpose of this session is to review the state of the science of the diagnosis and treatment of ADHD in young adults and college students. This population poses unique developmental challenges in evaluation of symptoms and adherence to treatment.

Aims The aim of this presentation is to promote a better understanding of the differential diagnosis and effective treatment options specific to this age group.

Methods Review of the literature.

Results Young adults diagnosed with ADHD in childhood demonstrate symptoms of inattention and hyperactivity that continue. In addition, this age group may present for the first time with previously undiagnosed symptoms that interfere with functioning. Further complicating evaluation and treatment may be the emergence of mood disorders or alcohol/substance abuse. Left untreated, ADHD symptoms affect functioning in several key areas including self-esteem, repeated academic failures, poor occupational performance, propensity for motor vehicle incidents, instability in relationships, alcohol/substance misuse and abuse, and overall successful transition to adulthood. Psychopharmacological studies of

adults reveal the efficacy of several classes of medication including psychostimulants, non-stimulants, and some antidepressants.

Conclusions Young adults with ADHD present a unique set of diagnostic challenges along with comorbid conditions, such as depression or alcohol/drug abuse. Accurate diagnosis and early intervention can prevent the development of significant problems into adulthood, reduce morbidity and promote healthy relationships and career/educational success.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

An approach to neuroleptic malignant syndrome from a clinical case

A. Gomez Peinado*, P. Cano Ruiz, M.D. Sanchez Garcia, S. Cañas Fraile, M. Gonzalez Cano, G.E. Barba Fajardo
Hospital Nuestra Señora del Perpetuo Socorro, Mental Health, Albacete, Spain

* Corresponding author.

Introduction Neuroleptic malignant syndrome (NMS) takes place in patients in treatment with neuroleptics and it is potentially lethal, being important an early diagnostic and therapeutic approach.

Objectives To analyze from a clinical case the clinical and epidemiological features, and therapeutical approach to NMS.

Method Review of some articles in Mental Health journals and analysis of the following clinical case: 68-year-old woman with bipolar disorder, hospitalized in manic phase. Usual treatment: lithium, trazodone, quetiapine and asenapine. During the admission to hospital, the patient started presenting hyperthermia, sweating, electrolyte disturbances, limb rigidity, and elevation of CPK levels. The suspicion was NMS, so neuroleptics were stopped and fluids and dantrolene were initiated, with favorable evolution.
Results The discharge diagnosis was NMS. Neuroleptics were gradually reintroduced under vigilance. The patient is stable and has not had new complications. NMS is an uncommon (0.02% to 3% among patients taking neuroleptic agents), but life-threatening condition. Its symptoms are hyperthermia, autonomic nervous system dysfunction, limb rigidity, altered consciousness... The attendant infections, consume of lithium, dehydration, iron deficiency and sharp changes in neuroleptic treatment are predisposing factors. The withdrawal of neuroleptics is the key of the treatment. Benzodiazepines can improve the prognosis, and electroconvulsive therapy can be necessary if there is no response to previous measures.

Conclusions Neuroleptic malignant syndrome is a life-threatening medical complication we should try to avoid by a correct and careful use of neuroleptics. Additionally, it is important the early treatment, taking withdrawal of neuroleptics as the key starting point.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Erotomania and mood disorder: A case report and literature review

V. Guillard^{1,*}, J. Mallet², F. Limosin³

¹ Charcot hospital, Psychiatry, Plaisir, France

² Louis-Mourier hospital, Psychiatry, Colombes, France

³ Corentin-Celton hospital, Psychiatry, Issy-les-Moulineaux, France

* Corresponding author.

Introduction Erotomania is a rare delusional disorder. De Clerambault, a French psychiatrist, was the first who advanced the concept of pure erotomania, one of the "passionate psychosis", as a distinct

disorder. However, some authors tend to consider this syndrome as related to other psychiatric disorders.

Objectives To describe the case of a female patient with erotomanic delusion with no remission under an antipsychotic and to review the links between erotomania and other psychiatric disorders.

Methods Literature review and a case report.

Results We report the case of a 32 year-old epileptic woman, hospitalized for a delusional erotomanic disorder. Initially, the patient was treated with an antipsychotic, with partial effectiveness. In fact, it appeared that the conviction of being loved began while she was depressed. After one month of combined antipsychotic and antidepressive medication, she became euthymic and her erotomanic delusions disappeared. Major depressive disorder with psychotic symptoms was diagnosed. After reviewing the literature we found that erotomanic symptoms frequently appear secondarily in other psychiatric disorders. Several publications indicate a frequent association between erotomania and mood disorder, especially bipolar affective disorder and major depression, and describe the efficacy of antidepressant and mood stabilizers. Numerous theories may explain the link between erotomania and mood disorder: from narcissistic needs, to the capacity of empathy and emotional processing. Further studies are needed to clarify the nature of this link.

Conclusion In clinical practice, a mood disorder must systematically be searched for and treated in a patient with erotomanic delusions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Practical teaching of behavioral sciences to medical students

M. Hammouda

Al-Azhar Faculty of Medicine, Cairo, Egypt

Introduction The teaching of behavioral sciences was in form of lectures to the medical students in the 2nd year of the college, because the lecture is the least beneficial method of teaching. As I have noticed also that students were more interested to practice behavioral skills. So I suggested to the authority of the faculty to teach part of the behavioral sciences in a practical way and proposal of that was introduced and accepted to teach in that way and to give 20% of marks to this practical part, this in addition to the same theoretical lectures.

Method The students were divided into groups of 30, every group present one day only through their 2nd year. This day divided into two parts each is 2 hours and in between have an hour break. The 1st part includes group discussion about communication, group dynamics, group leading and scientific way of problem solving. The 2nd part is dividing students into small groups of 10 students, to practice the previous skills in group interaction to solve one problem in a scientific way. All groups collected again to see what they have done.

Results The results revealed more interest and more enthusiasm to learn in that way and make it easy to practice in their daily life.

Conclusion We have to change into more practice in our teaching of medical students especially skills of human communication, group leading group dynamics as well as problem solving.

A comparative study between the attachment styles of adults who were raised by mothers with schizophrenic disorders, depression, and those raised by mentally healthy mothers

S. Hatam*, D. Lea Baranovich

University of Malaya, Faculty of Education, Kuala Lumpur, Malaysia

* Corresponding author.

Introduction Maternal psychopathology can have a server effect on the ability of mothers to attach to their children.

Aim To ascertain the level of attachment of adults between the ages of 18–25 years of age who were raised by mothers who suffer from schizophrenic disorders and depressive spectrum disorders, then compared to adults who were raised by mothers with no formal clinical diagnosis.

Method This study used the Adult Attachment Questioner (AAQ), by Simpson Rholes Philips (1996) to ascertain the level of attachment of adults between the ages of 18–25 years of age who were raised by mothers who suffer from schizophrenic disorders ($n = 30$) and depressive spectrum disorders ($n = 30$). The findings of these two groups were then compared to adults who were raised by mothers with no formal clinical diagnosis ($n = 30$).

Result The findings indicated that there is a significant difference between adults who were raised by mothers with the aforementioned mental disorders (schizophrenic and depression), as compared to those who were raised by mentally healthy mothers.

Conclusion The style of attachment in adults who were raised by mothers with the aforementioned clinical diagnosis (schizophrenic and depression) have insecure attachments, while the children who were raised by mentally healthy mothers have almost secure attachment style.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1393

Impulsivity among migraine patients in a series of 239 cases: Analyzing subscales of Plutchik Scale

M.S. Hernandez^{1,*}, I. Munoz², E. Dominguez¹, G. Isidro¹, E. Martinez³, M. De Lera³, M. Ruiz³, V. Molina¹, A.L. Guerrero³, F. Uribe¹

¹ Hospital Clínico Universitario de Valladolid, Psiquiatría, Valladolid, Spain

² Hospital Río Hortega, Psiquiatría, Valladolid, Spain

³ Hospital Clínico Universitario de Valladolid, Neurología, Valladolid, Spain

* Corresponding author.

Introduction Impulsivity may be related to an anxious anticipation of pain. It might explain an increased consumption of symptomatic treatments in migraine patients, one of main risk factors for Chronic Migraine (CM). Plutchik Scale (PS) is a screening test designed to assess impulsive behaviours grouped in four subscales: ability to plan, control of emotional states, control of basic behaviours, and control of other behaviours.

We aim to analyze influence of impulsivity on CM or Medication Overuse (MO).

Methods Patients attended in an outpatient headache office in a tertiary hospital (January 2013–January 2015). Episodic migraine (EM), CM and MO diagnosed accordingly to International Classification of Headache Disorders, III edition. Patients answered PS (15 multiple choice items, positive if score > 20). We analysed results including four subscales.

