Results Empathy level in close relation to type of psychiatric disorder ($F = 26.84, P < 0.001$). Depression level in relation with type of psychic disorder ($P < 0.001$). There is a relation between the positive affectivity and the psychiatric diagnosis of schizophrenia, affective disorder or the absence of the diagnosis ($F = 9.15, P < 0.001$). The level of negative affectivity is in relation with the psychiatric diagnosis ($F = 4.83, P = 0.011$). Capacity of recognition of facial expression in relation with psychiatric diagnosis ($P < 0.001$).

Conclusions The conclusions of the research highlight the changes emerging at the level of affectivity in pathology, as well as the effects these changes have over the patient's contact with his/her own emotions and with the emotions of those around.

Evolution of schizophrenia under treatment with atypical versus conventional antipsychotic

S. Trifu^{1,*}, A. Badea²

¹ UMF Carol Davila, Psychiatry, Bucharest, Romania

² University of Bucharest, Psychology, Bucharest, Romania

* Corresponding author.

Introduction Over the time, schizophrenia experienced various phases of the treatment methods, at the beginning dealing with simple tranquilizers, more disagreeable methods following, some of them even controversial. Finally, medical progresses

revolutionized the life of ill persons, creating antipsychotics, the element around which their entire evolution orbits.

Objectives Establishment of an eventual change in the evolution of patients, in the 1st or 2nd phase, on the three underscores of PANSS, according to their treatment; establishing the election treatment medication.

Aims Using PANSS hetero-assessment scale we had as purpose the category evaluation of phenomena related to schizophrenia under two treatment methods.

Methods The 40 patients were divided in two groups with distinct treatments; performance of an initial clinical interview, followed by a second interview at an interval of 2 weeks, having as purpose to notice an eventual change in the evolution of patients, according to the type of treatment used. Half of them were following a treatment with conventional antipsychotic, and the other part an atypical antipsychotic treatment.

Results There are no significant evolutionary differences between scores on the positive scale and on the general scale, as regards the interval of two weeks during which PANSS scale was repeated. As regards the results of the negative scale, it is highlighted the evolution of schizophrenia on the negative scale, in relation with the atypical antipsychotic treatment underlying its efficiency.

Conclusions We have noticed that the only change of evolution occurred on the negative scale of symptoms.

Long term cognitive training associated with psychotropic medication – an improvement in schizophrenic life

S. Trifu^{1,*}, A.I. Trifu²

¹ UMF Carol Davila, Psychiatry, Bucharest, Romania

² Institute for Military Medicine, Education, Bucharest, Romania

* Corresponding author.

Introduction Schizophrenia is a condition of chronically evolving cognitive invalidation. The average debut for the paranoid form is the third decade of life, affecting the social and family evolution through deficiencies in the mnemonic prosexic area and that of thinking.

Objectives Association of psychotropic medication with long-term cognitive training; distance (home) training and monitoring (visual via Internet); development of dual treatment procedure and medical protocol.

Aims Impact of long-term cognitive training on young schizophrenic patients to improve their quality of life.

Methods Twenty schizophrenic patients (aged 25 to 30) with a family member were committed to the Psychiatric Hospital for 10 days, were taught to utilize a set of computerized cognitive tests from the second day of treatment. The cognitive training aimed at developing: attention (focus on concentration, stability, selectivity and distributive action), memory (retention and evoking) and thinking (superior cognition, organizing, sequencing, planning, operational control) After being released, the patients continued their training practice (at home) under the supervision of family member.

Results Cognitive markers analyzed were maintained and improved, the adapting and social functioning, the family cohesion finely increased. The direct and indirect costs of hospitalization per patient decreased, the inpatient care period was kept to a minimum (10 days), the further follow up being done outpatient, therefore we managed to obtain a better supervision of the patient in time.

Conclusions For young schizophrenic patients, in their first psychotic episodes, the association between psychotropic medication

and cognitive computerized training, reduces the post process defect.

Role of rs6313 and rs1799978 variants as pharmacogenomic biomarkers in Greek, Italian and Croatian schizophrenia patients

E.E. Tsermpini^{1,*}, K. Assimakopoulos², M. Skokou², P. Gourtzi², G. Iconomou², G. Patrinos¹

² University of Patras, Department of Medicine, Patras, Greece

* Corresponding author.

Introduction Schizophrenia (SZ) is a serious mental disorder that significantly affects patients' quality of life (QoL). Its etiology is still unknown; however, both environmental and genetic factors play important role. Atypical antipsychotics, fight mainly against its psychotic symptoms but can also cause various side effects.

Objectives/aims The study was based on a literature review and a meta-analysis which revealed pharmacogenomic biomarkers for the individualization of treatment with atypical antipsychotics. Main aim was to investigate emerging polymorphisms, in Caucasian healthy individuals and schizophrenics.

Materials & methods Four hundred and eighty-five schizophrenic patients and 393 matched controls of healthy donors were studied. Patients were of Greek, Italian, Croatian and Slovenian origin. The group of patients was divided into two subgroups; TRS (treatment resistant schizophrenia) and responders in atypical antipsychotics. Genotyping was performed by Sanger sequencing and PCR/BpEI-based method.

Results rs6313 and rs1799978 were indicated as potential biomarkers of patients' response on antipsychotics. Experimental results suggest non-correlation of polymorphisms with patients' response to these drugs in Greek, Italian, Croatian and Slovenian populations.

Conclusions SZ's etiology is highly complex, however, pharmacogenomic studies can lead to the identification of genetic loci important for disease pathobiology and management as well as patient stratification. Herein, no correlation was evident regarding rs6313 and rs1799978 and drug response in the Caucasian populations studied. Next, sample number will be extended and a more wide cross-population assessment will occur. Knowledge acquired and technology improvement, will lead to a better understanding of the underlying mechanisms, and will subsequently contribute to the improvement of patients' QoL.

Odors hedonic judgment in patients with schizophrenia. Influence of negative symptoms and β -endorphin levels

M. Urban-Kowalczyk

Medical University of Lodz, Department of Psychotic and Affective Disorders, Lodz, Poland

Introduction The relationship between olfactory and emotional processing is an area of increasing interest in schizophrenia research.

Objectives Olfactory identification deficits are well described in schizophrenia while the results for pleasantness ratings remain unclear.

Aims Evaluation of odor identification and hedonic judgment related to severity of negative symptoms and β -endorphin concentration.

Methods Fifty outpatients with schizophrenia were included in the study: 25 with negative symptoms (PN) and 25 without predominant negative symptoms (P). They were compared with 23 healthy individuals. In all study groups University of Pennsylvania Smell Identification Test (UPSIT) and odor hedonic evaluation were performed. Clinical symptoms severity was evaluated using PANSS. Plasma concentrations of β -endorphin were assayed in all participants.

Results PN made more odor identification errors than controls ($P=0.000$) and P sample ($P=0.001$). Hedonic judgments of unpleasant odors were significantly more pleasant in PN sample than in P ($P=0.03$) and controls ($P=0.041$). PN had significantly higher concentration of β -endorphin than P sample ($P=0.014$) and controls ($P=0.009$). No relationship between β -endorphin concentration and odors identification and odor hedonic judgment was found in both patient samples and controls.

Conclusions Increased level of β -endorphin is related to predominance of negative symptoms but probably it is not involved in olfactory identification performance and hedonic judgment in schizophrenia. Patients with predominant negative symptoms revealed different pattern of pleasantness rating – they experience unpleasant odors as more pleasant. Alterations in smell identification and hedonic judgment could be differentially expressed in some subtypes of schizophrenia.

Assessment of suicide risk in schizophrenia with addictive comorbidity

D. Vasile*, O. Vasiliu, D.G. Vasiliu, F. Vasile
Central University and Emergency Military Hospital “Dr. Carol Davila”, Psychiatry, Bucharest, Romania
* Corresponding author.

Introduction Comorbid drug use disorders are associated with greater risk for relapse in schizophrenia and lower adherence to treatment. A comprehensive evaluation of patients with dual diagnosis should address the problem of suicide risk, which is a reputed complication of both psychotic disorders and drug use disorders.

Objectives Depression and suicide risk assessment in subjects diagnosed with schizophrenia and drug related disorders.

Aims To establish a protocol for early intervention in cases with depressive features that associate suicide risk.

Methods All the patients ($n=37$, female $n=15$, male $n=12$) with both schizophrenia and a drug related disorder, consecutively admitted in our department during a 6-month period, were evaluated using Calgary Depression Scale for Schizophrenia (CDSS), Positive and Negative Syndrome Scale (PANSS), Inventory of Drug Taking Situations (IDTS), Clinical Global Impression–Severity (CGI-S). Subjects were evaluated at admission, discharge and after 3 months.

Results A percentage of 21.6 of all patients registered CDSS score at baseline above the cut-off score for a major depressive episode of 6, while 10.8% had CDSS score of 6 and 8.1% had a CDSS score of 5. IDTS had greater scores in all these 15 patients with high CDSS values, comparative to the other, <4 CDSS score patients. Psychological counseling and treatment adjustments were made accordingly, and after 3 months CDSS scores declined in all the subjects ($P<0.01$).

Conclusions Using a specific method for depression and suicide risk in patients with schizophrenia and drug related disorder is very useful for establishing a specific treatment approach and monitoring plan.

Insight, self-stigma and depressive symptoms among patients with schizophrenia

D. Vidovic^{1,*}, P. Brecic², I. Jolic³, V. Jukic³
¹ University Psychiatric Hospital Vrapce, Department for Psychophysiology, Zagreb, Croatia

² University Psychiatric Hospital Vrapce, Department for Treatment and Rehabilitation, Zagreb, Croatia

³ University Psychiatric Hospital Vrapce, Department for Forensic Psychiatry, Zagreb, Croatia

* Corresponding author.

Depressive symptoms are rather prevalent among patients with schizophrenia and various factors can influence them. Insight and self-stigma shows complex and contradictory relationship, both are among most important features of schizophrenia with strong impact on depressive symptoms. We wanted to test hypothesis that preserved insight is related to depressive symptoms only when self-stigma is also high. Our cross-sectional research comprised 149 patients with diagnosis of schizophrenia, both gender, age span 25–45 years. Rating scales used were Calgary Depression Scale (CDS), Scale to assess Unawareness of Mental Disorder (SUMD) and Internalized Stigma in Mental Illness (ISMI) which are specifically designed for patients with schizophrenia. Majority of patients were male (72%), single or separated (85%). Relation between selfstigma and depressive symptoms was statistically significant ($b=0.12$, 95% CI=[0.06, 0.19], $\beta=0.32$, $t(135)=3.89$, $P<0.001$) such as relation between selfstigma and insight ($b=-0.01$, 95% CI=[-0.02,-0.001], $\beta=-0.17$, $t(135)=-2.20$, $P=0.029$). Post-hoc analysis showed that among patients with extremely high selfstigma (more than 90 centile), higher insight was related to more depressive symptoms ($b=-0.22$, 95% CI=[-0.42,-0.02], $\beta=-0.34$, $t=-2.23$, $P=0.028$). These results are important for tailoring specific antistigma programs for patients with high level of insight in order to prevent deleterious impact of depressive symptoms on course of schizophrenia.

* Corresponding author.

Introduction Negative symptoms have long been recognized as a central feature of schizophrenia, which limit recovery, having a strong negative impact on real-life functioning. External validators

of the negative symptoms domains might help refining hypotheses on their pathophysiological basis.

Aims The objective of this study was to evaluate, in the context of the multicenter study of the Italian Network for Research on Psychoses, the relationships between auditory event-related potentials (ERPs) components and negative symptom domains in patients with schizophrenia (SCZ).

Methods We examined ERPs recorded during an auditory odd-ball task in 115 chronic stabilized SCZ (78% on second-generation antipsychotics) and 62 matched healthy controls (HC). Negative symptoms were assessed using the Brief Negative Symptom Scale. **Results** Our main findings included significant N100 and P3b amplitude reductions in SCZ compared to HC. P3b amplitude did not correlate with any negative symptom domain, while N100 amplitude correlated with both anhedonia and avolition domains.

Conclusions Avolition and anhedonia, often clustering in the same factor, are related to abnormalities of early components of the ERPs correlated with perceptual and automatic attention processes. None of the negative symptom domains is associated with abnormalities of the later stages indexed by P3 amplitude.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-Stigma and adherence to medication in patients with psychotic disorders – cross-sectional study

K. Vrbova*, D. Kamaradova, K. Latalova, M. Ociskova, J. Prasko, B. Mainerova, A. Cinculova, R. Kubinek, A. Tichackova
Faculty of Medicine and Dentistry- Palacky University Olomouc and University Hos, Department of Psychiatry, Olomouc, Czech Republic
* Corresponding author.

Introduction Adherence to treatment of mental disorders is one of the key factors influencing its success and, secondarily, the patients' quality of life and social adaptation.

Aims The cross-sectional study of 90 outpatients diagnosed with psychotic disorders aimed at determining if there was a relationship between discontinuation of medication in the past, current adherence to treatment and self-stigma.

Methods The assessment was made with the objective and subjective Clinical Global Impression – Severity scale, Drug Attitude Inventory, Internalized Stigma of Mental Illness (ISMI) scale and demographic data.

Results The questionnaires were filled out by 79 patients, of whom 5 handed in incomplete questionnaires. Complete sets of data were obtained from 74 patients. The data analysis showed that the levels of self-stigma as assessed by the total ISMI scores was not statistically significantly correlated with most of the demographic factors (age, age of illness onset, gender, education, marital status, employment, duration of the illness, number of hospitalizations and antipsychotic dosage). However, there was a significant negative correlation with current adherence to treatment.

Conclusions Adherence to treatment is one of the most important prerequisites for successful therapy. Adherence may be enhanced through better motivation and education of patients on the necessity of adhering to treatment recommendations and the consequences of non-adherent behavior. Important factors in adherence also seem to be patients' stigmatization and self-stigma. Adherence may be increased by promising self-stigma-reducing strategies performed by systematic psychoeducation of patients or as a part of psychotherapeutic counseling.

⁴ Janssen Research & Development - LLC, Biostatistics, Titusville, USA

* Corresponding author.

Introduction PSY-3011 was a randomized, multicenter, double-blind, non-inferiority study of paliperidone palmitate 3-month injection (PP3M) vs. paliperidone palmitate 1-month injection (PP1M). Adults with schizophrenia were stabilized on PP1M in an open-label (OL) 17-week transition phase. Qualifying subjects at the end of the OL phase were then randomized to PP3M or PP1M in the 48-week double-blind (DB) phase. Healthcare resource utilization (HCRU) between PP3M and PP1M was compared using the HCRU questionnaire during the double-blind (DB) phase.

Methods HCRU was measured at the start of the OL and DB phases, and every 12 weeks during DB until end of study/early withdrawal. Information included hospitalizations, ER visits, day or night clinic stays, outpatient treatment, daily living conditions, and occupational status. Logistic regressions modeled the probability of hospitalization vs. no hospitalization for psychiatric and social reasons, as well as hospitalizations for psychiatric reasons only, during the DB phase. The models controlled for OL baseline hospitalizations, OL phase hospitalizations, and time in study.

Results The analysis set included 483 subjects randomized to PP3M and 512 subjects to PP1M during the DB phase. The odds of hospitalization for psychiatric/social reasons during 1 year for PP1M subjects were 1.16 times the odds of hospitalization for PP3M subjects (95% CI: 0.70, 1.93, $P=0.56$). For psychiatric reasons only, the odds of hospitalization during 1 year for PP1M subjects were 1.63 times the odds of hospitalization for PP3M subjects (95% CI: 0.88, 3.02, $P=0.12$).

Conclusions PP3M and PP1M demonstrated similar trends in hospitalizations throughout the course of the study.

The effects of fluvoxamine on cognition in patients with schizophrenia

S.M. Zamir*, S.A. Haji Seyed Javadi, Z. Farzaneh Khanshir
Qazvin university of medical sciences, Psychiatry, Qazvin, Iran

* Corresponding author.

Introduction Schizophrenia is a severe disease which affects different aspects of behavior, including cognitive functions. The most important fields of cognitive disorders in schizophrenia are working memory, vigilance/attention, learning by oral and visual memory, argument and resolving, analysis rate and social knowledge.

Aims This study was designed to assess the effects of fluvoxamine on cognitive functions of schizophrenic patients.

Method Thirty-six patients with schizophrenia, all male, were treated with 100mg fluvoxamine and a second generation antipsychotic for 4 weeks and before and after treatment, their cognitive functions were assessed by Wechsler-3 memory scale

(WMS-revised) and negative symptoms by scale for the assessment of negative symptoms (SANS).

Results In our study, the average patients' scores increased in Wechsler-3 memory scale (WMS-revised) before and after receiving fluvoxamine ($P < 0.001$). This study couldn't show a statistically significant difference between the patients' scores in negative symptoms (SANS test) before and after the treatment course ($P = 0.59$) There was a negative statistically significant correlation found between WMS score before and after the intervention and the level of education, living area and cigarette smoking. Increasing scores in the test was statistically correlated with lower education, cigarette smoking and living in rural area.

Conclusion Augmented treatment with fluvoxamine, probably has effects on some parts of cognitive abilities of male schizophrenic patients which are assessable by Wechsler-3 memory scale. Therefore further studies on evaluation of fluvoxamine effects in other fields of cognitive abilities like concentration and attention in schizophrenic patients are still required.

Keywords Fluvoxamine; Schizophrenia; Cognition; Wechsler-3 memory scale

Questionnaire on sexual attitude and function 2009: A novel clinical and epidemiological computer based tool

K. Pirkalani^{1,*}, Z. Talaeerad²

¹ Mehr Medical Group, Internal Medicine, Tehran, Iran

² Mehr Medical Group, Gynecology, Tehran, Iran

* Corresponding author.

Objective To study sexual problems of our patients and standardizing it for patients with or without religious and cultural restrains we developed a questionnaire with 240 phrases that were extracted from a pool of 1400 sentences addressing sexual problems. Sixty-four scales under four headings (sexual general characteristics, deviations, dysfunctions and psychodynamic syndromes) (16 items each) were evaluated based on criteria of DSM-V and ICD 10. Five validity scales (honesty, desirability, debasement, guilt feeling and overall validity) were also used for better assessment.

Methods A total of 1300 patients in the four variants of the test were evaluated during a time span of 7 years. The questions were presented to examinees at 8th grade and higher in a calm environment and the results were evaluated by a computer software specifically developed for this purpose.

Results The last version of the test was completed by 734 patients with excellent compliance. It was of nice politeness and comprehensiveness. For almost all scales the sensitivity and specificity were around 85 and 92% respectively.

Conclusion We conclude that QSAF 2009 is an excellent tool both in clinics (diagnosis and follow up) and epidemiology with high sensitivity and specificity. It has also application in cross-cultural studies, medico – legal issues and medical documentation. It prevents face-to-face interviews, breaks patients' resistance and is less time consuming than scheduled interviews.

Keywords Sexual assessment; Deviation; Dysfunction

Sexual function in diabetic women and non-diabetic women

Z. Sepehrmanesh

Kashan University of Medical Sciences, Kashan, Iran

Objective Diabetes is a serious disease, which has short term and long-term complications. Sexual dysfunction is a chronic problem in diabetic patients, which is ignored in many patients. Although the majority of studies about sexual problems had done in men, these studies had done less in women. This study evaluates and compares sexual function in diabetic's women and non-diabetic women.

Material and method In this study, fifty married diabetic females and fifty married non-diabetic females has been selected randomly. Demographic questionnaire and FSFI questionnaire (female sexual function index) for evaluation sexual function were used in two groups. Also another questionnaire about complications of diabetes, duration of diabetes, HbA1c, method of treatment and BP in group of diabetic women were used. Data were analyzed by *t*-test and Chi² tests.

Results Prevalence of sexual problems in two groups of women was 98%. Frequency of sexual problems in two group's women was not significant difference in overall. Two group's women had significant difference in sexual satisfaction ($P = 0.02$). Diabetic women had less satisfaction than non-diabetic women. In diabetic women; there was significant relation between HbA1c and desire and arousal items ($P = 0.01$, $P = 0.008$). There was not significance relation between sexual function of diabetic women and diabetic complications, age, educational level, job.

Conclusion The majority of women had sexual problems. In diabetic women sexual satisfaction was significance less than non-diabetic women. In diabetic women, duration of diabetes and HbA1c had significance relation with sexual problems. So that attention to sexual function in diabetic women and education about sexual function is necessary.

Parental Attachment in subjects with female-to-male gender dysphoria

S. Turan*, T. Öcek Baş, A. Baş, Ö.F. Demirel, M. Emül

Istanbul University - Cerrahpasa Medical Faculty, Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Attachment has been defined as a deep and enduring emotional bond that connects one person to another across time and space. Subjects with gender dysphoria (GD) are sometimes accompanied by psychiatric problems because they face potential parent and peer rejection.

Objectives The present study aims to investigate the parental attachment in subjects with female-to-male (FtM) GD.

Methods Sixty-six subjects with FtM GD (DSM-5 criteria) and 67 female controls were assessed using: short version of the Inventory of Parent and Peer Attachment (IPPA).

Results Main findings highlighted that female controls were significantly more attached to their parents than subjects with FtM GD. The scores of specific dimensions of attachment such as trust, communication and alienation were significantly higher in control females than subjects with FtM GD.

Conclusions The results of this study indicate that subjects with FtM GD have significantly poor parental attachment compared to female controls, measured by IPPA. These findings may suggest that psychological basis underlying the development of psychiatric disorders, which was seen in subjects with FtM GD.

Introduction Pregnancy experience with profound physical and psychological changes associated in the life of every woman. The fears, concerns and wrong attitudes of pregnant women about sex during pregnancy can have a negative impact on the sexual relations between couples and their sexual performance.

Objectives It seems cognitive behavior counselling can help to couples achieve sexual satisfaction during pregnancy.

Aims This study was done to determine the effectiveness of cognitive-behavioral training (CBT) on negative sexual attitudes in pregnant women.

Methods This study was a randomized Educational trial was done in five clinics were randomly selected between centers. After out of 200 pregnant women who had obtaining written informed consent filled sexual attitudes pregnancy questionnaire (SAP-Q) only 22 women were selected who had the lowest score attitude. 22 women were randomly allocated for CBT and control group. After the training sessions, the sexual attitude post-test questionnaire, completed by the intervention and control groups. After that results were compared in past and three months later. Results by using descriptive and analytic statistics and SPSS software 20 were analyzed.

Findings The mean sexual attitude of the intervention group was (113.3 + 11.16) and control group was (76.90 + 19.07), which reflects the significant differences between the two groups ($P < 0.001$). But after three months of follow-up there was no significant difference in the intervention group. So results showed that the attitude was maintained positive during 3 months ($P > 0.5$).

Conclusion According to the results, CBT has been effective on the reducing negative sexual attitudes in pregnant women.

* Corresponding author.

This study aimed to evaluate sexual function of male patients treated with methadone maintenance therapy (MMT) compared with that of buprenorphine maintenance therapy (BMT) in Kerman city, Iran, 2015. The research approach was a causal comparison with statistical population consisted of all married male patients who intake MMT or BMT in Kerman Substance Abuse Treatment Center (418 people) during first quarter of 2015 that 200 which of them were selected according to Morgan table (for each group, $n = 100$). The International Index of Erectile Function (IIEF) questionnaire was employed to collect the data. Data Analysis was achieved using SPSS 20 software. The results showed that mean sexual function in male patients who treated with BMT is greater than MMT ($P = 0.004$). Mean erectile function ($P = 0.029$), orgasm ($P = 0.001$) and sexual desire ($P = 0.001$) in the patients who treated with BMT exceeded than MMT. However, satisfaction of intercourse ($P = 0.727$) and overall sexual satisfaction (0.743) in the patients who treated with MMT were not significantly different with BMT. According to the research achievements, methadone is caused more affection on sexual function decrease and erectile dysfunction compared with buprenorphine so that BMT should be used as much as possible to drug addicts rather than MMT.

Internalized homophobia, social pain, severity of depressive symptoms and quality of sexual life among homosexual young adults

A. Wiszniewicz^{1,*}, E. Wojtyna²

¹ Hospice Cordis, Hospice Cordis, Katowice, Poland

² University of Silesia, Institute of Psychology, Katowice, Poland

* Corresponding author.

Background Being a homosexual may be burdened by several psychological problems. This is due to the minority stress that results from feeling excluded and it is characteristic of social minorities. Negative beliefs about their psychosexual orientation and sense of exclusion may be the cause of both depressive disorders and internalized homophobia. These factors can affect the quality of sexual life.

Aim The aim of the study is to analyze the relationship between internalized homophobia, social pain and the severity of depressive symptoms and quality of sexual life.

Methods The study included 103 young adults remaining in permanent homosexual relationships. The study was cross-sectional. The study used Beck Depression Inventory, Social Pain Thermometer, Internalized Homophobia Scale and Quality of Sexual Life Questionnaire.

Results It observed the significant correlations between the level of internalized homophobia and a sense of social pain and the severity of depressive symptoms. Both internalized homophobia, and severe social pain and depressive symptoms proved to be significant predictors of reduced quality of sexual life of homosexuals.

Conclusions During the treatment of depressive symptoms and discomfort associated with the sexual life of homosexuals, it is important to take into account the phenomenon of internalized homophobia.

Sleep quality in epileptic children

M. Abouzed^{1,*}, S. Kinawy²¹ Al-azhar Faculty of Medicine, Psychiatry, Cairo, Egypt² Aswan University, Pulmonology Department, Aswan, Egypt

* Corresponding author.

Sleep problems frequently coexist in epileptic patient. The effect of them on each the other has been extensively evaluated. Little review exists on the reciprocal interaction of sleep problems and epilepsy in the children.

Aim of study To evaluate prevalence, pattern and risk factors of sleep problems in epileptic children.

Method Eighty-two epileptic children and 40 healthy controlled children were evaluated using children's sleep habits questionnaire – Arabic form and night polysomnography (2 consecutive nights).

Result Prevalence of sleep problem in epileptic children was 45% and 17% of normal control children with significant difference in sleep latency, total sleep time and number of awaking per night with significant prevalence with partial epilepsy, poly therapy and poor controlled epilepsy.

Conclusion Sleep problems are common in epileptic children with close relation to partial epilepsy, number of anti epileptic and poor controlled epilepsy. This is important to deal with it in order to better control of sleep problems in such patient.

Correlates of sleep difficulties in young adults: A gender comparison

A.P. Amaral^{1,*}, M.J. Soares², A.T. Pereira², S. Bos², M. Marques², J. Valente², A. Macedo²¹ Institute Polytechnic of Coimbra and University of Coimbra,

Coimbra Health School and Department of Psychological Medicine, Coimbra, Portugal

² University of Coimbra- Faculty of Medicine, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Sleep disturbance is one of the most common health complaints among late adolescents and young adults. Women report more sleep-related complaints than men (Krishnan and Collop, 2006) and more anxiety or depressive symptoms (Voderholzer et al., 2003). Higher levels of repetitive negative thinking appear to be causally involved in the initiation/maintenance of emotional problems (Ehring and Watkins, 2008).

Aims To analyze the sleep difficulties differences by gender and its associations with stress, cognitive emotion regulation, perseverative thinking and negative affect.

Methods Five hundred and forty-nine students (80.1% females) from two Universities filled in the PSS-10 (Cohen et al., 1983; Amaral et al., 2014), CERQ (Garnefski et al., 2001; Castro et al., 2013), PTQ (Ehring et al., 2011; Chaves et al., 2013) and POMS-58 (McNair et al., 1971; Azevedo et al., 1991; Amaral et al., 2013). Three questions were used to access difficulties of initiating sleep (DIS), maintaining sleep (DMS) and early morning waking (EMA).

Results Females reported more sleep difficulties (excluding DIS), stress, perseverative thinking than males. Males reported higher levels in self-blame and blaming-others dimensions. In female sample we found significant correlations between all sleep difficulties and stress, perseverative thinking, emotional regulation (rumination, self-blame, catastrophizing) and negative affect. In male

sample only the difficulties of initiating sleep are correlated with stress, perseverative thinking, self-blame and negative affect.

Conclusions There are no gender differences in frequency and most of correlates of DIS. DMS and EMA were higher in females and were related to perseverative thinking and emotional regulation mechanisms in this sample.

Epworth Sleepiness Scale results in medical students. A preliminary study

M. Henry^{1,*}, A.A. Perez-Morell², L. Hueriga-Garcia², A.A. Henry-Gonzalez³¹ University of La Laguna, Department of Internal Medicine-Dermatology and Psychiatry, Santa Cruz De Tenerife, Spain² University of La Laguna Medical School, Health Sciences Campus, Santa Cruz De Tenerife, Spain³ Gerencia de Atención Primaria, Health Care Department of the Canary Islands, Santa Cruz De Tenerife, Spain

* Corresponding author.

Introduction Sleep disorders, especially insomnia and excessive daytime sleepiness, are common complaints. They are associated with an increased prevalence of various somatic diseases and/or psychiatric disorders as well as psychosocial problems. Previous general population studies have estimated that the prevalence of sleep disorders ranges between 15 and 42%.

Objectives and aim Studying sleepiness in younger medical students, that is, in the carrier initial or lower grades.

Methods The Epworth Sleepiness Scale was administered to a 135 (mean age 19.90 y.o.) (76% female/33% male) voluntary agreeing sample of first cycle medical students in Tenerife during 2014–2015. EES measures daytime sleepiness. The Statistical Package for Social Science was applied.

Results and discussion 1. Age is about the same than that of a Brazilian medical students sample (20.16). 2. Just over 50% (68 out of 135) had daytime sleepiness, higher than the Brazilian's and much higher than that observed in an Australian medical students sample. Curiously, 29 percent of our students with diurnal sleepiness had reported a good quality sleep in the previous month. 3. This figure (>50%) is really higher than the recorded proportion in adult general population. 4. No intersex differences were noticed ($P > 0.05$).

Conclusions Our study points out that complaints about sleepiness are very common in younger medical students. The question remains whether adjustment, personality traits, high tasks and curricula burdens associated with fatigue may have a causal link with sleepiness in a very demanding carrier. Moreover, we should highlight that sleepiness, as a subjective variable, could be confounded with fatigue.

Sleep disorders among adolescents in Nigeria: The development of an assessment instrument (Sleep Disorders in Nigeria Questionnaire [SDINQ])

D. Igbokwe^{1,*}, B.A. Ola², A. Odeunmi³, M.A. Gesinde¹, A. Alao¹, J. Agbu⁴, R.J.E. Ndom⁵, S.O. Adeusi¹, O.A. Adekeye¹, B.C.E. Agoha¹¹ Covenant University, Psychology, Ota, Nigeria

⁵ University of Ilorin, Behavioural Sciences, Ilorin, Nigeria

* Corresponding author.

Introduction Nigerian adolescents report various sleep disorders metaphorically based on the local/native description of such disorders. Hence, it is sometimes difficult for clinicians without a good grasp of the nuance in their description to understand their presentation.

Aim To develop a culturally relevant (Nigerian) instrument for assessing sleep disorders.

Methods One thousand two hundred and twenty-seven Nigerian Secondary School adolescents (634 males and 593 females) between 12–19 years with mean age of 15.20 (SD=1.5) were administered a 44 item instrument developed following the DSM (V), American Association of Sleep Medicine's International Classification of Sleep Disorders (ICSD, 2005) criteria, and case reports of sleep disorders. The data was subjected to a Principal Component Analysis using Varimax rotation.

Result Ten factors instead of the original eleven factors suggested by the authors emerged in the analysis and on closer examination and in juxtaposition with cultural nuances, it was found the ten factors were in line with what is generally reported by adolescents. Sleep walking disorders and sleep related movement disorders loaded in one factor labelled sleep movement disorders, while items representing non restorative sleep experiences, sleep talking, sleep paralysis, sleep apnea, circadian rhythm sleep disorder, narcolepsy, insomnia, sleep terror disorder and nightmare disorder loaded on their individual factors. The SDINQ showed a Cronbach Alpha of .916 and a good correlation with subscales of the School Sleep Habits Survey (SSHS).

Conclusions The SDINQ has been found to be a valid and reliable instrument for assessing the presence of sleep disorders among adolescents in Nigeria.

³ Medical University of Lodz, DynamoLab, Lodz, Poland

⁴ Medsolver Psychiatric Clinic, Medsolver in Lodz, Lodz, Poland

* Corresponding author.

Introduction Restless legs syndrome (RLS) is a sleep disorder affecting a significant part of general population. Clinically RLS is characterized by abnormal sensations of irresistible urge to move legs, becoming worse at night, and frequently causing insomnia. Consequences of RLS include daytime dysfunction, depressed mood, anxiety and decreased quality of life.

Objectives Determine prevalence of RLS in professional cyclists.

Aims The aim of this study was to examine the prevalence of RLS in professional cyclists. According to our knowledge this is the first research of RLS in professional cyclists.

Methods A total of 43 professional cyclists were asked to complete 4-item questionnaire based on IRLSSG Diagnostic Criteria for RLS. Data from questionnaire was compared to anthropometric

measurements, epidemiologic data, age of starting trainings and total years of professional performance.

Results The results indicated that prevalence of RLS in professional cyclists is 14% and is higher than expected in this age group. We found statistically significant relationship between RLS and age ($P < 0,001$) and years of experience as a professional cyclist ($P < 0,001$). Results revealed no significant differences between genders (Table 1).

Conclusions RLS seems to be a common problem in professional cyclists. It can affect sport performance. Future efforts to estimate the influence of RLS on professional sport performance should be considered.

Self-criticism and self-compassion role in the occurrence of insomnia on college students

I. Teixeira, S. Simões, M. Marques, H. Espírito-Santo, L. Lemos*
Miguel Torga Institute, Psychology, Coimbra, Portugal

* Corresponding author.

Introduction To our knowledge there are no research about the influence of self-criticism and self-compassion in the occurrence of insomnia.

Objectives To study the association between self-criticism, self-compassion and insomnia on university students; to explore differences in these associations on two moments of student's lives—examination and no examination period.

Aims We anticipate that the stress and pressure of the examination period have an impact on student's sleep and there are, also, differences by age and gender.

Method Self-Criticism and Self-Reassurance Scale, Self-Compassion Scale, Pre-Activation Sleep Scale, Insomnia Assessment Scale and Anxiety and Depression and Stress Scales were answered by 160 college students (M=26.45, SD=7.98; range=19–54 years) during an examination period and by 108 college students during a no examination period (M=26.34; SD=0.43; range=19–54 years).

Results In both periods (examination and no examination period) older students (30–54 years) tended to be more self-compassionate and tolerant, such as less self-critical and punitive. During the

examination period, younger students (19–29 years) showed higher levels of self-criticism, cognitive, and somatic activation before falling asleep. There was also a higher proportion of younger students in the insomniac and insomnia symptomatic groups. Moreover, significant correlations were found between cognitive and somatic activation and depression, anxiety, and stress in both moments.

Conclusions In the examination period, the youngest students are more critical and less compassionate, what might lead to greater cognitive and somatic activation before sleep and, consequently, to insomnia symptoms and insomnia itself.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-compassion and insomnia at pregnancy

M. Marques^{1,2}, A.T. Pereira¹, V. Freitas¹, E. Bento¹, J. Azevedo¹, S. Xavier¹, M.J. Soares¹, M.J. Martins^{1,*}, A. Macedo^{1,2}

¹ University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre, Department of Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Mindfulness based programs during pregnancy (some including self-compassion components) increase self-compassion, mindfulness and maternal self-efficacy, and reduce anxiety, stress and psychological distress in pregnant women. According to our knowledge, there are no studies about the association between self-compassion and sleep outcomes in pregnancy.