Results Two hundred and thirty-nine patients (34 males, 205 females), age 38.1 ± 11 years (range: 18–70). One hundred and sixty-one cases (67.4%) CM and, among them, 115 (71.4%) with MO. Plutchik score 13.1 ± 6.8 (1–40); 36 patients (15.1%) met criteria for impulsivity. Considering subscales 12.6% of patients were over the cut-point regarding ability to plan, 20.5% for emotional states, 4.6% for common behaviours and 26.4% for other behaviours. We found no differences in Plutchik or subscales scores or presence of impulsivity when comparing EM and CM groups and CM patients with or without MO.

Conclusion In our migraine population, impulsivity assessed by Plutchik scale is frequent, mainly when considering emotional states or common behaviours. However, neither Plutchik nor subscales scores correlated with CM or MO.

Irritable bowel syndrome (IBS) and stress; a study of international medical school students

M. Husain^{1,*}, D.L. Dumitrascu², I. Chaudhry³

¹ Manchester, United Kingdom

² Iuliu Hatieganu University of Medicine and Pharmacy, Second Medical Department, Cluj-Napoca, Romania

³ Lancashire Care NHS Trust Early Intervention Service, The Mount, Accrington, United Kingdom

* Corresponding author.

Introduction Irritable bowel syndrome is one of the most commonly diagnosed functional gastrointestinal disorders. Irritable bowel syndrome (IBS) and its association with stress have not been researched in regards to foreign medical students in Cluj-Napoca, Romania.

Objective To establish the prevalence of IBS in foreign medical school students and the relationship with stress.

Methods This observational case-controlled study was carried out in "Iuliu Hatieganu" University of Medicine and Pharmacy in Cluj-Napoca, Romania. The sample size was 102, and the data was collected using an online self-report questionnaire. The 'Rome 3 criteria' was used to diagnose IBS and 'Stressful Life Events Check-list' was used to measure levels of stress.

Results The prevalence of IBS was 24.5%, with females having higher rates (34%) compared to males (16.4%). The types of IBS were IBS-M (mixed form) 8.8%, IBS-D (diarrhoea dominant) 6.9%, IBS-C (constipation dominant) 5.9% and IBS-U (undefined) 2.9%. Students with IBS reported higher social stress compared to students without IBS.

Conclusions More efforts should be made to combat stress that medical students experience in order to reduce the number of IBS cases. This may involve an increased role of the medical school to develop initiatives and support, with the aim of helping medical school students better cope with stress and stressful events.

Correlation of birth order with psychiatric morbidity

J. Hussain

Indus Medical College, Psychiatry, Tando Muhammad Khan, Pakistan

Background Etiologically birth order is a growing precipitator of various psychiatric illnesses. Sociologically most cultures across the world give more importance to males as compared to females for

many justifiable or ill reasons. In Pakistani society, lower socio-economic class describes it, more children means more helping hands. Higher birth order with male gender is conceived a desirable fulfilment of family.

Design Cross sectional study.

Place and duration Out patients clinic of Liqueate University Hospital Hyderabad during 1st January 2012 to 31st January 2012.

Measures One hundred consecutive subjects attending a psychiatric OPD with psychiatric symptoms have been assessed for the total siblings, birth order among siblings and their psychiatric diagnosis. The socio-demographic data was recorded through a designed semi structured proforma, and diagnosis was established by Diagnostic and Statistical Manual-IV Text Revised Criteria (DSM-IV TR).

Results The age range remained 9–60 years and numbers of siblings were in the range of 1–12 siblings and fourth birth order was found to be dominant in this study to have psychiatric morbidity (38%). While first order birth was 17%. Generalized anxiety disorder and depressive disorders were dominant diagnosis (55%), while GAD was more in the male gender.

Conclusion This study shows that psychiatric morbidity was more common in the lower birth order. This study may be carried out at different centres of psychiatry for the better assessment of psychiatric morbidity.

Keywords Gender; Birth order; Diagnostic; Psychiatry; Hyderabad

A non-smoking program in the psychiatric clinic: Eradicating tobacco from the therapeutic space

J. Jaber*, A. Tomé, B. Reys

Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The work describes the well-succeeded experience of the Non-Smoking Program developed in a psychiatric clinic in Rio de Janeiro city, Rio de Janeiro, Brazil.

Objective To treat the tobacco dependence in patients with disorders for the use of substances and other psychiatric disorders. To transform the clinic therapeutic space in a free tobacco environment.

Aims To promote the restoring of the patients' health integrally, considering the use of tobacco is responsible for a large number of avoidable deaths, in addition to much harm to health.

Methods In a clinic of hospitalization for diverse mental disorders treatment, especially disorders for the use of substances, in the city of Rio de Janeiro, Rio de Janeiro, Brazil, was simultaneously established a non-smoking treatment program. It was used the pharmacological therapy, associated with cognitive-behavioral therapy, occupational therapy and moderate physical activity. The average time of permanence in the non-smoking program was on average 90 days.

Results There was significant acceptance to the proposed program. In the long-term monitoring, over 12 months, it was evidenced that most patients found themselves in tobacco abstinence.

Conclusion The project achieved its objectives, promoting the tobacco abstinence in patients with comorbidities in hospital treatment. The study proved that it is possible to remove tobacco in patients dependent on this substance during a psychiatric hospitalization.

Attachment style and significant relationships in severe mental illness adults

M. Jiménez Pérez^{1,*}, J. Sáiz Galdós^{1,2}

¹ Grupo 5, Centro de Día Aranjuez 2, Aranjuez, Spain

² UCM, Social Psychology, Madrid, Spain

* Corresponding author.

Introduction The way in which we establish our relationships, our attachment styles, it is crucial for a more active and fulfilling social life, as well as to achieve greater personal satisfaction and quality of life. Attachment style, learned during the early stages of life, regarding to parental figures or other figures, seems to have some relation to the quality of relationships that we will have later in adulthood.

Objectives/aims Describe attachment styles established with significant people in a sample of patients with severe mental illness (SMI).

Methods Implementation of an ad hoc questionnaire based on the "interview adult attachment prototypes" (EPAA), which explores attachment relationships with the father, mother and significant others. A sample of 24 participants diagnosed with SMI was explored.

Results After examination of "past" relationships, we found more extreme scores in "significant others" above "mother" and "father." Especially in dimensions that would be closer to a secure attachment. The analysis of the "actual" relationship again identified the "significant others" as establishing closer interactions to secure attachment. The "significant others" were composed mainly by "grandfathers" and "brothers" in the past, and "brothers" and "friends" in the present.

Conclusions It is important to note that, for our sample, parents appear less associated to a secure attachment, highlighting this the importance of intervening with families to develop healthier relationships. On the other hand, we found fluctuations in time of significant others, which might suggest the need to intervene on these issues from a psychosocial and historical perspective.

* Corresponding author.

Introduction The use of coercion raises ethical dilemmas, as it deprives patients of their autonomy. In Denmark, the subject has gained political attention, and decreases in the use of coercion are demanded. In the attempt of reducing the use of coercion, it is of interest to obtain more knowledge about the circumstances bound to it.

Aim The aim of this study was to investigate a possible correlation between the incidence of mechanical restraint (MR), and staffing level, staff demographics, patient characteristics, type of shift (day/evening/night) and change of shifts.

Methods A naturalistic descriptive method was used to study cases of mechanical restraint in patients admitted to a psychiatric ward. In the study period of one year, 114 cases of MR were

carried out. In 66% of cases, the patient was diagnosed with borderline personality disorder. Each case of MR was obtained from Statens Serum Institut's Electronic Reporting System. The care workers from each shift were identified using duty rosters. The statistical package SPSS version 20 was used for data processing, including a logistic regression analysis.

Results A significant association was found between the use of MR and the presence of male care workers on the ward, OR= 1.639, 95% CI: 1.163–2.311, $P=0.005$. The risk of MR is increased during evening shifts, compared to day and night shifts, OR= 1.868, 95% CI: 1.165–2.995, $P=0.009$. No significant associations were found between MR and staffing level, age, education, or experience of care workers.

A glance at potential neuropsychological theories and explanations for the higher creative functioning of Leonardo da Vinci

S. Kumar

Liverpool, United Kingdom

Introduction It has been universally regarded that Leonardo da Vinci was one of the all time geniuses in terms of his contribution to art and sciences. A number of theories have been proposed to explain his genius that range from neurological, psychological uniqueness, and enhanced functional intelligence.

Aim The primary aim is to explore these theories in detail and register their pros and cons alongside contextualizing their credibility and weightage against the extant evidence in science.

Method A detailed literature search has been undertaken to identify variety of models and theories either:

- dealing with neurological, psychological or neuro-philosophical explanations;
- have been proposed by psychiatrist or psychologist and neurologists pertaining to Leonardo's brain or mind;
- theories around occult and religion have been excluded.

Discussion The results are synthesized and presented in a tabular form. The discussion expands on the various theories and the relevance of Leonardo da Vinci to the merging unified field of neurology, psychology, technology and philosophy (consciousness studies)

Formal caregivers' perceptions of working in a home-based care for elderly

C. Laranjeira^{1,*}, Z. Azeredo¹, M. Guerra², C. Rodrigues²

¹ Piaget Institute, Research in Education and Community Intervention RECI I&D, Viseu, Portugal

² Piaget Institute, High School of Health Sciences, Viseu, Portugal

* Corresponding author.

Introduction Population aging is an issue increasingly gaining more prominence, as evidenced by the number of inquiries regarding the "problems" that this entails for society. This leads to a need to understand the role of caregiver for the elderly as the central figure of support in old age.

Aim The purpose of this study was to describe formal caregivers' perceptions of working conditions, difficulties and factors

associated with quality of care in a Portuguese home-based care for elderly.

Methods The participants were 8 formal caregivers whose profession falls under the categories of Direct Action Helper and Auxiliary Workers. The data were collected through individual face-to-face interviews and analysed using a content analysis following Bardin's method.

Results The results show that the sample is female, aged from 32 to 53 years, with a professional exercise time between 8 and 16 years. Regarding the main conclusions of our research, we can say that our group of participants has a strong sense of team work which contributes to avoid situations of physical and emotional exhaustion; mostly caregivers can separate their personal and professional lives; there are some difficulties in communication between the caregivers and the elderly, however the most difficult situations are usually overcome due to the caregiver's understanding of the characteristics of institutionalized elderly; the matter of death is frequently seen as the most difficult situation to face.

Conclusions The caregivers should have an awareness of the importance of kindness and respect, supporting positive thoughts and help the older people to retain control over their lives.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1401

The meaning of fatigue compassion in the context of healthcare

C. Laranjeira

Piaget Institute, Research in Education and Community Intervention RECI I&D, Viseu, Portugal

Introduction Studies confirm that caregivers play host to a high level of compassion fatigue. Day in, day out, nurses struggle to function in care giving environments that constantly present heart wrenching, emotional challenges.

Aim This concept analysis will aim to capture the current meaning of fatigue compassion in the context of healthcare and explore how it may be recognised and measured in education and clinical practice.

Methods Using the same search terms, findings from a literature search in 2000 and from a follow-up search in 2014 were used to conduct the concept analysis. The Walker and Avant theoretical framework was used to develop a model case of fatigue compassion in nursing care. The attributes, antecedents, consequences and references were delineated.

Results Four attributes of fatigue compassion were delineated. (1) Perceptual incongruence and appraising defines how an individual perceives role demand in relation to capabilities or resources. (2) Multidimensionality consists of physiological and psychological effects on a person. (3) Interactional feedback is the experienced acknowledgement/validation communicated by others during compassionate stressful situations at a workplace. (4) Response pattern describes the coping mechanisms used by an individual experiencing fatigue compassion.

Conclusions The concept analysis of fatigue compassion among nurses at the workplace recognized the vulnerability of the nursing discipline towards distress in general. There needs to be greater research within the field of role stress and nursing, specifically in the development of scales or tools to assist in the identification of fatigue compassion amongst nurses.

Bobby Fischer: Chess, genius and madness at the height of the cold war

C. Llanes Álvarez^{1,*}, A. San Román Uría¹, S. Gómez Sánchez², R. Hernández Antón², J. Valdés Valdazo³, A.M. Del Brio González¹, J.M. Martínez Sánchez¹, J.L. Muñoz Sánchez¹, M.Á. Franco Martín¹

¹ Complejo Asistencial de Zamora, Psiquiatría, Zamora, Spain

² Hospital Clínico Universitario de Valladolid, Psiquiatría, Valladolid, Spain

³ Complejo Asistencial Universitario de León, Psiquiatría, León, Spain

* Corresponding author.

Introduction Directed by Edward Zwick “Pawn Sacrifice” is a biographical film released on September 2015. The film stars Tobey Maguire as Bobby Fischer, the American World Chess Champion, considered one of greatest player of all time. His career’s peak was in 1972 when he captured the World Chess Championship from Boris Spassky of the USSR.

Aims We tried to dig a little in the biography of Bobby Fischer who many described as mentally ill. We tried to figure out what is reality and what is just legend about Fischer. Our goal is promote chess, and also honour the great Fischer. Moreover, we wanted to explore the scientific literature published about the benefits of playing chess, especially in childhood.

Methods We made an exhaustive review of the author’s life, and also testimonies of people who knew him. Moreover, we found some articles that review the relationship between chess and IQ trying to confirm or debunk some myths about this legendary game.

Results It was incomprehensible to everyone that the top of the career of Bobby Fischer at the same time meant an abrupt and complete fall. One possible explanation for this attitude would be a mentally unbalance not specified disorder throughout his lifespan.

Conclusions Not all geniuses are crazy, neither all crazy are geniuses. A genius is a person with extraordinary capabilities, that focused on a topic, has the ability to enlight new ways to explain this complex world, whether it is to create a symphony, paint masterpiece or the next move on the chessboard.

Evaluation of the stigma in transgender’s sexual partners

M. Seyedreza^{1,*}, M. Asadi¹, M. Eftekhari²

¹ Tehran university of medical science, psychiatry, Tehran, Iran

² Iran university of medical science, psychiatry, Tehran, Iran

* Corresponding author.

Introduction Gender dysphoria and its treatment have been legalized in Iran since 1976. Study on transgender people in Iran is very difficult. Perhaps, one of the most problems is stigma. Negative attitudes and discrimination in society make them and their partners to be socially isolated. No extensive research has been done entirely on their sexual partners in the field of stigma.

Aim The aim of this study is to evaluate the attitude toward stigma of sexual partners of transgender people. If there are problems, what are they? What is the impact of stigma on their life?

Method Because there is little information about the research subject, grounded theory methodology was used. This methodology can be used to build a theory. Participants were partners of transgenders who referred from the Forensic Medicine Center to Tehran Institute of Psychiatry and met these inclusion criteria: 1 – being in the relationship for at least 6 months and meet at least one of these criterias: A: they are cohabiting, B: they have regular sexual relationship, C: they recognize each other as their steady partners. 2 – at least 18 years of age. Five males and 6 females participated.

All of them had given a written consent. In depth face-to-face and semi-structured interview were used to collect information. Participants were asked to attend to second interview after coding and analyzing the first session. The codes were classified and categories, using the constant comparative method.

Conclusion It seems that transgender’s sexual partners suffer from the stigma. According to the codes, they suffer from multiple problems in their personal and social life.

* Corresponding author.

Introduction Mindfulness is a form of meditation that cultivates present moment awareness in a non-judging way. It has a Buddhist origin but has been practiced in the last 40 years without relation to any religious belief. It has been proposed as a treatment for a variety of ailments.

Objectives To carry out an overview of systematic reviews of the evidence on mindfulness as a therapeutic tool.

Aims To summarize the existing evidence on the efficacy of mindfulness.

Methods We searched for systematic reviews in the Cochrane Database of Systematic Reviews (Cochrane Library).

Results We found nine Cochrane reviews (for fibromyalgia, aggressiveness in intellectually disabled people, mechanical neck disorders, reducing sedentariness at work, anxiety, somatoform disorders, and post-stroke fatigue), two Cochrane review protocols (stress reduction of patients with breast cancer, and substance use disorders), 50 non-Cochrane reviews (29 provisional abstracts and 21 structured abstracts from the Centre for Reviews and Dissemination) on the efficacy of mindfulness. The Cochrane reviews showed a lack of conclusive evidence for fibromyalgia, aggressiveness in intellectually disabled people, anxiety disorders, somatoform disorders and post-stroke fatigue. Mindfulness training induced a non-significant reduction in workplace sitting time. For chronic neck pain, mindfulness exercises minimally improved function but no global effect was perceived at short term.

Conclusions According to the existing Cochrane reviews, there is a general lack of evidence mindfulness as an effective treatment. For chronic neck pain, mindfulness exercises minimally improved function. We have detected important areas where high quality clinical trials are needed.

* Corresponding author.

The postictal psychosis is a psychotic disorder that begins shortly after a crisis. Most often it affects patients with partial epilepsy and

especially those with temporal lobe epilepsy. The postictal psychosis according to several publications can occur in up to 25% of patients with epilepsy. The psychotic disorder usually occurs within 24–48 hours after, be transient, with good response to treatment with antipsychotics and complete remission of psychotic symptoms. This case is for a woman of 58 years diagnosed with structural epilepsy after brain abscess left temporal intervened in childhood. The patient is being followed by neurology for complex partial seizures with secondary generalization in anti-epileptic treatment. The patient has previous studies of EEG, video EEG and brain MRI, evidence involvement of temporal lobe and hippocampus. The patient is brought to the emergency room after episode of sensory aphasia, unconsciousness and tonic-clonic limb movements, decreasing with diazepam. The patient, during the stay under observation, has auditory hallucinations, that generate anxiety must initiate being him quetiapina and clonazepam orally, yielding partially psychotic disorder, acute intracranial lesions are discarded and the patient is admitted by neurology. The evolution of psychotic disorder with antipsychotic down in a few weeks remaining asymptomatic. Epileptic psychosis is more common in refractory epilepsy. In all cases, you should make a joint approach between psychiatry and neurology, usually they have good response to antipsychotics.