Objective To explore differences in self-compassion, between three sleep groups, in a sample of Portuguese pregnant women.

Methods Four hundred and nineteen pregnant women (mean age: 32.51 ± 4.759 ; weeks of gestation: 17.32 ± 4.803) completed the Self-Compassion Scale (SCS, Bento et al., 2015), presenting six dimensions (self-kindness, self-judgment, common humanity, isolation, mindfulness and over-identification) and the Insomnia Assessment Scale (Marques et al., 2015). Three sleep groups were formed: good sleepers (no insomnia symptoms; no associated daily impairment); insomnia symptoms groups (one/more insomnia symptoms; no associated daily impairment); insomniacs (one/more insomnia symptoms; daily associated impairment).

Results There were significant differences in the total SCS, self-judgment, isolation and over-identification scores, between sleep groups [respectively, $F(2,396) = 7,926, P \leq 0,001$; $F(2,409) = 19,155, P \leq 0,001$; $F(2,410) = 13,016, P \leq 0,001$; $F(2,412) = 11,258, P \leq 0,001$]. Self-judgment, isolation and over-identification scores of good sleepers and insomnia symptoms group were higher than of insomniacs. Total SCS score of good sleepers was higher than of insomniacs and the same score of symptoms of insomnia group was also higher than of insomniacs.

Conclusions Results seem to show the importance of developing self-compassion to improve sleep in pregnancy or reduce the impact of insomnia symptoms (common at pregnancy).

Sleep disorders, depression and anxiety among medicine university students in Sfax

M. Moalla^{1,*}, M. Maalej¹, C. Nada¹, R. Sellami², J. Ben Thabet¹, L. Zouari¹, M. Maalej¹

¹ CHU Hédi Chaker S Department of Psychiatry “C”, Sfax, Tunisia

² CHU Hédi Chaker S Department of Psychiatry “A”, Sfax, Tunisia
* Corresponding author.

Introduction Sleep symptoms, depression and anxiety often coexist and tertiary students are a population group that are increasingly recognised to be at risk. However the rates of these conditions in the tunisian population are poorly understood.

Aim The aim of this study was to evaluate sleep quality among medicine students during exam periods and identify correlations with anxiety and depression.

Methods This is a descriptive and analytical cross-sectional study. It involved students of medicine University of Sfax during the period of exams. Each student filled out demographic questionnaire, the Pittsburgh Sleep Quality Index (PSQI) to assess the quality of sleep and Hospital Anxiety and Depression scale (HAD) to screen for anxiety and depressive disorders.

Results The average age was 22.27 years. The sex ratio M/F was 0.66. The students were single in 96.7% of cases. The average score of PSQI was 6.67 ± 3.23 . According to the PSQI, 53.3% of students had poor sleep quality. The anxiety score ranged from 0 to 7 with an average of 8.37. The depression score ranged from 0 to 16 with an average of 7.47. Anxiety and depressive symptoms were present in 26.7% of students. The PSQI score was significantly correlated with anxiety ($p < 0.01$) and depression scores ($P = 0.019$).

Conclusion Anxiety and depressive symptoms are common among students during exam periods. They are associated with poor quality sleep. The establishment of a helpline for students during exam time, with psychologists and psychiatrists, would help them better manage this difficult period.

* Corresponding author.

Introduction Pregnancy is characterized by important changes in sleep and some of them (as insomnia) predict negative outcomes, like depression, through all the perinatal period. There are few Portuguese adapted and validated instruments assessing insomnia in pregnancy.

Objective To validate the Insomnia Assessment Scale in a sample of Portuguese pregnant women.

Methods 419 pregnant women (mean age: 32.51 ± 4.759 ; weeks of gestation: 17.32 ± 4.803) answered the Insomnia Assessment Scale (IAS), constructed according to the DSM-V and the ICD-3 criteria and presenting fourteen items: three evaluating insomnia symptoms (1 to 3); one assessing if sleep difficulties were present although there were adequate conditions to sleep (item 4); one assessing if sleep difficulties occurred three times/week (item 5); one evaluating if sleep was not restorative (item 6); three assessing daily impairment associated to insomnia symptoms (7 to 9); two assessing the use of prescribed and/or homemade medication (10 and 11); three excluding that sleep difficulties were not due to another sleep disorder, substance use, a physical condition or a mental disorder) (12 to 14).

Results The IAS Kuder-Richardson alpha was very good ($\alpha = 0.85$) and none of the items increased the alpha if removed. A principal

component analysis revealed a three factors solution, explaining a variance/EV of 63,74%: F1/Insomnia symptoms (items 1 to 6) (EV 36.02%; $\alpha=0.81$); F2/Daily impairment associated to insomnia symptoms (items 7 to 9) (EV 18.67%; $\alpha=0.79$); F3/Differential diagnosis (items 12 to 14) (EV 8.38%; $\alpha=0.81$).

Conclusions The IAS adapted for Portuguese pregnant women presented good reliability and validity.

Mindfulness and insomnia at pregnancy

M. Marques^{1,2}, A.T. Pereira¹, E. Bento¹, S. Xavier¹, J. Azevedo^{1,*}, M.J. Soares¹, V. Freitas¹, A. Macedo^{1,2}

¹ Faculty of Medicine - University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction The impact of mindfulness in improving insomnia symptoms is documented in different samples (e.g. anxiety disorders; insomnia samples) and mindfulness based programs for pregnancy refer the association between mindfulness development and the reduction of insomnia symptoms/improvement of sleep.

Objective To explore differences in the Facets Mindfulness Questionnaire-10 (FMQ-10; Azevedo et al. 2015), between sleep groups, in Portuguese pregnant women.

Methods Four hundred and nineteen pregnant women (mean age: 32.51 ± 4.759 ; weeks of gestation: 17.32 ± 4.803) answered the Facets Mindfulness Questionnaire-10 and the Insomnia Assessment Scale (IAS, Marques et al., 2015). Three sleep groups were created considering all the IAS items: good sleepers (no insomnia symptoms; no associated daily impairment); insomnia symptoms groups (one/more insomnia symptoms; no associated daily impairment; exclusion of other conditions/disorders explaining the symptoms); insomniacs (one/more insomnia symptoms; one/more daily associated impairment; exclusion of other conditions/disorders explaining the symptoms).

Results There were significant differences in the total FMQ-10 score, the F1/Nonjudging of inner experience and the F2/acting with awareness, between sleep groups [respectively, $F(2,402)=6,933$; $P=0.001$; $F(2,406)=10.243$; $P=0.001$; $F(2,406)=37.431$; $P=0.002$]. Tukey tests indicated that the mean total FMQ-10 and F1/Nonjudging of inner experience scores of good sleepers and insomnia symptoms group were significantly higher than of the insomniacs. The mean value of F2/acting with awareness in the good sleepers was significantly higher than of the insomniacs.

Conclusions It seems important to develop mindfulness to improve sleep in pregnancy or reduce the impact of insomnia symptoms (common at pregnancy).

Perceived causes for changes in sleep pattern in postpartum women

S. Santos¹, A.T. Pereira^{1,*}, M.J. Soares¹, E. Bento¹, M. Marques^{1,2}, A. Macedo^{1,2}

¹ Faculty of Medicine - University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

Aim To investigate the causes that postpartum women most mention for changes in sleep pattern and its associations with obstetric and sleep variables and depressive symptoms.

Methods At three months postpartum 192 women fill in a booklet containing obstetric and sleep variables and the Postpartum Depression Screening Scale (PDSS; Pereira et al., 2010). If they experienced changes in their sleep pattern, they were asked about the perceived cause(s) (multiple choice). Chi-squared and Student *t* tests were applied as appropriate.

Results A total of 64.6% women referred to some cause(s); the most mentioned were feeding/baby care and older children care (32.3%) and worries (baby and life problems related) (29.5%). Women who mentioned feeding/baby and older children care as a cause did not significantly differ in relation to type of delivery, feeding method proportions and in PDSS mean scores. Women who identified worries as a cause vs. women who did not – presented significant differences in proportions of vaginal (20.0%) vs. assisted delivery (52.2%) (OR 4.444), caesarean-section (22.2%) vs. assisted delivery (52.6%) (OR 3.827), in breast-feeding (36.0%) vs. bottle-feeding (12.9%) (OR .263) and in “having trouble sleeping even when the baby is asleep” (28.0% vs. 2.9%) (OR 12.833) (all $P<.05$). PDSS mean scores were also significantly higher in women who mentioned worries as a cause (50.20 ± 20.622 vs. 58.640 ± 15.766 , $P<0.05$).

Conclusion It is important to distinguish the causes for changes in sleep pattern in postpartum women. Worries as a perceived cause have a higher impact and clinical significance than causes related to baby care demands.

Children and sleep disturbance: A case for psychiatric intervention?

P. Seibert

Saint Alphonsus Regional Medical Center, Research Institute, Boise, USA

From birth through adolescence changes occur in children's sleep architecture, schedule, and duration including several key interactions in the concomitance of sleep/wake domains and child development. Research investigating the suspected affiliation between inefficient sleep and mental dysfunction in children has been largely enigmatic. We constructed a 111-item questionnaire relative to sleep disturbance in all ages and a 12-item questionnaire specific to pediatrics to use in conjunction with nocturnal polysomnography (PSG), and medical chart reviews of children under the age of 17 referred to our institution for evaluation of SDs. We analyzed these data to create a characterization specific to children/youth ($n=57$; age 1–16 mean 9.28; 36 male, 21, female). Examples of findings reveal a characterization distinctive from the general demographic of adults who are referred for sleep studies. For example, 55.6% presented with disabilities ranging from neurological to neuromuscular; 73.3% reported learning disabilities; 66.7% possessed a range of behavioral control challenges; half used prescribed medications for psychiatric issues (despite a paucity of psychiatric evaluation). Another example, is that post-PSG, 69.6% of this sample were diagnosed with abnormal sleep architecture which was statistically related to medication use. These data revealed a pattern of children being more likely to be referred for a professional sleep study in the presence of significant medical symptomatology. Although we found some similarities when comparing this children/youth group to adults, we also found striking differences that were opposite when comparing the age groups.

Impact of dialectical behavior therapy on incidence of suicidal attempts and non-suicidal self injury among a sample of Egyptian borderline personality disorder patients

A. Abdelkarim^{1,*}, D. Nagui Rizk¹, M. Esmail², H. Helal²¹ Alexandria Faculty of Medicine, Neuropsychiatry, Alexandria, Egypt² Alexandria Faculty of Arts, Psychology, Alexandria, Egypt

* Corresponding author.

Introduction Dialectical behavior therapy (DBT) is a comprehensive psycho-social treatment developed by Marsha Linehan and originally designed for persons meeting criteria for borderline personality disorder (BPD). DBT is considered as a standard evidence based treatment for suicidal BPD patients in most international guidelines. Although its effectiveness has been proved in multiple studies across different patient populations but almost all the research was conducted in North American or European countries. The current study was the first trial to apply DBT in Egypt with a different language and culture than where the treatment was originally developed.

Objectives Assessment of incidence of suicidal attempts and non-suicidal self-injury (NSSI) among a sample of Egyptian BPD patients enrolled in an outpatient DBT program.

Aim The aim of the current study was to estimate impact of comprehensive DBT on suicidal attempts and NSSI when applied to Egyptian BPD patients.

Methods Twenty-five BPD patients, 4 males and 21 females, were included in a comprehensive outpatient DBT program for one year and incidence of suicidal attempts and NSSI were calculated.

Results Five patients only attempted suicide again with an incidence of 20% and a mean of one attempt/patient. Seven patients attempted NSSI with an incidence of 28%, an overall 22 incidents and a mean of 3 incidents/patient.

Conclusion Although this was the first time to apply DBT in an Egyptian population, DBT proved to be an effective psychotherapeutic intervention for suicidal BPD patients across regardless of different language or culture.

Factors related to suicidal behavior in Korean patients with bipolar disorder: The effect of mixed features on suicidality

H.J. Seo¹, H.R. Wang¹, Y.S. Woo¹, H.C. Kim², W.M. Bahk^{1,*}, B.W. Nam³, E. Lim⁴, K.J. Min⁵¹ Yeouido St. Mary's Hospital, Psychiatry, Seoul, Republic of Korea² Kosin University-College of Medicine, psychiatry, Busan, Republic of Korea³ School of Medicine- Konkuk University-Chungju Hospital, psychiatry, Chungju, Republic of Korea⁴ Shinsegye hospital, psychiatry, Gimje, Republic of Korea⁵ College of Medicine- Chung-Ang University, psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction The aim of the present study was to investigate various risk factors of suicidal behaviors, including the mixed features specifier, in Korean patients with bipolar disorder.

Methods We retrospectively reviewed medical charts from 2005 to 2014. A total of 334 patients diagnosed with bipolar disorder using the DSM-IV TR were enrolled. Subjects were categorized into two groups according to their history of suicidal behavior and the demographic and clinical characteristics of the groups were compared, including the mixed features specifier. We re-evaluated the index episode using DSM-5 criteria and classified subjects into an index episode with mixed features group and an index episode without mixed features group. Logistic regression was performed to evaluate significant risk factors associated with suicidal behavior.

Results Suicidal behavior had an independent relationship with mixed features at the index episode using DSM-5 criteria (OR = 3.39; 95% CI: 1.57–7.34) and number of previous depressive episodes (OR = 1.62; 95% CI: 1.34–1.95) in Korean bipolar patients. The mixed feature specifier was the strongest risk factor for suicidal behavior in the present study. Limitations: this was a retrospective study and structured psychiatric interviews were not conducted.

Conclusions This study may help clinicians understand potential risk factors and manage bipolar disorders with suicidal behaviors. Clinicians should carefully monitor patients with bipolar disorder who exhibit numerous depressive episodes or mixed features for suicidal behavior.

Survivors of suicide: A research on the consequences of a loss for suicide

S. Bellini^{*}, F. Ricci, M. Migliorati, G. Giordano, D. Erbuto, M. Milelli, M. Pompili

Sant'Andrea Hospital, Department of Neurosciences, Mental Health and Sensory Organ, Suicide Prevention Centre, Sapienza University of Rome, Rome, Italy

* Corresponding author.

Introduction Suicide loss requires more time to grieve than other losses and it is often associated with suicidal thoughts and suicide attempts in the survivors.

Objectives Survivors are often neglected and there is no real understanding of the both psychological and psychopathological consequences of losing a dear one by suicide.

Aims To assess the relationship between hopelessness, depression, suicide risk, complicated grief, intrusive memories and avoidance in a sample of suicide survivors. To define the permanence of particular variables associated with a specific type of loss, defined "complicated grief", even after many years from the loss.

Methods We recruited 35 survivors of suicide, searching for help to the Suicide Prevention Centre of Sant'Andrea Hospital in Rome. Subjects were administered BDI II, BHS, ICG, BRFL, IES, SHS, SWLS and an informative schedule.

Results A total of 62.8% of the survivors shows a higher scores on Complicated Grief referred more intrusiveness of thoughts and memories ($\rho = 0.6$; $P < 0.01$) and the attempt to prevent the thoughts and emotions related to the event ($\rho = 0.42$; $P < 0.05$), more depressive symptoms ($\rho = 0.53$; $P < 0.01$) and increased hopelessness ($\rho = 0.54$; $P < 0.01$), a lower feeling of happiness ($\rho = -0.60$; $P < 0.01$) and satisfaction with their life ($\rho = -0.57$; $P < 0.01$) than survivors that reported a lower scores in the complicated grief.

Conclusions The permanence of the symptoms of complicated grief suggests that in the case of suicide is harder to achieve a degree of acceptance and emotional balance, which usually happens within six months from the loss.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Dissociative experiences are related with a higher suicide risk in subjects with specific early traumatic life events.

Objectives To evaluate the relation between trauma, hopelessness, dissociative experiences and suicide risk in hospitalized patients.

Aim To evaluate the predictive value of early traumatic experiences on the onset of dissociative experiences and suicide risk.

Methods The sample consisted of 342 subjects consecutive psychiatric inpatients, 163 males (47,5%) and 179 females (52,5%) with an average age was 40.28 years \pm 13.25. Hopelessness levels, dissociation, trauma and suicide risk have been evaluated. We assessed the following variables: hopelessness BHS, suicide risk (MINI, C module), dissociation (DES), child abuse (CTQ).

Results Patients with early traumatic experiences reported higher scores on dissociative experiences and suicide risk, especially in female patients ($M=2.06$; $DS=1.21$), $P=0.005$ ($t: 1.927$), who referred sexual abuse. Statistically significant correlation between hopelessness and suicide risk ($0.427 < 0.01$), physical abuse and dissociative experiences ($0.431 < 0.01$) were found.

Conclusions Suicidal behavior and traumatic life-events are common among psychiatric patients.

Outpatient treatment engagement after suicidal attempt: A multicentre prospective study

B. Boniface^{1,*}, E. Castaigne², E. Balaguer³, T. Ghanem⁴, A. Bouhhal⁵, E.B. Ivascu⁵, A. Youssouf Abdou¹, P. Hardy²

⁴ Groupe Hospitalier Nord Essonne, Psychiatrie, Orsay, France

⁵ Établissement Public de Santé, Psychiatrie, Etampes, France

* Corresponding author.

Introduction Most suicide attempters are referred to community health professionals (CHP) after discharge from emergency department (ED). Thereafter, outpatient treatment engagement (OTE) is often poor. Strengthening it seems likely to reduce the risk of repeat suicidal behaviour.

Objectives To identify the predictive factors of OTE.

Methods Multicentre prospective study in true life conducted in adult patients (≥ 18) in 4 EDs of the Southern Paris region. Patients were referred to CHP. OTE was assessed by telephone calls at 1 and 3 months. OTE at 1 month was defined as having booked 1 appointment; OTE at 3 months as having attended 2 appointments and booked another one.

Results One hundred and fifty-five patients were assessed at 1 month and 144 at 3 months. OTE at 1 and 3 months was observed in 58% and 51% respectively. A multivariate analysis showed factors significantly predictive of OTE at 1 month: a psychiatric follow-up before the suicide attempt (SA), ≥ 2 psychiatric interviews during

the stay at ED, appointment with CHP booked before discharge from the ED; and at 3 months: college or university education, absence of alcohol intake during the SA, psychiatric follow-up before the SA, appointment with CHP booked before discharge from the ED.

Conclusions This multicentre prospective study highlights the benefit of booking outpatient appointment before discharge from ED; of allowing patient to benefit from at least two psychiatric interviews; of being particularly cautious with patients who took alcohol concomitantly to their SA, patients with low level of academic achievement and patients without psychiatric follow-up.

Psychiatric follow up after a suicide attempt

D. de la Vega Sánchez^{1,*}, M. Reina Domínguez², S. Fernández León²

¹ Hospital Virgen Macarena, Psiquiatría, Sevilla, Spain

² Hospital Juan Ramón Jiménez, Psiquiatría, Huelva, Spain

* Corresponding author.

Introduction Suicide is a global public health problem. More than 800,000 people die due to suicide every year according to the WHOM. In Spain, about 9 people die due to suicide every day, and the rates increase every year. The presence of previous suicide attempts is one of the strongest risk factors for suicide consumption. Nevertheless, patients sometimes do not receive a correct assistance after a suicide attempt.

Objective To study the follow-up of patients, without previous psychiatric history, who commit a first suicide attempt in the area of Huelva (Spain).

Method Retrospective review of the electronic clinical histories of patients attended in the Emergency service of Juan Ramón Jiménez Hospital after a first suicide attempt during the first six months of 2015.

Results From January to June of 2015 we collected a total of 159 patients who committed a first suicide attempt in our area. A total of 69.18% were women and 30.82 were men. In both sex the mean age was 39 years. Out of the 159 attended after a first suicide attempt, only 54% were referred to the Psychiatry service to be followed up. Out of those referred, only 62% actually attended and only half of them really staying treatment.

Conclusions An adequate psychiatric follow up after a suicide attempt is needed to reduce the risk of more suicide attempts or consumption. A minority (30.8%) of the patients attended in our area after a first suicide attempt received an adequate attention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction It has been suggested that there is a relationship between BMI and suicide. Thus, BMI of subjects who commit suicide would be lower than the BMI of other unnatural deaths (Flaig 2013).

Objectives Explore the possible relationship between BMI and suicide.

Material and methods A total of 1197 suicides and 473 unnatural deaths (not by suicide) were collected systematically for 60 months at the Institute of Legal Medicine of Seville. Age, sex, weight, height and cause of death were recorded. Statistical analysis was performed using SPSS v19.0.

Results (Table 1)

Discussion In our study we found that suicide (of all age groups and both sexes) have a lower BMI than controls. However, the relationship between these two variables is complex and not all studies support it. Moreover, the relationships between depression, suicide and overweight point in different directions. More and more studies indicate the existence of a relationship between depression and overweight, suggesting that perhaps the “epidemic” of depression and overweight that we see in Western societies has some connection. In addition, depression is a risk factor for suicide well established. Our results indicate that suicide group tends to have lower BMI (less weight in relation to its size) than the controls.

Introduction Psychological autopsy studies have constantly indicated a clear relation between mental disorders and suicide. This relation has been found in studies across the world, although the percentage of cases with at least one mental disorder diagnosed may vary between studies and specially, between countries and geographical regions.

Methods Review of psychological autopsy studies of suicide completers which contained information on diagnostic distribution. Only studies carried out in Europe and North America were included.

Results A total of 14 studies, including 1519 suicides, were analyzed (Table 1).

Conclusions Suicide risk is a multifactor phenomenon, however, it is strongly related to mental disorders. Mental health strategies should be directed to target clinical groups at high risk of suicide.

Gender differences in suicide in Serbia within the period 2006–2015

G. Dedic
 New Belgrade, Serbia

Introduction The complex multifactorial etiology of the suicide suggests the need to consider gender differences when developing effective strategies for suicide prevention. The aim of this study was to examine the suicide rates and/or trends obtained for population as a whole, including gender differences in cases of committed suicide and to consider socio-demographic factors associated with it in Serbia within the period 2006–2015.

Methods Data were obtained from the Republic Institute for Statistics of Serbia. Statistical analysis was done by using the crude specific suicide rate.

Results Within the period 2006–2015, the suicide rate decreased from 19.15 per 100,000 persons (2006) to 15.9 per 100,000 persons (2014). In this period, males committed suicide 2.56 to 3.20 times on average more often than females. The suicide was most often

committed by the married males and females with completed high school, pensioners. The suicide rate has been increasing with the age of the suicide committers and it is the highest in subjects of both genders aged over 75 years. The most common suicide method in males and in females is hanging and strangling. The second most common method in males is by firearm and in females poisoning.

Conclusions Suicide Prevention Programme in Serbia should be primarily oriented toward the male population because they were more exposed to stress in the period of social transition in recent years. But the problem is that males are still less ready to ask psychiatrists for help when having some problems with mental health.

The spatial pattern of suicides in Russia: Does alcohol matter?

Y. Razvodovsky^{1,*}, S. Kandrychyn²

¹ Grodno State Medical University, Pathological Physiology, Grodno, Belarus

² Minsk regional clinical hospital, Cardiology, Minsk, Belarus

* Corresponding author.

Introduction Russia retains one of the highest suicides rate in the world, despite a gradual decline over the past decade. Epidemiological evidence suggests that suicide mortality vary noticeably between the regions in Russia with the regular spatial pattern in suicides distribution.

Objectives The aim of this study was to consider the role of alcohol as a factor responsible for the spatial pattern of suicides mortality in Russia.

Methods The cross-sectional time series analysis of suicides and fatal alcohol poisonings (as a proxy for alcohol consumption) rates in 73 regions of European Russia over the period 1980–2013 was performed. This analysis was followed by a more detail examination of the mortality distribution across the north-south axis by using latitudinal approach.

Results The stable south-north gradient in suicides and alcohol poisonings mortality rates is manifested on the European territory of Russia. The analysis indicates that the regional variations of suicides and alcohol poisonings mortality rates have a similar spatial regularity, which means that the regions with a high suicides rate also have a high alcohol poisonings mortality rates. The results also suggest the long-term similarity and continuity in the suicides and alcohol poisonings mortality geographical pattern.

Conclusions The findings on spatial relationship between suicides and alcohol poisonings mortality rates seem to support the hypothesis that considers regional pattern of alcohol-related problems as a factor responsible for the spatial pattern of suicides mortality in Russia.

Introduction Spatial patterns of mortality could help us to focus research to achieve prevention. On the other hand, recent research has shown an association between unemployment and suicide, but the mediating factors in this relationship are still unknown.

Objectives We investigated the provincial spatial patterns of suicide mortality in Spain, and the effect of unemployment and economic recession on suicide mortality rates in the Spanish region of Galicia that has high suicide rates.

Method To describe regional suicide mortality in Spain and to assess its association with recession and unemployment in Galicia, we calculated age-standardized suicide rates in men and women throughout 1975–2012 by region and performed a time-trend Generalized Additive Model using mortality data provided by National Statistics Institute and employment data collected from Statistics Institute of Galicia.

Results In Spain, during the study period, there were 105,134 suicides with an age-adjusted rate of 10.2 and 3.02 per 100,000 population in men and women, respectively. There is a high variability in mortality rates across Spanish provinces. Madrid had the lower rates and Asturias and Galicia the higher ones. In Galicia, suicide rates were 13.7 in men and 4.3 in women per 100,000 and we found that economic recession and unemployment interacted with regards to suicide rates ($P=9.80E-4$) and after stratifying by sex, the effect was confirmed only among men ($P=8.70E-3$).

Conclusions In Spain, suicide mortality varies greatly by region and in Galicia that is one of Spanish regions with higher suicide rates, unemployment was related with suicide during economic recession periods.

Introduction Suicide is a major public health problem and one of the common causes of maternal mortality. Rates of suicide and self-harm are higher in British South Asian women compared to the majority white population. Suicidal Ideation (SI) is a significant risk factor associated with self-harm and suicide.

Objective To explore the prevalence and risk factors of SI in British Pakistani women.

Aim To identify risk factors associated with SI, in order to inform future preventive strategies.

Method This is a secondary analysis of a larger study which looked at depression during pregnancy and infant outcomes. Participants who consented (women aged 18 or over, in their third pregnancy trimester) were initially assessed for maternal depression using the Edinburgh Post-Natal Depression Scale (EPDS), with one of the questions on the EPDS being on SI. Participants who met the study criteria, were further assessed regarding socio-demographic factors, perceived social support, social adversity and isolation.

Results The rate of SI in this group of women was 8.1%, with baseline interview results suggesting that women with SI being significantly more likely to be aged 20 or less, have experience of severe life events and being less likely to have social support.

Conclusion This area of research is key to understanding SI in British Pakistani women, to better develop culturally sensitive interventions for use within this group.

Introduction In the last few years, Spain has suffered from a severe economic downturn which resulted in high unemployment rates. Association between unemployment and suicide is controversial.

Objectives To know the association between unemployment and suicide and to investigate if there could be a lag between increased of unemployment and increased of suicide.

Methods The authors collected the official data about completed suicides and unemployment from the database of the National Statistics Institute (INE) and the National Employment Institute of Spain. We assessed annual variations in unemployment figures and correlated these figures with the annual change in the number of suicides. Pearson correlation coefficient between unemployment and suicide was calculated both, for the same year and after 1–6 years.

Results The correlation of annual changes of unemployed and suicides varies depending on the latency period that applies to annual changes in suicide for comparison with index unemployment change, with a peak correlation in the fourth and fifth year and a clear decline in the correlation in the sixth year (Table 1).

Conclusion The results suggest that unemployment might be associated with suicide but mainly after 4–5 years.

Table 1 Pearson correlation coefficients between index unemployment change and suicidality change after 1–6 years (latency) for the total men and women.

Latency years	men	women	total
0	0,564	0,221	0,383
1	0,403	0,199	0,252
2	0,337	0,318	0,311
3	0,494	0,488	0,542
4	0,748	0,633	0,722
5	0,768	0,624	0,549

* Corresponding author.

Objective The aim of this study was to analyze the clinical characteristics of individuals who used alcohol at the time of attempting suicide.

Methods We divided 143 individuals who attempted suicide by consuming drugs into two groups on the basis of their blood alcohol concentration level: drinker group ($n = 79$) and non-drinker group ($n = 64$). We compared epidemiological characteristics and suicidal behavior between the groups by using the Suicidal Intent Scale (SIS) and the Risk Rescue Rating Scale (RRRS). In addition, we administered the Glasgow Coma Scale (GCS) and the Acute Physiology and Chronic Health Evaluation–II (APACHE–II) to evaluate the medical lethality of the individuals who attempted suicide. We used Student's t -test, Pearson's correlation analysis, and multiple linear regression to analyze the data.

Results The drinker group scored lower on the SIS's planning subscale than the non-drinker group did ($P = 0.022$). The drinker group's blood alcohol concentration levels were negatively correlated with the rescue potential of their suicidal attempt ($P = 0.031$) and the APACHE-II score ($P = 0.003$). Higher blood alcohol concentration levels predicted poorer medical outcomes measured by the APACHE-II ($P = 0.004$).

Conclusion Our findings support the notion that alcohol use increases suicidal impulsivity, decreases rescue potential, and worsens medical outcomes. Therefore, suicide prevention programs need to include education and counselling about the risks associated with alcohol use.

* Corresponding author.

Introduction Suicide is a major public-health problem in Canada. Data from 'Statistics Canada' suggests that there was a 10% increase in suicide rate between the years 1997 and 1999. Studies have found substantial differences in suicide rates (and patterns) amongst ethnic immigrants compared to Canadian-born individuals.

Aim The aim of the study was to investigate whether ethnic-immigrant patients differed from Canadian-born patients in their social, demographic, psychiatric and historical associations.

Methods All registered patients ($n=276$) known to have completed suicide from 1966–1997 constituted the study sample. Data were extracted from the written case audits, autopsy and toxicology reports, and medical records.

Results Of the 276 known cases of suicide, 11 were Afro-Caribbean, 24 were Eastern European, 14 were Asian and 215 were Canadian-born patients. The ethnic-immigrant groups were broadly comparable to the Canadian-born group in terms of the social, demographic, psychiatric and background historical factors (except that the latter had a higher prevalence of alcohol and substance misuse). There were no significant differences between different ethnic immigrant groups themselves.

Conclusions The most salient implication of the findings are that social, psychiatric and historical associations of mentally ill patients who complete suicide are common across different ethnic immigrant groups, and as such a universal approach to mental health promotion, early identification and treatment would be similarly applicable to patients belonging to all groups.

Empathy in adolescent suicidal behaviors: Perspectives from the adolescents, their parents and their healthcare professionals

J. Lachal^{1,*}, M. Orri², A. Revah-Levy³, M.R. Moro¹

¹ Hôpital Cochin- Maison de Solenn, Université Paris Descartes, Sorbonne Paris Cité, Paris, France

² Inserm, U1178, Paris, France

³ Centre de soins psychothérapeutiques de transition pour adolescents, Argenteuil, Université Paris Diderot, Sorbonne Paris Cité, U1153 CRESS, Paris, France

* Corresponding author.

Introduction Suicide is the second leading cause of death among 15–25years, and the rate of suicide attempts is 10–20 times higher than that of completed suicides. Past research improved the knowledge on risk and protective factors, and resulted in large-scale campaigns of prevention and reduction of deaths by suicide.

However, their effect seems to decline, and the prevalence rates of suicidal attempts have stopped decreasing (either becoming stable or increasing again).

Method Qualitative synthesis on adolescents' suicidal behaviors, from the perspectives of 900 participants (adolescents presenting suicidal behaviors, their parents, and their healthcare professionals), including 44 studies (1990–2014, having good quality according to CASP evaluation) systematically found on five databases (Medline, PsycINFO, EMBASE, CINAHL, SSCI).

Results The suicidal experience is organized around three superordinate themes: the individual experience (the individual burden and suffering related to suicide attempts); the relational experience (the importance of relationships with others at all stages of the process of suicidal behavior); and the social and cultural experience (how cultural groups and society accept/reject youths in distress and their families, and how this affects the suicidal process and its management).

Conclusions The violence of the message of a suicidal act and the fears associated with death lead to incomprehension and interfere with the capacity for empathy of both family and professionals. How can we treat someone when our capacity of empathy is dumbfounded? Exploring the concept of intersubjectivity, we found a possible viable answer. Especially, the need of a "third place" in the suicidal patient care is discussed.

³ School of Medicine, Universidad Autonoma de Madrid, Madrid, Spain

* Corresponding author.

Introduction Acute suicidality or a condition after attempted suicide frequently leads patients to both voluntary or involuntary inpatient admission. Emergency room psychiatrists decide whether such patients can be treated on an outpatient basis.

Objectives To identify if immigration status is associated with the decision whether a patient needs a hospital admission.

Aims To detect social determinants of hospital-based health resource uses.

Methods A cross-sectional study including data from 323 patients treated in a general hospital's emergency room after a suicidal attempt during year 2014.

Results Seventy-six patients were admitted to the hospital (23.5%). Hospitalization frequencies for immigrant and non-immigrant individuals were 6.3% and 26.5% ($P=0.002$). No significant association was found between psychiatric admission and history of a diagnosed psychiatric disorder, previous suicidal attempts, previous emergency room care use, family support or current drug use. A subgroup of patients ($n=37$; 9%) answered Beck's suicidal intent scale (SIS), a measure of risk in suicidal attempters. Mean SIS was found to be higher among hospitalized than discharged patients (8.5 vs. 16.5; $P=0.01$). No significant difference was found in mean SIS between immigrant and non-immigrant patients (9.3 vs. 9.1; $P=0.3$).

Conclusions These preliminary results call for consideration. The highly significant lower rate of psychiatric admission among

immigrant patients, without significant differences in mean SIS score in regard to non-immigrants, needs further study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Suicide and socio-demographic characteristics as a risk factor in Belgrade, Serbia

G. Nikolic Balkoski*, D. Tiosavljevic

Clinic for psychiatry CCS, Day hospital, Belgrade, Serbia

* Corresponding author.

Objectives suicide and self-inflicted injuries are the leading causes of injury-related deaths worldwide. The aim of this work is to investigate sociodemographic characteristics as a risk factor for suicide. The investigation covers the period from 1997 to 2011 on the territory of the capital of Serbia, the city of Belgrade methods. The data was taken from the index books of suicides committed in the city of Belgrade, held at the Institute of Informatics and Statistics. Statistical analysis was done using the crude specific rate. The variability of the rate was estimated by computing a confidence interval.

Results The average suicide rate in the observed period is 9.88. The suicide rate shows a regular decline until 2005, and from that time on mild growth (the highest in 2000, the lowest in 2004). The results of our study point out the following sociodemographic profile as a risk factor for suicide: male with uncompleted elementary school who lives in a suburban community, aged 66 and over; suicides are usually realized in the area of residence during the day, in late spring, and hanging is the most frequent method of suicide.

Conclusion Preventive public health measures should be implemented focusing on typical socio-demographic profile. Prospective studies should include more variables in order to identify more risk factors for suicide and suicidal behavior. To achieve this, a serious national strategy for recording suicide and suicide prevention would have to be developed.

Talking suicide on Twitter: Linguistic style and language processes of suicide-related posts

B. O'Dea^{1,*}, M. Larsen¹, P. Batterham², A. Callear², H. Christensen¹

¹ University of New South Wales, Black Dog Institute, Sydney, Australia

² The Australian National University, National Institute for Mental Health Research, Canberra, Australia

* Corresponding author.

Introduction Suicide is a leading cause of death worldwide and is largely preventable. The social media site Twitter is used by individuals to express suicidal intentions. It is not yet feasible to contact each Twitter user to confirm risk. Instead, it may be possible to validate risk by linguistic analysis. Psychological linguistic theory suggests that language is a reliable way of measuring people's internal thoughts and emotions; however, the linguistics of suicidality on Twitter is yet to be fully explored.

Objectives & aim The aim of this study is to characterise the linguistic styles of suicide-related posts on Twitter for the purposes of predicting suicide risk.

Methods The Linguistic Inquiry and Word Count (LIWC) program was used to compare the linguistic features of suicide-related

tweets previously coded for suicide risk by humans with a set of matched controls. Logistic regression was then used for predictive modelling.

Results The suicide-related tweets had significantly different linguistic profiles to the control tweets. The "strongly concerning" suicide tweets were found to have fewer words than all other tweets and not surprisingly, references to 'death' were significantly higher in this group. A number of other results were found. The final model which distinguished "strongly concerning" suicide risk from the controls was found to have 97.7% sensitivity and 99.8% specificity.

Conclusions This study confirms that the linguistic features of suicide-related Twitter posts are different from general Twitter posts and that these linguistic profiles may be used to predict suicide risk in Twitter users.

The suicide crisis assessment nurse (SCAN) service in Donegal; an activity profile

M. Osman^{1,*}, S. Toye², E. Duffy², C. Haley²

¹ Co. Donegal, Ireland

² Letterkenny General Hospital, Department of Psychiatry, Letterkenny, Ireland

* Corresponding author.

Introduction We previously reported on a series of sudden and unexpected deaths in Donegal patients (EPA 2015). We are now presenting some initial data on a Suicide Crisis intervention service established in February 2015 as part of the response to the increasing service user suicides in Co. Donegal, Ireland. The Donegal Suicide Crisis Assessment Nurse (SCAN) is a nurse led service which works closely with General Practitioners (GP's), mainstream mental health services, and non-statutory service providers.

Objectives/aims Our audit presents the activity of SCAN service in Donegal over the February–August 2015 period.

Method We extracted the demographic data pertaining to the referrals from the SCAN data-base using R software for statistical analysis.

Results There were ($n = 65$) referrals during the five-month study period (41.5% men and 51% women). There were ($n = 60$) 90.9% referrals for suicidal ideations, ($n = 6$) 9.1% for engagement in deliberate self-harm and ($n = 9$) 13.6% following suicidal attempts. Alcohol misuse was a significant issue in ($n = 16$) 24.2% referrals. The mean age was 36.0 years ($SD = 16.0$ years); 40.7 years ($SD = 16.8$ years) for males, and 32.7 years ($SD = 14.8$ years) for females. The male-female age difference was significant ($P = 0.0461$). The majority of patients ($n = 24$) were seen the following day. There were ($n = 16$) who were seen the same day of referral. Only ($n = 5$) were seen two days after their referral, with ($n = 4$) patients seen the third day or more.

Conclusion The SCAN service in Donegal is growing month-by-month. Males referred tend to be significantly older than females, otherwise, no demographic difference was apparent.

² *Epilepsy Group, Atkinson Morley Regional Neuroscience Centre, St. George's University Hospitals NHS Foundation Trust, London, United Kingdom*

* *Corresponding author.*

Introduction The social and economic impact of mood disorders and suicide is extremely high. In depression, suicide is included among the cognitive disturbances, together with guilt, paranoid and obsessive-compulsive symptoms, depersonalization/derealization and agitation [1,2]. The aim of this report is to study a sample of depressed patients with bipolar disorder or major depressive disorder, to evaluate the level of impulsivity and dissociation in a context of a suicidal plan.

Method Twenty inpatients with suicidal plan were assessed with: the SCID-P for Axis I diagnosis, SCI-DER, DSS, HRSD, HAS, YMRS, GSR. We conducted a systematic literature review (PubMed, Embase, PsychInfo) using the key terms "depression", "suicide", "suicidal plan", "depersonalization", "derealization" AND "dissociation".

Results An independent sample T-Test analysis suggested that the patient with high suicidal plan present significant higher score at SCI-DER TOT ($P=0.015$), DSS TOT ($P=0.037$), BIS-11 motor perseveration factor ($P=0.023$) and inversely significant HAS TOT ($P=.029$).

Discussion and conclusion It's suggestive that when are lost the boundaries of the self, the clarity of suicidal's purpose reduces the levels of anxiety and suicide appears the only way to achieve the liberation of the suffering of depression. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Spousal abuse in married women with suicidal attempt in Shiraz, Iran

A. Sahraian*, S. Bahreini, A. Mani

Research Center for Psychiatry and Behavioral Sciences, Shiraz University of Medical Sciences, Shiraz, Iran

* *Corresponding author.*

Introduction Epidemiological studies revealed that 21 to 34 percent of women around the world have been victim of physical assault by their spouse and spouse abuse have been more prevalent in developing countries.

Objectives The most common form of violence against women is spousal abuse which is a dangerous factor and leads to serious psychological damages while it is one of the most important causes of suicide in married women.

Aims The study of factors related to spousal abuse in the population where they attempt to suicide is important for recognizing it and preventing spousal abuse, consequently, preventing suicide.

Methods The study was conducted cross-sectional on 360 married women who attempted suicide and referred to Shoshtari Hospital in Shiraz. Instruments for data collection comprised of about spousal abuse questionnaire and demographic cases questionnaire which were filled through interview.

Results A total of 43.9% of domestic violence prevalence, 61.7% of economic violence, 45.3% of psychological violence, 38.1% of social violence, 38.1% physical violence, 35.9% of sexual violence was reported. There was a relation between spousal abuse and some factors such as: age difference between spouses, wife and husband's education, husband's substance abuse, husband's medical illness, wife's psychiatry disorder, spouses' obligatory marriage, polygamy and husband's job.

Conclusions Considering relatively high prevalence of spousal abuse in people who attempted suicide and the relation between some demographic factors with violence, besides regarding spousal abuse as one causes of suicide, the women's screening, particularly those who attempt suicide in regard to spousal abuse and its related factors seems necessary.

Patient assessment following substance overdose: Can we predict memory of the psychiatric interview?

J. Salles^{1,*}, E. Very¹, J. Pariente², L. Schmitt¹

¹ *CHU Toulouse, psychiatry, Toulouse, France*

² *CHU Toulouse, neurology, Toulouse, France*

* *Corresponding author.*

Suicide is a major public health issue, and a critical step in its prevention is a psychiatric assessment of individuals following suicide attempts (NICE 2008). In cases where patients attempt suicide through substance overdose, the central nervous system and consciousness are altered in significant ways. This is problematic, given that patients must have recovered sufficient cognitive capacity if a psychiatric assessment is to yield a meaningful and suitable care plan that the patient will recall and follow (Lukens 2006). Currently, there is no validated tool to assess whether sufficient cognitive recovery has occurred in such patients to ensure their memory of the assessment. Therefore, our goal was to identify indicators that predict preserved memory of undergoing a psychiatric assessment. We carried out a prospective study with 41 patients recruited from an emergency department. We collected data on cognitive tests (including WAIS coding test), memory self-assessment, plasma benzodiazepine levels, age, gender, and educational level at the time of psychiatric assessment. We then assessed patients' memory for undergoing a psychiatric interview 24 hours post-assessment, using an episodic memory score. Whereas memory self-assessment did not predict the episodic memory score, age, plasma benzodiazepine level, and cognitive test scores significantly influenced it, predicting 70% of memory score variation. Among these factors, the WAIS coding test predicted 57% of the memory score variation. To improve clinical practice, it may be useful to assess visual scanning, processing speed, and attentional function prior to psychiatric interview to ensure later patient recall.

Suicidal ideation and organic diseases in acute female psychiatric patients

P. Solano^{1,*}, M. Ustulin¹, R. Vecchio¹, A. Rreshketa¹,

E. Pizzorno², G. Serafini¹, M. Amore¹

¹ *Clinica Psichiatrica, Psychiatry, Genoa, Italy*

² *Legal Medicine, Health Sciences and Legal Medicine, Genova, Italy*

* *Corresponding author.*

Introduction Physical illness has been recognized as a major risk factor for suicidal behaviours, especially among females. A higher number of physical comorbidities has been associated with higher suicide- risk, thus having a greater burden among the elderly.

Objectives investigate this evidence to be able to estimate the load of physical illness on suicidality among psychiatric females of different age.

Aims Evaluate the association between suicidal ideation, age, depression and physical comorbidities in a sample of acute females psychiatric in-patients.

Methods 81 psychiatric female in-patients were evaluated during their first day of hospitalization through MADRS, SSI and the presence of organic comorbidity has been collected together with demographic data. All the evaluations were carried out at the Psychiatric Clinic, University of Genova, Italy.

Results Mean age 48 (age-range value: 74, high variability). Pearson's Chi-squared test showed: significant association between SSI and MADRS ($P=0,027$; $\alpha=0,05$); no association between SSI and age ($P=0,194$; $\alpha=0,05$); no association between SSI and presence medical illness ($P=0,132$; $\alpha=0,05$); no association between SSI and number of medical illness ($P=0,186$; $\alpha=0,05$).

Conclusions Our results show that the levels of suicidal ideation in psychiatric females are independent from age, presence and number of physical comorbidities. Suicidal ideation appears to be associated only with levels of depression. Our results challenge evidence from a large number of current studies and, if confirmed by further research, would lead to reconsider major suicide risk factors. Further research to investigate these associations on larger samples is needed.

Information modeling of suicidal behavior in adolescents from Far East of Russia and Northern China

E. Solodkaia^{1,*}, I. Loginov¹, S. Savin², H. Jian³

¹ Far Eastern State Medical University, Psychiatry and Narcology, Khabarovsk, Russia

² Computer Center of FEB RAS, Laboratory of medical information, Khabarovsk, Russia

³ Harbin Medical University, Psychiatry and narcology, Harbin, China

* Corresponding author.

Objectives Creating information model of suicidal behavior in adolescents from Russia and Northern China. Computer information model of society based on the description of game-theoretic approach to complex conflict systems.

Methods Information modeling, ethnographic method.

Results A questionnaire was conducted through the process of reverse translation for correct interpretation of specific terms. In the Chinese group, 25% had a tendency to suicidal behavior, 34.2% thought about the possibility of suicide. First among the factors shaping suicidal behavior – social and economic (difficulty entering the study and employment, low social security), followed by interpersonal factors (break with a partner), psychopathological family history, depression, high anxiety, alcoholism and drug use, factors social immaturity (responsibility, independence), loneliness. The Russian group 20% had a tendency to suicidal behavior, 24.6% of them thought about the possibility of suicide. The main cause of suicidal behavior in adolescents Russian – interpersonal factor (failed love, personally-family conflict), then the conflicts associated with antisocial behavior, and only then - the socio-economic factors (material and living difficulties, conflicts related to education and career, drug addiction, substance abuse, anxiety disorders and depression).

Conclusions The method of information modeling allows to investigate the causes of conflict between the individual teenager using game-theoretic methods and the most effective in treating suicidal behavior in teenagers aggressive information environment (kiberbullies), thereby reducing the level of suicidality in adolescents. Suicidal behavior among Chinese adolescents occurs because of fear of the future, and in Russian – the past. A need for more high-quality comprehensive prevention of suicidal behavior.

Development and psychometric testing of the triggers of suicidal ideation inventory for assessing older outpatients in primary care settings

Y.F. Tsai^{1,*}, S.H. Lee², Y.W. Wang¹, Y.J. Chen³

¹ Chang Gung University, School of Nursing, Taoyuan, Taiwan

² Chang Gung Memorial Hospital at Linkou, Department of Psychiatry, Tao-Yuan, Taiwan

³ Chang Gung Memorial Hospital at Linkou, Department of Internal Medicine, Tao-Yuan, Taiwan

* Corresponding author.

Introduction Older adults with depression resist accepting depression screening and seeking treatment due to stigmatization of mental disorders and little knowledge about depression. This study was undertaken to develop and determine the psychometrics of an instrument for assessing triggers of suicidal ideation among older outpatients.

Method Participants were recruited from older outpatients of two hospitals in northern Taiwan. An initial 32-item Triggers of Suicidal Ideation Inventory (TSII) was developed, and its items were validated by experts in two runs of Delphi technique survey. After this TSII was pre-tested in 200 elderly outpatients, 12 items were retained. The 12-item TSII was examined by criterion validity, construct validity, internal consistency reliability, and test-retest reliability.

Results TSII scores were significantly and positively correlated with the Beck Scale for Suicide Ideation ($r=0.45$, $P<0.01$), and UCLA Loneliness scores ($r=0.55$, $P<0.01$), indicating satisfied criterion validity. Participants with depressive tendency tended to have higher TSII scores than participants with no depressive tendency ($t=8.62$, $P<0.01$), indicating good construct validity. Cronbach's α and the intraclass correlation coefficient for the TSII were 0.70 and 0.99 respectively, indicating acceptable internal consistency reliability and excellent test-retest reliability. Receiver operating characteristic analysis revealed that the area under the curve was 0.83, indicating excellent ability to detect triggers of suicidal ideation. With a cutoff point of 2, the sensitivity and specificity were 0.86 and 0.67, respectively.

Conclusions The TSII can be completed in 5 minutes and is perceived as easy to complete. Moreover, the inventory yielded highly acceptable parameters of validity and reliability.

Suicidal ideation among former prisoners of war's wives – a longitudinal dyadic study

G. Zerach^{1,*}, Y. Levi-Belz², M. Michelson³, Z. Solomon⁴

¹ Ariel University, Behavioral Sciences, Ariel, Israel

² Ruppin Academic Center, Behavioral Sciences, Emek-Hefer, Israel

³ Ariel University, Psychology, Ariel, Israel

⁴ Tel-Aviv University, Social Work, Tel-Aviv, Israel

* Corresponding author.

Introduction The long-term associations between posttraumatic stress disorder (PTSD) and suicidal ideation (SI) among ex-prisoners of war (ex-POWs) has recently been exemplified. Several studies have revealed the toll of war captivity on secondary traumatization'

(ST) of ex-POWs' wives. However, a question remains regarding the possible SI among ex-POWs' wives.

Objectives Understanding of SI phenomena among wives of severely traumatized ex-POWs in a longitudinal dyadic designed study.

Aims Assessment of SI among ex-POWs' wives and the longitudinal associations with their husbands' PTSD. We also aim to assess the moderating role of the couple's dyadic adjustment in these associations.

Method A sample of 233 Israeli couples (142 ex-POWs couples and a comparison group of 91 veteran couples) completed self-report measures at two time points: T1 30 (2003–4) and T2 37 (2010) years after the 'Yom Kipur' 1973 war.

Results Surprisingly, no significant differences were found between ex-POWs wives and veterans' wives, with and without husbands' PTSD, in SI at T1 and T2. Only among ex-POW couples, an increase in the husband's level of PTSD and SI was related to a more moderate increase in their wives' SI between T1 and T2. Interestingly, the more a wife reported positive dyadic adjustment, the more moderate the increase in her SI between T1 to T2, regardless of the study group.

Conclusions Suicidal ideation among ex-POWs' wives is closely related to their husbands' PTSD and is moderated by their perception of marital adjustment.

Online destigmatization of schizophrenia: A Romanian experience

M. Ladea^{1,*}, M. Bran^{2,*}, S. Marcel Claudiu³

¹ University of Medicine and Pharmacy "Carol Davila", Psychiatry, Bucharest, Romania

² Coltea Clinical Hospital, Psychiatry, Bucharest, Romania

³ CMI Marcel Sarpe, Psychiatry, Focsani, Romania

* Corresponding author.

Introduction Mental illness stigma existed long before psychiatry, although sometimes the institution of psychiatry has not helped enough in reducing either stereotyping or discriminatory practices. Stigma of mental illness involves problems with knowledge, attitudes, and behavior and has important negative consequences for patients and their families. As new technologies become more reliable and accessible, mental health specialists are developing new and innovative methods through which they may provide services. Internet has an important role in the delivery of information because of its ability to reach a large number of people in a cost-effective manner.

Objectives In order to reduce stigma an online platform with relevant information about schizophrenia was developed. Simultaneously a social media campaign to increase awareness was launched.

Methods A multidisciplinary team of psychiatrists, web-developers, IT specialists and designers developed the platform www.schizophrenia.ro. The platform is intended to be simple and with a great visual impact and it gathers general information about schizophrenia. The social media campaign used emotional messages like "Diagnosis is not the end of the road" or "I'm a person not a diagnosis" combined with high impact images.

Results From 1st January to end of September 2015 the platform had about 22,500 users and about 70,500 page views. The social media campaign had a reach of approximately 9700 people in just 2 months.

Conclusions The World Wide Web is increasingly recognized as a powerful tool for prevention and intervention programs and could also play an important role in destigmatization campaigns.

Therapist-guided internet-based cognitive-behavioural therapy for adult obsessive-compulsive disorder: A meta-analysis

A. Pozza^{1,*}, G. Andersson², D. Dèttore³

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden

³ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Cognitive-behavioural therapy (CBT) is the first-line psychological treatment for obsessive-compulsive disorder (OCD). However, most individuals suffering from OCD do not receive CBT. An innovative approach to improve access to evidence-based care is the use of the Internet to deliver effective treatments. Therapist-guided Internet-based cognitive-behavioural therapy (iCBT) involves the administration of structured online lessons that provide the same information and skills typically taught in clinician-administered CBT, often with email support from a therapist. Accumulating evidence on iCBT for OCD has been produced, but a meta-analysis has not been conducted.

Objectives Through meta-analytic methods, the present study summarized evidence on iCBT for OCD.

Aims Efficacy on OCD symptoms and comorbid depression versus control conditions at post-treatment and follow-up was evaluated.

Methods A PRISMA meta-analysis was performed on randomized controlled trials. Treatments were classified as iCBT if they included CBT components for OCD (eg, exposure and response prevention) delivered through the Internet with or without email/phone support from a therapist.

Results Four trials were included ($n = 238$), which were classified at low bias risk. At post-treatment iCBT outperformed control conditions with a high effect size on OCD symptoms ($d = 0.85$, $P < .05$) and a medium on comorbid depression ($d = 0.52$, $P < .05$). Treatment effects were stable at 4-month follow-up with a high effect size on OCD ($d = 1.45$, $P < .05$), but not on comorbid depression ($d = 0.33$, $P < .05$).

Conclusions iCBT seems a promising treatment modality for OCD. Further trials should assess long-term outcomes and effects on quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychological factors of excessive TV viewing in senior pupils

A. Vasylychenko^{1,*}, S. Tukaiev², G. Abbasova³, L. Derevinskaya⁴

¹ National Taras Shevchenko University of Kyiv, Educational and Scientific Centre "Institute of Biology", Kiev, Ukraine

² National Taras Shevchenko University of Kyiv, Educational and Scientific Centre “Institute of Biology”- Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine

³ High School 6, Student Government, Chernihiv, Ukraine

⁴ High School 6, Department of Biology, Chernihiv, Ukraine

* Corresponding author.

Media influence on a person qualifies in the context of negative evaluations of a person's dependence, especially children, on the media. The aim of this study was to reveal the influence of TV news on psycho-emotional state of youth audience, and the extent to which psychological traits determine their propensity for television watching. Forty-two healthy volunteers aged 14–17 years, the senior pupils of one of high schools in Chernihiv, Ukraine, participated in this study. Participants recorded the time they spend watching TV news and commercials during the month. We used Temperament and Character Inventory by Cloninger, Cloninger Tridimensional Personality Questionnaire, Technique of Diagnostics of Ability to Predict by Regush, School Anxiety Test by Philips, Beck Depression Inventory, Technique of Diagnostics of a Potential of Communicative Impulsiveness by Losenkov, the Method of Diagnostics of the Level of Empathic Abilities by Boyko, Maddi Hardiness Survey, and the Emotional Intelligence Self-Evaluation by Hall. We found that excessive TV viewing has been linked to the development of depression among the participants. There was an inverse correlation between the cognitive-affective and somatic symptoms of depression and the reward dependence, mediated by the noradrenergic brain system. The main independent determinants influencing excessive TV viewing were low levels of the reward dependence and the novelty seeking (which reflects the activity of dopaminergic brain system). We argue that the propensity for watching TV and depression development can be predicted by psychological traits, related to the activity of monoaminergic brain systems.

³ University of Wollongong, Clinical Psychology, Wollongong, Australia

* Corresponding author.

Introduction The therapeutic alliance might be the most important part of beginning clinical relationship and may have an important impact in treatment adherence. In fact, many studies indicate that the therapeutic alliance is the best predictor of treatment outcome.

Objectives To assess clinical skills and attitudes in mental health professionals (MHP).

Aims This study explore the impact of clinical skills and socio-demographic factors related MHP may have on treatment adherence of patients with mental health disorders (MHD).

Methods In this cross sectional study, we use a convenience sample of MHP working in the mental health departments of

three general hospitals in Lisbon great area. Data is being collected through individual interviews. We used a optimism scale (ETOS), Medication Alliance Beliefs Questionnaire (MABQ), and socio-demographic and clinical questionnaire.

Results A convenience sample composed of sixty-five mental health clinician working in a variety of settings is being collected. We don't found statistically significant differences between the therapeutic optimism and the socio-demographic and clinical characteristics of MHP. The average values of optimism found in MHP with additional training in skills training it was higher (t test = 1,64). The results demonstrate that the most of clinicians ($n = 42$; agree 64,6%; strongly agree, $n = 19$; 29,2%) believe that have the capacity to positively influence outcomes for people with mental disorders.

Conclusion This topic, along with a detailed examination of the relationship between therapeutic alliance and treatment adherence, will be the subject of future research projects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antipsychotic prescribing patterns in outpatients with severe mental illness

P. Kizilay Cankaya^{1,*}, A. Tiryaki²

¹ Fatih State Hospital, Psychiatry, Trabzon, Turkey

² Karadeniz Technical University, Psychiatry, Trabzon, Turkey

* Corresponding author.

Introduction Prescribing more than one antipsychotic at the same time is becoming common in the treatment of patients with severe mental illness (SMI), although most guidelines recommend monotherapy.

Objectives The aim of this study was to examine the prevalence of antipsychotic polypharmacy and to compare the practices of polypharmacy and monotherapy in terms of the rationale and compatibility of the treatment.

Methods This study included 235 patients with SMI between 18 and 65 years of age who were followed at KTU Psychiatry Department Schizophrenia-Bipolar Disorder outpatient clinic between January 2007 and December 2014. The sociodemographic and clinical data were evaluated by a chart review form which was prepared by the researcher and designed according to American Psychiatric Association treatment algorithm and National Associated Mental Health Program Directors polypharmacy classification.

Results 138 patients (58.7%) were diagnosed with schizophrenia, 75 patients (31.9%) were diagnosed with bipolar disorder and 22 patients (9.4%) were diagnosed with schizoaffective disorder. 62 patients (26.4%) were receiving antipsychotic polypharmacy. Combinations of two second-generation antipsychotics were most common. Anticholinergic drug use was significantly more common in patients on antipsychotic polypharmacy. Reported adverse events were more common in patients on polypharmacy but did not reach the level of statistical significance. Patients on antipsychotic polypharmacy were more likely to be diagnosed with schizophrenia. Polypharmacy patients were also more likely to receive clozapine and amisulpride whereas monotherapy patients were more likely to receive olanzapine.

Conclusion Our results confirm previous reports that indicate patients with SMI are most likely to receive antipsychotic polypharmacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antipsychotic monotherapy versus combination in schizophrenia: Are there differences in cognition?

A. Ruiz¹, A. Brañas¹, M. Vicens¹, A. Orozco¹, G. Lahera^{2,*}

¹ Príncipe de Asturias University Hospital, Psychiatry, Alcalá- Madrid, Spain

² University of Alcalá- IRyCIS- CIBERSAM, Medicine and Medical Specialties, Madrid, Spain

* Corresponding author.

Introduction Influential protocols in the treatment of schizophrenia recommend the use of antipsychotics in monotherapy, although combination is common in clinical practice.

Objectives/aims To compare cognitive performance of patients with schizophrenia treated by antipsychotic monotherapy or polytherapy; secondly, to analyze clinical and sociodemographic differences.

Methods Ninety-eight outpatients between 18 and 65 years, diagnosed with schizophrenia, based on the DSM-V were recruited. Seventy were in monotherapy and 28 in antipsychotic combination. Patients with comorbidity, moderate to severe motor impregnation, abuse-substance dependence or serious somatic illness were excluded. Both groups were compared in sociodemographic, clinical and cognitive measures: PANSS scale, short Akathisia Scale Simpson-Angus Scale, State-Trait Anxiety Inventory (STAI), face emotion recognition (FEIT) and global Functioning (GAF), speed processing - through the Trail Making Test, parte A, subtest of symbol coding of the Brief Assessment of Cognition in Schizophrenia (BACS) and Verbal fluency (animals)- and sustained attention (SA)-through the Continuous Performance Test (CPT).

Results Both groups showed similar age, gender, number of hospitalizations, score in STAI-Trait, STAI-State, ANGUS, GAF, TMT-A, verbal fluency and face emotion recognition. Patients in polytherapy had more years of evolution ($P 0.047$), higher score in positive PANSS ($P 0.007$), negative PANSS ($P 0.008$), general PANSS ($P 0.001$); they showed more detection errors in the CPT ($P 0.008$), and a trend towards less processing speed through the symbol coding ($P 0.063$), compared to patients in monotherapy.

Conclusions Antipsychotic polypharmacy is associated with an impairment in sustained attention in patients with schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

DECIDE Study Effectiveness of shared decision making in treatment planning at discharge of inpatient with schizophrenia: interim analysis.

Introduction Shared decision-making denotes a structured process that encourages full participation by patient and provider in

making complex medical decisions. Hamann et al. conducted a few years ago a randomized controlled trial with schizophrenic inpatients and found increased knowledge and perceived involvement in decisions about antipsychotic treatment at discharge by the experimental group, but not clear beneficial effects on long term outcomes. The present communication introduces the DECIDE study.

Aims and objectives Of the study: to demonstrate the effectiveness, measured as treatment adherence and readmissions at 3, 6 and 12 months, of shared decision making in the choice of antipsychotic treatment at discharge in a sample of schizophrenics hospitalized after an acute episode of their disorder. Of the oral presentation: to present preliminary conclusions with more of the half of the sample.

Methods Randomized controlled trial, prospective, two parallel groups, not masked, comparing two interventions (shared decision making and treatment as usual). Study population: inpatients diagnosed of schizophrenia and schizoaffective disorders (ICD-10/DSM-IV-R: F20 y F25) at Adult Acute Hospitalization Unit at Jerez General Hospital.

Results At discharge, increased scale score COMRADE, both subscales (Satisfacción in communication and trust in the decision) statistically significant. At 3 months follow-up, intensification of these differences in effect size and statistical significance and shows trends in health outcomes. We will present results for 6 and 12 months.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Attention-deficit/hyperactivity disorder (ADHD) is a psychiatric chronic disorder of childhood that persists into adolescence and adulthood in the most part of cases. There are various ways of treating ADHD.

Objectives Assess the effectiveness and tolerability of atomoxetine long-term and routine clinical practice in adult ADHD treatment. Study the clinical profile of the patients who take atomoxetine.

Aims The aim of this is to study the treatment of ADHD in adults with a non-stimulant drug atomoxetine.

Methods We obtain results from 126 patients recruited from July 2009 to May 2013 who have been prescribed Atomoxetine as a treatment for ADHD from the hospital pharmacy.

Results Comorbid disorders were presented in 57.1% of the patients included at the study (25.3% of which belong to the group of anxiety disorders). The use of other psychotropic drugs associated with atomoxetine was observed in 54.8% of patients. The 62.7% of the patients concerned continued treatment beyond 225 weeks (4 years 3 months) of observation. The Clinical Global Impression Improvement scale (CGI-I) and side effects determine monitoring treatment. A total of 61.9% of patients responded satisfactory to treatment with atomoxetine getting the CGI-I scale a score of 1-2. The duration of therapy and patient age are factors that influence the response. Furthermore, the clinical profile

of patients treated with atomoxetine is characterized by different comorbidities, anxious symptomatology and personality disorders. Atomoxetine treatment with has also been shown its effectiveness and safe despite the presence of concomitant comorbidities and psychopharmacological treatment.

Conclusion Atomoxetine treatment with has been effective and has proven good tolerability profile during treatment.

Effects of rTMS on cognitive and negative symptoms of schizophrenia: A randomized double-blind sham-controlled study

K. Zhuo*, Y. Wang, Z. Song, D. Liu

Shanghai Mental Health Center, Department of psychiatry, Shanghai, China

* Corresponding author.

Background Investigators are urgently searching for options to treat cognitive and negative symptoms in schizophrenia because these symptoms are disabling and do not respond adequately to antipsychotic or psychosocial treatment. This study evaluated the efficacy of 20-Hz repetitive transcranial magnetic stimulation (rTMS) applied to the left dorsolateral prefrontal cortex for the treatment of cognitive and negative symptoms in schizophrenia.

Methods The study was a randomized double-blind sham-controlled trial for 4 weeks. Seventy patients with schizophrenia were randomly assigned into two treatment groups. After a 2-week pretreatment phase, 34 patients were treated with 20-Hz rTMS applied 5 days per week for 4 weeks to the left dorsolateral prefrontal cortex (added to the ongoing treatment), and 33 patients were subjected to sham rTMS applied similarly. Negative symptoms were assessed with the Scale for the Assessment of Negative Symptoms (SANS), the Positive and Negative symptom scale (PANSS), and Cognitive symptoms were assessed by MATRICS cognitive test battery (MCCB) Chinese version.

Results Sixty patients (33 individuals in active group and the other 27 in the sham group) completed the treatment protocol. We found that treatment with 20-Hz rTMS for 4 weeks significantly improved negative symptoms in the active group as compared to the sham group. However, There was no statistically significant difference in improvement in cognitive symptoms between the two groups.

Conclusions These findings indicate that application of 20-Hz rTMS to the left dorsolateral prefrontal cortex can effectively improve the negative symptoms, while more optimized parameters are needed to achieve improved therapeutic efficacy for the treatment of cognitive symptoms.

The effects of vitamin B1 on ameliorating of mental symptoms of the premenstrual syndrome

S. Abdollahifard^{1,*}, M. Maddahfar²

¹ Jahrom University of Medical Sciences, Nursing & Midwifery Department, Jahrom, Iran

² BHOWCO trading GmbH, BHOWCO trading GmbH, Frankfurt, Germany

* Corresponding author.

Background & objective The premenstrual syndrome is a series of physical, mental, and behavioral symptoms with various severities. Different treatments have been introduced for the syndrome due to its unknown complicated causes. Vitamin B1 (thiamin) may reduce mental symptoms of the syndrome through affecting the performance of coenzymes in the metabolism of carbohydrates and main branch of amino acid that plays an important role in appearance of mental symptoms of the PMS.

Methods In this double-blind placebo-controlled clinical trial, 80 students with PMS residing at dormitories of Jahrom University were divided randomly into two groups, vitamin B1 and placebo. The severity of the mental symptoms of PMS in two cycles, before the intervention and during the intervention, was recorded by the students. The data were collected using an information collection form, PMS provisional diagnosis form, daily status record form, Beck Depression Inventory. The data were analyzed using descriptive and inferential statistics.

Results The comparison of vitamin B1 group before the intervention with that after the intervention showed that vitamin B1 reduced mean mental symptoms (35.08%) significantly ($P < 0.0001$). Moreover, there was a significant difference between vitamin B1 and placebo groups in terms of mean mental symptoms, as mean symptoms in vitamin B1 group was significantly lower than that in the placebo group ($P < 0.0001$).

Conclusion It seems that vitamin B1 is effective in recovery of mental symptoms of PMS. Therefore, this vitamin can be used to reach a major goal of midwifery, that is, reduction of mental symptom severity of PMS, without any side effects.

⁶ University of Manchester, Academic Health Sciences Centre, Manchester, United Kingdom

⁷ University of Liverpool, Institute of Psychology- Health & Society, Liverpool, United Kingdom

* Corresponding author.

Introduction The rates of postnatal depression (PND) in British South Asian (BSA) women are higher than the general population. PND is known to cause disability and suffering in women and negative consequences for their infants and their family with huge costs

to society. Due to linguistic and cultural barriers, BSA women do not access health care services.

Objectives To conduct an exploratory trial to test the feasibility and acceptability of a culturally adapted group Cognitive Behavioural Therapy (CBT) intervention (Positive Health Programme (PHP)).

Aim We aimed to determine if depressed BSA women receiving the PHP intervention will show significant improvements in terms of severity of depression, marital support, and social support as compared to the control group.

Methods We used a two-arm pragmatic single-blind randomised controlled design. Women meeting the inclusion criteria were randomised either to the experimental group receiving PHP or treatment as usual (TAU) that is standard care usually provided by the GP.

Results A total of 615 mothers were screened for participation in the trial, of these 137 were assessed further to determine eligibility. Eighty-three mothers were randomized to receive either PHP ($n = 42$) or treatment as usual (TAU) ($n = 41$). Mothers found the intervention to be acceptable and felt an overall positive change in their attitudes, behaviour and confidence level.

Conclusion The recruitment and retention figures (70%) highlight the ability of the research team to engage with the population. The findings suggest the acceptability of the culturally adapted PHP intervention for British South Asian women with postnatal depression.

Comparison of the expected outcome of the mastectomy with perceived treatment outcomes based on self-efficacy in women with breast cancer

S.S. Hoseini Omam^{1,*}, J. Davoodi², M. Habibi Asgaraabadi², F. Richard³

¹ Semnan university, Psychology, Tehran, Iran

² Shahid Beheshti university, Family Therapy, Tehran, Iran

³ University of Hong Kong, Centre for Psycho-Oncological Research and Training, Hong Kong, China

* Corresponding author.

Aim Breast cancer causes concerns about treatment, complications, hospital stay and cost in patients which are common. Because self-efficacy is one of the unique factors, can affect an individual's ability and understanding of what to expect before, during, and after Breast cancer surgery. In the Present study the expected outcome of the mastectomy compared with perceived treatment outcomes based on self-efficacy in women with breast cancer.

Method In the current study, 300 female patients with breast cancer were studied before and after mastectomy using the General Self-efficacy Scale and Expectancy Outcome Incongruence.

Results The finding yielded that there was significant difference between patients with the high and low self-efficacy based on the expectation of the result of surgery and perceived outcome of surgery. Similarly there is significant difference between the level of disease progression based on the expectation of the surgery outcome and perceived outcome of surgery. In addition, there was significant difference between breast tumor size based on the expected outcome of surgical treatment and perceived outcome of surgery. There was significant difference between elderly and non-elderly women self-efficacy.

Conclusions Results show the higher level of self-efficacy can be useful in establishing primary social adjustment but lead to underestimate the negative effects of surgery and may disturb

psychological adjustment. Thus, high self-efficacy indirectly plays a significant role in increasing problems after mastectomy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Objectives To assess the prescription of benzodiazepines (BZD) in elderly patients, and to explore any gender differences.

Methods Six hundred and fifty-four patients (≥ 65) admitted in an emergency service of a general hospital due to a fall. BZD use information was collected (dose, half-life profile).