Hypersensitivity to electricity: What place in clinical psychiatry?

V. Maria Iulia*, B.D. Diane

University Hospital of Reims, Adult psychiatry, Reims, France

* Corresponding author.

Hypersensitivity to electricity (EHS) is a self-defined syndrome where individuals experience symptoms while using or being in the proximity of equipment or devices that use electric, magnetic or electromagnetic fields. We present the case of a 45-year-old patient who received an EHS diagnosis several years ago. This patient was first sent to us for hospitalization in the psychiatric ward with mystic delusions and secondary behavior disorders. He had no remarkable psychiatric history and the thorough somatic examinations performed showed no anomaly. The EHS had first appeared 10 years ago with associated symptoms like fatigue, dizziness, headache, cognitive disturbances, as well as physically painful sensations. These symptoms had become gradually invalidating, preventing the patient from pursuing his professional activity. Nevertheless, he maintained his social and familial obligations, and, together with his wife, was still able to care for his 2 children. The patient presented, in the emergency ward, with delusions of mystical and persecuting nature of multiple mechanisms with total adherence. The initial symptomatology gradually improved under antipsychotic treatment without any real improvement of the EHS complaint. This case brought several questions. What is the place of the EHS diagnosis within the framework of a delirious episode? Is there a link between these two diagnoses and more generally is there a psychiatric profile more frequently found in EHS patients?

Autoimmune limbic encephalitis. A rising differential diagnosis between diseases with psychiatric symptoms

C. Martín Álvarez^{1,*}, F. Cadenas Extremera¹, V. Alonso García¹, M. del Valle Loarte², M. Bravo Arraez³, V. Mainar de Paz³

¹ Fuenlabrada University Hospital, Fuenlabrada, Department of Psychiatry, Fuenlabrada, Spain

² Fuenlabrada University Hospital, Fuenlabrada, Department of Neurology, Fuenlabrada, Spain

³ José Germain Psychiatric Institute, Department of Psychiatry, Leganes, Spain

* Corresponding author.

Introduction In psychiatric clinical practice, we can face numerous organic diseases in the differential diagnosis between primary psychiatric disorders. As an example of this, we can see the autoimmune limbic encephalitis (LE), which in a significant percentage of cases begins with psychiatric symptoms. Currently, one of the theories of the origin of the LE is as a idiopathic autoimmune entity, leaving behind the idea of been generated only by a viral or paraneoplastic etiology.

Objective To achieve a better knowledge about this underdiagnosed entity, presenting a case of an anti-LGI1 limbic encephalitis.

Case A 60-year-old Caucasian woman who starts with neuropsychiatric symptoms as: behavioral disorders, manic symptoms, memory impairment and attention deficit.

Results Finally, the diagnosis was confirmed when the patient had positive results in both serum and CSF samples for anti-LGI1 antibodies. Gastric neuroendocrine tumour type I was discovered. Neither paraneoplastic syndrome nor onconeural antibodies were shown. A thin hyperintense signal was identified in the left hippocampus using a brain MRI. Despite the patient had been treated with corticosteroids, immunosuppressants and immunoglobulins, she still showed positive antibodies in CSF samples with poor clinical results, especially psychiatric symptoms. The patient required one psychiatric hospitalization due to reference and persecutory delusions and manic symptoms.

Conclusion Our patient had an unsatisfactory evolution with little response to immune treatment. Given the possible underdiagnosis of this condition, the importance of a differential diagnosis and an early treatment, we consider that there is an important need for a greater knowledge and scientific divulgation of this clinical entity.

Burnout and associated factors among Tunisian teachers

R. Masmoudi*, D. Trigui, S. Ellouze, R. Sellami, I. Baati, I. Feki, J. Masmoudi

Hédi Chaker University Hospital, Psychiatry "A", Sfax, Tunisia

* Corresponding author.

Introduction Teachers are confronted with increasing difficulties and demands that make them vulnerable to burnout.

Aims To evaluate burnout among a population of Tunisian teachers and to identify factors that may be involved.

Methods It was a cross-sectional, descriptive and analytic study, involving 165 teachers working in 10 primary schools and 7 high schools in Sfax, Tunisia. The participants completed a self-questionnaire containing their socio-demographic and professional characteristics. They were explored by the scale of the burnout: Le Maslach Burnout Inventory General Survey (MBI-GS).

Results The mean age of teachers was 39.96 years. The sex ratio (M:F) was 1.32. The majority (75.2%) was married. The burnout syndrome was found in 49.7% of teachers. Moderate burnout was found

in 43% of cases and severe burnout in 6.7%. The causes of burnout reported by our population were bad working conditions (71.50%), quality of working relationships (65.5%) and overload work (30.3%). Bad working conditions were associated with a high level of emotional exhaustion ($P < 0.005$) and a low level of professional efficacy ($P < 0.001$), while poor quality of work relationships and overload work were associated to a high score on cynicism ($P < 0.001$) and a low score on professional efficacy ($P < 0.001$).

Conclusion According to our study, poor working conditions, overload work and bad quality of relationships seem to be risk factors of burnout in teachers. Preventive measures should be instituted against those factors to reduce the constraints of work and improve the professional quality of life of these individuals, essential thing to optimize the educational level in our country.

EV1409

The treatment of “shell shock” in World War 1: Early attitudes and treatments for post-traumatic stress disorder and combat stress reaction

H. Matson

Portsmouth, United Kingdom

Combat stress reaction is a mental health disorder first documented in the latter half of the 19th century. But it was not until World War 1 when men were put through the horrific ordeals of trench warfare that the term, “shell shocked” was coined. Many soldiers with shell shock then developed what is now called post-traumatic stress disorder (though the term was not defined until 1983) or acute stress disorder. The prevailing opinion was that these men who had often not suffered from any physical trauma were sufferers of cowardice. The British army created the PIE (proximity, immediacy, and expectancy) principles to get such men back to the trenches promptly where manpower was always needed. It was rarely regarded as a real psychiatric condition, which had two consequences. Firstly, that many soldiers progressed from shell shock to post-traumatic stress disorder and secondly, over 150 soldiers were executed by the British army for, “displaying cowardice” whilst in the grip of the illness. The diagnosis of “shell shock” was to be made increasingly frequently as wars became larger and more mechanized throughout the 20th century. Psychiatrists' management of such patients initially was primitive and influenced by the zeitgeist that such servicemen were not ill, having never come across such a widespread prevalence of mental health problems until the Great War. These ranged from prescriptions of milk to lobotomies. Understanding how “shell shock” was understood, treated and learning from the mistakes made then, continues to inform management of our patients today.

The chaos involved in Münchausen syndrome and Münchausen syndrome by proxy

L.D. Gherman, A.M. Ciobanu, N. Căpraru, A.I. Mihăilescu*, L.M. Gâză

Clinical Hospital of Psychiatry “Prof dr Al. Obregia”, Clinic, Bucharest, Romania

* Corresponding author.

Background Encountering a patient with Münchausen syndrome (MS) or with MS by proxy is more frequent than it is assumed.

Treating this type of patient is indeed a challenge, thus, knowing to depict the signs is important for every doctor. A specific therapeutic approach is needed and sometimes, even law enforcement must be involved.

Objective We plan to highlight the signs and consequences of Münchausen syndrome and Münchausen syndrome by proxy.

Method Clinical data were collected during admissions of patients in the psychiatric hospital. A literature review has been performed.

Results We report the case of a nurse diagnosed with MS, who had multiple admissions with different diagnostics, before the patient was exposed with the factitious disorder diagnosis. We also report the case of a mother diagnosed with MS by proxy and the case of another mother where the obsessive-compulsive elements of her depressive disorder are combined with signs of MS by proxy, both of them inflicting consequences upon the child in care.

Discussion and conclusions Patients suffering from Münchausen syndrome and Münchausen syndrome by proxy can be a burden for society and for themselves. The relationship with them is sabotaged from the start. The diagnostic is difficult to establish. Numerous expensive procedures are being taken and a considerable amount of funds is spent. Most importantly, the abuse of a child with a parent or guardian suffering from this disease is incommensurable and can even lead to death. It is vital to take action as soon as these syndromes are discovered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Theory of mind (ToM) is the intuitive understanding of one's own and other people's minds or mental states – including thoughts, beliefs, perceptions, knowledge, intentions, desires, and emotions – and of how those mental states influence behavior. Theory of mind is an innate human ability that is sometimes called intuitive psychology, folk psychology, or even mind reading. Social maturity is the process of appropriate attitudes for personal, interpersonal and social adequacies of an individual, which are essential for functioning effectively in the society. According to the findings, there were not statistically significant relationship between theory of mind and social maturity and there is a need for more research in this area.