Results BZD are significantly more prescribed to women (47.6%) than men (36.1%) ($X^2 = 8.097$, $P = 0.004$). We conducted a logistic regression analysis using as dependent variable taking or not BZD and sex as the independent one, covarying the model by age. We noted that sex remains significant despite enter the age variable in the model ($OR = 1.5$, $P = 0.013$). A total of 21.6% of patients consumed intermediate or long half-life BZDs, appearing a greater tendency to prescribe such BZD to women ($X^2 = 3.606$, $P = 0.058$). In the 58.0% of prescriptions, prescribed dose was higher than the recommended for the elderly. The percentage is significantly higher for men (70.0%) than women (53.1%). Furthermore, a total of 54 prescriptions (15.8%) were even higher than the recommended adult dose, with no significant differences between men and women.

Conclusions We found evidence of a higher prescription of BZD in women independently of age. Despite not being recommended, prescription of intermediate or long half-life BZD continues, in a slightly higher manner in women. BZD are prescribed above the recommended dose for elderly in a large number of patients, especially in men. A considerable proportion of elderly patients (15.8%) consume BZD doses even higher than the recommended for adults.

Motherhood and postnatal disorder in an Italian sample

L. Rollè^{1,*}, E. Gerino¹, A.M. Caldarera¹, U. Merlone¹, D. Lyrakos², P. Brustia¹

¹ University of Torino, Psychology, Torino, Italy

² Filistos Psychosocial Testing and Consulting, Psychology, Athens, Greece

* Corresponding author.

Introduction Motherhood is a very intense psychological experience because it implies a deep reorganization of identity (Rollè

et al., 2012). For some women to become mother is not only a “happy event” as our cultural system wish or as say that should be, but it can be a difficult moment.

Aims To explore the level of post-natal depression (PND) and the risk factors for PND onset 1 month after the delivery.

Methods Eight hundred and eighty-seven participants were recruited in an Italian hospital (mean age = 33.23 years; SD = 4.45). The EPDS (Cox et al., 1987), the CES-D (Radloff, 1977) and a risk factor data sheet were used.

Results The CES-D and EPDS scores were significantly correlated ($r = .677$; $P < .001$). Unexpected and not searched pregnancy ($F = 2.540$; $P < .05$), experiencing episodes of sadness ($t = 7.567$; $P < .001$), uncontrollable crying ($t = 7.579$; $P < .001$), tendency to reject the child ($t = 3.241$; $P < .05$), anxiety ($t = 7.248$; $P < .001$), anguish ($t = 4.221$; $P < .001$) and loneliness ($t = 6.209$; $P < .001$) in the perinatal period imply higher levels of EPDS in the post-partum. Moreover, to have a planned caesarean delivery ($F = 7.393$; $P < .001$) and experiencing physical health problems ($t = 3.836$; $P < .001$) appeared to be additional risk factors.

Conclusions The strong relation between the risk factors in the perinatal period and PND onset is confirmed. Support during pregnancy could be a protection factor for PND and thus for possible related difficulties in the relation between mother and child.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Lakuabizkarra Health Center-OSAKIDETZA, Matron, Vitoria-Gasteiz, Spain

⁴ Gros Health Center-OSAKIDETZA, Matron, Donostia, Spain

* Corresponding author.

Introduction Postpartum depression has a prevalence of 15% and has consequences for mother and baby (delayed physical, social and cognitive development). It's essential to prevent the illness with an early identification of Risk Factors (RF).

Methods Five hundred and seventy-two women in 3rd trimester of pregnancy were evaluated and selected those with ≥ 1 RF ($n = 290$). We re-evaluated in the postpartum with Edinburgh Depression Scale and selected those with subsyndromal depressive symptoms (≥ 7.5) ($n = 57$). Clinical, demographic and functional data were collected.

Results A total of 50.7% had RF. A percentage of 48.6 had family history of mental illness (MI), 34.1% had personal history of (MI) and 34.1% had some pregnancy associated illness. Twenty percent had needed some assisted reproductive technique, 14.1% had little family support and 15.2% had little couple support, 3.8% showed anxiety-depressive disorders during pregnancy, 19.7% had depressive symptoms after delivery. The mean age was 33.67. No significant differences between patients with and without RF ($T = 1858$, $P = 0.064$). Among women with RF, 59.6% were married, 35.1% single and 3.0% had other situation. 89.5% live with their own family, 8.8% with their family of origin, 1.8% alone. 50.8% had university studies.

Conclusions Assessing RF during pregnancy can help these women, since we see that the 19.7% will have serious risk of developing postpartum depression. The RF to take more into account are not those related to social-academic development, neither the presence of anxiety-depressive symptoms during pregnancy, but the family or personal history of (MI) and the presence of a pregnancy associated illness. Early detection and treatment may prevent the development of this disease improving the quality of life of mother and babies' development.

⁴ Norwich Medical School, UEA, ENT Department James Paget University Hospital NHS Foundation Trust, Great Yarmouth, UK

* Corresponding author.

Introduction Chronic rhinosinusitis (CRS) is a condition of inflammation of the nose and paranasal sinuses affecting 6.8 million Britons. It has a great impact on quality of life and productivity. CRS is currently subdivided into two main types – with and without nasal polyps (CRSwnPs and CRSsNPs respectively). Allergic fungal rhinosinusitis (AFRS) is severe subtype of CRSwnPs.

Objectives This study is part of the Chronic Rhinosinusitis Epidemiology Study (CRES). The overarching aim is to determine factors influencing onset and severity of CRS.

Aims To determine whether those with CRS are more likely to report mood disturbance compared with healthy controls.

Methods CRES is study-specific questionnaire asking about demographic and socioeconomic factors and past medical history as well as a nasal symptom score (SNOT-22) and SF-36 (QoL – quality of life tool). Questionnaires were distributed to patients with CRS attending ENT outpatient clinics at 30 centres across the United Kingdom from 2007–2013.

Results A total of 1470 participants were recruited (Table 1). Differences between those with CRS and controls were found; those with CRSsNPs reported significantly more consultations with their GP for depression and anxiety. Patients with CRS also showed significantly poorer mental well-being than controls across the mental health and emotional well-being domains of the QoL tools used. Those with CRSsNPs scored significantly worse than those with nasal polyps across all domains.

Conclusions Mood disturbance is significantly more common in patients with CRS compared to healthy controls, especially in those with CRSsNPs. This added mental health morbidity needs consideration when managing such patients.

Table 1

	Controls	CRSsNP	CRSwNP	AFRS
Participants	221	553	651	45
Females	143 (68.4%)	259 (53.1%)	185 (32.2%)	19 (43.2%)
Mean Age (s.d)	47.3 (14.9)	51.8 (15.3)	56.0 (14.6)	56.1 (12.7)
Range	19-82	18-84	17-102	20-76

Impact on personal growth and environment conservation self-perception in a volunteering program with adults with severe mental illness (SMI)

D. Cabezas Sánchez^{1,*}, A. Ramírez Macías¹, J. Sáiz Galdós^{1,2}

¹ Grupo 5, Centro de Día Aranjuez 2, Aranjuez, Spain

² UCM, Social Psychology, Madrid, Spain

* Corresponding author.

Introduction “Viaje del Parnaso” is a volunteering project developed at the Day Center Aranjuez2 (CD2) for helping adults with SMI to get a satisfactory and responsible occupation through their implication in a volunteering work in the community, while involved in the maintenance of a green area in the city of Aranjuez. **Objectives/aims** The aim of this study was to evaluate the impact of the project on the volunteers' lives in terms of personal growth and environment conservation and compare its results with non-volunteers also attended at the CD2.

Methods The project was carried once a week during 45 weeks. 11 volunteers participated on the project, plus 5 non-volunteers were considered as quasi-control group. The instruments applied were an item on “environment conservation” and 2 subscale items of “Personal Growth” from the Ryff Scales of psychological well-being. Measures were applied at baseline, 6 and 12 months after.

Results Significant differences were found on the environment conservation item between volunteers at baseline and 6 months after ($P < 0.05$). Results also revealed a significant difference ($P < 0.05$) between volunteers and non-volunteers at both variables (“environment conservation” and “Personal Growth”) in baseline and 6 months after treatment.

Conclusions The data from this study suggest that a volunteering program seems to be an effective intervention for bringing about improvements in well-being of people with SMI, and also for increasing their environmental awareness. These improvements may also help to change the stigma of SMI reinforcing mental health patient's contributions to society.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁹ South Staffordshire and Shropshire Healthcare, Consultant Psychiatrist- General acute inpatient Psychiatry-St George's Hospital, Stafford, United Kingdom

* Corresponding author.

Objectives To assess the general cardiac health of inpatients in acute psychiatric units and to evaluate the practice of ECG use in this setting.

Aims Overall cardiac risk is assessed using QRISK2. Clinically significant ECG abnormality detection by psychiatric teams are compared with same by cardiologist.

Methods Ten percent of patients ($n = 113$) admitted to five acute psychiatric wards during a period of 13 months across three hospital sites, covering a population of 1.1 million, were randomly selected. Electronic health care records were used to collect all data, in the form of typed entries and scanned notes. An experienced cardiologist, blind to the psychiatrist assessments, performed ECG analysis. The QRISK2 online calculator was used to calculate 10-year cardiovascular risk as recommended by NIHR, UK.

Results A score of 10% or more indicates a need for further intervention to lower risk. 13.5% of patients had a QRISK2 score of 10–20%, 5.2% had a score of 20–30%, and 1 patient had a QRISK2 score > 30%. In total, 19.7% had a QRISK2 of 10% or greater. A total of 2.9% had prolonged QTC interval (> 440 ms), with 2.9% having a borderline QTC (421–440). A total of 34.3% of ECGs were identified by the ward doctors as abnormal, with action being taken on 41.6% of these abnormal ECGs. Cardiologist analysis identified 57.1% of ECGs with abnormalities of potential clinical significance.

Conclusions One in five patients admitted to psychiatry wards have poor cardiac health requiring interventions. Though QTC interval prolongation is rare, half of patients may have abnormal ECGs that require further analysis.

The agitated patient; need for mechanical restraint and prevention measures in relation to psychiatric diagnosis

F. Dinamarca*, L. Galindo, M. Grifell, E. Perez, V. Chavarria, P. Salgado, S. Perez

Hospital Del Mar, Psychiatry service – INAD, Barcelona, Spain

* Corresponding author.

Introduction Psychomotor agitation is a common psychiatric emergency in our environment that can occur in a wide clinical spectrum. Both the agitation itself as the procedures for their control, carry an implicit risk to patient safety and health workers.

Objective To describe the prevention measures used in patients requiring mechanical restraint in relation to diagnosis of psychiatric disorders.

Material and methods This is a naturalistic descriptive study. Mechanical restraints made in brief psychiatric hospitalization units of “Hospital del Mar” between January of 2013 to March of 2015, were analyzed by diagnosis. Proportions of the prevention intervention performed by nurses in each episode were compared. The groups of prevention interventions done were: “verbal approach”, “environmental measures”, “psychopharmacological intervention”, “observation increase” and “inability for applying any measure because unpredictability”.

Results A total of 2986 mechanical restraints were done in brief hospitalization units. Among the results, we find that verbal approach measure was used in 77.23% of patient with personality disorders. Environmental measures were used in 40% of the total of restraints. The most of psychopharmacological intervention was done in alcohol intoxication (50%) and then in psychotic spectrum (42.01%). The inability for applying measures was greater in alcohol intoxication (45.4%).

Conclusion Some of the results of this study are interesting and consistent with clinical practice (for example, effectivity of pharmacological intervention in psychosis and bipolar disorders, as well verbal approach in anxiety, etc.), we can predict the usefulness of measures applied to prevent a mechanical restraint. Further research is needed in this topic.

Disclosure of interest L. Galindo is a Rio-Hortega-fellowship – (ISC-III; CM14/00111).

Interim results of remotely provided, one-on-one, tailored psycho-education and skills training to caregivers of patients with mental health difficulties

K. Ashcroft (BA MPhil D ClinPsy) (Consultant Clinical Psychologist)^{1,*},

B. Insua-Summerhays (BSc) (Research Assistant – MyHealios)²

¹ London, UK

² Southampton, UK

* Corresponding author.

In the past several decades, considerable evidence has emerged on the efficacy of caregiver and family interventions in the treatment of severe and enduring mental health disorders, particularly schizophrenia. Studies have demonstrated benefits of these interventions with regard to both reduced rates of burden in caregivers, and a reduction in relapse and improvement in symptoms of the person with psychosis. However, many caregivers who may benefit from such interventions are unable to access them, due to limited resources and geographical factors. Additionally, concerns about stigma and time constraints may deter caregivers from accessing support. The following study is among the first to address these barriers using a remotely delivered, one-on-one caregiver intervention. Caregivers ($n=93$) of patients with severe and enduring mental health difficulties took part in a tailored psychoeducation and skills training intervention, consisting of weekly 40 minute videoconference or telephone sessions with a trained clinician. Caregivers completed the Involvement Evaluation Questionnaire (IEQ) and General Health Questionnaire (GHQ-12) at baseline, and

eight sessions (mid treatment). It was hypothesized that caregivers would show a reduction of distress and burden in response to the intervention. Interim comparison of pre- versus 8th session measures demonstrated a highly significant reduction in GHQ scores ($P<0.01$), as well as a highly significant reduction in IEQ scores ($P<0.01$). Results suggest that remotely provided, one-on-one, tailored psycho-education and skills training may be an effective and accessible intervention to improve the well-being of, and decrease burden in, caregivers of mental health patients.

Résumé

Introduction Several studies show that the first period after discharge has an higher suicide risk.

Objectives Following up psychiatric inpatients after discharge may be important in order to better understand the risk and the protective factors of suicide.

Aim The aim of our follow-up study is to evaluate the predictive factors of suicide in a sample of psychiatric inpatients after discharge.

Methods We analyzed the temperament and the levels of hopelessness, depression, suicide risk in a sample of 87 (54% males) inpatients at time T0 (during the hospitalization), T1 (12 months after discharge) and T2 (8 months after T1). We administered the following scales: BHS, MINI, TEMPS, GMDS, CGI.

Results A statistically significant difference on the risk of suicide with substance abuse was found among patients who were followed up and who refused to participate, respectively at T1 ($\chi^2_4=2.61$; $P<0.05$) and T2 ($\chi^2_4=1.57$; $P=0.05$). At T1, 4 patients attempted suicide and 18 showed suicidal ideation. In the second follow-up, 1 patient successful committed suicide, 1 subject attempted suicide and 10 patients showed suicidal ideation. Patients with suicidal ideation at T1 showed higher levels of hopelessness and a diagnosis of bipolar disorder type I ($\chi^2_4=10.28$; $P=0.05$). Sixty-seven percent of subjects with suicidal ideation showed higher scores in the BHS at T1. Significant differences were found on the anxious temperament at T2 between two groups.

Conclusions The follow-up could represent a significant strategy to prevent suicide in psychiatric patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Mental illness is still surrounded by false myths, stereotypes and prejudices. Stigmatization is a social problem on a national and international level and may lead to discrimination.

Objectives Stigmatization has a negative impact on patient's life, treatment seeking, self-image, adherence and mental health recovery.

Aims The aim of the study was to examine the tendency to stigmatization of mentally ill people by university students in the Czech Republic.

Methods The constructed questionnaire called Tendency to stigmatization TTS (Cronbach's alpha = 0.952), demographic questionnaire and tentative shortened version of personality questionnaire NEO-PI-R were administered on Facebook offered to student groups.

Results The statistical analysis of data from 1350 students showed a relatively high tendency to stigmatization depending on age (stigma is lower with age), gender (women have a lower TTS than men), studied university, faculty, educational focus. The lowest rate of stigmatization had students of psychology. Students of economics, management, informatics and engineering disciplines stigmatize in a high degree. Social oriented students had the lowest TTS, technically orientated the highest. The TTS also depends on personal agreeableness (low-friendly students had a higher TTS) and neuroticism (mentally unstable students had slight TTS). Lower TTS had students who attended psychopathological/psychiatric subject at school, also students, who personally met or know somebody with mental disease and students with mental health problems (Table 1).

Conclusions Our study suggests the importance of stigmatization already among university students according to their academic orientation. Understanding the process of stigmatization is important for future efforts to find possible solutions and de-stigmatization of mental illness in society.

Capturing depression with your smartphone: Validity and utilization of iHOPE for depressed patients in Taiwan

G. Chin-Lun Hung^{1,*}, M.S. Li¹, Y.L. Chen², J.H. Chiang²

¹ Department of Psychiatry, Taipei City Psychiatric Center, Taipei City Hospital, Taipei, Taiwan

² Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan

* Corresponding author.

Introduction Clinical assessment for depression, to date, has relied heavily on patients' retrospective report, which is liable to recall bias.

Objectives A number of mobile applications for ecological momentary assessment (EMA) of depressive disorder have been piloted, however, evidence regarding their validity and acceptance is limited.

Aims In this study, we examined the association between Hamilton Rating Scale for Depression (HAM-D) and EMA of depressive symptoms via a smartphone application and demonstrated the level and determinants of utilization.

Methods Our mobile phone application, iHOPE, would perform EMA of depression, anxiety, sleep and cognitive ability. Outpatients with depressive disorder were invited to use iHOPE for 8 weeks. Smartphone usage patterns and clinical characteristics were assessed.

Results We enrolled 59 outpatients with depression (38 [64.4%] women; mean [SD] age = 37.3 [13.9] years). In 8 weeks, participants interacted with iHOPE for an average of 10.8 (SD = 12.3) days; a trend of decreased frequency of use ($P=0.03$) was observed. Scores of HAM-D at baseline was associated with, of the first 14 days, scores of PHQ-9 ($P=0.005$), visual analogue scale of depression ($P=0.003$) and anxiety.

Conclusions EMA via mobile technology appears to be valid and feasible for Asian patients with depression. Mobile health has a potential for the assessment of depressive disorder in areas with limited awareness and resource for mental health conditions.

The effect of the financial crisis in Greece on the health habits of young adults

D. Menti¹, V. Fanioudaki¹, G. Lyrakos^{2,*}

¹ City Unity College, MSc Health Psychology, Psychology Department, Athens, Greece

² General Hospital Nikaia "Ag. Panteleimon", Psychiatric Department, Nikaia, Greece

* Corresponding author.

Background Periods of financial crisis have been strongly associated with changes in the health habits of affected individuals. Previous research suggests that these periods usually affect drinking, smoking, physical activity and eating habits, thus affecting our psychophysical health as well.

Aim To investigate the effect of the financial crisis in Greece on the health habits of young adults.

Method Two hundred and seven Greek young adults participated in the study, 75 (36.2%) males and 132 (63.8%) females, with a mean age of 29. Analysis of data was conducted with ANOVA, Ancova, regression and correlation analyses, using the SPSS software.

Results The findings showed a significant effect of the financial crisis on drinking patterns ($F(1.173)=4.488, P=0.036$). Individuals whose income was reduced consumed less alcohol ($M=11.646$,

SD=1.434) compared to individuals who had not experienced such a reduction ($M=17.957$, $SD=2.611$). There was a significant effect of annual income on BMI ($F(4.10)=3.74$, $P=0.001$, $\eta_p^2=0.96$), after controlling for the effect of exercise intensity ($F(1.10)=4.58$, $P=0.034$, $\eta_p^2=0.31$). However, the financial crisis did not significantly affect exercise, smoking behaviour or eating habits ($P>0.05$). Significant correlations between tobacco use and drinking were found ($r(206)=0.22$, $P<0.001$). A significant correlation was also found between exercise and the consumption of fruits and vegetables ($r(174)=0.26$, $P<0.001$).

Conclusion The financial crisis reduced alcohol consumption whilst it did not affect physical activity, smoking or eating habits. These findings allow us to propose that, despite the bleak reality of a period of financial crisis, such periods could actually lead to the reduction of unhealthy behaviours.

Comparison of metabolic syndrome between patients with severe mental disorders

B. Mata Saenz^{1,*}, S.L. Romero Guillena²,

B.O. Plasencia García de Diego³

¹ Hospital General Universitario de Ciudad Real, Psychiatry, Ciudad Real, Spain

² Hospital Universitario Virgen Macarena, Psychiatry, Seville, Spain

³ Hospital de la Merced, Psychiatry, Osuna, Spain

* Corresponding author.

Introduction Metabolic alterations are one of the main causes of mortality and morbidity associated with cardiovascular disease in patients with severe mental disorders. Polypharmacy has been shown to increase the risk.

Objectives To check the patients with schizophrenia and bipolar disorder admitted to our unit and their metabolic parameters.

Aims To assess the prevalence of thyroid dysfunction, diabetes and dyslipidemia in patients diagnosed with these disorders admitted to our unit between 2013 and 2014, and compare the results.

Methods We conducted an epidemiological, observational, retrospective study of patients with these disorders admitted to our unit in this period. Clinical and socio-demographic variables were collected and analyzed by The Statistical Package for Social Science version 19.0.

Results No association was detected between treatment with antipsychotics (typical/atypical) and metabolic variables. This may be due to the fact that mostly of patients received a combination treatment of both (Table 1).

Conclusions Dyslipidemia and diabetes seem to be more prevalent in patients with schizophrenia in our sample, but thyroid dysfunction is more prevalent in patients with bipolar disorder. However, the two samples are very different so more studies are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Table 1

	Schizophrenia	Bipolar disorder
Number	397	69
Gender (% males)	76.1	33.3
Average age (years)	44.02	44.54
Dyslipidemia (%)	29.7	24.6
Diabetes (%)	18.6	7.3
Thyroid dysfunction (%)	11.6	20.3
Relationship	Rural origin-prevalence of diabetes ($\chi^2=5.862$; $p<0.05$) Age-glycemia ($r=0.317$; $p<0.01$)	Lithium-thyroid dysfunction ($\chi^2=14.59$ $p<0.001$)

The impact of anxiety and depression on academic performance in undergraduate medical students

A.I. Mihăilescu^{1,*}, L.V. Diaconescu¹, A.M. Ciobanu², T. Donisan¹, C. Mihailescu³

¹ University of Medicine and Pharmacy "Carol Davila", Medical Psychology, Bucharest, Romania

² University of Medicine and Pharmacy "Carol Davila", Psychiatry, Bucharest, Romania

³ CMI dr Mihailescu S. Cristian, Family Medicine, Bucharest, Romania

* Corresponding author.

Introduction Stress associated with medical education, correlated with symptoms of depression and anxiety, has been involved in generating academic performance problems and thus, long-term consequences, such as poor quality of medical care. If anxiety and depression are proved to influence quality of academic achievement, their prevention could lead to better outcomes also in the quality of medical care.

Objective The objective of the study was to analyze if anxiety and depression decrease academic performance in first and second year medical students.

Methods As a measure of anxiety and depression symptoms we used Zung Self-rating Anxiety score >36 , respectively Zung Self-rating Depression Scale score >40 , in the periods before the examination session, in the first semester (in no-stress conditions). As a measure of academic performance, we have obtained the average grade at the end of the academic year from 254 of the total population of 356 first and second year medical students. Statistical analyses were carried out with SPSS version 16 (Spearman correlations and logistic regression).

Results Academic performance decreases inversely in rapport of anxiety ($\rho=-0.144$, $P<0.05$) and depression ($\rho=-0.192$, $P<0.05$) scores in the period before the examination session. Also, depression in this period predicts low levels of academic performance with average grade in the inferior quarter (grades lower than 7.52) particularly in first year students, irrespective of gender ($\chi^2=8.922$, $P<0.01$, OR=0.928; IC 95%=0.864–0.997).

Conclusion These findings suggest the necessity of coming up with prophylactic methods to prevent anxiety and depression

especially in first year medical students, as these prove to be factors that impend academic performance.

EW644

Grief cognitions and cognitive-emotional regulation associated with romantic breakup distress among college students

A. Mirsu-Paun

Bucharest, Romania

Introduction Individuals manage differently the experience of a romantic breakup [RB]. These differences may in part be related to the use of different cognitive-emotional regulation strategies [CERS]. Also, global negative beliefs and catastrophic misinterpretations regarding the RB may contribute to the emotional distress (Boelen and Reijntjes, 2009).

Objectives To explore the associations between CERS, grief cognitions related to RBs, and depression and suicidal ideation/behaviors in a sample of college students.

Aims To conduct regression analyses to predict depression, anxiety, hostility, and suicide behaviors from CERS and grief cognitions (as independent variables).

Methods Cross-sectional, self-report data was collected from 359 college students who experienced a RB. The assessments used were: Cognitive-Emotional Regulation Questionnaire- Short Form (Garnefski et al., 2002); the Grief Cognitions Questionnaire adjusted to grief after RBs (Boelen et al., 2003); the subscales of Depression, Anxiety, and Hostility of the Counseling Center Assessment of Psychological Symptoms-62; and the Suicide Behaviors Questionnaire-Revised, Osman et al., 2001).

Results Past suicide thoughts or attempts were predicted by Other-Blame; self-reported likelihood of future suicide attempt was predicted by Self-Blame, Other-Blame, and Positive Reappraisal, Grief Cognitions-Future, and Grief Cognitions-Appropriateness. Depression was predicted by all cognitive-emotional regulation subscales except Acceptance and Perspective, and by RB grief cognitions (self, future, self-blame, others, and perceived appropriateness of own grief reaction).

Conclusions Clinical assessment to evaluate at-risk young adults after RBs could incorporate evaluations of cognitions regarding the RB and self-blaming, appropriateness of one's own grief reaction, and thoughts about the future.

SOMA Score, cardiovascular risk screening tool for psychiatric patients

M. Páv^{1,*}, M. Hollý¹, M. Cendelinová¹, J. Gojda², J. Polák³

¹ Psychiatric hospital Bohnice, Psychiatry, Prague 9, Czech Republic

² Hospital Royal Vinohrady-II, interní klinika, internal medicine, Prague, Czech Republic

³ Hospital Royal Vinohrady-II, interní klinika, internal medicine, Prague, Czech Republic

* Corresponding author.

Introduction Life expectancy of patients with severe mental illness (SMI) is two decades shorter than that of general population. The most important cause of death are cardiovascular diseases (CVD).

Objectives There is a need for CVD risk screening tools development and validation in the context of the Czech Republic.

Aims Methodological approach to a CVD risk screening, risk stratification and specific life-style interventions development is presented. In a context of the psychiatric hospital with c. 7000 admissions per year.

Methods There are no concise data on CVD risk of psychiatric patients in the Czech Republic so cross-sectional analysis of one day hospitalized patients was performed.

Results A sample of 1056 pts. was obtained. Database allowed extraction data on CVD risk factors (RF): diagnosis, age, sex, BMI and blood pressure (BP). The most common diagnosis were F20 and F10. Multicriterial analysis according to diagnosis (frequency of highest BMI and BP) showed the worst results in the F20 followed by F10 group. Would we define the CVD RF as BMI ≥ 30 , age ≥ 65 , sBP ≥ 140 , dBP ≥ 90 , then no RF is present in 368, one in 238, two in 191, three in 92 and four RF in 33 pts. Two step screening protocol was developed – SOMA score. Variables and cut-offs for positivity were set based on the results.

Conclusion Methodological process of SOMA score screening is presented as well as consecutive health care interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional state in employed caregivers of frail elderly relatives

M. Crespo^{1,*}, A.T. Piccini¹, R. Cáceres², R.P. María³

¹ Complutense University, Clinical Psychology, Madrid, Spain

² State Reference Care Centre of people with Alzheimer's disease and other dementias IMSERSO, Psychology department, Salamanca, Spain

³ Alzheimer Association of Zamora, Psychology department, Zamora, Spain

* Corresponding author.

Introduction Research has long suggested that care giving can be a stressful role that adversely affects physical and mental well-being of those who provided care. The effects of combining work and care giving can be negative and may have different outcomes on caregivers.

Objectives This study examined the effects of gender, kinship and work-related experiences on the emotional state of employed caregivers.

Aim This study allows us to gain a better understanding of the influence of gender and kinship on the emotional state of working caregivers.

Method We have carried out a cross sectional study on 81 employed caregivers of elderly dependent. Using multivariate analysis of covariance ($2 \times 2 \times 2$ MANCOVA), we examined the main and interaction effects of gender (male vs. female), kinship (spouses vs. adult children), and two types of work-related experiences (work-caregiving conflict and positive work experience; both of them with two levels: high vs. low) on burden, depression, negative and positive affect, and role overload.

Results We found that women caregivers in this study experience higher levels of burden, negative affect, and role overload than their men counterparts. However, in the case of kinship, this variable has not been shown to be related to a worse emotional state on employed caregivers. Higher levels of work-caregiving conflict were associated with greater emotional distress in caregivers. Regarding to positive work experiences, significant differences were only found in positive affect.

Conclusion These findings suggest that gender is a central factor that influences emotional distress in employed caregivers in the two types of work-related experiences.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Kynurenine pathway metabolites and suicide attempters among psychiatric inpatients: Preliminary results

M. Pompili^{1,*}, D. Erbuto², A. Forte², F. Montebovi², L. Lionetto², P. Girardi²

¹ Rome, Italy

² Sapienza University of Rome, Department of Neurosciences-Mental Health and Sensory Organs, Rome, Italy

* Corresponding author.

Introduction Increased concentrations of kynurenine (KYN) pathway metabolites have been associated to several groups of psychiatric disorders. As for suicide risk literature is still inconclusive due to the limited evidence.

Objectives to test the hypothesis of Increased concentrations of kynurenine as related to suicide attempter.

Aims We aim to investigate the association between kynurenine pathway metabolites blood levels and suicidal behaviour, in affective disorder patients, in order to explore if kynurenine pathway metabolites could be potential diagnostic biomarkers.

Sample We enrolled a sample of affective disorder patients and perform detailed diagnoses, as well as detailed assessment of suicidal behaviour using validated questionnaires. We also aim to follow-up individuals included in the current study.

Methods Plasma KYN was assayed by high performance liquid chromatography in three groups: healthy volunteers ($n=90$), patients with mood disorders with a recent suicide attempt ($n=44$) and without ($n=44$) history of suicide attempt. Analysis of variance tested for group differences in KYN levels. Each was evaluated with psychometric scales. Patients were sampled for 10 cc of venous blood for assay. The preparation of blood samples and assay was processed by a specialist using high performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS).

Results Preliminary results will be presented as to shed light if KYN levels differed across groups. According to preliminary calculations we expect that KYN is higher in suicide attempters compared with non-attempters, who did not differ from healthy volunteers.

Conclusions Our work-in-progress study suggests that KYN and related molecular pathways may be implicated in the precipitation of suicidal behavior.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁹ University of Lille, Lille, France

¹⁰ Ruhr-University Bochum, LWL-University Hospital for Child and Adolescent Psychiatry, Hamm, Germany

* Corresponding author.

Introduction Recruitment of medical students and junior doctors in to psychiatry is a long-standing concern in many countries, with low proportions of medical graduates choosing it as a specialty and ongoing stigma from within the medical profession. In some countries the reverse problem is the case, with too many doctors wishing to enter psychiatry, and insufficient training places available.

Objectives To understand the current situation within Europe with regards to recruitment in to psychiatry and to identify existing recruitment initiatives.

Methods The European Federation of Psychiatric Trainees conducts an annual survey of all member organisations. A delegate of each national association of psychiatric trainees is asked to identify if their country has a problem with recruitment and if so, whether there were too many or too few applicants for training places. Delegates from countries with recruitment initiatives were contacted to provide further details.

Results In 2014, a total of 31 countries completed the survey, with 17 stating that too few medical practitioners choose psychiatry. In total 8 countries with recruitment problems reported that initiatives exist to encourage doctors to enter psychiatric training. Of these, 7 responded to describe the initiatives, which included national recruitment strategies, financial incentives, careers fairs, mentoring schemes and a whole host of other projects.

Conclusions Recruitment in to psychiatry remains a serious problem in a significant proportion of European countries, but a wide range of initiatives exist which aim to combat this shortfall. It will be important over the coming years to establish which initiatives are most effective at increasing recruitment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Study of the sexual dysfunction secondary to antidepressants in animal models

Y. Santana Hernández^{1,*}, M.V. Redondo Vega¹, E. Zamora Gracia¹, A.L. Montejo Gonzalez¹, J.L. Blázquez Arroyo², G. Llorca Ramón¹

¹ Universidad de Salamanca, Psiquiatría, Salamanca, Spain

² Universidad de Salamanca, Anatomía e histología humanas, Salamanca, Spain

* Corresponding author.

Introduction Sexual dysfunction is a very important problem in western countries. One of the causes is the treatment with antidepressants; most of the currently available produce sexual dysfunction in men and women (lower libido, anorgasmia, etc.).

Objective Comparing the nervous system of the animals we expect to find differences to explain the biological substratum of the sexual dysfunction that produce the selective serotonin reuptake inhibitors.

Method Twenty Wistar rats; approximate weight 150 g. It is divided into 4 groups: 2 experimental (paroxetine and agomelatina mouth) and 2 controls. There is a daily conduct. Weighing at the beginning of the study, 14 and 28 days. Is performed sacrifice by decapitation, is extracted from the brain and after fixing paraffin cuts are carried out for their subsequent staining

(immunohistochemistry) with their corresponding murine antibody and viewing through optical microscope.

Results Lower immunoreactivity with the antibody anti-TH in the animals treated with paroxetine, at all levels of the dopaminergic activity (tracks mesolimbica, cortical circuit, nigrostriatal pathway and tubero-infundibular). This decrease is reaffirmed after the statistical treatment of data.

Conclusions Treatment with paroxetine in animal models causes a depletion of the dopaminergic system that can be one of the biological bases of sexual dysfunction, altering the reward mechanisms as well as producing hyperprolactinemia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Curcumin (CUR), a polyphenolic compound, extracted from *Curcuma longa*, is known for its neuroprotective, antioxidant and anti-inflammatory effects.

Objectives To evaluate the effect of CUR on ambulatory activity, spatial working memory and on oxidative stress in rats induced by Diazepam (DZP) administration.

Aims To analyze whether CUR may improve the cognitive performance and offer systemic protection from oxidative stress.

Methods The effect of CUR on DZP-induced memory impairment and oxidative stress was studied on Wistar rats. Group I received a vehicle, group II – vehicle and CUR, group III – vehicle and DZP, group IV – vehicle, CUR and DZP. CUR (150 mg/kg bw) and vehicle were orally administered for five weeks long. DZP (2 mg/kg bw) was administered i.p. 20 minutes before the behavioral tests. Behavioral tests, i.e. Open Field and Y Maze Test, were performed. Malondialdehyde and reduced glutathione/oxidized glutathione ratio were determined in the serum and brain tissue homogenate. Hippocampal sections were histologically assessed. The data were statistically analyzed by one-way ANOVA, followed by Dunns post-test.

Results DZP decreased ($P < 0.01$) the number of spontaneous alternations, as compared to control group, thus suggesting an impairment of spatial working memory. Behavioral tests revealed no enhancing effect of CUR on spontaneous alternation behaviors in Y Maze. CUR reversed ($P < 0.01$) the inhibitory effect of diazepam ($P < 0.05$) on the ambulatory activity in OFT and decreased the lipid peroxidation in the serum ($P < 0.05$).

Conclusions The results show that CUR may offer systemic protection from oxidative stress, thus improving the cognitive performance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ Ben-Gurion University of the Negev, Sede Boqer, Israel

² Ben-Gurion University of the Negev, Life sciences, Sede Boqer, Israel

* Corresponding author.

Introduction The validated treatment for ADHD is chronic administration of psychostimulants, which is associated with side effects and occasionally not tolerated. Deep TMS using special coil designs for targeting neural networks linked with ADHD, may become a potential alternative.

Objectives Comparison of rTMS treatment using deep, figure-8 and sham coils on ADHD symptoms.

Methods In the current randomized, sham-controlled study, adult ADHD patients ($n = 30$) received 15 daily sessions of high-frequency rTMS directed to the right PFC, using either deep, figure-8, or a sham coil. ADHD symptoms and cognitive alterations were assessed using the CAARS-INV, self-report questionnaires and performance tests. Additionally, the stop signal task (SST) combined with EEG measures was used to assess behavioural inhibition and ERPs. EEG responses to an inhibitory protocol of paired TMS pulses over the rPFC were measured before and after treatments. A healthy control group was evaluated at baseline for comparison ($n = 39$).

Results dTMS treated patients (but not standard figure-8 or sham) showed improvement of ADHD symptoms. Differences between ADHD patients and healthy controls were demonstrated in N200 and P300 components of ERP during the SST, and in response to single and paired TMS pulses. The amplitudes of ERPs in patients correlated with ADHD symptoms and behavioural inhibition measures. Neurophysiological measures were found to serve as predictors for effectiveness of dTMS treatment.

Conclusions Repeated stimulation of deep areas in the rPFC has therapeutic potential in ADHD patients. Ongoing analysis attempts to evaluate the extent of these findings and establish biomarkers for treatment efficacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The F-Multidimensional Perfectionism Scale-18 (FMSP-18): Internal consistency, construct, concurrent and divergent validity

M.J. Soares^{1,*}, A.T. Pereira¹, A. Araújo¹, D. Silva¹, A.P. Amaral², J. Valente¹, N. Madeira¹, M. Bajouco¹, A. Macedo¹

¹ Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

² Institute Polytechnic of Coimbra, College of Health Technologies, Coimbra, Portugal

* Corresponding author.

Introduction The FMPS is a 35-item self-report questionnaire to measure perfectionism. It evaluates: concern over mistakes/CM, doubts about actions/DA, parental criticism/PC and expectations/PE, personal standards/PS and organization/O.

Objectives To develop a shortened version of FMPS and study its internal consistency, the construct, concurrent and divergent validity.

Methods One hundred and ninety-two university students (78.1% females), aged 19.74 years ($sd = 2.10$) completed the

Portuguese versions of the: FMPS, Hewitt and Flett MPS/H&FMPS, Life Orientation Test Revised/LOT-R, State-Trait Anxiety Inventory/STAI, and Profile of Mood States/POMS.

Results Correlations between each item and corrected FMPS total scores/corrected total subscales scores were ≥ 0.20 for the items 13, 15, 25, 31, 35 and 10, 2, 25, and 26, respectively. The internal consistency of FMPS was high ($\alpha: .857$) with 32 items contributing for this consistency (exceptions: 13, 25 and 31). The principal component analysis of the 35 items with factors varimax rotation was performed. The three items with higher loading in each factor that also contributed to the FMPS reliability were selected for the FMPS shortened version (FMPS-18). The principal component analysis of the 18 items with factors varimax rotation showed that six factors explained 74.6% of FMPS-18 total variance. These factors revealed adequate internal consistency ($\alpha: O = 0.740$; $PC = 0.859$; $PE = 0.847$; $PS = 0.726$; $CM = 0.740$; $DA = 0.832$; $total = 0.768$). Convergent correlations between FMPS and the matched FMPS-18 scores were 0.839 to 0.971 (all $P < .01$). Correlations of the FMPS-18 and FMPS with H&F-MPS, STAI, LOT-R and NA/PA scores were of similar significance and valence.

Conclusion FMPS-18 is a brief, reliable and valid instrument to measure perfectionism.

The H&F-Multidimensional Perfectionism Scale 13 (H&F-MSP13): Construct and convergent validity

M.J. Soares*, A.T. Pereira, A. Araújo, D. Silva, J. Valente, V. Nogueira, C. Roque, A. Macedo

Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction The Hewitt and Flett Multidimensional Perfectionism Scale (H&F-MPS) is one of the most used measures of perfectionism. Their 45-items evaluate self-Oriented (SOP), Self-Prescribed (SPP), and Other Oriented (OOP) perfectionism.

Objectives To study the internal consistency and convergent validity of the H&F-MSP13.

Methods One hundred and ninety-two university students (78.1% females), aged 19.74 years ($sd = 2.10$; range: 17–28) completed the Portuguese versions of H&F-MPS (Soares et al., 2003) and of Frost et al. MPS (F-MPS) (Amaral et al., 2013). Thirteen items were selected from the Portuguese version of the H&F-MPS, based on their loading in the factor (0.60 and over) (Soares et al., 2003).

Results The H&FMPS13 revealed good internal consistency ($\alpha = 0.816$). The corrected item-total subscale Spearman's correlations were high (from 0.418 to 0.820). The principal component analysis with factors varimax rotation produced three factors, which revealed acceptable/good internal consistency (SOP: explained variance/EV = 35.4%, $\alpha = .900$; SPP: EV = 16.3%, $\alpha = 0.695$; OOP: EV = 10.8%, $\alpha = 0.709$). The correlations between the H&F-MSP13 scores and the matching scores of the H&F-MPS were high (from $r = 0.745$ to $r = 0.945$, all $P < .01$), suggesting that both scales measure similarly the constructs. The H&F-MSP13 and the H&F-MPS total scores demonstrate good convergent validity with the total score of F-MPS, as indicated by the correlations ($r = 0.581/r = 0.636$, respectively). The correlations similarities between the H&F-MSP13 and H&F-MSP dimensions and the F-MPS dimensions and total scores were also considerable.

Conclusions The H&F-MSP13 is a valid instrument to measure perfectionism that reveals convergent validity with the F-MPS, retaining the adequate psychometric properties of the H&F-MPS and its administration is less time consuming.

Impact of psychotic symptoms in functionality and quality of life of major depression patients in maintenance/continuation electroconvulsive therapy (M/C ECT)

A. Tarelho^{1,*}, A. De Arriba Arnau², M. Robles Martínez³, M. Sarachaga Urretavizcaya², V. Soria Tomás², J.M. Menchón Magriñá², N. Salvat Pujol²

¹ Centro Hospitalar de Leiria, EPE, Psychiatry service, Leiria, Portugal

² Bellvitge University Hospital, Psychiatry Department, Barcelona, Spain

³ Hospital Universitario Puerta del Mar, Psychiatry, Cádiz, Spain

* Corresponding author.

Introduction Psychotic depression has a higher rate of disability and relapse than non psychotic depression, however the optimal maintenance treatment after an acute response to either the antidepressant/antipsychotic combination or an ECT course is unclear (Rothschild, 2013). Although ECT is an effective therapy in affective disorders and M/C ECT is used to achieve and maintain patient's stability (Brown, 2014), very little is known about its implications in functionality or quality of life.

Objectives To study the relation between psychotic symptoms and functionality and quality of life in patients with Major Depressive Disorder (MDD) undergoing M/C ECT.

Methodology Transversal descriptive study of a sample of 17 MDD patients in M/C ECT. Administration of SF-36 (quality of life related to health), FAQ (functionality), Family APGAR, MMSE, GAF, HDRS. Informed consent. Statistical analysis with SPSS18.

Results The mean age of the sample was 72.47 years, 58.8% presented with psychotic symptoms and 41.2% with melancholic symptoms. We only found a statistically significant negative correlation between the Family APGAR and the presence of psychotic symptoms ($U = -2.291$, $P = 0.025$), without other differences in terms of functionality or quality of life.

Conclusions This study supports that there is no implication in the presence of psychotic symptoms regarding functionality or quality of life among the patients undergoing M/C ECT. We emphasize the need for randomized control trials to disentangle the effects of multiple variables on the functionality and quality of life of patients in M/C ECT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A novel, disease-specific clinical global impression scale (CGI) in Down syndrome

B. Rothman

ProPhase LLC, Science, New York City, USA

Background The CGI receives criticism due to its ambiguous scoring criteria, unstable reliability, and because CGI ratings may be too general to provide meaningful information about patient status or treatment response. This is problematic in studies of neurodevelopmental disorders such as Down syndrome (DS) that violate key assumptions underlying the CGI (i.e., that the disease is potentially reversible) and are highly variable in observed impairments. In DS, the CGI requires a higher level of standardization. This study examined the psychometric properties of a novel standardized CGI

scoring system for use in phase 2/3 clinical trials with DS populations.

Methods Impairment in functional and adaptive behaviors in DS – “speech”, “activities of daily living”, “social functioning” and “non-compliance” – were proposed as anchors for assessment in determining a global score of severity and improvement/deterioration. In a non-intervention study among individuals with DS ($n=90$, M age = 18.23, SD = 23.27), the CGI was conducted with the ADAMS, CELF-2, CELF-4, BRIEF-P and VABS-II. Descriptive and comparative analyses were performed.

Results At screening, the CGI-S speech, social functioning, and non-compliant domains correlated positively with ADAMS Social avoidance ($r=0.400$, 0.272 and 0.294 , respectively) supporting construct validity. The CELF negatively correlated with CGI-S Speech ($r=-0.469$, $P=0.037$). The CGI-I correlated negatively with the VABS-II at Day 1, W4 and W24.

Conclusions The CGI developed for Down syndrome (DS) is a valid clinical outcome measure. It offers a number of advantages including established utility in clinical research, sensitivity to change, and consistency with neurocognitive measures in DS.

Are there clinical and care differences in real care intensity among patients in general hospitals suffering from psychiatric comorbidity?

J. Valdes-Stauber^{1,*}, S. Bachthaler²

¹ Zentrum für Psychiatrie Südwürttemberg, Psychosomatic Medicine, Ravensburg, Germany

² Zentrum für Psychiatrie Südwürttemberg Germany, Head Physician, Psychosomatics, Ravensburg, Germany

* Corresponding author.

Background According to literature, about 30–40% of individuals admitted in general hospitals suffer from psychiatric comorbidity. Consultation-liaison services (CLS) cover internationally 1–10% of admissions and are able to improve care quality, treatment adherence and to reduce length of stay.

Objectives To assess possible clinical and care differences between individuals with and without psychiatric comorbidity as well as differences among principal diagnostic groups.

Aims To find out, whether individuals suffering from specific psychiatric diagnoses show a higher degree of care needs held by a CLS.

Method Retrospective, ethical approved full-survey assessment ($n=2940$) over three years (2012–2014). ICD-10 diagnoses, clinical factors and care variables were considered. Group differences were calculated by means of chi-square and ANOVA as well as Scheffé post-hoc estimation. Associations were conducted by means of multivariate regression as well as logistic regression models.

Results Individuals suffering from psychiatric comorbidity (48% of sample) were seldom primarily oncologic patients (30%), they showed more distress (DT=6.5), more performance limitations (ECOG=1.38), and less functionality (GAF=59.6). They received more contacts by CLS (1.95), more cumulative treatment time (89.7 min), and more psychopharmacological interventions (30.6%). People suffering from recurrent depressive and somatoform disorders received much more contacts and treatment time than other diagnostic groups. Age was negatively associated with care intensity.

Conclusions CLS services are able to offer differentiated psychiatric care depending on diagnoses. Individuals suffering from classical psychiatric disorders received rather treatment as usual, oncologic patients more psychotherapeutic interventions.

Depressive as well as somatoform patients seem to need more time and personal resources.

Psychopathology, temperament and suicide risk in adolescence: The role of early traumatic experience

P. Venturini^{1,*}, F. Fagioli², L. Sapienza¹, T. Boldrini^{2,3}, E. Bonaccorsi², D. Erbuto¹, F. Montebovi¹, P. Girardi¹, M. Pompili¹

¹ Department of Neurosciences, Mental Health and Sensory Functions, Suicide Prevention Center, Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy

² Department of Mental Health, Rome E Health Trust. Adolescents Department Via Plinio 31, Rome, Italy

³ Department of Dynamic and Clinical Psychology. Sapienza University of Rome, Rome, Italy

* Corresponding author.

Introduction Previous researches showed that adolescents are at high risk of suicide. Suicide is a trans-nosographic phenomenon regardless of psychiatric diagnosis. Trauma is an important risk factor for suicide and young help-seeking patients usually refer traumatic experiences, especially during childhood.

Objectives The objective of this study is to assess the relationship between traumatic experience and suicide risk comparing adolescents with suicide risk with adolescents without suicide risk.

Aims To investigate correlations between trauma, psychopathology and suicide risk in a sample of young help-seeking outpatients.

Methods We recruited 99 outpatients aged between 14 and 21 years admitted to department for prevention and early intervention in adolescence of Rome. We administered psychometric instruments exploring suicide risk (SHSS, BHS), prodromal (SIPS/SOPS), affective and anxious symptoms (HAM-A, HAM-D, MRS), child abuse (CTQ) and experiences of depersonalization (CDS).

Results Sample is composed of 31 men and 68 women. A total of 34.3% had mood disorder. A total of 28.3% reported history of emotional neglect, 20.2% emotional abuse, 9.15% sexual abuse, 5.1% physical neglect, 9.1% sexual abuse, 4% physical abuse. More than 30% of patients were at increased suicide risk. Depressive, irritable, anxious and cyclothymic temperament was associated with suicide risk. Patients with suicide risk had higher score at HAM-D ($t_{63}=2.65$; $P=0.01$), CDS ($t_{63}=2.77$; $P=0.007$), in CTQ ($t_{63}=3.20$; $P=0.002$) and BHS ($t_{63}=3.23$; $P=0.002$).

Conclusions Adolescents with suicide risk, compared with those without, reported more frequently early traumatic experiences and psychiatric symptoms. Early traumatic experiences constitute a risk factor for both suicide risk and psychiatric symptoms during adolescence.

Sexual well-being among a cross-national sample of older adults

S. von Humboldt*, I. Leal, A. Monteiro

ISPA-Instituto Universitário, William James Research Center, Lisbon, Portugal

* Corresponding author.

Introduction Sexual well-being (SWB) has been an ignored dimension that may contribute to successful aging.

Objectives To analyze SWB in older adults' perspective, to investigate the latent constructs that can work as major determinants in SWB and to examine the potential explanatory mechanisms of a SWB overall model, in an older cross-national sample.

Methods Measures were completed, using a variety of appropriate methods, including demographics and interviews. Complete data were available for 163 older adults aged between 65–97 years ($M = 74.2$; $SD = 4.743$). Data were subjected to content analysis. Representation of the associations and latent constructs were analyzed by a multiple correspondence analysis (MCA).

Results The most prevalent response of the interviewed participants for SWB was 'affection and care' (11.0%). A three-dimension model formed by 'intimacy and well-being', 'care, eroticism and desire', and 'sexual activity and health' was presented as a best-fit solution for German older adults. SWB for Portuguese older adults were explained by a three-factor model: 'intimacy, health and desire', 'affection and well-being' and 'sexual activity'.

Conclusions The outcomes presented in this paper emphasized the need to explore the indicators of SWB among older adults and the under-developed potential of a SWB overall model for the older population.

What predicts adjustment to aging among older women in breast cancer remission? The influence of subjective well-being, sense of coherence, and socio-demographic, lifestyle and health-related factors

S. von Humboldt*, I. Leal, F. Carneiro

ISPA-Instituto Universitário, William James Research Center, Lisbon, Portugal

* Corresponding author.

Objectives To build a structural model to explore the predictors of adjustment to aging (AtA) reported by older women in breast cancer remission.

Methods Older women in breast cancer remission ($n = 214$) aged between 75 and 94 years participated in this study. A questionnaire to determine socio-demographic (age, income, professional and marital status, education, household, living setting and self-reported spirituality), lifestyle and health-related characteristics (physical activity, leisure, perceived health, recent disease and medication), and measures to assess AtA, sense of coherence and subjective well-being, were employed. Structural equation modeling was used to explore a structural model of the self-reported AtA, encompassing all variables.

Results Preliminary results indicated that self-reported spirituality ($\beta = .397$; $P < .001$), leisure ($\beta = .383$; $P < .001$), physical activity ($\beta = .267$; $P < .001$), perceived health ($\beta = .211$; $P < .001$), marital status ($\beta = .173$; $P < .001$), professional status ($\beta = .156$; $P = .009$), sense of coherence ($\beta = .138$; $P < .001$), and living setting ($\beta = .129$; $P = .007$), predicted AtA. The variables accounted for 79.2% of the variability of AtA.

Conclusion Self-reported spirituality and leisure were the strongest predictors of AtA. Our preliminary findings suggest that health care interventions with older women in breast cancer remission still living in the community may benefit from clearly including predictors of AtA, as these are essential for promoting older women's aging well.

Analysing correlates for the younger-old and the oldest-old: Adjustment to aging

S. von Humboldt^{1,*}, I. Leal²

¹ ISPA-Instituto Universitário, Lisbon, Portugal

² ISPA, Instituto Universitário, William James Research Center, Lisbon, Portugal

* Corresponding author.

Introduction Diverse factors may predict the adjustment to aging (AtA) of the younger-old and oldest-old adults'.

Objectives To build a structural model for exploring whether socio-demographic, health and lifestyle-related variables are predictors of AtA for both groups.

Methods Research encompassed a community-dwelling sample, of 447 older adults aged 75 years and above ($M = 86.27$; $SD = 6.78$; range 75–100). Measures included demographics (sex, marital status, education, household, adult children, family's annual income, and self-reported spirituality), lifestyle and health-related characteristics (perceived health, recent disease, physical activity and leisure), and the Adjustment to Aging Scale. Structural equation modeling was used to investigate a structural model of the self-reported AtA, encompassing all the above variables.

Results Significant predictors for the younger-old are perceived health ($\beta = .425$; $P < .001$), leisure ($\beta = .324$; $P < .001$), professional status ($\beta = .243$; $P < .001$). Significant predictors for the oldest-old are self-reported spirituality ($\beta = .816$; $P < .001$), perceived health ($\beta = .232$; $P < .001$), and income ($\beta = .233$; $P = .035$). The variables explained respectively 64.5% and 61.6% of the variability of AtA, respectively.

Conclusions Perceived health is the strongest predictor of AtA for the younger-old participants whilst self-reported spirituality is the strongest predictor of AtA for the oldest-old adults.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The orientation to life questionnaire: Assessing older adults' sense of coherence

S. von Humboldt^{1,*}, I. Leal²

¹ ISPA-Instituto Universitário, Lisbon, Portugal

² ISPA-Instituto Universitário, William James Research Center, Lisbon, Portugal

* Corresponding author.

Introduction Growing literature suggests that the sense of coherence (SOC) positively influences well-being in later life.

Objectives This study reports the assessment the following psychometric properties: distributional properties, construct, criterion and external-related validities, and reliability, of the Orientation to Life Questionnaire (OtLQ) in a cross-national population of older adults.

Methods We recruited 1291 community-dwelling older adults aged between 75–102 years ($M = 83.9$; $SD = 6.68$). Convenience sampling was used to gather questionnaire data. The construct validity was asserted by confirmatory factor analysis, convergent and discriminant validity. Moreover, criterion and external-related validities, as well as distributional properties and reliability were also tested.

Results Data gathered with the 29-items OtLQ scale showed overall good psychometric properties, in terms of distributional properties, construct, criterion and external-related validities, as well as reliability. Three factors were validated for the OtLQ scale: (a) comprehensibility; (b) manageability; and (c) meaningfulness.

Conclusion We validated the 3-factor OtLQ scale, which produced valid and reliable data for a cross-national sample with older adults. Hence, it is an adequate instrument for assessing sense of coherence among older people in health care practice and program development contexts.

The effect of Qing Huan Ling combined risperidone on the open field behavior of schizophrenic mice model

Y. Zhang*, F. Liu, Z. Dai, B. Wu, Q. Wu
Xi'an Mental Health Center, Pharmacy Lab, China

* Corresponding author.

Objective To observe the effect of Qing Huan Ling and (or) risperidone on locomotor activity and explorative behavior of schizophrenia mice model by open field test.

Methods Seventy kunming mice were randomly divided into 5 groups, one group as blank group. The rest groups ip MK-801 continuously 14 day, then randomly numbered: model group, risperidone group, Qing Huan Ling group and risperidone combined Qing Huan Ling group. Ig give corresponding drugs for each group 4 weeks, observe the change of locomotor activity and explorative behavior by open field test.

Results After Ig 4 weeks, compared with the blank group, there were no obvious difference in locomotor activity and explorative behavior between risperidone group, Qing Huan Ling group and the combined group. Compared with the model group, risperidone had statistics meaning in the repression of explorative behavior ($P < 0.05$), the combined group has statistics meaning in the repression of locomotor activity and explorative behavior (78.92 ± 36.18 m vs. 186.92 ± 41.08 m, $P < 0.01$).

Conclusion Qing Huan Ling regulate the central nervous system of schizophrenia mice model; when combined with risperidone, it restrain the central nervous system of schizophrenia mice model and the effect is stronger than risperidone alone.

Efficacy of nalmefene in a sample of patients with alcohol dependence

J.A. Aguado Mañas^{1,*}, O. Segurado²

¹ Centro Hospitalario Benito Menni, Psychiatry, Valladolid, Spain

² Hospital Universitario Rio Hortega, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction It is well known the high rate of alcohol abuse and dependence in Spain. Specifically, in Castilla and León as a wine region, the risk of developing alcoholism is 1 of 10 men and 1 of 15 women [1].

Objective The aim of the study is to assess the efficacy of nalmefene in reducing alcohol consumption and its complications, in a sample of patients with alcoholism.

Materials and methods It is an open, naturalistic, observational and descriptive study in a sample of 18 patients with alcohol dependence diagnosis.

We collected standard demographic variables, but also living alone, social support and work.

In addition, clinical variables as SD (standard drinks) per day, time of illness, concomitant diseases, number of admissions, periods of abstinence, abstinence longer duration, nalmefene doses and other treatments were collected. These variables were reassessed at first, 3th and 6th month.

Results In our sample the average profile is a man (75%) with an age of 46, who lives alone (68%), in urban area and with poor social support.

Average SD consumed at the beginning was 53, one month later was 26, after three months was 14 and 6 months later was 5, with a total abstinence rate of 65% at the end of the period. Logically there was also a dramatic reduction in somatic and social complications.

Conclusions Nalmefene is demonstrated as a useful drug in reducing alcohol consumption and its complications.

Nalmefene also proves to be effective for achieving complete alcohol abstinence starting with a reduction plan.

Prevalence rate, demographic and clinical predictors of substance use disorders in emergency room psychiatric patients of a tertiary hospital in Canada

V. Agyapong^{1,*}, M. Juhas²

¹ Department of Psychiatry, Fort McMurray, University of Alberta, Canada

² Department of Psychiatry, Edmonton, University of Alberta, Canada

* Corresponding author.

Background There is only a limited body of literature which has examined the factors which can predict the presence of substance use disorders (SUD) in psychiatric patients seeking emergency room (ER) treatment.

Objective To examine the factors that can predict the likelihood that a patient presenting to the emergency room and referred to the liaison psychiatric team will suffer from a SUD.

Methods Nineteen independent demographic and clinical factors from data assessment tools for 477 patients assessed by the liaison psychiatric team in the ER over 12 months were compiled and analysed using univariate analyses and logistic regression in SPSS (version 20).

Results The 12-month prevalence rate of all SUDs in our clinical sample was 24.7%. Patients who presented to the ER with a chief alcohol and/or drug related complaint (withdrawal or intoxication) were 142 times more likely to fulfill the diagnostic criteria for SUD compared to those who presented with non-SUD related complaints. Male patients or patients with forensic history were both three times more likely to suffer from SUD than female patients or patients with no forensic history, respectively.

Conclusion There is a high prevalence of SUDs among psychiatric patients assessed in the ER. In addition to targeting patients who present to the ER with an alcohol or drug withdrawal/intoxication for brief psycho-educational interventions and referrals to addiction treatment services, patients with forensic history and male patients should be targeted for SUD screening.

Kleptomania – “it was just a small fragrance in a Chinese store. . .”

M. Almeida*, J. Ferreira
Centro Hospitalar Baixo Vouga, Departamento de Psiquiatria e Saúde Mental, Aveiro, Portugal
* Corresponding author.

Introduction The idea that some people may not be able to control their stealing impulses emerged in 1838, when Esquirol and Marc coined the term Kleptomanie. Although there are not many studies regarding this issue, becoming therefore difficult to establish epidemiological data, various clinical samples suggest a high prevalence of the disorder. As the problem most likely become chronic when left untreated, the diagnostic approach is very important.

Aims Literature review and discussion about kleptomania, regarding a case report.

Methods Clinical interviews and literature review in PUBMED database.

Results (case report) Female patient, 62 years, with history of Personality Disorder and Persistent Depressive Disorder, confesses in psychiatric appointment that she had been caught stealing. She says that she has this “addiction to steal” since childhood, always stealing cheap stuff, that she does not need, usually giving it away to other people. She has this behavior as she feels an unexpected and irresistible impulse to steal, with increasing anxiety, which relieves when action is consumed. Afterwards she experiences feelings of shame and guilt. The patient symptoms appear to get worse in depressive relapses.

Conclusions Regarding individual, family and social impact of kleptomania is essential to assess it and to treat it promptly. Most of the patients are ashamed of their behavior, so they may not self-report. There are few and controversial data concerning treatment, but it is widely accepted that co-morbidity with mood disorders or substance use disorders is common and may interfere with treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Methamphetamine as a risk factor for myopathy

A. Azhari
Mashhad University of Medical Sciences, Physical & Rehabilitation medicine, Mashhad, Iran

Introduction Cardiotoxic effects of methamphetamine have been proposed in many investigations, but the risk of striated muscles involvement among methamphetamine abusers is unknown.

Methods A case-control study has begun in our teaching hospital to examine the association between methamphetamine abuse and myopathy. The study population are adult clients who admit in the electrodiagnostic medicine clinic since January 2015 with complains of weakness. For each subject with myopathy, 2 controls without myopathy are randomly selected from the same population. Self-reported history of methamphetamine abuse is acceptable in both groups.

Results A total of 56 persons with myopathy and 112 controls have been identified, of whom 5 (9 percent) and 3 (3 percent) had history of methamphetamine abuse, respectively. Persons with history of methamphetamine abuse have about three times greater chance to develop myopathy (95% CI: 1.5–5.1) as compared with controls.

Conclusion There is a misconception among some workers that some illicit drugs such as psycho stimulants can improve their ability to work. In contrast, this study demonstrates that due to harmful effect on the muscles, methamphetamine could diminish the ability to work in long time.

Rehabilitation for drug users in Moldova

A. Bandati
Republican Dispensary of Addictions, Outpatient department, Chisinau, Republic of Moldova

Rehabilitation center (RC) for drug users was inaugurated in 2007. Its aims are prophylactic assistance, advisory, medical and social adaptation of drug users with medical and social consequences generated by drug consumption.

RC's program includes several strategic objectives:

- psychological and social support;
- healing and maintaining long-term abstinence;
- social and professional integration;
- family integration and improving relations with others;
- formation of interests that contribute to healthy lifestyles.

Rehabilitation process lasts 2–4 months and includes several stages:

- the initial stage;
- basic or general step;
- the final stage.

Each phase integrates sub steps:

- adaptation;
 - active intervention or integration;
 - stabilization and keeping.
- Adaptation (2 weeks):
- examination and consulting;
 - familiarity with RC regime;
 - framing in rehabilitation activities;
 - motivation for behavior change training.

Integration or basic stage (2–12 weeks):

- integration to the activity of RC;
- psychotherapeutic activities;
- group activities;

- instructional and educational programs;
- revival of health;
- restoring and improving relationships with family and others;
- healthy living skills training (positive thinking).

The final stage:

- application of skills gained throughout the program;
- consolidation and implementation of skills and responsible behavior;
- obtaining of health conditions for further work and studies.

Mean year number of the RC's clients is 252 (± 10.5).

In terms of the rehabilitation potential with advanced grade were 176 people (48%), average potential – 165 persons (45%), and low potential – 26 people (7%) in 2014.

Providing of medical and psychosocial services, knowledge in drug addiction prevention denotes desired effect of RC's program.

Disclosure of interest The author has not supplied his declaration of competing interest.

Introduction The western societies have a rapidly aging population and an increasing number of elderly with alcohol use disorders. **Objective** The purpose of the elderly study is to develop and test an outpatient behavior therapy program for people with an alcohol use disorders.

Aim of this abstract To investigate the association between ages, gender, drinking pattern and psychology distress.

Method The study is a randomized study expected to enroll and treat 1000 participants aged 60+ years before April 2017; 200 in USA; 400 in Germany and 400 in Denmark. To be included in the study the participants have to fulfil the DSM-5 criteria for alcohol use disorder. All participants are examined at baseline, and at four follow up interviews. After the baseline interview all participants are randomized to Motivational Enhancement Therapy (MET); or MET followed by 8 weeks of counseling based on the Community Reinforcement Approach (CRA) with a module added to address problems relevant to elderly people.

Results The presentation will include baseline characteristics of the Danish participants including demographics, expectations to treatment, history of drinking in the last 90 days before baseline and their psychological distress. We have now enrolled 259 participants in the Danish database. We expect to present results from 320 patients.

Conclusion The data will present information about the profile of 60+ years' individuals seeking treatment for alcohol use disorder, and thereby provide knowledge about which characteristics that may be important when planning treatment for this age group.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Mental Health Research Institute, Affective States Department, Tomsk, Russia

* Corresponding author.

Objective To assess severity of cognitive disturbances during use of individualized therapy.

Materials and methods Study sample included 40 men with diagnosis of alcohol dependence in the period of remission formation. Methods of pictograms, “ten words”, techniques “analogs”, “number square”, “index of functional flexibility of nervous processes” were applied. Measurement was conducted before and after individualized therapy. Depending on structure of cognitive disturbances the individualized therapy included the following: pharmacotherapy, audiovisual, vibrotactile, oxygen-hyperthermic, resonance-acoustic and psychotherapeutic interventions.

Results Assessment of drawings of the method of pictograms before and after individualized therapy testifies to increase of number of adequate associations in 36.4% of cases, decrease of inadequate symbolic in average from 1.91 scores to 1.77. After therapy part of graphic phenomena-indicators of organic diseases (in 63.64% of patients) and index of severity of organic graphic symptom complex (from 2.14 ± 1.04 to 1.43 ± 0.98 , differences are reliable at $P < 0.05$) decreased. A set of associations was widened, number of abstractions of high level increased in 31.82% of cases. It was revealed that abilities to generalize and abstract did not change after therapy. Average productivity of mediated remembering after therapy increased from 58.08% to 71.67%. Increase of volume of attention and its switchover capability, increase of average index of functional flexibility of nervous processes from 1.19 ± 0.26 to 1.62 ± 0.16 (differences are reliable at $P < 0.05$) were revealed.

Thus, administered with account for structure of disorders individualized therapy allows significant improvement of cognitive functions of alcoholic patients.

Toxic role in schizophrenia: A review by a clinical case

M. Canseco Navarro^{*}, A. Peña Serrano, J.M. Hernández Sánchez, M. Cancino Botello, F. Molina López, M. Machado Vera

Consorcio Hospital General Universitario, Conselleria de Sanitat, Valencia, Spain

* Corresponding author.

Introduction Often find it difficult diagnostic approach to patients with symptoms that could correspond to several clinical entities. This requires making a correct differential diagnosis to enable a better understanding and addressing the disease in an individualized way.

Objective Describe pathogenetic factors of paranoid schizophrenia highlighting their relationship with drug consumption.

Methods Review of the clinical history of a patient admitted to acute ward of the Hospital General Universitario of Valencia.

Results A case of a 30-year-old man, whose income is motivated by persistent and structured autolytic ideation occurs. It presents positive symptoms for several years and amotivational

syndrome ago. It has a history of cannabis, cocaine and alcohol since he was thirteen and remains abstinent for more than six months ago. Differential diagnosis arises between amotivational toxic syndrome, reactive depressive symptoms to the disease and negative symptoms for chronic psychotic process. Finally diagnosed with paranoid schizophrenia and is included in the program of first psychotic episodes.

Today the productive symptoms disappeared and remain negative though with less intensity achieving an improvement in overall activity.

Conclusions Consumption of toxic influences the development of a chronic psychotic process that may appear years later, becoming an etiological and maintainer factor, not only if its consumption continues, but other effects that occur long term amotivational syndrome and worsening prognosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cannabis and cyclical vomiting

M. Canseco Navarro*, M. Canccino Botello, M.M. Machado Vera, J.M. Hernández Sánchez, F. Molina López
Consorcio Hospital General Universitario, Conselleria de Sanitat, Valencia, Spain

* Corresponding author.

Introduction Traditionally, cannabis is associated with antiemetic action after acute consumption. However, in 2004 the cannabinoid hyperemesis as paradoxical effect of chronic users, after years of exposure described.

Objectives Description of the cannabinoid hyperemesis.

Method OLOGYA case is presented.

Results Clinical case of a woman who repeatedly comes to the emergency service because of abdominal, nausea and vomiting pain.

This is cyclical and hardly controllable. The gastroenterology service studied in depth with negative results. She was followed up by mental health borderline personality disorder and she consumed cannabis at an early age, 20–30 joints daily.

When she reaches abstinence in short periods, ceases digestive discomfort. However, appears digestive symptoms with each relapse. The present case showed improvement with cessation of cannabis so it probably was the cannabinoid hyperemesis syndrome.

Conclusions The cannabinoid hyperemesis is characterized by recurrent episodes of nausea, vomiting, abdominal pain, and chronic cannabis use. Temporary relief is achieved with hot baths. Ceases when abstinence is achieved. It is a clinical entity that does not have much information and requires further study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Legal and illegal drugs can cause psychotic symptoms, in cocaine-dependent patients the prevalence of these symptoms may reach 86% (Vorspan, 2012). It is estimated that 13–32% of cocaine-dependent patients have kinaesthetic hallucinations (Siegel, 1978; Mahoney, 2008; Roncero, 2012).

Objectives To compare the prevalence of substance-induced psychotic symptoms and compare the use of welfare/social resources and social adjustment among cocaine-dependent patients (CD) and other substances dependences (OtherD).

Methods Two hundred and six patients seeking treatment at the Addictions and Dual Diagnosis Unit of the Vall d'Hebron. Patients were assessed by ad hoc questionnaire designed to collect demographic data and psychotic symptoms associated with consumption, a record of the care/social resources used by the patient and the scale of social adaptation (SASS). A descriptive and bivariate analysis of the data was performed.

Results CD were 47.1% vs. 52.9% OtherD (66.1% alcohol, 17.4% cannabis, 8.3% opioid, 8.3% benzodiazepines/other drugs). Of cocaine dependent-patients, 65.6% present psychotic symptoms vs. 32.1% for the OtherD. Different exhibiting psychotic symptoms are: self-referential (69.7% vs. 30.7%), delusions of persecution (43.4% vs. 12.2%), hallucinations (49.4% vs. 14.3%), auditory hallucinations (43.5% vs. 11.4%), visual hallucinations (30.4% vs. 5.7%) and kinaesthetic hallucinations (7.2% vs. 2.9%).

Cocaine-dependent patients significantly use more health care resources in reference addiction unit (76.3% vs. 62.4%, *P*.035) and infectious diseases (22.7% vs. 5.5%, *P*.000) and justice-related (50.5% vs. 26 resources 0.6%; *P*:1.001) and less resources and mental health (25.8% vs. 43.1%; *P*.013).

Regarding social adaptation, no differences were found in the SASS. Kinaesthetic hallucinations do not appear to be related to a greater use of resources and in social adaptation.

* Corresponding author.

Introduction Accident rate have a high social cost. Cocaine consumption increases the risk of traffic crashes (Monras, 2011; Fierro, 2011). However, there is not extensively studies in addicts.

Objective Compare and analyze the history of accidents and risk behaviors while driving in cocaine dependent patients (DC) and of other substances (OtherD).