Objective The objective of this study is to survey preschool children's theory of mind and its relationship with social maturity.

Method Research method is correlational research and sample included 30 children between 5–6 years old. In this study, theory of mind test and Vineland social maturity scale were used.

Results The results showed that 5- and 6-years-old children's performance in third-level theory of mind had significant difference and in first and second level theory of mind had no significant difference. The findings also showed that there was no relationship between theory of mind and social maturity in preschool children.

Conclusion According to the findings, there was no statistically significant relationship between theory of mind and social maturity and there is a need for more research in this area.

* Corresponding author.

Introduction Apathy is commonly defined as lack of, or diminished, emotion, interest, concern, interest and motivation manifesting as poor engagement with others and loss of pleasure in usual interests. Occurs in various medical condition (stroke, HIV, dementia and Parkinson disease) and other psychiatric disorders. It has been related with thalamus stroke, and seen on clinical practice as a blunted emotional response and indifference.

Objective We have tried to link cases of apathy associated with thalamic stroke and systematically review the literature for similar case reports.

Methods We have searched MEDLINE, EMBASE, IBIDS, and the Cochrane Collaboration Database until October 2015. Published case reports of apathy in persons who had suffered a brain stroke were selected.

Results Support the evidence in the literature of the multidimensional nature of apathy and correlate the psychiatric manifestation with the neurological findings. We find similar case reports that could support the anatomical substrate of the apathy and it's also correlated with the previous data reports.

Conclusions These findings are discussed and interpreted in the seeking of regarding the neurobiological substrate of apathy.

A case of neurosarcoidosis presenting with isolated psychotic symptomsO. Onur^{1,*}, E. Carpar¹, Y. Altunkaynak²¹ Istanbul Bakirkoy Research and Training Hospital for Psychiatry Neurology and Ne, Psychiatry, Istanbul, Turkey² Istanbul Bakirkoy Research and Training Hospital for Psychiatry Neurology and Ne, Neurology, Istanbul, Turkey

* Corresponding author.

Neurosarcoidosis (NS) is a neurologic manifestation of sarcoidosis, a rare multisystemic granulomatous disease. Although psychiatric symptoms have been reported to occur in 20% of patients with NS, isolated NS without any signs of systemic disease is a rarity.

Case A 56-year-old female admitted to psychiatry clinic due to complaints of forgetfulness, visual and auditory hallucinations, inability to go outside alone, washing hands in closet cabin, difficulty finding words for the last one year, progressing in last four months. Personal and family background was unremarkable. Vital signs and physical examination revealed no abnormalities. In neuropsychiatric examination, Glasgow Coma Scale score was 15 without any meningeal irritation signs or gait abnormalities. Cranial nerves, extrapyramidal, motor, cerebellar, and sensory systems were intact. All aspects of orientation (time, place and person) were impaired. She scored 12 points out of 30 in Mini Mental Test. Speech was non-fluent with looseness of associations. Impaired recall, abstract thinking, judgment, behaviour planning and attention were noted. Visiospatial disorientation and constructional dressing apraxia were revealed. MR Imaging reported a T2-weighted signal intensity change in nodular fashion suggesting a granulomatous lesion. Differential diagnoses included granulomatous diseases,

neoplasms, infections and Behcet's disease. After necessary excluding evaluations were undergone, a diagnosis of NS was made due to increased angiotensin converting enzyme levels in cerebrospinal fluid. The clinical picture responded well to prednisone treatment and symptoms resolved within one month.

Conclusion Increased awareness is essential to identify rare granulomatous diseases as a differential diagnosis in encountering psychotic symptoms accompanying demantial clinic presentation.

Neurocognitive mechanisms behind mindfulness

J. Perestrelo*, B. Teixeira

Centro Hospitalar de Vila Nova de Gaia/Espinho, Psychiatry, Porto, Portugal

* Corresponding author.

Introduction Clinical applications of mindfulness have become widespread since the introduction of the mindfulness-based stress reduction (MBSR), a treatment program originally developed for the management of chronic pain. Neuroimaging techniques have allowed uncovering the neural mechanisms behind Mindfulness techniques.

Objective To review some of the psychological and neural mechanisms behind mindfulness practice in order to explore the unique factors that account for its positive impact on emotional regulation and health.

Aims Psychological and neural mechanisms behind mindfulness practice are reviewed.

Methods A literature review of the theme is surveyed. Several articles were searched on Medline with the keywords "mindfulness", "meditation", "neurobiology" and "neurocognitive".

Results Mindfulness may achieve effective outcomes in the treatment of anxiety, depression, and other psychopathologies through the contribution of emotional regulation. Cognitive reappraisal has been suggested as a core cognitive control skill whereby mindfulness practice may regulate emotions. It seems that a neural circuit comprising the prefrontal cortex (PFC), the anterior cingulate cortex (ACC), the amygdala (A), and the insula (I) are involved in the unique processes of mindful emotion regulation.

Conclusions Recent models of mindfulness allow for more rigorous examination and operationalization of the method to guide research. Increasingly investigators are focusing on the impact that mindfulness has on emotional regulation, which accounts for the effects on mental health.

Influence of clinical and organizational changes in the use of mechanical restraint. Eight-year retrospective analysis in Mental Health Hospital Unit of Jerez de FronteraJ. Pérez Revuelta^{1,*}, Y. Montero Beltran², L. Fernandez Cepillo¹, T. Molina Molina¹, R. Guerrero Vida¹, J.M. Villagran Moreno¹¹ Hospital del S.A.S. de Jerez, Clinical Management Unit of Mental Health, Jerez de la Frontera Cádiz, Spain² Servicio Andaluz Salud, Macarena Mental Health Unit, Sevilla, Spain

* Corresponding author.

Introduction Aggressiveness is a multidimensional phenomenon, characterized by many cognitive and emotional processes, which is often present in psychiatric disorders. Until the present time, mechanical restraint has been a tool used in order to avoid risks for patients or other people around them. It should be used as a last option, so new strategies to reduce the use of these measures favoring others are being developed.

Aim We try to analyze the influence of clinical and organizational changes in the frequency and duration of mechanical restraints, in order to provide new data and built hypothesis for future intervention plans.

Methodology This oral communication presents a retrospective analysis of mechanical restraints carried out in the Mental Health Hospital Unit of Jerez de la Frontera between 2007 and 2014, both inclusive, a sample of 950 episodes. Several variables will be analyzed and related to the different organizational events conducted in the Clinical Management Unit of Jerez de la Frontera.

Results There has been a gradual reduction in the duration of mechanical restraints carried out in the Mental Health Unit Hospital of Jerez de la Frontera over the eight years studied, specially after the implementation of the agitation protocol developed in 2011.

Conclusion In our experience, the implementation of a comprehensive clinical record, deep observation of the patient by the professionals and the development of protocols to regularize interventions performed during an episode of psychomotor agitation are useful strategies to reduce the duration of each mechanical restraint episode.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Descriptive study of mechanical restraint in acute psychiatric inpatient unit of Jerez De La Frontera: Analysis of a risk profile

J. Pérez Revuelta^{1,*}, B. Carabias Contreras¹, E. Fernández Nicolás², E. Valverde González¹, A. Jiménez Espinosa¹, R. Guerrero Vida¹, J.M. Villagrán Moreno¹
¹ Hospital del S.A.S. de Jerez, Clinical Management Unit of Mental Health, Jerez de la Frontera Cádiz, Spain

² Hospital del S.A.S. de Málaga, Clinical Management Unit of Mental Health, Málaga, Spain

* Corresponding author.

Introduction Various medical and psychiatric conditions can determine the occurrence of disruptive behavior and aggression. Mechanical restraint is part of the strategies for managing these risks. Its use implies a multidisciplinary, phased and individualized for each case strategy, with attention to the ethical and legal issues surrounding this coercive intervention.

Objective The objective of this work is the analysis of the profile of patients who required mechanical restraint during hospitalization in a psychiatric inpatient unit.

Methodology Retrospective descriptive analysis by collecting data of patients, who required mechanical restraint during admission, between 2007 and 2014. The data sources were medical clinical history and nursing records. Variables analyzed were sex, age, clinical diagnosis at discharge and clinical state during the episode of mechanical restraint.

Results Of the total sample of patients requiring restraint ($n=266$), 66.92% were men. The mean age of patients was 38.01 years. Distribution of clinical diagnoses based on ICD-10 coding: 30.23% F60 personality disorder ($n=289$), 19.56% diagnosed with F31 bipolar disorder ($n=187$) and 14.02% F20 schizophrenia. Regarding the clinical characteristics of the episode, 49.47% of

patients had an agitation/violent state and in 23.11% risk of impulsive self-injury was evident, 13.47% had confusional syndrome.