Methods One hundred and eighty-two patients seeking treatment since January 2014 to September 2015. Sociodemographic and accident-related variables were collected, also administered the MDBQ. Descriptive analysis and bivariate analysis using Chi-square test for categorical variables and Student t test was performed for quantitative.

Results Of women, 30.3%, and 69.7% men, mean age 43.67 years (SD = 13). 65.6% currently driving or above. 45.2% DC vs. 54.8% Other (35.6% alcohol, cannabis 8.3%, 5.8% opioid and 5.1% other drugs). Comparing accident rate on the DC is a tendency to have suffered more accidents (χ^2 : 2.62 P = .072). Patients addicted to cocaine referred further potentially dangerous activities both under the influence of consumption (65.9% vs. 33.3%) and abstinence (41.7% vs. 12%).

As for the results of MDBQ, it has been detected that cocaine addicts show more errors and traffic violations. No differences in the lapses identified by patients of different groups.

Conclusion Patients with cocaine dependence have more accidents, reduced risk perception and recognize more mistakes and traffic violations. Cocaine implies a high risk of road accidents and exposure to high-risk situations compared to the use of other substances.

E-cigarettes and tobacco cessation: An online survey of electronic cigarette users in France

C. Chevallier, A. Batisse, M. Marillier*, S. Djeddar
GH Lariboisière-Fernand Widal, CEIP, Paris, France

* Corresponding author.

Introduction E-cigarettes (EC) are widely used in general population and may facilitate smoking cessation. However, efficacy and addictive potential of EC remain insufficiently studied.

Objectives To characterize e-cigarette use and its impact on tobacco use/cessation.

Methods Online survey was available on CEIP website (September 2014–March 2015). Questionnaire assessed smoking status, tobacco and e-cigarette use, including reasons for use, efficacy, adverse effects and dependence (Fagerström test of cigarette dependence [F] and an adapted version to e-cigarette use [Fm]).

Results One thousand one hundred and twenty-one EC users answered (1008 ex-smokers, 113 current smokers), with mean age of 39 ± 10 years and 72% female. Ninety-six percent e-cigarette users agreed that vaping is useful for tobacco cessation, 80% succeeded to quit/reduce their smoking. Reasons for EC use are partial/complete alternative to smoking, lower toxicity, less side effects and lower cost. Most of ex-smokers (66%) has no/low dependence to EC ($F_m \leq 4$) since current smokers reduced dramatically their tobacco consumption by EC use. Among all EC users, 75% had a craving for EC. Use of EC is described as pleasant as tobacco for 59% ex-smokers and 39% smokers. Eighty-three percent of ex-smokers and 68% of smokers do not intend to stop vaping.

Conclusion E-cigarettes are used primarily for smoking cessation and show effectiveness for harm-reduction, but a secondary dependence to nicotine contains in EC can be observed (Figure 1).

Compulsiveness dimension in a case of pathological gambling

S. Chiappini*, R. Testa, F. Maisto, B. Leone, M. Di Paolo, M. Pascucci, P. Polidori, P. Grandinetti, G. Conte

Institute of Psychology, Psychiatry Department, Roma, Italy

* Corresponding author.

Introduction Pathological gambling (PG) is currently included among Addictive Disorders (DSM-5). However, its phenomenology resembles features of Obsessive Compulsive Disorder. Several models of addiction conceptualize a progression from impulsivity to compulsivity transitioning from initial positive reinforcement motivations to later negative reinforcement and less pleasurable and automaticity mechanisms.

Clinical presentation A 34-year-old male, since diagnosed with PG in 2013 and prescribed a group rehabilitation therapy, presented in 2015 complaining of intrusive thoughts and depression symptoms. During the psychiatric examination emerged: low mental concentration; dysphoria; hyporexia; irritability; insomnia; persistent ideas and excessive preoccupations to be betrayed by his girlfriend; and behaviours of hyper control on her life. He has been evaluated using MMPI-2 (obsessivity Tscore 70, depression Tscore 67) and BIS-11 (high score of non-planning impulsiveness).

Treatment It appeared there was a shift from ego-syntonic novelty driven/impulsive behaviours focused primarily on gambling to ego-dystonic habit driven/compulsive behaviours focused on her girlfriend. He started an individual psychodynamic psychotherapy centred on dysfunctional beliefs and behavioural strategies for treating the compulsive features. As thought content was the most relevant aspect, he was prescribed olanzapine, not a SSRI (normally indicated for OCD), up to 10 mg/die. After a month obsessions and compulsions reduced, and he seemed to reach a good level of personal functioning, despite a rigid anankastic personality trait.

Conclusions As the management of compulsive behaviours is complex, physician should better assess and recognize psychological personality aspect, collecting patients' complete history, also testing them psychometrically, and paying more attention to an eventual treatment (both psychological and pharmacological).

* Corresponding author.

Introduction One of the main risk factors for both HIV-infection and syphilis is addictive behavior.

The objective of the study was to determine the impact of addictions on the HIV and syphilis coinfection.

Method Sixty-five HIV-infected patients with syphilis were examined by a clinical method.

Results The sample included 45 men (average age 32.09 ± 9.83) and 20 women (average age 31.7 ± 5.97). All patients were characterized by risky behavior. Seventy-one percent of men belonged to the category of men who have sex with men (MSM). Eighty-five percent of women had drug dependence (as compared to 61% for men who have sex with women (MSW) and 19% for MSM; $P < 0.05$). Women were more likely to have opiate dependence ($P < 0.001$; as compared to men). We revealed a high incidence of drug addiction and alcoholism with the prevalence of dependence on opioids (F11; 55.0%; 7.7%), polysubstance use (F19; 25.0%; 23.1%) and alcoholism (F10; 50.0%; 61.25%) among women and MSW respectively ($P < 0.05$ as compared to MSM). Only 50% of women and 23% of MSW were in remission. MSM regularly consumed stimulants and cannabinoids without developing dependence.

Conclusions Injecting drug use is typical of women and MSW and plays a leading role in the risk factors for HIV infection and syphilis. Addictive behavior among MSM increases risky sexual behavior and thus influences infection with HIV and syphilis.

* Corresponding author.

Introduction There are no data in literature on mental disorders in HIV-infected patients with syphilis.

The objective of the study was to determine the structure of mental disorders in HIV-infected patients with syphilis.

Method Sixty-five HIV-infected patients with syphilis were examined by a clinical method.

Results The sample included 45 men (average age 32.09 ± 9.83) and 20 women (average age 31.7 ± 5.97). We divided the sample into three comparison groups (according to the importance of risk factors): women, men who have sex with men (MSM), and men who have sex with women (MSW).

Mental disorders were identified in most patients (83%). Opiate dependence (F11, ICD-10) was established in 55% of women (7.7% for MSW, 0% in MSM; $P < 0.001$). The dependence on multiple drug use (F19) was revealed with nearly the same frequency in women (25.0%) and in MSW (23.1%); but far less frequently in MSM (3.2%; $P = 0.047$). The dependence on stimulants (F15) was found in women (5.0%) and MSM (6.3%). The dependence on alcohol (F10) was more common among MSW (61.5%) and women (50.0%) (9.4% in MSM; $P < 0.001$). 20% of women had Depressive episode (F32). Adjustment disorders (F43) were found much more often in men (43.8% for MSM; 38.5% for MSW; 10% for women; $P = 0.035$). Personality disorders (F60) were found in all the groups.

Conclusions We revealed a high incidence of addictions among women and MSW. Affective disorders were represented by depressive episode in women and adjustment disorders in men.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Kratom (*Mitragyna speciosa* Korth) is a tropical tree, indigenous to South East Asia. Historically, the plant is locally used as a stimulant, a remedy in traditional medicine and in social context. Imported to Western countries, Kratom is classified as a novel psychoactive substance (NPS).

A systematic review of the literature on *Mitragyna speciosa* and its main constituents was carried by our international multidisciplinary group. Results were qualitatively analysed in three main areas of interest: in-vitro and preclinical data on pharmacology and behavioral effects, laboratoristic techniques for identification/characterization, epidemiological/toxicological reports on humans.

At present, there is no systematic data on the prevalence of Kratom use in all the native countries, but it seems to be considerable. In South-East Asia, Kratom, even if banned, might be still considered a better option than other illicit drugs, an alternative opioid treatment, a "natural" remedy with no real social stigma attached to its consumption. In parallel, this ethno-drug seems to be popular in Western countries, largely unregulated, easily available on the Internet. Kratom pharmacology appears to be

complex, with many alkaloids involved. The subjective effects in humans are very peculiar and seem to be dose-dependent, ranging from psycho-stimulant to sedative-narcotic. Available data on Kratom suggest caution: this psychoactive plant could exhibit a serious harmful potential. Kratom use seems to be associated with drug dependency, development of withdrawal symptoms, craving, serious adverse effects and life-threatening effects in a multidrug-intoxicating scenario. On the other hand, its anxiolytic, antidepressant and analgesic properties deserve to be further studied.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessing Comorbidities and service use among patients with benzodiazepine abuse

B. Cook^{1,*}, L. Chavez², R. Carmona³, M. Alegria⁴

¹ CMMHR – Cambridge Health Alliance and Harvard Medical School, Psychiatry, Cambridge, USA

² University of Puerto Rico, Medical Sciences, San Juan, PR, USA

³ Fundacion Jimenez Diaz, Psychiatry, Madrid, Spain

⁴ Massachusetts General Hospital/Harvard Medical School, Medicine, Boston, USA

* Corresponding author.

Prior studies have identified that individuals with comorbid substance use disorder and mental health disorder are at a greater risk of benzodiazepine abuse compared to individuals that present with mental health disorder without an accompanying substance use disorder. These studies were conducted in predominantly white populations, and little is known if the same associations are seen in safety net health care networks. Also, the literature is mixed as to whether or not psychiatrists' prescription of benzodiazepines places individuals at undue risk of benzodiazepine abuse.

We use 2013–2015 electronic health record data from a Boston healthcare system. Patients with benzodiazepine abuse were identified if they had received treatment under the ICD-9 code 304.1. Benzodiazepine abuse was compared between patients with only mental illness and patients with existing comorbid substance and mental health disorder, in unadjusted comparisons and adjusted regression models. Covariates in regression models were used to identify subgroups at higher risk of benzodiazepine abuse.

Individuals with benzodiazepine abuse had higher rates of emergency room and inpatient use than patients with other mental health and/or substance use disorders. Those with comorbid substance and mental disorder were significantly more likely than individuals with mental or substance use disorder alone to abuse benzodiazepines ($P < .01$). Among those with benzodiazepine abuse, 93.3% were diagnosed with a mental illness, 75.6% were diagnosed with a substance use disorder (other than benzodiazepine), and 64.4% had comorbid anxiety disorder and substance use disorder. These analyses suggest that patients with benzodiazepine abuse have complex presentations and intensive service use.

Methadone withdrawal psychosis – case report

A. Coutinho^{1,*}, L. Maia², J. Perestrelo², I. Carvalho², L. Ribeiro²

¹ V.N. de Gaia, Portugal

² Centro Hospitalar V.N. Gaia/Espinho, Psychiatry and Mental Health, V.N. Gaia, Portugal

* Corresponding author.

Introduction Opiates's substitution therapy with methadone is one of the main approaches used for drug-addicted patients, in Portugal. The symptoms of withdrawal of methadone are the same as the classical abstinence syndrome of opiates. In a minority of cases, withdrawal of methadone has been related to the sudden appearance of affective disorders and to a minor degree with psychotic disorders.

Objectives The authors propose to do a brief literature review about methadone and its neuromodulation in central opiate-dopamine system.

Aims The authors intend to report a clinical case illustrative of a psychosis possible related to methadone rapid withdrawal, in a 39-year-old woman without previous personal or familiar psychiatric illness, except for the use of toxic substances.

Methods Literature review in scientific databases – Pubmed; ScienceDirect. Case report of a patient admitted in Psychiatry Department of Vila Nova de Gaia Hospital Center.

Results During admission, the patient's condition consisted of disorganized behavior, paranoid delusions and the presence of auditory hallucinations. Was excluded other possible causes of psychotic conditions and was admitted rapid methadone detoxification as the probable etiology. Neuroleptic treatment was prescribed and psychotic symptoms improved progressively.

Conclusions In test animals, the behavioral effects of methadone withdrawal have been related to its effects on cerebral amines, especially on dopamine. A change in the neuromodulation of the central opiate-dopamine systems, due to opiates's substitution therapy with methadone, could be related to psychotic pathogenesis. This work supports other authors that suggest that methadone withdrawal can cause psychosis in individuals without previous psychiatric conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Egypt is one of the most famous endemic areas for hepatitis C virus. Drug use in Egypt is rising exponentially. Drug use is always considered one of the main risk factors for HCV.

Objectives To assess the effect the route of drug use on the incidence of HCV in the Egyptian population.

Aim To study the effects of opiates (tramadol and heroin) use and the route of intake on the incidence of HCV infection among addicts treated in Mamoura mental state hospital, Alexandria, Egypt.

Methods This is a cross-sectional study on drug dependence patients visiting the out patient clinic for addiction in Elmamora Hospital.

Subjects were divided into two groups.

Group I: Control group.

Twenty non-addict volunteers.

Group II: Cases groups (comprising 60 subjects)

This group will be divided into three sub-groups each contains 20 cases.

Group IIa: consuming tramadol.

Group IIb: consuming tramadol and heroin by injection.

Group IIc: consuming tramadol and heroin by inhalation.

All studied groups were subjected to:

1. detailed history taking, urine screening tests for drugs of abuse, liver functions tests and HCV screening.

Results The study showed deterioration in liver function tests in the heroin and tramadol use groups compared to the tramadol only use.

There was a statistical significant difference in the incidence of HCV infection in the heroin injection group (85%) compared to 35% in the heroin non injector users and only 5% in tramadol users had HCV positive.

Conclusion Heroin injection showed the highest risk for both liver function deterioration and HCV infection.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between patient's personality traits and outcome of hospital treatment of opioid addiction

M. Delic^{1,*}, K. Kajdič², P. Pregelj³

¹ Ljubljana, Slovenia

² University Psychiatric Hospital- Ljubljana, Center for Treatment of Drug Addiction, Ljubljana, Slovenia

³ University Psychiatric Hospital Ljubljana – University of Ljubljana, Faculty of Medicine, Department of Psychiatry, Ljubljana, Slovenia

* Corresponding author.

Introduction Despite different treatment approaches many drug addicted patients continue to use drugs during and after treatment. **Objectives** Personality traits are considered risk factors for drug use, and, in turn, the psychoactive substances impact individuals' traits.

Aims To describe the sample of 186 opioid addicted patients entered hospital treatment and assessing the differences in personality traits between abstinent and non-abstinent after one year.

Methods A cohort of 186 patients consecutively admitted to the detoxification unit was investigated. The research interview, the Big Five Inventory (BFI), the Treatment Outcomes Profile (TOP) were administered during the first week of admission to the detoxification unit. Urine test was administered on the day of admission and at each follow-up point in combination with the TOP (after three, six and twelve months). Illicit drugs abstinence during one year after intake was selected as a treatment outcome measure.

Results Twelve months after admission 82 (44.9%) patients abstained completely. Agreeable patients remain in treatment longer ($r = 0.20, P = 0.07$). Extraversion and openness are negatively correlated with abstinence after six and twelve months ($r = -0.15, P = 0.041; r = -0.15, P = 0.044$). Neuroticism is in negative correlation with duration of treatment ($r = -0.20, P = 0.006$). Patients who are less open to new experiences are more likely to abstain from drugs 6 months after admission ($r = -0.17, P = 0.021$).

Conclusion Personality measured with BFI correlates with treatment outcome poorly. At the same time personality could have an important role in responding to treatment, but personality traits could be at the same time protective as well as risk factors.

Craving phenomenon and its role in relapse prevention in patients with substance dependence

H. Dessoki^{1,*}, F. Mousa², M. Nasr², O. Shaheen², A. Mostafa²

¹ Beni-Sewef, Egypt

² Kasr Aini, Psychiatry, Cairo, Egypt

* Corresponding author.

Objectives To explore the phenomenon of craving in illicit drug dependent and nicotine dependent population, and to assess craving including etiological, diagnostic, psychometric and prognostic aspect.

Subjects The total sample of the study consisted of 90 subjects who were selected as consecutive procedure, from the detoxification unit in El-Abassia hospital and some private psychiatric hospitals. The sample was divided into three groups, illicit drug dependent group ($n = 30$) they were diagnosed as substance dependent after application of structural clinical interview SCID based on the diagnostic and statistical manual of mental disorders DSM-IV diagnostic criteria exclusively nicotine dependent group ($n = 30$) they were selected from the medical, nursing staff and some of the relatives of the illicit drug dependent group and control group ($n = 30$) selected from those visiting the outpatient clinic at the same hospitals for follow up after complete abstinence for at least 2 years and some subjects were selected from the Narcotic Anonymous.

Methods Psychiatric examination through structural clinical interview based on the diagnostic and statistical manual of mental disorders, Wechsler-Bellevue Adult Intelligence Scale, Eysenck Personality Questionnaire, Hamilton Depression Scale, Hamilton Anxiety Scale, The Obsessive Compulsive Drinking Scale, The Minnesota Cocaine Craving Scale and Inventory of Rituals to the use of opioids.

Results The illicit drug dependent groups expressed highest resistance control impairment, obsessions and interference related to the use of the drugs; i.e., high addictive propulsions. The illicit drug dependent patients showed highest expectations of relapse as a prognostic outcome compared to other groups.

Gender difference in trauma exposure among a sample of egyptian patients with substance use disorder

H. Eldabah^{1,*}, H. Salama¹, M. Attia², O. Elkholy¹

¹ Elhadra University Hospital- Alexandria University, Psychiatry, Alexandria, Egypt

² High Institute of Public Health University of Alexandria, Mental Health, Alexandria, Egypt

* Corresponding author.

E-mail address: Heshamaru@gmail.com (H. Eldabah)

Background Studies have shown high association between trauma exposure in childhood and adulthood, post-traumatic stress disorder (PTSD) and substance use disorder (SUD). Women seeking treatment for SUD are more likely to have histories of sexual and physical abuse.

Aim To study the effect of gender difference on the history of traumatic experiences and the mental health problems of the SUD patients.

Method Cross-sectional comparative study was conducted at the Addiction Treatment Center at El Maamoura psychiatric hospital. Two hundred adult inpatients were recruited and assessed using a structured interview questionnaire to collect sociodemographic data, substance-use history, and medical and psychiatric history. The semi structured psychiatric interview was applied,

and psychometric assessment was performed using Arabic version of Trauma History Screen (THS) for assessment of trauma exposure, and the Arabic version of the Post-traumatic Stress Disorder Checklist, civilian version (PCL-C) for assessment of current PTSD. **Results** One hundred and fifty-six were males (78.0%), 44 were females (22.0%). Females were significantly more likely to be exposed to sexual abuse at childhood ($P=0.002$) and adulthood ($P=0.050$), score higher on PCL-C ($P=0.002$), to have major depressive disorder (MDD) ($P=0.028$), and have suicidal plans and attempts ($P=0.001$).

Conclusions Females with substance use disorder are more likely to be victims of sexual trauma, to develop Post-traumatic stress disorder and to have more complicated psychiatric comorbidities than their male counterparts.

Keywords Substance use disorder; Post-traumatic Stress Disorder; Trauma exposure; Gender difference

Alcoholic psychoses incidence in urban and rural regions of Belarus

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction Belarus ranks among the world's heaviest drinking countries with the high alcoholic psychoses incidence rate.

Objectives To examine the incidence of alcoholic psychoses in urban and rural regions of Belarus.

Methods Age- and gender-specific data on alcoholic psychoses incidence rate (per 100,000 of the population) for urban and rural regions of Belarus were obtained from the Ministry of Statistics.

Results Significant rural–urban gradient in the incidence of alcoholic psychoses was found (Table 1). The alcoholic psychoses rate in rural areas was 39.7% higher for males and 16.7% higher for females. The male to female ratio was 5.3:1 in urban regions and 6.3:1 in rural regions. The largest disparities in rural–urban alcoholic psychoses rate ratios have been recorded amongst the age group 18–39 years. The highest rates in all regions were recorded among men and women aged 40–59 years.

Conclusions Although the alcoholic psychoses rate is high in all regions, there may be factors that are specific to rural locations, such as poor provision of medical services that account for the extreme alcoholic psychoses rate being recorded there. This requires urgent intervention by the authorities to ameliorate this situation.

Table 1 The alcoholic psychoses incidence rates for different age groups in urban and rural regions of Belarus.

Age	All		Urban		Rural	
	Males	Females	Males	Females	Males	Females
0–17	0.21	0	0.3	0	0	0
18–39	41.5	8.7	36.0	8.2	60.6	10.5
40–59	61.2	10.8	51.5	9.2	79.4	16.7
60+	13.6	1.6	13.5	1.8	12.9	1.5
0–60+	35.1	6.2	31.7	6.0	44.3	7.0

* Corresponding author.

Objective Turkish version of the UPPS Impulsive Behavior Scale was previously validated in a sample of psychiatric inpatients. The aim of the present study was to evaluate psychometric properties of the sensation seeking subscale of this scale in a sample of inpatients with alcohol use disorder.

Method Participants ($n=190$) were evaluated with the sensation seeking subscale of UPPS Impulsive Behavior Scale.

Results Sensation seeking subscale had two factors, which together accounted for 63.80% of total variance. As similar with original subscale internal consistency for the sensation seeking (coefficient $\alpha=0.859$), factor 1 ($\alpha=0.862$) and factor 2 ($\alpha=0.755$) examined by Cronbach's alpha, were high. Factor 1 ($r=0.894$) and factor 2 ($r=0.863$) were highly correlated with total score, whereas moderately correlated ($r=0.544$) with each other. Test-retest correlation for sensation seeking ($n=120$) was mild ($r=0.460$). Test-retest correlation for factor 1 was moderate ($r=0.518$) and for factor 2 was mild ($r=0.431$).

Conclusion These findings support the Turkish versions of the sensation seeking subscale of the UPPS has good psychometric properties among inpatients with alcohol use disorder.

Relationship of impulsivity with severity of ADHD symptoms while controlling the effects of anxiety and depression in a sample of inpatients with alcohol use disorder

C. Evren^{1,*}, G. Umut¹, B. Evren², M. Bozkurt¹, Y. Can¹

¹ Bakirkoy Training and Research Hospital for Psychiatry –

Neurology & Neurosurger, Alcohol and Drug Research Treatment and Training Center AMATEM, Istanbul, Turkey

² Baltalimani State Hospital for Musculoskeletal Disorders, Department of Psychiatry, Istanbul, Turkey

* Corresponding author.

Objective The aim of the present study was to evaluate relationship of impulsivity with severity of ADHD symptoms while controlling the effects of anxiety and depression in a sample of inpatients with alcohol use disorder.

Method Participants included 190 inpatients with alcohol use disorder. Participants were evaluated with the State-Trait Anxiety Inventory (STAI), the Beck Depression Inventory (BDI), the Short Form Barratt Impulsiveness Scale (BIS-11-SF) and the Adult ADHD Self-Report Scale (ASRS).

Results Impulsivity predicted both severity of ADHD symptoms and inattentive and hyperactive/impulsive dimensions, even after controlling the effects of depression and anxiety in linear regression models. Types of negative affect that predicted dimensions of ADHD differed; similar with severity of ADHD symptoms, depression and

trait anxiety also predicted inattentive dimension, whereas trait and state anxiety predicted hyperactive/impulsive dimension.

Conclusion Impulsivity is related with severity of ADHD symptoms and dimensions of ADHD although negative affect that is related with dimensions may differ.

The role of modified states of consciousness in drug use

C. Freitas^{1,*}, A.M. Mendes², S. Queirós¹

¹ Centro Hospitalar do Tâmega e Sousa, Psiquiatria e Saude Mental, Amarante, Portugal

² Centro Respostas Integradas do Porto Central, ET Cedofeita, Porto, Portugal

* Corresponding author.

Modified state of consciousness (MSC) is defined as a mental state that can be subjectively recognized by an individual or by an objective observer of the individual, as representing a difference in the psychological functioning of the "normal" state, alert and awake of the individual. Drugs are products with definitions and conceptual boundaries, historically defined. The use of psychoactive drugs is related to the increased plasticity of human subjectivity which is reflected in various technical means to change the perception, cognition, affect and mood. The authors propose to conduct a literature review on the types of MSC, the way to achieve them and their implications in drug consumption pattern.

A MSC consists of dimensions such as self-oceanic limitlessness, agonizing self-dissolution and visionary restructuring.

Normal MSC includes dreams, hypnagogic state and sleep. Others may be induced by hypnosis, meditation or psychoactive substances. Those achieved by drugs allow the subject to access feelings and sensations which go beyond the everyday reality or, on the other hand, leakage of reality.

Anthropological studies show that in almost all civilizations, man sought ways to induce MSC.

What characterizes the problematic or abusive use of certain substances is not necessarily the amount and frequency of drug use, but the disharmony in the socio-cultural, family and psychosocial contexts of the individual.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV28

Are there more mechanical restraint in patients admitted for substance use disorder?

L. Galindo^{1,*}, M. Grifell², E.J. Pérez², F. Dinamarca², V. Chavarria², P. Salgado², V. Pérez²

¹ Barcelona, Spain

² Instituto de Neuropsiquiatria y Adicciones – Parc de Salut Mar, Psiquiatria, Barcelona, Spain

* Corresponding author.

Introduction and objectives Mechanical restraint is a therapeutic procedure commonly applied in acute units in response to psychomotor agitation. Its frequency is between 21 and 59% of patients admitted. These patients represent a risk to both themselves and for health workers. There is a myth that patients with substance use disorder (SUD) are more aggressive and require more forceful measures. There are not clinical studies that compared if there are differences of the frequency of mechanical restraint in patients with SUD.

The aim of this study is to explore the differences of frequency of mechanical restraint on patients with SUD in the psychiatry acute and dual pathology units and others psychiatric diagnostics.

Material and methods We reviewed retrospectively the informatics record of all the mechanical restraints made and the total discharges of the three acute care units and dual disorders of Neuropsychiatry and Addictions Institute (INAD) of the Parc de Salut Mar de Barcelona, between January 2012 and January 2015. For every discharge the presence of at least one mechanical restraint and the DSM-IV diagnostic were coded. Then was calculated the frequency and proportion of mechanical restraints in every diagnostic group.

Results The number of discharges analyzed was 4659 from which 838 had an episode of mechanical restraint. The 37% of patients with SUD of cocaine had an episode of mechanical restraint. The patients with SUD of alcohol only the 4%, and there no one case on patients with SUD of Cannabis. Thirty percent of patients with schizophrenia and 28% of bipolar disorder.

* Corresponding author.

Introduction Smoking is an addictive and chronic disease. Twenty-four percent of the Spanish population in 2012 smoked daily.

Aims and objectives To evaluate a smoking cessation program in a Primary Care Center.

Methods Observational, prospective study. We describe an individualized smoking cessation in Plaza del Ejército Health Center (Valladolid). Inclusion criteria: active smoker, ≥ 18 years old and belonging to the Health Center. Exclusion: severe mental illness. Included patients from November 2013 until January 2014. Ended in July 2014. Four Medical residents participated, we present the results of one of them. During the first consultation motivational interviewing was conducted, physical examination and treatment was prescribed (cognitive behavioral therapy or drug treatment: varenicline). In subsequent consultations interview and follow-up. Variables: age, gender, pack-years, nicotine dependence (Fagerstrom) and Prochaska and DiClemente phase, weight, treatment used, dropout rate and final withdrawal of snuff.

Results Eleven patients, mean age 48.18 (13.61), 7 (63.6) women. Comorbidity: 6 (54.5) anxious-depressive pathology, 1 (9.1) dysthymia, 2 (18.2) endocrine pathology and 1 (9.1) respiratory disease. Four (36.4) showed high dependency and 2 (18.2) extreme. Media packages 20.50/year (19.20). Seven (63.6) were in action phase of Prochaska and DiClemente and 2 (18.2) in preparation. Visits range: 1-11. The average was 4.55 (3.64). Three (27.27)

patients attended only the first visit. Four (36.4) achieved complete abstinence, 3 (27.27) met maintenance phase. One (9.1) reduced consumption in half. Patients gained average 0.5 kg (2.47).

Conclusions The results are similar to those reported in other series. Modest dropout rate. No pharmacological treatment was used due to high coexistence of comorbidities, the only patient who used varenicline suffered insomnia. Average age and media packages were superior to other series.

Smoking reduction/cessation and psychiatric patients: What about weight control?

I. Ganhao^{1,*}, M. Trigo², A. Paixao², J. Cardoso²

¹ *Qta do Anjo, Portugal*

² *Centro Hospitalar Psiquiatrico de Lisboa, Smoking Reduction/Cessation Program, Lisbon, Portugal*

* *Corresponding author.*

Introduction Smoking cessation has long been associated with weight gain and is one of the many reasons that smokers invoke for not giving up smoking. Many psychiatric medications are also associated with increased weight gain and metabolic syndrome. Unhealthy lifestyles reflect symptoms of illness with poor coping strategies and financial and social difficulties.

There are many reasons why smoking cessation may be viewed as much more difficult for psychiatric patients and weight gain is one of them.

Objective To study how patients' weight evolves during smoking reduction and cessation in a smoking reduction/cessation program in a psychiatric hospital.

Aims To demystify weight gain as a significant problem in smoking reduction and cessation in this patient population.

Methods Every patient entering the smoking reduction/cessation program is evaluated initially with regard to weight and BMI.

Patients' weights are evaluated during the duration of the program for each patient as is smoking status.

Results We are still collecting data at this time.

Conclusions There are three groups of patient according to weight changes during the program: those who gain weight, those who maintain the same weight (± 1 kg) and those who lose weight.

Most patients who gain weight end up recuperating their initial weight or are able to lose weight later.

Some patients had weight control issues and their fear of gaining weight led them to overcompensate leading to weight loss.

We have included interventions on healthy lifestyles that have aided patients in controlling their weight.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Personality dimensions and drug of choice: A descriptive study using Cloninger's temperament and character inventory revised

G. Hurtado^{1,*}, G. Mateu¹, R. Martinez², A. Farre¹, J. Marti¹, R. Sanchez², L. Diaz², M. Campillo¹

¹ *Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions Centre Emili Mira, Santa Coloma Gramenet, Spain*

² *Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions Centre Emili Mira, Barcelona, Spain*

* *Corresponding author.*

Personality dimensions related with drug use are novelty seeking, impulsivity and harm avoidance. Studies predicting drug of choice over personality variables are controversial.

Objective To describe personality profile of drug users in relation to substance of choice.

Aims To know personality dimension differences according to drug used.

Methods Cloninger's TCI-R was administered to 218 patients in a dual diagnosis unit.

SPSS was applied.

Results Of the patients, 33.94% had personality disorder. Principal substances used were alcohol, cocaine and cannabis.

Most of drug users had normal scores in each dimension. No high scores were found in reward dependence, self-directedness and cooperativeness with any drug.

High scores were observed for novelty seeking in 42.9% of timulants users; for arm avoidance in a quarter of cocaine, alcohol and methadone users and for persistence in 18.2% of hypnotics users.

Low scores were observed for reward dependence in 45% of heroine and hypnotics users; for persistence in 50% of methadone and 32% of cocaine users; for self-directedness in most of types of drug users and for cooperativeness in up to 50% in heroine, hypnotics, stimulants and cocaine users.

Statistical significant differences were observed for cocaine use and high novelty seeking and low cooperation; for non cannabis use and high harm avoidance; for non amphetamine use and low scores in reward dependence; for opiate use and low self-directedness.

Conclusions Most of patients had normal scores in the different dimensions.

Presence of comorbid personality disorder led us to consider the results with caution.

* *Corresponding author.*

Introduction Depression, anxiety and panic disorders are often encountered in chronic respiratory disorders, like chronic obstructive pulmonary disease (COPD), especially in severe disease stages with impaired quality of life.

Aim To assess anxiety, depression and panic disorders among patients diagnosed with COPD and to correlate them with respiratory disease severity and quality of life.

Material and method We investigated the profile of anxiety, depression and panic attacks in relation to patients' medical history, demographic data, smoking status, COPD staging and disease severity (estimated by CAT quality of life questionnaire, GOLD guideline staging).

Results A total of 60 COPD patients were enrolled. Smoking profile showed more intensive smoking in men (35.81 mean packs-years versus 24.38 in women). The COPD high-risk group type D was predominant, with severe dyspnea, decreased lung function, frequent exacerbations and low quality of life (mean CAT score:

21.75). Mean distribution of anxiety and depression symptoms among COPD subjects was corresponding to a 10.65 ± 3.54 SD anxiety score, respectively to 9.93 ± 3.80 SD depression score. Panic attacks were found in 43.3% of the patients.

Conclusions Anxiety, depression and panic attacks were frequent findings among severe, unstable COPD patients. More carefully screening for anxiety, depression and panic attacks in this category of patients, thus adding a specific psychotherapeutic component to the COPD general treatment plan, would improve patients' health benefits.

* Corresponding author.

Introduction Baclofen, a drug currently used in the treatment of spasticity, has been reported to be useful in reducing the intensity of withdrawal symptoms of substance use disorders of alcohol or other psychotropic drugs.

Objectives With our clinical case we aim to demonstrate that baclofen reduces severe withdrawal symptoms and also helps to achieve and maintain abstinence in severe cases, in agreement with the current literature.

Aims/methods We present a clinical case of a 68 year-old patient with alcohol use disorder since his childhood, with familiar antecedents, multiples relapses and associated organic pathology such as alcoholic polyneuropathy and Wernicke syndrome. We used to high doses of baclofen to reduce the craving and withdrawal symptoms. Additionally, we searched in PubMed for more case reports and for a systematic review of the efficacy and tolerability of baclofen.

Results We were able to demonstrate that high doses of baclofen can be useful in resistant cases of substance use disorders like alcoholism. For our case study, we obtained positive results with a large remission, in comparison with the previous detoxifications, with doses up to 150 mg/day.

Conclusions We conclude that baclofen is an interesting alternative for resistant cases, with a good outcome and tolerability, in complicated patients, with important organic repercussions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

² Hospital Regional Universitario, Málaga, Spain

* Corresponding author.

Introduction High rates of substance abuse have been reported in the general population and users of mental health services. In

our environment, relationship between substance abuse and manic phase has not been well characterized.

Aims Determining the prevalence of active substance abuse among patients admitted to acute mental health unit at Virgen de la Victoria Hospital at Malaga, diagnosed with mania or hipomanía.

Methods We analysed urine and blood seeking for ethanol, cannabis and other 11 substances in 140 patients previously diagnosed with bipolar disorder prior to their admission at the Hospital for mania or hipomanía phase.

Results Thirty-seven percent of the patients were positive for drugs. Eighteen percent were positive for two or more drugs. Males had higher rates of abuse than females, except in MDMA and amphetamines. By subtypes, cannabis (37.2%) and ethanol (29.62%) were the most consumed drugs. In young age cohorts had higher rates of active substance abuse. Dual patients had longer average stays at hospital (2.6 days more) (Fig. 1).

Conclusions Substance abuse is a major comorbidity in bipolar patients with manic phase. The active consumption of cannabis and ethanol especially emphasizes in men younger than 35 years.

We believe priority should be given to recognition and multidisciplinary approach to substance use disorders in bipolar patients. Bipolar patients with comorbid substance abuse may have a more severe course, and may be a preventable factor of new relapses. This rate could increase healthcare costs and worse quality of life of these patients.

³ University Hospital San Cecilio, University of Granada, CIBERSAM Granada, Psychiatry, Granada, Spain

* Corresponding author.

Introduction Epidemiological studies have reported associations between alcohol consumption or abuse and occurrence of

delusional disorder (F.22) rather than in general population. Alcohol has not been described as the main cause of the delusional idea, but is an enhancer factor which would inhibit behavioral brake and executive function in prefrontal cortex facilitating the development of the existing delusional idea.

Hypothesis We want to confirm this association in our influence area so this study aims to report compared frequency of alcoholism in DD versus a control group published in andalusian population.

Aims To review the literature on the potential links between alcohol abuse and delusional disorder and this relationship in general population.

Results This poster presents a brief but updated systematic literature review on the associations between DD and alcohol abuse. We will also present data from a relatively large case-mix of 2049 patients with the diagnosis of delusional disorder resulting from a thorough retrospective, medical-record based, assessment of patients attended in our clinical catchment area.

In our sample, alcohol abuse and other drugs consumption was significantly less common in Delusional Disorder than in other psychoses.

This result suggests that alcohol and other drugs consumption can be a greater importance parameter in other psychoses correlates than in delusional disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Opiate addiction recovery: New treatment with buprenorphine and naloxone (suboxone) helps bring families together in Bosnia and Herzegovina

M. Hasanovic^{1,*}, I. Pajević², A. Kuldija², A. Sutović², E. Avdibegović²

¹ Tuzla, Bosnia and Herzegovina

² University Clinical Center Tuzla, Department of Psychiatry, Tuzla, Bosnia and Herzegovina

* Corresponding author.

Background The centre for medical prevention of opiate addiction established, as a part of the Tuzla University Clinical Centre's Department of Psychiatry, is a result of several years of cooperation between the Tuzla department of psychiatry and the centre for addiction of the University Hospital in Orebro, Sweden. By working together, the scientists have developed the Tuzla model for opiate addiction in 2009, a first ever project of such kind in Bosnia and Herzegovina.

Objectives To describe principles of organization and results of six years working period with buprenorphine + naloxone program.

Method Authors described principles of organization and results of six years working period of the centre for medical prevention of opiate addiction in Tuzla.

Results Once a patient is admitted to the center, a family member or a close friend signs a statement, committing to ensure that the patient will take the prescribed medicine regularly and always sticks around, from the very first psychiatric interview until the treatment finalization. This program helps create a bond between the addict and another person, which makes it different from other treatment programs which usually tend to isolate addicts in institutions. Another difference is that instead of methadone, patients receive another drug that has shown much better results—buprenorphine + naloxone (Suboxone®).

Currently, the centre has about 160 patients who come for regular treatment and check-ups. Since the centre was established, over 260 patients were successfully treated.

Conclusion The program helps families to rebuild their homes and relationships torn-apart by addictions, through rehabilitation, re-socialization and reintegration.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV37

What impact does a state of alcohol hangover have upon everyday prospective memory and does this differ for men and women?

T. Heffernan

Northumbria University, Psychology, Newcastle upon Tyne, United Kingdom

Introduction The Alcohol Hangover State (AHS) is characterized by range of symptoms (e.g., drowsiness, fatigue, gastro-intestinal problems, dry mouth, nausea, sweating) that remain after ones blood-alcohol level returns to zero following a recent bout of excessive drinking. A recent study found deficits in everyday prospective memory (PM: memory for future plans/actions; such as remembering to meet with friends or to perform a task at a specific time) associated with the AHS.

Objectives Given the importance of PM to everyday living, it is important to attempt to verify these findings.

Aims The present study aimed to provide converging evidence on the impact AHS has upon PM and extend this focus to explore whether any sex differences relating to AHS and PM exist.

Methods Twenty-six AHS participants (13 males/13 females) were compared with 27 non-AHS controls (12 males/15 females) using a between-groups design. All completed a Virtual Reality Prospective Memory Test (VRPMT) was used as an objective test of time-based and event-based PM.

Results The AHS group recalled significantly fewer time-based and event-based PM tasks on VRPMT compared with the non-AHS control group. There was a sex and hangover interaction on time based PM, with the male AHS group recalling significantly fewer items than the female AHS group.

Conclusions These results confirm the deleterious impact of AHS upon PM and further reveal that males who are in an AHS are significantly more impaired in their time-based PM than females in an AHS, a novel addition to the literature.

EV38

The separate and combined effects of drinking and smoking upon everyday prospective memory

T. Heffernan

Northumbria University, Psychology, Newcastle upon Tyne, United Kingdom

Introduction Prospective memory (PM) refers to memory for future plans/actions; such as remembering to meet with friends or to perform a task at a specific time. Independent research has demonstrated that smoking and excessive alcohol consumption produce PM deficits on both self-reported and objective measures of PM.

Objectives No research to date has looked at the combined use of excessive alcohol and tobacco smoking upon PM, which is the focus of this study.

Aims The present study aimed to provide compare a group of excessive drinkers, a group of smokers (not excessively drinking)

and a poly-drug excessive drinking and smoking group, on an objective measure of PM.

Methods A between-subjects design will be used to compare three groups: (1) a group of excessive drinkers who do not smoke; (2) a group of smokers who do not drink excessively and (3) a group of excessive drinkers who also smoke. The Cambridge Prospective Memory Task will measure both time and event based PM; and two self-reports will measure covariates of substance use and everyday mood (since these can impact upon PM independent of smoking/drinking status).

Results Descriptive statistics will be applied to observe the trends across all three groups with regards the covariates and main dependent measures of time and event based PM. A series of ANOVAs will be applied to determine significance across the groups on the covariates and on the main dependent measures.

Conclusions The conclusions and implications will be presented at the conference, along with suggestions for future research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relation between substance of abuse and demographic characteristics, medical and psychiatric history in patients with substance related disorders

S. Herrera^{1,*}, A. Riquelme¹, T. León², M. Babul²

¹ Pontificia Universidad Católica de Chile, School of Medicine, Santiago, Chile

² Pontificia Universidad Católica, School of Medicine, Department of Psychiatry, Santiago, Chile

* Corresponding author.

Introduction Substance related disorders is a problem of global concern because of the high prevalence and costs for patients and society. In one of the latest surveys, 52% of the American population reported being current alcohol drinkers and 6.3% admitted being heavy drinkers. In addition, 9.4% are illicit drug users, being marijuana the most commonly used.

Objectives To determine whether there is a relation between the substance of abuse and the demographic characteristics, medical and psychiatric comorbidities of patients with substance use disorder.

Patients and methods This correlational study examined data of 218 patients with substance use disorder (DSM-5), that consulted at the Addiction Unit of "Red de Salud, Pontificia Universidad Católica de Chile", between April 2012 and September 2015. Data included: demographics, medical and psychiatric history, laboratory and imaging tests.

Results Out of all the patients, 57% suffered from alcohol use disorder, whereas 21% abused of marijuana, 20% of cocaine and 8% of benzodiazepines. There was a correlation between alcohol use disorder and being over 40 years of age, being separated and having higher educational studies. For marijuana, being under 40 years of age, being single and having no medical comorbidities. For cocaine, not being single. For benzodiazepines, being over 40 years of age, being separated and having medical comorbidities. All of these correlations were statistically significant.

Conclusion These results emphasize on the complexity of these patients and on the important contrast created between age, marital status, level of education and prevalence of comorbidity depending on the abused substance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Demographic characteristics, medical and psychiatric history of patients with prescription opioid use disorder

S. Herrera^{1,*}, A. Riquelme¹, T. León², M. Babul²

¹ Pontificia Universidad Católica, School of Medicine, Santiago, Chile

² Pontificia Universidad Católica, School of Medicine, Department of Psychiatry, Santiago, Chile

* Corresponding author.

Introduction Over the past two decades the prescription of opioid analgesics has increased with a subsequent escalating in prescription opioid misuse. It is estimated that 4.5 million (2.5%) of the United States of America population abuse of pain relievers; opioids are among the most commonly.

In Chile there are few reports about the prevalence of opioid use disorder.

Objectives The aim of this study is to describe the demographic characteristics, medical and psychiatric comorbidity of patients that suffer from opioid addiction.

Patients and methods This transversal study examined data of 7 patients with opioid use disorder (OUD; DSM-5) that consulted at the addiction unit of "Red de Salud, Pontificia Universidad Católica de Chile", between November 2013 and October 2015. Data included: demographics, medical and psychiatric history, laboratory and imaging tests.

Results Of all the patients, 57% were men, 25 to 67 years of age, 43% between 35-40 years; 57% were married; 57% had completed studies at university. 43% had also alcohol use disorder, 28% marijuana, 28% cocaine and 28% benzodiazepines than in most cases began before OUD. In addition; 57% had medical comorbidity among which stand out obesity (17%), osteoarthritis (17%) and chronic low back pain (17%). Eighty-three percent require hospitalization. Twenty-eight percent had abnormal liver tests and one patient had positive hepatitis B core antibody. Opioids used were: morphine(14%), codeine (43%), tramadol (42%).

Conclusion These results emphasize on the misuse of prescription opioids analgesics, the complexity of patients with OUD and the prevalence of other substance use disorder that precedes and accompany OUD.

Predictors of quality of life in opiate-dependent individuals undergoing methadone maintenance treatment

C. Hornillos*, M. Crespo

Universidad Complutense de Madrid – School of Psychology,

Personalidad – Evaluación y Tratamientos Psicológicos I

Personalidad – Evaluación y Psicología Clínica, Pozuelo de Alarcón, Spain

* Corresponding author.

Introduction Quality of Life (QoL) is an important outcome variable in Methadone Maintenance Treatment (MMT) for opiate dependence. Previous research has focused on demographic variables, treatment features, drug use and physical and mental health as possible predictors of QoL in this condition but interest in genuinely psychological variables (skills and personal repertoires) has been lacking. Experiential Avoidance (EA), the tendency to behave in order to decrease some kind of internal distress, has a strong relationship to psychological disorders and holds promise as a potential predictor of QoL.

Objectives To identify predictors of QoL in clients undergoing MMT, taking into account psychological variables.

Aims To see if EA is related to QoL in clients undergoing MMT.

Methods Using a cross-sectional design, information was gathered from 48 opiate-dependent individuals undergoing MMT. Variables included were QoL (IDUQOL), severity of drug use, social adjustment and physical and mental health (ASI-6), emotional distress (HAD) and EA (AAQ and its version for substance-abusing individuals, AAQ-SA). Mean-comparison tests and correlation tests were carried out, and several variables were entered into a stepwise multiple regression analysis.

Results Anxiety and EA were the only variables which made it into the regression model, accounting for 41.9% of variance of QoL.

Conclusions Contrary to previous research, the predictors of QoL were psychological. It is the first time that EA is related to QoL in this population. Interventions should explicitly target EA and anxiety. Additional research should make use of longitudinal designs and take into account further psychological variables (emotion regulation, coping).

The relationship between previous trauma and alcohol and substance misuse in women

M. Husain^{1,*}, K. Moosa², K. Khan³

¹ Manchester, United Kingdom

² Leicester Medical School, Medical School, Leicester, United Kingdom

³ University of Liverpool, School of Psychology, Liverpool, United Kingdom

* Corresponding author.

Introduction The association between previous trauma and the development of alcohol and substance misuse is well established, however, much of the research is focused on the association of PTSD with alcohol and substance misuse. This research will be focussing on trauma in general and its influence on the development of alcohol and substance misuse in women.

Objectives The main objective of this study was to investigate the relationship between previous traumatic events and the development of alcohol and substance misuse in women.

Methods This was a retrospective case note study of 146 female patients from a UK based detoxification and rehabilitation centre. Trauma history from patient files were audited, with the trauma experienced being assigned a category.

Results Out of 146 women with alcohol and/or substance misuse, 132 (90%) had experienced a previous trauma. The types of trauma experienced include; domestic (53%), traumatic grief (36%), sexual abuse (35%), physical (15%), bullying (4%) and neglect (4%). These results show that women who suffer from alcohol/substance misuse are highly likely to have suffered a previous trauma.

Conclusions The results from this study suggest that women who have suffered previous trauma are high risk for alcohol and substance misuse problems, therefore early intervention and a robust psychological support system should be provided to women who have a history of trauma. Furthermore in addition to addiction treatment and behaviour focused therapy already in place trauma focussed therapy may prove beneficial.

Dynamics of psychopathological symptomatology at patients with opiate addiction in the process of complex rehabilitation

S. Igunnov^{1,*}, E. Stanko²

¹ Institute of Management and Social Technologies of Belarusian State University, Social Work and Rehabilitology, Minsk, Belarus

² Grodno State Medical University, Psychiatry, Grodno, Belarus

* Corresponding author.

The aim of the work was to study the structure and dynamics of psychopathological symptoms among HIV-positive and HIV-negative patients with opiate addiction.

Material and methods The survey was attended by 820 patients. We studied the parameters of the main psychopathological symptoms using a questionnaire SCL-90-R in the dynamics. The structure of psychopathology in patients with opiate addiction is presented. The changes psychopathological indicators of the state of the examined patients before and after complex rehabilitation, after 1, 3, 6 and 12 months from the start of observation are given.

Results The findings suggest the presence of more severe psychopathology HIV-positive patients than HIV-negative patients with opiate addiction. It was found that the quantity indicators SCL-90-R in the examined patients, despite the positive trend at discharge significantly higher than in healthy individuals.

Conclusion The results of the study indicate a lack of short-stage therapy to normalize the mental state of opiate addiction and the need to develop an algorithm of a long, corrected with the needs of patients, comprehensive rehabilitation programs.

Torsades-de-Pointes Predisposing Risk Factors (TdPPRFs) in a cohort of patients maintained on high dose methadone – a clinical safety caseload analysis

R. Iosub^{1,*}, S. Hawkins², C. McCarville², H. Kennedy², K. Williams¹, B. Watson¹

¹ Avon and Wiltshire Mental Health Partnership NHS Trust, Bristol Specialist Drug & Alcohol Service, Bristol, United Kingdom

² University of Bristol, School of Physiology & Pharmacology, Bristol, United Kingdom

* Corresponding author.

Introduction Methadone, a long-acting opioid agonist commonly used in the treatment of opiate dependence, has been reported to cause QTc interval prolongation, increasing the risk of a fatal cardiac arrhythmia – Torsades-de-Pointes (TdP). This effect seems to be attributable to methadone's inhibitory effect on the cardiac "hERG"-K⁺ ion channel and is dose-dependent. There is a lack of consensus regarding when to perform an ECG for patients on methadone.

Objectives Identifying other TdPPRFs in a cohort of patients receiving ≥ 85 mg (high dose) methadone daily to inform local clinical safety guidelines.

Methods Our outpatient caseload was filtered to select opiate-dependent patients receiving more than 85 mg methadone daily. Primary care summaries and laboratory results databases were analysed for the presence of other TdPPRFs: female sex a documented history of ECG abnormalities, electrolyte imbalance, liver

or renal failure, and concomitant use of other QT prolonging medication or stimulants.

Results Fourteen opiate-dependent patients (10.29% of patients on methadone) were maintained on ≥ 85 mg methadone daily. Gender distribution was F:M = 1:1.8; 64% misused illicit stimulants; 57% were prescribed other QTc prolonging medication and 29% had a documented history of liver/renal failure or electrolyte imbalance. Only 14% had previous ECGs documented in primary care summaries. Of patients on high dose methadone, 85.7% had at least one TdPPRFs present and 64.3% had at least two.

Conclusions These results demonstrate an increased rate of TdPPRFs in this patient group and highlight the importance of ECG monitoring which ideally should be offered to patients receiving even lower doses of methadone.

* Corresponding author.

Introduction Substance abuse is a widespread phenomenon in Tunisia. However, although the principles of prevention and addiction treatment are accepted in Tunisia, the laws of our country remains sketchy and marked by the traditional punitive approach to drug users.

Aims Assess knowledge of methadone, opioid substitution therapy, among Tunisian psychiatrists.

Methods This is a descriptive cross-sectional study that included psychiatrists in the public sector, liberal sector or in training courses. These doctors completed a self-administered questionnaire posted on the website of the Tunisian Society of Psychiatry and the Association of Tunisian residents and young psychiatrists. The survey includes 18 items. The questions were grouped under three main headings:

- sociodemographic data;
- general knowledge of methadone;
- methadone and its place in their daily practice.

Results The participation rate was 15% ($n = 35$).

The average participant age was 32.13 years.

Psychiatry residents were the most represented grade 94%.

Twenty-eight percent of participants had training in addiction ($n = 10$)

Eighty-five percent have heard about methadone.

Conclusion Given the importance of the scourge of drug abuse including opioids, political circles have expressed the desire to improve the Tunisian legislation on substitution treatment. Nevertheless, others projects more directly related to “Arab Spring” are government priorities.

* Corresponding author.

Comorbidity of borderline personality disorder (BPD) and Bipolar disorder (BD) has frequently been seen in psychiatry. Some authors consider them separate psychiatric diagnoses appears in the same patient as comorbidity; some others consider affective oscillations a part of BPD diagnosis. Often in mentioned patients secondary appears different kind of addictions, mostly drug addiction, but also alcohol addiction (AA).

In this study we going to present 2 case reports of patients with all 3 diagnoses: AA, BPD and BD. First, female patient, 40 years of age, about 10 years in psychiatric treatment, with primarily diagnosed AA, and secondary diagnosed BPD and BD in development. She had marital problems for many years, now in phase of divorcing, and several suicide attempts. Second, male patient, 30 years of age, working as nurse, not married, living with parents, more than 5 years in psychiatric treatment. Primarily diagnosed as AA than BD and BPD and suspect, but undiagnosed gambling. Both were treated several times in Department of Addictions at Psychiatric Hospital Rab in Croatia. Both were also only in partialy, not continued psychotherapeutic treatment during years of psychiatric treatment. Still now, both were alcohol addicted.

In conclusion, we realized that both of them were primarily comorbidity of BPD and BD with secondary developed alcohol addiction. Without continued, long-term, systematic psychotherapeutic and family treatment completed with psychopharmacological treatment of BD, we could not expect successful treatment of alcohol addiction.

Gamma-hydroxybutyrate (GHB) withdrawal syndrome: First case report in Lithuania (Kaunas addiction treatment center)

K. Jucys^{1,*}, A. Leleikiene², D. Jokuboonis²

¹ Birstonas, Lithuania

² LSMUL, Psychiatric, Kaunas, Lithuania

* Corresponding author.

Gamma-hydroxybutyrate (GHB) is a γ -aminobutyric acid (GABA) precursor and metabolite that naturally occurs in the human body. Initially, GHB was used as an anaesthetic agent but was later also found to have anabolic, hypnotic, antidepressant, anxiolytic as well as cholesterol lowering effects. Recently though, research into GHB has been carried out primarily in assessing its effectiveness in treating alcohol and opioid withdrawal syndrome. There are no epidemiological data about GHB consumption in Lithuania, however during last decade there were observed many fatal cases of GHB users due to GHB intoxication or withdrawal abroad. In this article we will present the clinical case and problems which face the patient of 2-year daily GHB consumption. There were observed mild to moderate abstinence state presented with its clinical course and peculiarities. Whereas using GHB is becoming more popular in Lithuania, it is very important to pay attention to this substance and problems related to its usage.

Tashkent medical academy, Psychiatry and Narcology, Tashkent, Uzbekistan

* Corresponding author.

To study the characteristics of medical and rehabilitation care for patients with opioid dependence we have investigated 50 patients. All patients on long-term use of opioids were divided into 2 groups. The duration of drug abuse in group 1 ranged from 4 months up to 5 years. In the second group, the duration of dependence was more than 5 years. Patients in the second group of somatic-neurological symptoms were having somatic disorders and organic brain damage. Systematic observation in drug treatment clinics at the place of and maintenance treatment of at least one year was achieved in 8.48% of patients of group 1 and 3.85% of the second group. Consequently, the role of the therapeutic factor in trying to achieve regression syndrome pathological attraction in early stages of the disease, we recognize more productive. Patients of the second group with a large weighting of disease duration was noted clinical abstinence syndrome both by somatic and neurological disorders, as well as by more severe anxiety, dysphoric disorders. These disorders require the inclusion in the scheme of treatment techniques aimed at more effective detoxification and immune reactivity of the organism. Patients of the second group was added to the treatment nootropics and immunomodulators. Analysis of the results of treatment in patients with drug addiction with different disease duration showed significant differences in the effectiveness. In the second group with a duration of more than 5 years of addiction, it is advisable to the treatment nootropics, immunomodulators.

¹ Kharkiv National Medical University, Psychiatry- Narcology and Medical Psychology, Kharkov, Ukraine

² Kharkiv Medical Academy of Postgraduate Education, Medical Psychology and Sexology, Kharkiv, Ukraine

* Corresponding author.

Introduction The current situation in Ukraine is characterized by multitude social-stress factors, resulting in an increase in alcohol consumption and alcohol addiction, which arises as a mechanism to compensate the adverse mental stress and different variant of chronic stress disorder.

Objective Substantiate the neurobiological basis of mutual influence of stress burden and alcohol addiction.

Aim To study the biochemical mechanisms that underlie the vicious circle of stress and alcohol addiction.

Methods Studies the features of hypothalamic-pituitary-adrenal (HPA) axis under stress and alcohol available in Medline, Institute for Scientific Information Databases (Science citation index expanded and Social sciences citation index), EMBASE, and Cochrane Library were identified and reviewed.

Results Alcohol, just like stress, affects the HPA axis, changing the reaction of its parts and, by reducing the production of

cortisol, which produces in response to stress and prolongs subjective experiences of nervous tension caused by stress. Stress, through the output of cortisol, reduces the effect of alcohol leads to a desire to further alcohol abuse. The system includes elements of the extended amygdala, which have as reinforcement and stress reactivity. Central nucleus amygdala plays a leading role in the reinforcing effects of pharmacological agents with narcogene potential and performs persuasive role in the activation of hypothalamic reinforcement mechanisms. This allows us to consider neurohormonal system, including the amygdala, hypothalamus, pituitary and adrenal glands as structural and functional basis of formation depending on various narcogene, primarily alcohol.

Conclusions Dysregulation of the HPA axis is a neurobiological basis of mutual influence of stress burden and alcohol addiction.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction The potential adverse consequences, personal distress, shame and guilt presented by patients who suffer from codependency require a more in-depth understanding of the phenomenology of this disorder.

Objective To determine targets of psychotherapy work with the codependency wives of men with alcohol dependence (AD).

Aim To determine the features of clinical manifestations of codependency as a model of health disorders associated with stress.

Methods Integrated clinical-psychopathological and psychodiagnostic research, using anxiety and depression scales M. Hamilton, scale of psychosocial stress L. Reeder and methods for determining stress and social adaptation of Holmes and Rahe.

Results One hundred and sixty wives of men with AD, depending on the type of AD (TF Babor's classification), were divided into two groups: group A, 80 patients with AD type A and 80 their wives, and group B, 80 men with AD by type B TF Babor, and 80 wives. Comparison group consisted of 50 married women whose husbands are not suffering from AD.

All the wives of men with AD distortions emotional state of the prevalence of pathological manifestations of depression and anxiety clinically delineated levels and high levels of psychosocial stress and low stress, unlike women men without alcohol problems. It was found that the more severe psychopathological manifestations occurring in the wives of men with a family history, burdened alcohol and drug abuse (group B).

Conclusions Available data suggest that a single mechanism of family experiences a stressful situation, we were put in the basis for developing a comprehensive treatment measures and psychotherapeutic support codependent wives patients with AD.

Introduction Use of the Internet lately has significantly been increased worldwide. The time users spend browsing the Internet is constantly increased resulting to serious consequences incurred in personal, professional and social life.

Aim The purpose was to explore whether the economic crisis is affecting the use and addiction to Internet, whether the economic crisis is a risk factor in the appearance of addiction to the Internet and if the occupation and the existence of extra-curricular activities act as barriers to the development of addiction to the Internet on students.

Methods A questionnaire was prepared based on the diagnostic tool IAT (Internet Addiction Test). The survey was conducted in June of 2014 on 632 students.

Result It was found that 6.2% of the sample population has moderately addictive behavior and 0.5% has a serious addiction. Addiction levels to the Internet are affected by someone working while studying and his monthly income, by daily time spent by the student in activities besides school, by the time spent daily on the Internet and by the operations mostly used. Also found that the risk of developing Internet addiction is higher among students who said they had difficulty paying their bills and Internet subscription and to those who due to economic crisis would stop all their activities in order to obtain money.

Conclusions The economic crisis is a factor that affects on Internet addiction and occupation and activities may act as a deterrent to the emergence of the phenomenon.

* Corresponding author.

Purpose To identify the personal and social everyday life consequences of patients with substance use disorder (SUD) with co-occurring attention deficit/hyperactivity disorder (ADHD) or autism spectrum disorder (ASD).

Design and methods A qualitative phenomenological study using in-depth interviews guided by a set of topics regarding the consequences of illness for everyday life.

Findings The personal and social everyday life consequences of patients with SUD with co-occurring ADHD or ASD were narrowed down to three themes; Jumble of Emotions and Thoughts, Substance Use and Structure. It can be concluded that the underlying mechanisms may be different for each group (impulsivity vs. passivity), but both groups describe the consequences of their illness for everyday life as being caught up in a vicious circle.

Practice implications This study provides insight in the meaning of SUD in the lives of patients with ADHD and ASD. It not only shows that SUD has meaning, but also shows how it functions and why it functions. The study also provides insight in what clinicians could do to break this vicious circle across lifespan.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Internet-use related addiction: The state of the art of clinical research

D. Kuss^{1,*}, O. Lopez-Fernandez²

¹ Nottingham Trent University, International Gaming Research Unit, Nottingham, United Kingdom

² Université Catholique de Louvain, Psychological Sciences Research Institute, Louvain-la-Neuve, Belgium

* Corresponding author.

Introduction In 2013, the American Psychiatric Association included Internet Gaming Disorder in the appendix of the 5th edition of the DSM-5, suggesting more research is necessary for the condition to be officially accepted as mental disorder. Criticisms have emerged as to the viability, validity and reliability of the proposed condition, and researchers have pointed out that the subsuming of Internet addiction under the umbrella term of Internet Gaming Disorder (as is the case in the DSM-5) is highly problematic.

Objectives and aims The objective of this talk is to provide a comprehensive and inclusive analysis of clinical research of Internet-use related addictions from a holistic perspective, given the ambiguity of previous research in the field.

Methods A systematic literature review was conducted using the database Web of Science, and a total of 44 empirical and clinically relevant studies were identified.

Results Results indicated that the published clinical research studies can be categorized into four areas, including (i) treatment seeker characteristics, (ii) psychopharmacotherapy, (iii), psychological therapy, and (iv) combined treatment, each of which will be discussed.

Conclusions At the present day, both diagnosis and research of Internet-use disorders appears rather broad. Furthermore, there appears a need for developing a gold standard of clinical assessment. This will support the establishment of efficacious and effective treatments which need to be tailored to the individual help seekers' needs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Regional Psychiatry, Randers, Denmark

* Corresponding author.

Introduction Physical comorbidities are common in patients with concurrent mental illness and substance use disorder. Interventional studies addressing health promotion for this group of patients are scarce.

Aims To examine the physical health condition of a non-selected group of patients with substance use disorder comorbid to other psychiatric disorders. Further, to analyze for possible changes in their health condition during a two-year intervention study in relation to physical measures and substance use. Finally, to analyze for possible associations between changes in physical measures and in substance use.

Methods The patients were enrolled in the project continuously from October 2013 through May 2015. Physical health measures were obtained at the enrolment date and continuously as part of daily clinical practice. Interventions consisted of individual consultations with a research nurse, group sessions and an opportunity to do physical exercise together with the research nurse. Interventions included health promotion activities, i.e. guidance on healthy food intake, smoking cessation and a physically active life.

Results In total, 64 patients (mean age 32.7 years, SD 10.7) were included in the study. Patients were mostly diagnosed with psychotic disorders (11%), affective disorders (44%) or developmental disorders (34%). Baseline measures showed that 89% of the patients smoked cigarettes daily, 61% had used cannabis and 20% had used amphetamines within the past month. Further, few patients did moderate or vigorous physical exercise. Further results are in progress.

Conclusions These interventions seem relevant and manageable in an outpatient setting.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Delusional symptoms with alcohol

L. Montes Reula^{1,*}, A. Ballesteros Prados²

¹ Instituto Salud Mental Gobierno Navarra, CHN Psychiatric, Pamplona, Spain

² Red Salud Mental Gobierno de Navarra, Mental health center, Estella, Navarra, Spain

* Corresponding author.

A patient is twenty-eight years old who comes to the emergency services because he has visual hallucinations related to alcohol consumption. He only consumes alcohol sporadically in leisure time. Since he began drinking at 18 years he has presented these symptoms in only four occasions. He does not relate with a more quantity of alcohol or another stressors. After a few minutes, these symptoms disappear and so he criticizes.

It is about of study through a clinical case the alcoholic hallucinosis, their characteristics and to see the differences in the patient. The patient in the acute phase presents a view of reality altered that later he recovers. There is no loss of consciousness or behavioral disorders. There are similarities with a pathological intoxication but there is not a regular relationship between consumption and symptoms.

Do medical students use cognitive enhancers to study? Prevalence and correlates from lithuanian medical students sample

A. Lengvenytė^{1,*}, R. Strumila²

¹ Lithuanian University of Health Sciences, Faculty of Medicine, Kaunas, Lithuania

² Vilnius University, Faculty of Medicine, Vilnius, Lithuania

* Corresponding author.

Introduction Use of prescription psychostimulants and nootropics for non-medical purpose is a growing trend, especially in academic environment. Seeing the risks of neuroenhancement we decided to investigate situation in Lithuania.

Objective Analyze the use of cognitive enhancers among medical students in Lithuania.

Aims 1. Determine the prevalence of cognitive enhancement. 2. Figure out what drugs are mostly used and reasons for the usage. 3. Evaluate the contributing factors.

Methods A cross-sectional survey study was performed in Vilnius University and Lithuanian University of Health Sciences. Students were asked to fill anonymous paper questionnaires consisting of 13 items concerning prevalence of substance use to enhance cognitive performance, reasons, and correlates during lecture time.

Results Results are summarized in Table 1. A total of 8.1% of responders indicated that they had used cognitive enhancers. Nootropics were the most frequently mentioned: 59.6%, while psychostimulants were mentioned less frequently: 38.3% (including modafinil, methylphenidate and amphetamine derived drugs), and 23.4% indicated other substances. Improvement of concentration and increased studying time were predominant purposes (55.3% and 48.9% of users). Male students reported 3 times higher prevalence rates than females (14.6% vs. 5.1%, $P < 0.05$). Prevalence were also higher in students, who knew someone using these substances as compared to those who did not (17.3% vs. 5.1%, $P < 0.05$); it was the most associated factor with cognitive-enhancing drug taking behavior (Table 1).

Conclusions In Lithuania, 1 of 12 medical students admits to having used neuroenhancing drugs. Nootropics were the most used drugs. Knowing user was the most important factor for usage.

Table 1 Main findings of this study.

	%	N
Students who indicated that they had used cognitive enhancers	8.1	47 (of 579)
Gender differences:		
Male	17.1	27 (of 185)
Female	5.4	20 (of 394)
Most used drugs:		
Nootropics	59.6	28 (of 47)
	%	p value, standardized coefficient
Factors which had the greatest influence on consuming drugs:		
Knowing someone who had used	17.3	<0.0001, 0.0395
Gender	17.1	<0.0001, 0.0388
Most important reasons for use:		
Improve concentration	55.3	<0.031, 0.2397

Exercise addicts with injuries are in risk of depression

M. Lichtenstein^{1,*}, K. Andersen², U. Jørgensen³

¹ Department of Psychology, University of Southern Denmark, Odense C, Denmark

² Research Unit of Clinical Alcohol Research, University of Southern Denmark, Odense, Denmark

³ Orthopaedic Department, Odense University Hospital, Odense, Denmark

* Corresponding author.

Introduction Exercise addiction is characterized by increasing exercise amounts, withdrawal symptoms and lack of control. Exercisers with addiction continue to exercise in spite of pain and injury because they use exercise to regulate emotions, identity and self-esteem. How do they react to injuries?

Objectives It is hypothesized that exercise addiction is a risk factor for emotional distress when an injury occur due to withdrawal symptoms and lack of identity.

Aims To estimate the prevalence of exercise addiction in exercisers with injuries at the musculoskeletal system and to test the relationship between addiction and emotional distress (depression and stress).

Methods The Exercise Addiction Inventory was used to identify exercise addiction. To measure depression and stress we used the Major Depression Inventory (MDI) and the Perceived Stress Scale (PSS). Participants ($n = 694$) were regular exercisers with injuries at foot, knee or shoulder at an orthopedic hospital department.

Results The prevalence of exercise addiction was 7.6%. We found that exercisers with addiction reported more emotional distress in terms of higher MDI-scores 18.0 (SD = 11.0) versus 11.7 (SD = 9.1); $P = 0.00$ and in total PSS-score 17.6 (SD = 7.2) versus 13.9 (SD = 6.8); $P = 0.00$. Chi² analyses showed that 25% of the addicted exercisers met the criteria for clinical depression, while only 11% of the non-addicted exercisers were depressed; $P = 0.00$.

Conclusions Exercisers with addiction appear at somatic departments treating musculoskeletal injuries. It is a vulnerable group characterized by elevated levels of depressive symptoms and clinical stress. We recommend to offer psychological interventions focusing on emotional distress and prevention of re-injury by reducing excessive and obsessive exercise patterns.

Qualitative study of patients with dual pathology in treatment with aripiprazole extended-release injectable suspension

L. Fernández Mayo*, D. Baño Rodrigo, E. Barbero García, M. Agujetas Rodríguez

CAID Majadahonda, Center for Attention to drug addicts, Majadahonda, Madrid, Spain

* Corresponding author.

Introduction Studies describe patients with dual pathology as subjects with worse clinical evolution and worse therapeutic response. These subjects have high percentages of worse therapeutic compliance and low adherence to psychopharmacological treatment. The conventional antipsychotics can induce dysphoria and worse craving and drug use. The long duration-injectable antipsychotics could serve as a good therapeutic alternative because they combine efficacy and tolerability.

Objectives We analyzed subjects treated with aripiprazole injectable to demonstrate its effectiveness on symptomatology, the reduction of craving and consumption of substances.

Materials and methods We studied subjects with dual disorders at a Center for Attention to drug addicts treated with aripiprazole extended-release injectable. All of them met criteria for the diagnosis of disorders for cannabis and cocaine use. All of them had been previously treated with oral antipsychotics and/or injectable

of long duration. Evolution of craving and consumption were evaluated through clinical interviews and urine analysis.

Results Cannabis was the main substance for all the patients. Three of them also often abused of cocaine. All of them were taking other treatments previously. The main causes of the change were: side effects and/or poor compliance. Only one patient discontinued follow-up. The rest of them showed good therapeutic adherence and better tolerability with aripiprazole injectable. The monthly dose was 400 mg.

Conclusions Aripiprazole extended-release injectable is a good choice for dual disorders. A good therapeutic adherence involves not only a psychopathological improvement but also respect to craving and consumption, which makes aripiprazole injectable a suitable therapeutic option.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Nalmefene and alcohol use disorder. Evaluation of clinical cases at a treatment centre for drug addicts

L. Fernández Mayo*, D. Baño Rodrigo, E. Barbero García, M. Agujetas Rodríguez

CAID Majadahonda, Treatment Centre for Drug Addicts, Majadahonda, Madrid, Spain

* Corresponding author.