Conclusion Data analyzed shows differences in frequency distribution because of patient profile and clinical diagnosis. Otherwise, organizational factors and appropriate amendments to this level appear to play a key role in minimizing the use of such coercive measures.

Can I have a quality seizure? A review

J. Ramos^{1,*}, A. Arriba², M. Urretavizcaya²
¹ Centro Hospitalar Tondela-viseu, Psychiatry, Viseu, Portugal
² Hospital Universitari de Bellvitge, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction After seventy-five years of its introduction, electroconvulsive therapy (ECT) remains the most effective treatment for severe depressive disorders. It is known that the antidepressant effect is not due only to the electric current itself, but by the general seizure activity. As so, for beneficial or adverse effects of ECTs, it's mainly important to induct a well-generalized seizure. Those can be influence by several variables like, seizure duration and threshold, ECT practice factors and medication, resulting in a lack efficacy. It's advantageous to treatment if physiological markers of adequacy are established to seizure quality, because a high seizure quality has been successfully correlated with better outcome in many studies.

Aims and methods The aim of this work is to review the available international literature regarding to identified parameters that influence and evidence seizure quality.

Conclusion Although throughout history ECT is embroiled in controversy, according to international bibliography, this is a technique of great therapeutic relevance and precise indications. It is noteworthy, that it has been shown to be an effective and safe treatment for many psychiatric disorders. Nevertheless, there is not a consensus regarding to the parameters to its efficacy, particularly the seizure quality. Thus, it's important to current practice, to do more studies in this field, in order to establish those parameters, have homogenise clinical practice and promote better results.

Autistic spectrum disorder masked by mental retardation and impulse control disorder

L. Rodríguez Andrés*, T. Ballesta Casanova, M.S. Hernández García, C. Noval Canga, L. Gallardo Borge, J.A. Espina Barrio
Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Clinical case report A 48-year-old male, diagnosed with impulsive control disorder, sex addiction disorder and mental retardation was followed-up by different psychiatrists for the last 20 years. He consults because of presenting depressive symptoms and behavioural disturbances related to the death of his mother two years before. The patient reports to experimenting depressed mood, irritability, insomnia and trends to cry. He has lost motivation for his job and hobbies (he used to show interest in topics such as physics, philosophy, maths, and medicine). He has feelings of loneliness, which make him look for social interaction and support through continuous calls to telephone sex lines. This act has made him spend large amounts of cash, thus, making him be in deep debts. He does not feel integrate in society.

Mental status examination Introvert, limited social skills, coherent language, echolalic, monotone, tangential speech, depressed mood, feelings of guilt and futility, dysphoria, partial anhedonia, ideas of hopelessness, structured death ideation, unconsciousness of his own acts, with trend to impulsiveness and compulsive behaviour and insomnia.

Complementary test Wais test: no mental retardation found.

Diagnosis Autistic spectrum disorder (F84.0); major depressive disorder (F32.1); bereavement (V62.82).

Discussion The patient showed classic diagnostic criteria DSM 5 associated with autistic spectrum disorder (Asperger's disorder in DSM-IV); the permanent inability for social interactions and repetitive, restricted and stereotypic behavioural patterns.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gestchwind syndrome and epileptic psychosis, beyond the schizophrenia frontier

V. Rodríguez^{1,*}, C. Gómez², C. Gomis², L. González³, E. Tercelán², J. Pérez², L. García², M. Ainbarro², C. Ortigosa²

¹ Alicante, Spain

² Hospital de San Juan, Servicio de Psiquiatría, Alicante, Spain

³ Hospital de San Juan, Servicio de Psiquiatría, Alicante, Spain

* Corresponding author.

During late 19th and early 20th century neuropsychiatrists began to identify common behavioral and cognitive disturbances in epilepsy, but it is not until 1973 that Norman Gestchwind described the basics of what we know as Gestchwind syndrome. This syndrome includes the triada of hyper-religiosity, hypergraphia and hypo/hypersexuality and it was mainly associated with temporal lobe epilepsy. Moreover, it is well known the association between epilepsy and psychotic symptoms, the so-called schizophrenia-like syndrome, which can lead us to a false diagnosis of schizophrenia. We report a 44-year-old man who was brought to the hospital with delusional ideation of prosecution and reference in his

work environment with important behavioral disruption, as well as delusional ideation of religious content. He had a diagnosis of schizophrenia since he was 18-years-old and personal history of generalized tonic-clonic convulsions in his twenties. During the admission, he recovered ad integrum very rapidly with low doses of risperidone, but referred recurrence of déjà vu episodes. After reviewing his patobiography and past medical history, we identified the presence of hypergraphia, hypersexuality and a profound religious feeling, fulfilling the criteria for Gestchwind syndrome, in the context of which was later diagnosed as chronic epileptic psychosis. It is very important a careful approach to the patobiography and personal history. Also, we should include classic differential diagnosis such as Gestchwind syndrome, as they can lead us finally to the correct diagnosis, which in this case meant not only a different treatment but also a better prognosis.

Trichotillomania in delusional infestation

P. Sales^{1,*}, A. Lopes¹, S. Hanemann²

¹ Hospital Garcia de Orta, Psiquiatria, Almada, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria, Lisboa, Portugal

* Corresponding author.

Introduction Trichotillomania is described as a recurrent failure to resist impulses to pull out hairs. It is usually associated with obsessive-compulsive disorder and body dysmorphic disorder. It is usually confined to one or two sites in the body.

Objective The aim of our work is to describe a case of delusional infestation with secondary trichotillomania and briefly review the theoretical aspects of this clinical presentation.

Methods We searched online databases and reviewed current case reports published, using the keywords “delusional infestation”, “Ekbom syndrome” and “trichotillomania” and compared similarities in the presentation, development and outcome. We present a clinical vignette of a 38-year-old female, with no relevant psychiatric history. The patient developed severe itching that she believed was caused by bugs that lived inside her hair follicles, so she pulled out completely all of her eyebrows, eyelashes, pubic and underarms hairs. She maintained some hair on her head, that she repeatedly pulled out and proceeded to break in order to kill the bugs. She claimed to have absolutely no itchiness in the hairless areas of her body.

Results The patient was referred to psychiatric consultation and was started on oral antipsychotics but, as the review from literature suggested, the clinical evolution only became satisfactory when an antidepressant (SSRI) was added.

Conclusion Although, trichotillomania is more commonly seen in clinical practice in association with other psychiatric disorders, it may also present itself as a symptom of delusional activity.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Malignant catatonia and neuroleptic malignant syndrome: How different/similar are they?

P. Sales*, M. Bernardo, A. Lopes, E. Trigo
Hospital Garcia de Orta, Psiquiatria, Almada, Portugal

* Corresponding author.

Introduction Catatonia is a neuropsychiatric syndrome that appears in medical, neurological or psychiatric conditions. There are presentation variants: “malignant catatonia” (MC) subtype shares many characteristics with the neuroleptic malignant syndrome (NMS), possibly reflecting common pathophysiology.

Objectives/methods We present a clinical vignette and review the literature available on online databases about MC/NMS.

Results We present a man, 41-years-old, black ethnicity, with no relevant medical history. He had two previous episodes compatible with brief psychosis, the last one in 2013, and a history of adverse reactions to low doses of antipsychotics. Since the last episode he was asymptomatic on olanzapine 2.5 mg id. He acutely presented to the Emergency Room with mutism, negativism, immobility and delusional speech, similar to the previous episodes mentioned and was admitted to a psychiatric infirmary, where his clinical condition worsened, showing muscle rigidity, hemodynamic instability, leukocytosis, rhabdomyolysis and fever. Supportive care was provided, olanzapine was suspended and electroconvulsive therapy (ECT) was initiated. After two months, he was discharged with no psychotic symptoms. He is still under ECT and no antipsychotic medication was reintroduced.

Discussion/conclusion Many studies suggest that clinical or laboratory tests do not distinguish MC from NMS and that they are the same entity. These two conditions are life-threatening and key to treatment is a high suspicion level. There is no specific treatment; supportive care and stopping involved medications are the most widely used measures. ECT is a useful alternative to medication.

Gynecomastia induced by trazodone: A case report

M.D. Sánchez García*, A. Gómez Peinado, P. Cano Ruiz, S. Cañas Fraile

HNSPS, Psychiatry, Albacete, Spain

* Corresponding author.

Introduction Trazodone is a heterocyclic antidepressant that exerts its effect via the inhibition of selective serotonin reuptake and the antagonism of 5-HT_{2A} and 5-HT_{2C} receptors. Antidepressant-induced gynecomastia and galactorrhea and increases in prolactin levels have rarely been reported.

Case report A 73-year-old man presented to the psychiatric clinic with depressive symptoms and insomnia that was the reason that his GP introduced paroxetine 20 mg/day three months before. One month later because the insomnia persisted, trazodone (100 mg/day) was added to the treatment. At a 2-month follow-up, the patient reported improvement in depressive symptoms but also presented gynecomastia on the left side that is non-tender on palpation. No other medications were noted. Laboratory testing was within normal limits, with the exception of an elevated prolactin level (38.2 ng/mL). Ultrasonography indicated normal results. Treatment included the tapering and discontinuation of trazodone with continued paroxetine therapy. Lorazepam was initiated for the treatment of insomnia. Two weeks later, the prolactin level was 13.1 ng/mL and gynecomastia was practically resolved. Lorazepam was initiated for the treatment of insomnia.

Conclusions Effects of trazodone on PRL are unclear, there is one study reported that trazodone increases the PRL level, and another one reported that trazodone reduces them, in our case, the trazodone use led to hyperprolactinemia via hypothalamic postsynaptic receptor stimulation and it should be remembered that gynecomastia and galactorrhea may appear as a rare side effect of trazodone.

Background International professional mobility is a reality, people have skills they can put in the global marketplace. The increasing migration of health professionals to wealthy countries is a phenomenon known as “brain drain”.

Objectives/Aims This work aims to present the push factors that pressure people to migrate from Portugal.

Methods A cross-sectional survey was carried out with the psychiatric trainees in Portugal. A self-administered structured questionnaire was distributed to collect psychiatry trainees’ demographic and educational characteristics.

Results In Portugal, the majority of trainees have a Portuguese citizenship. Almost 2/3 did not have a short-mobility experience, and the majority never migrated to another country. Less than half consider staying in Portugal in the next years, and nearly 4/5 have considered leaving the country. Working conditions ranked first as the priority condition to be improved in psychiatry in Portugal, followed by financial conditions. In fact, an attractive job for psychiatry trainees in Portugal must have as the most important feature a pleasant work environment.

Conclusions An alarming percentage of psychiatry trainees from Portugal intend to migrate. Impact on future career, financial conditions of doctors, job opportunities and better working conditions were some of the motivating factors behind the migration.

¹ Lev Hasharon, Mental Health Center, Netanya, Israel

² Lev-Hasharon, mental health center, Netanya, Israel

³ Ben Gurion University of the Negev, Nursing Department–Recanati School for Health Professions, Beer Sheva, Israel

* Corresponding author.

In addition to the physical and psychological signs and symptoms of their disorder, people who have schizophrenia also experience severe repercussions associated with social isolation [1]. Internalization of social stigma was found to be a statistically significant core factor that affects self-esteem and the ability to create intimacy among Jewish patients with schizophrenia. Significantly more Muslim patients were married in comparison to Jewish patients. There was statistically significantly less internalization of stigma of

mental illness among hospitalized patients than among individuals with schizophrenia who live in the community [2]. The current study examines the relationship between internalization of stigma, self-esteem, and the ability of people diagnosed with schizophrenia to form intimate attachments with loved ones, in Arab patients compare to the existing sample of 24 patients from the Jewish sector. Data is gathered for 27 Muslim patients with schizophrenia who live in the community, ages 18–60, men and women from the following four questionnaires: Demographics Questionnaire, Self-Esteem Scale, Internalized Stigma of Mental Illness Scale and the Intimacy Attitude Scale-Revised. The study received the approval of the Ethics Committee. There was statistically significantly less internalization of stigma of mental illness, high self-esteem and high capacity for intimacy among Jewish patients than among Muslim patients. Knowledge of how these variables affect the capacity for intimacy provides a therapeutic window for advanced nursing interventions that will eventually provide support and guidance cultural adapted, for people with schizophrenia in creating intimate relationships.

Psychiatric symptoms in Huntington's disease the importance of reliable information – A case report

G. Sobreira*, C. Ferreira, S. Alves

Centro Hospitalar Psiquiátrico de Lisboa, ward–First Psychosis Unit, Lisboa, Portugal

* Corresponding author.

Introduction Huntington's Disease is an autosomal dominant neurodegenerative disease characterized by motor, psychiatric and cognitive symptoms. Irritability, affective disorders, apathy and psychosis are among the most frequent psychiatric symptoms and can predate the pre-clinical period.

Objective The authors' goal is to understand the complexity of Huntington's disease clinical presentation. Additionally, we present an illustrative clinical case.

Aims To convey the importance of collecting reliable information in order to make a proper diagnosis.

Methods A PubMed database review was performed using "Psychiatry", "Psychiatric", "Symptoms" and "Huntington's Disease" as keywords; retrieved papers were selected according to their relevance. The patient clinical record was reviewed.

Results The authors report a case of a 39-year-old woman, who was referred in 2014, to a psychiatrist because of depressive mood and suicidal ideation with two suicidal attempts in the past 5 years. However, she did not disclose her family history of Huntington's disease neither to her GP nor her psychiatrist. She never complied with the treatment plan and was admitted, in November, into a psychiatric unit because of subtle motor changes and apathy, which had resulted in personal neglect. The diagnosis could only be made after a family interview was held and the family medical history was revealed.

Conclusions Corroborative history from caregivers is of extreme importance in psychiatry. Early detection of symptoms can help mitigate the disease social impact. In our patient's case, by the time of proper diagnosis, she was estranged from her family and had endured distressing psychiatric symptoms without adequate treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Placebo and placebo effect, variability of the clinical response according to the therapists' behavior

A. Soler Iborte^{1,*}, S. Galiano Rus², Á. López Díaz²

¹ Servicio Andaluz de Salud – UGC Jaén Norte, Unidad de Salud Mental Comunitaria Linares, Linares-Jaén, Spain

² Servicio Andaluz de Salud – UGC Jaén Norte, Hospital San Juan de la Cruz, Úbeda-Jaén, Spain

* Corresponding author.

Introduction From a historical perspective, the first data related to the placebo effect on "mental health" date to the 1950s decade, when evidence was first shown of the important percentage of people with a psychiatric pathology that benefited from the consumption of placebos. It is believed that the responses to placebos and nocebos are influenced by the content and the way of informing the patient, which influences in the quality of life and therapy adherence. Among the factors that influence the magnitude of the placebo effect, we find variables related to the patient, with the placebo itself and the therapist.

Objectives To determine the relationship between the clinical response of a placebo and the behavior and information on the placebo contributed by the health worker.

Methodology Systemic review of the articles published in Medline-PubMed from 2005 to the present.

Results Being kind, friendly, interested, nice, emphatic, and considerate as well as having a positive attitude toward the patient and the treatment as well as the expectations of the therapist are variables that are associated to a beneficial effect in a placebo situation as well as in active treatment.

Conclusion The patient's expectations, a product of selective processing of the information that she/he receives about the effect of a placebo or active treatment, and the behavior of the health worker in clinical practice, produces variability in the symptomatic response through its influence on the magnitude of the placebo effect. In the bibliography reviewed, there is a marked lack of attention dedicated to clinical studies in the addressing of this phenomenon.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Mindfulness is defined as the ability of paying attention to the present moment with intentionality, moment to moment without making judgments of value.

Objectives To describe the effectiveness of group therapy performed in our mental health center according to the results in the SOFI scale of patients. This scale is designed to assess different qualities, which evolve through training in meditation practice based on mindfulness.

Methods Group therapy consisted of 12 weekly sessions of an hour and a half. A total of 11 patients, 7 of which having completed therapy. The questionnaires were answered in the first and final session of therapy.

Results The questionnaire items were divided before and after treatment, into four categories with the following results: positive (friendly, happy, acceptance, compassion) to himself: 1.86 (0.54)/2.75 (0.78) and to others 3.57 (0.86)/3.89 (0.54); negative (hate, angry, cruel, bad) to himself: 2.92 (0.54)/2 (0.23); and to others: 2.28 (0.41)/1.96 (0.36)

Conclusions In keeping with similar studies, the scale shows effectiveness of therapy in all sets of items, highlighting the variation of the aspects related to himself.

EV1429

“Incomprehensibility” as an approach to the contemporary understanding-explanation dichotomy

J. Valdes-Stauber

Zentrum für Psychiatrie Südwürttemberg, Psychosomatic Medicine, Ravensburg, Germany

Background Traditionally, “understanding” is related to the comprehension of the particular and of individualities as historical unique; “explanation” is conversely related to the sciences of general laws, preferential expressed mathematically. Within the “Methodenstreit”, first method is related to an idiographic second to a nomothetic approach. This dichotomy was transferred by Jaspers into psychiatry.

Objective How the understanding-explanation dichotomy could be dialectically kept, but also surmounted in contemporary psychiatry and psychosomatics in the light of a broader concept of “comprehensibility” as dialectically opposed to “incomprehensibility”.

Method Possible steps in development of the understanding-explanation dichotomy are rebuilt historically from Neo-Kantian and hermeneutic approaches onwards. Starting from reflections on analytic action theory as well as from a critique of Cartesian dualism of substance and from the assumption of incomprehensibility, we try to state an integrative conceptual network.

Results Ways of comprehensibility and incomprehensibility as well as understanding and not understanding are explored by crossing epistemological and ontological perspectives. Four implicit categories of understanding and a dialectically built conceptual network of dimensional dualities are stated.

Discussion The methods of “understanding” and “explanation” maintain in contemporary psychiatry a heuristic importance, but not in a segregative manner. This epistemological dichotomy might be integrated in a network of superordinate dualities.

Keywords Duality; Epistemology; Understanding; Explanation; Ontology; Incomprehensibility

Objective Determine the incidence of suicide attempts in women exposed to sexual violence in Ecuador.

Materials We applied a transversal descriptive study accomplished by the National Institute of Statistics and Census (INEC). The INEC recruited Ecuadorian women from 15-years-old and ahead,

the surveys were focused on this population. Eighteen thousand and eight hundred (18,800) rural and urban housings were selected all over the country, 24 provinces. Date of the survey: November 16–December 15 of 2011. The sample included 737 women of several marital status (single, married and separated woman) who reported had been victims of sexual violence.

Results The average age of the sample was 28-years-old. The standard deviation was 21 years, ages: 15–25 years old: 14.265 (21.6%), 25–35-years-old: 9.324 (14.1%), 35–45-years-old: 8.132 (12.3%), 45–55-years-old: 6.283 (9.5%), 55–65-years-old: 4.302 (6.5%) and > 65 years old: 23.745 (35.9%). The incidence of women who had attempted suicide due to sexual violence was 73.95% (545 of 737 women surveyed). According to the marital status, the incidence was 79.3% on single, 65.5% on married and 79.0% on separated women.

Conclusion The rate of suicide attempts in Ecuadorian women undergoing situations of sexual violence is very elevated. The traumatic incident in descending order according to the classification by marital status is: single, separated and married. It was identified the population of unmarried women in our society to be the most vulnerable to develop suicidal behaviors (8 out of 10 women). However, we must keep in mind that these statistics could be even higher due to the fear and rejection to expose personal traumatic experiences in conservative societies such as the Ecuadorian. These results represent a powerful call to the Mental Health Systems. They must increase protection and follow-up programs on sexually abused women in Ecuador and other Latin-American countries.

Introduction The Ciempozuelos Mental House was the largest institution of its kind in the Madrid province. After the outbreak of the Spanish Civil War, the Ciempozuelos city was under Government of the Republic until 6th February 1937, moment from which the city was occupied by Franco's troops, including the asylum.

Objectives and aims This work examines the Ciempozuelos Mental Hospital and its patient population movement during the Spanish Civil War. The aim of this study is to discuss the implications that the war situation had on the operation of this Madrid institution.

Methods Documents (letters, notifications, etc.) mainly located at the Regional Archives of the Community of Madrid were analysed following traditional historiography methods, as well as social history of medicine and institutional history methods.

Results The Ciempozuelos Mental Hospital was located near the battlefield. Due to this situation, it suffered bombings during virtually the entire duration of the war, causing the death of several patients and the escape of many others. Similarly, and depending on the evolution of the war, the Ciempozuelos Mental House had to switch between sheltering patients evacuated from other areas, and evacuating some of his own patients to other institutions in the country when the situation worsened, such as the Valladolid Mental Hospital or Las Piqueñas Asylum.

Conclusions The location of the mental hospital, the economic strain and the continuous bombing altered the normal operation of the institution and the assistance provide to its patients.

Application of psychiatric laws in Santa Isabel mental hospital (Leganés) during the Civil War and first decades of the Spanish post-war (1936–1952)

P. Vázquez de la Torre Escalera^{1,*}, A. Conseglieri Gámez², R. Candela Ramírez¹

Introduction The Republican psychiatric reform, particularly the promulgation of the Decree of 3rd July 1931, marked the first serious attempt by the Government to transform psychiatric assistance in Spain. However, the literature examining the implementation of these legislative changes in the clinical practice of the mental institutions is still very scarce.

Objectives and aims We intend to analyse the actual extent of the Republican reforms in the assistance of mental patients admitted to the Leganés Asylum during this turbulent period of the history of Spain, mainly focusing on the implementation of the Decree of 3rd July 1931.

Methods The method followed includes a review of the medical records, statistic registers and other documents kept at the institution's historical archive.

Result During the study period, all the statistical forms on mental patients required by law were completed. However, during the years of the war (1936–1939) other documents required under the Decree of 1931 were quite irregularly compiled in the clinical records. Furthermore, the semester medical bulletins that had to be submitted to Court, whenever a patient's clinical condition required a hospital sojourn beyond six months, were systematically suppressed. These administrative procedures were restored after the war. Similarly, during the war, assumptions of admissions not covered by previous legislation were added, such as admissions by military order, which were abolished once the war ended.

Conclusions The exceptional situation lived during the Civil War prevented the regular implementation of psychiatric legislation at the Leganés Mental Hospital. Once the war ended, its enforcement was restored.

The use of repetitive transcranial magnetic stimulation in Malta – A clinical perspective

M. Xuereb

University of Malta, Psychiatry, Msida, Malta

Repetitive Transcranial Magnetic Stimulation (rTMS) has been approved by the FDA for treatment resistant, severe, non-psychotic unipolar affective disorder. The aim of this presentation is to share our experience setting up the rTMS clinic – a first on our small island. We will also be showing data of patients over the treatment period through individual comments made by patients as well as through established depression scales. Finally, a modus operandi of managing side effects, community monitoring and follow-up will be suggested.

* Corresponding author.

Objective To report re-challenges of antipsychotic drugs after neuroleptic malignant syndrome (NMS) in a case of Cotard syndrome and considering electroconvulsive treatment as an option in these cases.

Case report A 17-year-old adolescent, treated for acute psychotic attack with multi-antipsychotic (olanzapine, risperidone) for 15 days, developed NMS within 48 hours of the addition of low doses of clozapine to his regimen. Symptoms included fever, agitation, dysautonomia, pulmonary edema, ventricular failure and laboratory findings, which included elevation of CK levels, leukocytes, transaminase, resolved after discontinuation of psychotropics, supportive management and 6 days of treatment with bromocriptine and amantadine. At first, patient was treated with low doses of quetiapine. Then, we decided to imply ECT because of two reasons. The first reason is low dosage of quetiapine was not believed to control symptoms which included Cotard syndrome based on assertions such as “I am dead”, “I cannot breathe”, “My teeth and my bones are melted”, suicidal thoughts, incoherence speech. The second reason is increasing quetiapine dose rapidly could have caused relapsing of NMS. Finally, we transferred our patient to another child psychiatry clinic where ECT can be applied.

Discussion Starting atypical antipsychotic drugs in re-emergence of post NMS psychosis and catatonia is a challenge. Because of the risk of relapsing NMS, anti-psychotic drugs must be started lower dosage, titrated up slowly then patient should be monitored at least two weeks until resumption of therapy. Process of monitoring depends on existing of clinical residua. Moreover, it is unclear when clinical residua exist, thus it is difficult to interpret the existing guidelines on safe reintroduction of antipsychotics. At that point, ECT can be considered as an option in order to control psychotic symptoms.

Conclusions Clinicians should closely monitor patients when restarting anti-psychotic drugs after NMS owing to risk of relapsing NMS and ECT should be considered as an option in order to control symptoms.

* Corresponding author.

Introduction The widespread nursing shortage and nurses' high turnover rate has become a global issue. Job satisfaction ranks highly as one of the main factors influencing turnover rates among nurses. Mental health nursing has been reported to be a particularly stressful specialty, yet little is known about the level of job satisfaction among psychiatric nurses in Singapore. Resilience is defined as a means of adapting to stress at the workplace, and may serve as a factor influencing job satisfaction.

Objectives/Aims This study aimed to explore the current level of job satisfaction in psychiatric nurses working in the only tertiary

psychiatric institution in Singapore, the influencing factors, and the relationship between resilience and job satisfaction. Results of the study would enable the hospital to develop work programmes for improvement.

Methods A survey questionnaire consisting of the following was administered to all eligible nurses working in the Institute of Mental Health between the period of 16–24 December 2014: the McCloskey & Mueller Satisfaction Scale, the Resilience Scale™, socio-demographic data form.

Results A total of 874 nurses were eligible for the study, and a total of 748 nurses responded, totalling 85.6% response. A mean

satisfaction score of 95.21 and mean resilience score of 125.74 were obtained. Mean satisfaction and resilience scores were the highest for nurses with longer working experience and those of older age group. A positive and significant association between satisfaction and resilience scores ($P < 0.001$) was obtained.

Conclusion Psychiatric nurses in Singapore are generally satisfied with their job but this can be further improved with strengthening of personal resilience.