Introduction Alcohol abuse causes dopamine release in the mesolimbic system, which activates the reward circuit. This is linked to an interdependent opioid, serotonergic and endocannabinoid system. Nalmefene is a modulator of the endogenous opioid system, with antagonistic effect on mu and delta receptors, and a partial agonist activity kappa. This means that reduces the reinforcing effects of alcohol consumption through the cortical-mesolimbic system. Therefore, when a patient takes nalmefene, the satisfaction obtained when he drinks is lower, which increases the possibility to have more control over drinking.

The efficacy of nalmefene was evaluated in two profiles of patients: 1. No abstinence in alcohol dependence disorder and continuous relapses, 2. Cocaine dependence disorder associated to alcohol abuse.

Objectives Improving the quality of life and compliance rates due to the difficulties of following a strict treatment to achieve the abstinence. Furthermore, in cases of patients with cocaine dependence disorder and alcohol abuse, the objective is to avoid cocaine use by reducing previous alcohol consumption.

Conclusion nalmefene offers the possibility of treating the addiction from a new perspective. Our current clinical experience has been able to treat subjects with conventional treatments failures and those who need to achieve the necessary control to reduce cocaine use.

Aripiprazole oral treatment in a sample of patients with dual diagnosis

C. Llanes Álvarez^{1,*}, A. San Román Uría¹, A. Caldero Alonso¹, M.Á. Garzón de Paz², M.Á. Franco Martín¹

¹ Complejo Asistencial de Zamora, Psiquiatría, Zamora, Spain

² Hospital Los Montalvos. Unidad Regional de Patología Dual,

Hospital Universitario de Salamanca, Psiquiatría, Salamanca, Spain

* Corresponding author.

Introduction Aripiprazole is the firstborn of the new dynasty of antipsychotic called third generation or neuromodulator of dopamine-serotonin system. It has proven to be an effective and well-tolerated antipsychotic. Dual Pathology represents the presence of comorbidity between mental illness and substance use disorders. It is an under-diagnosed problem and it is increasing frequency.

Objectives The aim of this study was to determine and describe the clinical profile of the patients admitted to the Dual Pathology Unit (UPD) at The Montalvos Hospital (Part of Salamanca University Teaching Hospital, Spain) treated with oral Aripiprazole.

Methods Descriptive, observational, retrospective study of a sample of patients admitted to the UPD to which oral aripiprazole was prescribed during hospitalization. A number of sociodemographic, clinical, and treatment-related variables are described.

Results From a sample of 25 patients and according to DSM-5 criteria (APA, 2013) main diagnoses were: 14 cases of substance-induced psychotic disorder, 3 cases of schizophrenia; 3 cases of schizoaffective disorder; 2 cases of bipolar disorder; 1 case of schizophreniform disorder; 1 case of borderline personality disorder; 1 case of personality syndrome. The most used drugs before the admittance were cocaine, cannabis and opioids. The average dose of aripiprazole was 9 mg and no side effects or drug interactions were reported.

Conclusions Apart from its well known efficacy in treatment of psychosis, oral aripiprazole may be a first line treatment for Dual diagnosis patients, specially those with problems of non-compliance, due to high level prolactin side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV61

Personality disorders: Which personality features lead to a comorbid substance use disorder?

A. Lombardi*, A. Rossi, C. Gramaglia, L. Girardi, P. Zeppego
Università del Piemonte Orientale, Traslatonal Medicine, Novara, Italy

* Corresponding author.

Introduction Dual Diagnosis (DD) refers to coexistence of a psychiatric disorder, which is often a Personality Disorder (PD), and a Substance Use Disorder (SUD). Despite DD is a topic of interest in recent years, few studies have focused on the temperament and character traits of PD patients with or without a comorbid SUD. Anyhow, the assessment of personality traits may be helpful to understand the relation among psychiatric disorder, drug use and environment in patients with addictive behaviors.

Aims The aim of this study is to compare two subgroups of PD patients, with and without a comorbid SUD. Sociodemographic, clinical and personality profile, as assessed with the Temperament and Character Inventory, will be compared.

Methods We are recruiting patients with a PD diagnosis referring either the psychiatry ward or outpatient service of the AOU "Maggiore della Carità", Novara, Italy; secondly, we will group them according to the presence/absence of SUD. Cloninger's TCI-R will be administered together with a structured interview to gather sociodemographic and clinical information.

Results Data collection is ongoing; we expect to find a different personality profile in PD and DD Patients.

Conclusions Temperament, which is the biological part of the personality, seems to have an important role in addictive behavior; therefore assessing the personality traits of DD patients can help to improve the differential diagnosis and to establish strategies for treatment and prevention. In particular, sensation seeking and impulsivity are temperamental characteristics that may favor SUD in patients with psychiatric disorders.

Video game addiction: Providing evidence for Internet gaming disorder through a systematic review of clinical studies

O. Lopez-Fernandez^{1,*}, D. Kuss², H. Pontes², M. Griffiths²

¹ IPSY, PSP, Louvain-la-neuve, Belgium

² IGRU, Division of Psychology, Nottingham, United Kingdom

* Corresponding author.

Introduction The American Psychiatric Association introduced in Internet Gaming Disorder (IGD) in the appendix as a tentative disorder in the last edition of the Diagnostic and Statistical Manual of Mental Disorders. However, currently no systematic review exists about excessive gaming viewed from a clinical perspective.

Objectives and aims To review clinical studies on gaming addiction in order to ascertain characteristics of both clinical and research studies to provide retrospective evidence in relation with the proposed IGD classification (including criteria, measures and therapies).

Methods A systematic literature review of studies published from 1980 to 2015 has been conducted using three major psychology databases: Academic Search Complete, PsycInfo, and PsycArticles. A total of 5033 results from peer-reviewed journals were obtained, where 32 were identified as empirical clinical papers focused on gaming addiction.

Results The clinical research studies on gaming identified were published between 1998 and 2015, most of which included patient samples. Categorizations identified in the research papers included: (i) patients' characteristics (e.g., socio-demographics), (ii) criteria and measures used (e.g., scales to diagnose), (iii) types of gaming problems (e.g., game genre), (iv) and treatments (e.g., type of therapy).

Conclusions Findings will be discussed against the background of the controversial IGD diagnostic criteria proposed in the DSM-5 in order to assess the extent to which previously published clinical knowledge matched the current proposal for including gaming addiction as behavioral addiction in the next diagnostic manual.

Cannabinoid hyperemesis syndrome

S. López-Romeo*, G. Ledesma-Iparraguirre
Parc Sanitari Sant Joan de Déu, Psychiatry, Barcelona, Spain

* Corresponding author.

Case report A 25-year-old man was attended in multiple times at Emergency Department by referring abdominal pain and vomiting. No organic disease was found and he was referred to Psychiatric Emergency to assess him. He had history of cannabis use (4–5 times/day) during last 5 years. He referred recurrent episodes of abdominal pain and vomiting since 4 years ago, he had found that having hot showers alleviate his symptoms. Urine screening was positive for THC and negative for other drugs. In results of blood tests, abdominal X-ray, abdominal ultrasonography, abdominal tomography and fibrogastroscopy didn't find any abnormality. He was diagnosed from suffering a somatoform disorder. Treatment with Setraline 50 mg/day was prescribed and cannabis abstinence was recommended. He was referred to Mental Health outpatient service. He maintained cannabis abstinence for 1 month and some symptoms disappeared. However, 2 months later, he relapsed in

cannabis use and all symptoms reappeared. Later he achieved cannabis abstinence again and he got full recovery, then he was diagnosed from cannabinoid hyperemesis syndrome.

Conclusion Cannabinoid hyperemesis syndrome is characterized by recurrent nausea, vomiting and colicky abdominal pain in patients with long-term cannabis use. These symptoms have been reported to be alleviated temporarily by taking a hot shower or more permanently by abstaining from the use of cannabis. The phenomenon of cannabinoid hyperemesis and clinical diagnosis remained obscure until recently. For this reason, it is necessary to take it into account in order to recognize it and help provide these patients early and better approach.

The role of personality traits in initiating and maintaining addictive behavior

M. Manea^{1,*}, B. Savu²

¹ UMF CLUJ NAPOCA IULIU HATIEGANU, Medical Education, Cluj-Napoca, Romania

² UMF CLUJ NAPOCA IULIU HATIEGANU, Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction It is well known that certain personality traits are more linked to drug abuse than others. Psychiatrists are more likely to emphasize the importance of impulsivity in the connection with substance disorders but in the following study we found an important percentage of patients that have a substance abuse were linked to anxiety through impulsiveness as a personality trait.

Objectives Most youths admitted for a substance abuse are highly impulsive. Our quest was to differentiate what component of impulsivity was more frequently linked to a substance use disorder.

Methods In the study were included 50 patients admitted in the 3rd Psychiatric Clinic, Substance Dependences Department, Cluj-Napoca. For the identification of the drug abused we used the multitest screening kit in correlation with the results from the Forensic Medicine Institute of Cluj-Napoca. Each patient completed the Barratt Impulsivity Scale and the Swedish Universities Scales of Personality.

Results High scores on BIS-11 strongly correlated with attentional impulsiveness (Pearson's r correlation = .838) which means high inattention and cognitive instability this being linked with anxiety disorders. Cognitive Instability was correlated with Psychic Trait Anxiety ($r = 0.29$) and Motor Impulsiveness with Somatic Trait Anxiety ($r = 0.3$). Normal 0 false false false EN-US X-NONE X-NONE.

Conclusions The underrecognized anxiety disorders in young adults whom are admitted for an addictive disorder prefrontal cortex is known to be the source of both impulsivity and could be linked to anxiety as well (valence asymmetry hypothesis). Normal 0 false false false EN-US X-NONE X-NONE.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Behavioral disorders and new psychoactive substances abuse, a French case series

M. Marillier*, A. Batisse, C. Chevallier, S. Djezzar

GH Lariboisière-Fernand Widal, CEIP-Addictovigilance, Paris, France

* Corresponding author.

Introduction Range of drugs has largely increased the past few years, especially with the emergence of the New Psychoactive Substances (NPS) sold online. In front of serious risks they cause on human health, they are more and more regulated by the law.

Objectives To describe cases of extreme behavioral disorders and highlight risks of potential forensic complications linked to these consumptions.

Methods We present a case series of serious auto or hetero-aggressive behavioral disorders related to NPS abuse and notified to the Parisian addictovigilance center.

Results Twenty cases were identified between 2010 and 2015. Users were exclusively men, with mean age of 35.5 years (min: 20, max: 51). Synthetic cathinones are the predominant class of reported NPS (65%). An association between NPS and sexuality is found in 60% of cases (12); among them cathinones are used by 11 men. We observed 6 deaths among which, 5 were associated to sexual practice. Two cases of consumptions of cathinones induced torture and barbarian acts. Concerning aggressive behavioral disorders, we quote 3 cases of hetero-aggressivity (one by stab wound and 2 others developed an hypersexuality ± exhibitionism) and 9 cases of auto-aggressivity characterized by genital mutilations (1), defenestration (3), suicidal attempt (3), and acute psychiatric disorder with endangering life (2). Only four cases have been confirmed by toxicological analysis.

Conclusion Behavioral disorders inducing forensics complications exist with NPS and particularly with cathinones. The problematic is certainly undervalued. A collaboration between addictovigilance and forensic services has to be improved.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Early alcohol use as prognostic factor for severity in dually diagnosed patients

R. Martinez-Riera, G. Mateu-Codina, A. Farre-Martinez*, J.L. Perez de Heredia, J. Marti-Bonany, M.G. Hurtado-Ruiz, M.T. Campillo-Saenz, R. Sanchez-Gonzalez, N. Ribas-Muñoz, C. Castillo-Buenaventura, M. Torrens-Melich

INAD, Psychiatry and Drug Abuse, Barcelona, Spain

* Corresponding author.

Objectives Describe the distinguishing characteristics between patients with early onset of alcohol use (EARLY, age < 15) and late onset of alcohol use (LATE, age > 16), both affected of acute non-substance use psychiatric disorders (non-SUD) and any substance use disorder admitted in a dual diagnosis unit.

Material and methods Data on demographic, family, and clinical factors were gathered among subjects admitted to our dual diagnosis unit along three years, all of them meeting DSM-IV criteria of any non-substance related Axis I or II disorder and comorbid substance use disorder (SUD). Statistical analysis was performed by using SPSS program.

Results We show results of 748 patients (437 of EARLY group and 311 of LATE group). Predominantly male (73,53%) with a mean age of $39,60 \pm 9,7$ years. Most prevalent non-SUD psychiatric disorders were psychotic disorder (39,97%) and personality disorder (39,30%). In our sample, most common substances of abuse were Alcohol (45,05%) and Cocaine (30,35%). EARLY patients had an earlier first contact all substances as well as an earlier age of problematic consumption of cocaine, alcohol, opioids and nicotine; they also had major prevalence of opioid SUD, sedatives SUD and amphetamines SUD (see Tables 1, 2 and 3).

Conclusions Patients who began earlier their consumptions of alcohol had major prevalence of opioid, sedatives and

amphetamine use. They also had earlier consumptions of other substances and earlier problematic consumptions of cocaine, alcohol, opioids and nicotine, what probably means greater severity of drug addiction in the long run.

Assessment of comparing psychiatric disorders in mono-opioid and poly-opioid dependents, according to SCL90-R Test, in cessation drug centers in Kerman City, Iran, 2015

A. Ghaffarinejad, A. Mehdizadeh Zare Anari*, N. Mahdinia
Kerman university of medical sciences, psychiatry, Kerman, Iran
* Corresponding author.

Background One of the hygienic-psychic issues throughout the country is drug dependency, which causes numerous problems in the society. These individuals are vulnerable in front of psychiatric disorders, and this is seen more in poly-opioid dependents.

Methods This causal-comparative research is cross-sectional study. Among of the poly-opioid and mono-opioid dependents in cessation drug centers in Kerman 1392–93, a sample of 234 persons (117 poly-opioid dependents and 117 mono-opioid dependents) were chosen randomly to answer SCL90-R test and demographic questionnaire. Analysis performed by SPSS18 by use of average, standard deviation, frequency and t test.

Findings According to the findings, on the whole somatization, anxiety, depression, phobia, sensitivity, psychosis, paranoid idea, aggression and obsessive-compulsive were significantly different (P<0.05) between mono-opioid and poly-opioid dependents, so that these 9 psychotic disorders in poly-opioid dependents were more than mono-opioid dependents.

Conclusion Finding of this research showed that these psychiatric disorders in several drugs abusers are more than one drug abusers.

Keywords Psychiatric disorders; Poly-opioid dependents; Mono-opioid dependents

 * Corresponding author.

Background Complicated grief causes clearly functional disorders, and grief signs lasts at least a month after six months going through unfortunate incident. Researches about grief and complicated grief, requires a deeper understanding in etiology of creation and several therapeutic procedures. In this study we want to evaluate the relationship between the use of methadone and complicated grief.

Methods Among methadone consumers in cessation drug centers in Mashhad in 2015 a sample of 285 person's were chosen randomly to answer ICG test (Inventory of Complicated Grief) and demographic questionnaire. Analysis performed by SPSS18.

Findings The results showed that 35% of methadone consumers had grief. Complicated grief is more frequent in men than women ($P=0.01$), and more in middle-aged people than the other ages ($P=0.002$). The most frequent complicated grief among those with postgraduate diploma and the lowest rate is among MA ($P=0.003$). People who have lost their first-grade relatives have more complicated grief than those who lost the other ones ($P=0.000$). The individuals who have lost someone due to disease are more frequent than those who have lost someone suddenly ($P=0.00$). Among the ICG test questions, hallucinations (seeing deceased) has the lowest frequency, and tendency to the places and things related to the deceased, has the greatest frequency.

Conclusion Finding of this research showed that, Men, people with postgraduate diploma and people who have lost their first-grade relatives have experienced more complicated grief. Gender of deceased and marital status do not effect on the frequency of complicated grief.

Study on relationship between general psychopathology and relapse in opioids dependence under treatment on methadone maintenance therapy, Kerman, Iran, 2014

A. Ghaffarinejad, A. Mehdizadeh Zare Anari*, A. Mahmoudi Meimand
 Kerman university of medical sciences, psychiatry, Kerman, Iran
 * Corresponding author.

Introduction Performed studies indicate association between drug abuse and other mental disorders. Mental disorders could be effective in response to treatment and also, accession of recurrence process in addiction treatment course.

Methods and materials This research is causal – comparative and of cross-sectional type was performed in 2014 on 200 drug abusers under methadone maintenance treatment (in two groups, with relapse in treatment process and without relapse) in drug rehabilitation centers of Kerman city. Questionnaire which includes demographic features and BPRS test was completed. Data were processed by suitable statistical methods via SPSS20 and SAS9.1 software.

Findings Results obtained from the research showed that the acquired scores average from BPRS test is more in relapsing group ($P<0.0001$). Subscales of somatic concern ($P=0.030$), anxiety ($P<0.0001$), depressive mood ($P<0.0001$), guilt feeling

($P=0.003$), hostility ($P<0.0001$), grandiosity ($P=0.008$), suspiciousness ($P=0.024$), hallucination ($P=0.009$), blunted affect ($P=0.030$), tension ($P=0.012$), uncooperativeness ($P=0.011$), excitement ($P=0.038$) and emotional withdrawal ($P=0.019$) in two abuser groups had significant difference (more in relapsing group). No significant difference was observed between subscales of unusual thought content, disorientation, conceptual disorganization, mannerism and posturing and motor retardation in two groups ($P>0.05$). In patients with more relapse in treatment process, score of BPRS is higher ($P<0.0001$).

Conclusion Findings of this study showed that intensity of psychiatric disorders in relapsing drug users is more than non-relapsing users and with growth of disorders intensity, the number of recurrence increases.

Keywords Psychiatric disorders; Addiction relapsing drug abusers; Non-relapsing drug abusers

Introduction Changing cultural values and increasing economic stress are leading to initiation into substance use. Despite religious and legal constraints on Muslims against the consumption of drugs, drug addiction is a widespread problem and is destroying the lives of many individuals and families, in Tunisia.

Objectives To examine the socio-demographic characteristics of Tunisian addicts and to identify the drugs commonly used.

Methods This was a cross-sectional study, which included 200 patients at the addiction treatment center "Aide et Ecoute" in Sfax (Tunisia). The survey was conducted during the month of January to September 2014.

Results Only males were found to get treatment in the addiction center for various addictions. The mean age was 33.32 years and the mean age for starting substance use was 17.30 years. More than half (65.9%) were not married and 59.5% had involvement with criminal justice. Substance dependence was commonly seen in poor and middle socioeconomic class. The most common substance used was buprenorphine (34.8%). There was a significant relation between buprenorphine consumption and immigration ($P=0.013$). Peer pressure was one of the most important factors for trial of substance in our study.

Conclusion As the mean age of initiation of substance abuse was early twenties, in liaison with schools and colleges, some recreational activities can be generated to prevent diversion of youth towards the devil of drug abuse.

Keywords Immigration; Injecting drug; Socio-demographic characteristics

Zolpidem abuse: About a case

R. Sellami^{1,*}, N. Messedi¹, I. Feki¹, I. Baati¹, A. Zahaf², J. Masmoudi¹

¹ Hedi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

² ATUPRET, Drug Abuse Prevention Center, Sfax, Tunisia

* Corresponding author.

Objective Zolpidem is a non-benzodiazepine hypnotic drug for treatment of insomnia and is generally believed that is a safe medication. Therefore has been introduced as a lower potential agent for dependency and abusive effects however its safety and dependence potential are of great concern.

Case report A 63 years old male patient had consulted a general physician in January 2015 for his insomnia. He started on zolpidem 10 mg at bedtime. Over the next few months he had gradually increased the dose as he found the prescribed dose to be having no significant effect. After abrupt discontinuation of zolpidem, he presented to a center for drug users “AIDE ET ECOUTE” with severe anxiety, impatience, loss of energy, insomnia, irritability, headaches, and increased craving for higher dosage of zolpidem. There was no history of any other substance abuse and he was diagnosed simultaneously a case of zolpidem dependence and major depressive disorder.

Conclusions Zolpidem has a potency to be abused with high risk of dependency and withdrawal syndromes particularly among elderly patients with comorbid anxiety and depressive disorders.

Nalmefene as an intermittent treatment for alcohol abuse triggering cocaine and sex consumption

A. Morera-Fumero^{1,2,*}, E. Diaz-Mesa³

¹ University of La Laguna, Internal Medicine – Dermatology and Psychiatry, Santa Cruz de Tenerife, Spain

² Psychiatric Consulting, Psychiatry, Santa Cruz de Tenerife, Spain

³ University Hospital of the Canary Islands, Psychiatry, La Laguna, Spain

* Corresponding author.

Nalmefene modulates the motivational system by blocking the opioids receptors. Nalmefene indication is the alcohol consumption reduction in alcohol dependent patients. We describe the case of a patient with weekend alcohol abuse that was followed by cocaine use and sex. After being treated with nalmefene, the patient decreased alcohol consumption and did not engage cocaine use and sex. The patient is a 36-year-old man with a previous history of cocaine, cannabis and alcohol abuse. After detoxification the patient became a weekend drinker. Two months later he started complaining that after drinking he needed to consume cocaine and this led him to having sex with prostitutes. These behaviours had a serious impact on his finances that lead him to asking for help. Nalmefene, 18 mg at dinner before going out, was prescribed. Taking one pill of nalmefene “allowed me to drink several shots without feeling a need to continue drinking and, most importantly, I didn’t feel the need to consume cocaine and have sex”. In an attempt to ascertain if what had happened the previous weekend was “psychological” the patient went out without taking nalmefene. The pattern of alcohol use, control loss, and consumption of cocaine and sex repeated itself. During the following two months, the patient took nalmefene during dinner before going out every weekend and the results were the same as when he first took the treatment.

Conclusion Nalmefene may be helpful in the treatment of several other addictions by blocking the positive reinforcements of the drugs.

A case of share psychotic disorder induced by mephedrone

R.A. Baena*, Y. Lázaro, J. Rodriguez, L. Olivares, A. Matas, L. Niell

Hospital Clinico San Carlos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Share psychotic disorder “folie à deux” is a rare condition characterized by the transmission of delusional aspects from a patient to another linked by a close relationship. We report the case of two Spanish men who have experienced a combined delusional episode induced by mephedrone.

Objectives Describe a case of share psychotic disorder induced by mephedrone. Make a review on scientific literature about the use of mephedrone (little is known about the psychiatric consequences of the use of these compounds). The patients had no psychiatric history.

Aims Show the danger of these novel drugs that are often bought as apparently safe and legal.

Conclusions Share psychotic disorder was first introduced by Lasegue and Falret who hypothesized that transmission of psychiatric disturbance from one person to another was possible under certain circumstances. The correlation of symptoms with the intake of these substances is supposed in the light of a negative psychiatric history and no other concomitant medical treatments. An important number of case reports documented deaths related to the ingestion of mephedrone. Another problem is that these substances are not detected by standard blood and urine test so that the diagnosis of intoxication is often delayed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The experience of using synthetic cannabinoids: A qualitative analysis of online user self-reports

M. Newman^{1,*}, G. Denton¹, T. Walker¹, J. Grewal²

¹ University of Warwick, Warwick Medical School, Coventry, United Kingdom

² Caludon centre, Addiction Psychiatry, Coventry, United Kingdom

* Corresponding author.

Introduction The number of novel psychoactive substances (NPS) available is increasing. Synthetic cannabinoids (SC) are one of many NPS sold. SC aim to emulate the effects of natural cannabis by acting on cannabinoid receptors. Despite much research into pharmacology, there is limited data on the user experience of SC.

Aim It is useful for psychiatrists, to understand what experiences people have whilst on illicit substances. The aim of this qualitative study is to gain an initial understanding of what characterizes the experiences of those who use SC.

Method Forty anonymously written online reports were collected from the “Erowid experience vaults” and analysed using the Empirical Phenomenological Psychological Method.

Results The analysis yielded 488 meaning units (MU). These were grouped into 36 categories revealing 5 broad themes: (1) physical affects; (2) sensory distortions and distortions of perception; (3) emotional and psychological effects; (4) re-dosing, addiction and comedown effects; (5) similarities to other substances.

Conclusion Synthetic cannabinoids have a mixed effect on users with a myriad of experiences reported. Some experienced positive results from their usage such as euphoria and relaxation, however these were counter balanced by those who experienced some serious negative emotional and physical side effects such as anxiety, paranoia, palpitations and convulsions. SC appear to often emulate that of their natural counterpart, yet there is an unpredictability

to them which can end with serious consequences. Online forum content gives us a strong base understanding of users experiences of SC. Further research is required to elucidate a more nuanced understanding.

* Corresponding author.

Introduction Hallucinogen Persisting Perception Disorder (HPPD) is a syndrome characterized by prolonged or reoccurring perceptual symptoms, reminiscent of acute hallucinogen effects. HPPD was associated with a broader range of LSD (lysergic acid diethylamide)-like substances, including cannabis, MDMA (methylenedioxyamphetamine), psilocybin, mescaline and other psychostimulants. Symptomatology mainly comprises visual disorders (i.e., geometric pseudo-hallucinations, halos, flashes of colours/lights, motion-perception deficits, afterimages, micropsy, more acute awareness of floaters, etc.), even though depressive symptoms and thought disorders may be comorbidly present.

Objective Although HPPD was firstly described in 1954, it was definitely established as a syndrome in 2000 with the revised forth version of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR). However, neuronal substrate, risk factors, aetiology and pathogenesis of HPPD remains still unknown and under investigation. Furthermore, there are still open questions about its pharmacological targets.

Aims A critical review on psychopathological bases, etiological hypothesis and psychopharmacological approaches towards HPPD was here provided.

Methods A systematic literature search on PubMed/Medline, GoogleScholar and Scopus databases without time restrictions, by using a specific set of keywords was here carried out. In addition, a case report was here described.

Results and conclusions Pharmacological and clinical issues are here considered and practical psychopharmacological recommendations and clinical guidelines here suggested.

⁶ University of “G. D’Annunzio”, Department of Neuroscience – Imaging and Clinical Science, Chieti, Italy

* Corresponding author.

Background and purpose Dandy Walker “syndrome” (DWS) was firstly defined by Dandy and Blackfan, and then described by Hart et al. [1] as a series of neurodevelopmental anomalies in the posterior fossa, including Dandy-Walker (DW) malformation, DW variant (cerebellar hypoplasia/aplasia of the cerebellar vermis and cystic dilatation of the fourth ventricle), mega-cisterna magna and posterior fossa arachnoid cyst. Mental symptoms have been associated with DWS in previous reports, but the spectrum of mental symptomatology widely varies between clinical cases, ranging from psychotic/schizophrenia-like to mood/cognitive symptoms [2].

Methods Here we describe a case of psychosis and polydrug abuse in a 27-year-old man with DW variant a 4-year history of polydrug abuse, sporadic alcohol abuse, epilepsy and psychotic symptoms including delusions of reference/persecution, suspiciousness, associated with obsessive thoughts, mood lability and persistent anxiety.

Results He was recovered for a 28-day program of detoxification from drug addiction/stabilization of psychiatric symptoms. Family history of Bipolar Disorder, gambling disorder (father) and depression (mother). The mental status examination at baseline revealed slowness of thought, psychomotor retardation, aboulia/anhedonia/apathy/hypomimic facies/asthenia/social withdrawal/deflected mood/poor thought content/blunted affect/self-neglect/poor insight, cognitive impairment and oppositional and partially collaborative attitude and behaviour. Borderline intelligence activity was found on WAIS-R (IQ=79). At the baseline, he was taking carbamazepine 400 mg BID (baseline serum level: 6.720 µg/ml), gabapentin (400 mg BID), paroxetine (20 mg/d), olanzapine (10 mg/d) and methadone (70 ml/d), with a poor response/control both on psychotic and seeking drug symptomatology.

References not available.

Conclusions Further DWS clinical cases should be evaluated in order to better investigate the role of this variant to addictive and psychotic symptoms.

Improved drug-use patterns at six months post discharge from inpatient substance use disorder treatment; results from compulsory and voluntary admitted patients

A. Pasareanu*, J.K. Vederhus, O. Kristensen, T. Clausen, A. Opsal Sørlandet Hospital Kristiansand, Addiction Unit, Kristiansand, Norway

* Corresponding author.

Background The Norwegian Municipal Health Care Act opens for mandated treatment for persons with severe and life-threatening substance use disorder. This study aims to examine substance use related outcomes at six-month following in-patient treatment and to analyse factors associated with improved outcomes and abstinence.

Method This prospective study followed 202 hospitalised patients with SUD that were admitted voluntarily (n=137) or

compulsorily ($n = 65$). The European Addiction Severity Index was used at baseline and at follow-up to assess socio-demographics and substance use variables. Regression analysis was conducted to investigate factors associated with abstinence at six-month follow-up.

Results The frequency of use of preferred substance showed markedly improvement for both voluntary admitted (VA) and compulsory admitted (CA) patients (61% and 37% respectively) at follow-up. Seventy-five percent of VA patients using amphetamine reported improvement compared to 53% of CA patients. At follow-up, the CA group continued to have a higher rate of injection use. The CA group had experienced higher rates of overdose the past six months and lower abstinence rates (24% versus 50%) at follow-up. Lower severity of drug use at intake (non-injection drug use), voluntary treatment modality and higher treatment involvement during follow-up all were significant factors associated with abstinence at follow-up.

Conclusion Voluntary treatment for SUD generally yielded better outcomes; nevertheless we found improved outcomes also for CA patients. It is important to keep in mind that the alternative to CA treatment in reality is no treatment at all and instead a continuation of life-threatening drug use behaviours.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cerebellar atrophy supporting diagnosis of alcohol dependence: A case report

F. Pavez Reyes^{1,*}, M. Sánchez¹, E. Moral¹, M. Terradillos², N. López¹, M. Roca¹, A. García¹, J. Russo¹

¹ Hospital General Universitario Reina Sofía, Psychiatry, Murcia, Spain

² Centro de Salud Mental Murcia Este, Psiquiatría, Murcia, Spain

* Corresponding author.

Chronic use of alcohol is a known cause of cerebellar atrophy. This finding could be a valuable diagnosis support when there are not other information sources. In this case report, we describe a 65-year-old male patient who was referred from primary care to specialized consultation because a depressive syndrome it was unresponsive to treatment with desvenlafaxine and lorazepam. In psychopathological exploration we found overvalued ideas of suffering some kind of injury and damage by the family, which oriented the diagnostic hypothesis of delusional disorder with secondary mood symptoms, although the clinical suspicion of abuse of alcohol was proposed as a differential diagnosis. The continuing minimization and denial of consumption by the patient as well as their reluctance to incorporate an external informant made that the workup was a key element to elucidate the diagnosis. We found a discrete increase in transaminases, gamma glutamyl transferase and alkaline phosphatase. Magnetic resonance imaging showed cerebellar atrophy (vermian and, in a lesser extent, in both hemispheres). Once the patient was confronted with these results, he agreed to disclose his problem, which fulfilled alcohol dependence criteria. After that, he accepted to initiate treatment and detoxification in a specialized unity.

Conclusions Although psychiatric diagnosis is based on the clinical features and the exclusion of associated medical conditions, in this case the workup provided support to our clinical suspicion, favouring recognition of the problem and willingness to treatment by the patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Addictive behaviour and bariatric surgery: Case report and literature review

F. Pavez^{1,*}, N. López¹, E. Saura², M. Roca¹, A. García¹, J. Russo¹, M. Sánchez¹, E. Moral¹

¹ Hospital General Universitario Reina Sofía, Psychiatry, Murcia, Spain

² Fundación Jesús Abandonado, Unidad de Asistencia Psicológica, Murcia, Spain

* Corresponding author.

Even though the scientific evidence supports the benefits of bariatric surgery, its indications and contraindications must be continually revised in order to avoid psychiatric complications. Substance use is more common in patients subjected to bariatric surgery than in the general population. There are reports of increased incidence of alcohol abuse in patients after bariatric surgery.

Objective To review the available evidence, after treat the case of a 50-year-old man with addiction history whose addictive behaviour worsened after undergoing bariatric surgery, with decreased tolerance to alcohol effect and increase of the intake, as well as changes in the graduation of alcohol used (including antiseptic). As a result, a dangerous revolving door that led him to repeated admissions, including Intensive Care Unit.

Results The case is consistent with the literature that suggests that there is an increased risk of later alcohol-related problems after bariatric surgery. This risk is higher several years post surgery, in patients with previous history of problems related to alcohol, young, men, and Roux-en-Y Gastric Bypass procedure.

Conclusions The indications for bariatric surgery should thoroughly consider the history of addiction, an adequate assessment of the patient's mental status and psychoeducation about the possible psychiatric side effects, in order to develop preventive strategies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Characteristics and outcome of methadone maintenance treatment (MMT) patients with depression

E. Peles^{*}, A. Sason, E. Malik, S. Schreiber, M. Adelson

Tel Aviv Medical Center, Adelson Clinic for Drug Abuse Treatment & Research, Tel Aviv, Israel

* Corresponding author.

Introduction Comorbidity of depression and opioid addiction is highly prevalent, but their outcome in MMT is not consistent.

Objectives To compare between depressed and non-depressed MMT patients.

Methods Hamilton depression scale scores (taken during a psychiatric assessment) were studied among MMT patients on admission or during treatment (cutoff for depression > 18).

Results A total of 498 MMT patients were studied. Depression proportion was 22.5%, and 23.2% among 263 who were studied on admission; the depressed vs. non-depressed on admission did not differ in female proportion (19.7% vs. 25.6%), age of admission (43.2 ± 10.4), opiate use onset (21.8 ± 6.3) and education years (9.5 ± 2.8), but had higher proportion of cocaine (55.7% vs. 35.1%, $P = 0.005$), and benzodiazepine abuse (73.8% vs. 58.4%, $P = 0.04$). Retention was high and similar (80.3 vs. 82.9% $P = 0.7$) and of those who stayed one year, cocaine and benzodiazepine were still higher among the depressed patients (cocaine: 43.8% vs. 23.2%, $P = 0.03$; BDZ: 61.2% vs. 40%, $P = 0.01$). Compared to the non-depressed,

among all study group ($n = 498$) the depressed patients presented higher proportion of rape history (25% vs. 9.5%, $P = 0.001$), of suicide attempts (43.8% vs. 25%, $P = 0.001$) with only a trend of shorter cumulative retention in MMT of mean 9.4y (95% CI 7.8–10.7) vs. 11.5 (95% CI 10.5–12.5, $P = 0.07$).

Conclusion Despite cocaine and benzodiazepine abuse on admission, depressed succeeded similarly to the non-depressed in the first year retention in treatment. Intervention is recommended since admission, as their long-term retention seems to be shorter, later on, and their ability to discontinue cocaine and benzodiazepine abuse is clearly hampered.

What triggers help-seeking behaviour in “early stage” alcohol-dependent drinkers

P. Ponizovskiy*, A. Gofman

Moscow Research Institute of Psychiatry, Department of mental disorders complicated by substance abuse, Moscow, Russia

* Corresponding author.

Abstract In early stages of alcohol addiction negative effects of alcohol often remain invisible to the patient or underestimated and considered “normal” by him. However, there is a cohort of alcohol drinkers who seek outpatient treatment in early stages of addiction. The study was conducted in order to investigate the triggers for seeking therapy in early stages of alcohol dependence when compulsive drinking, impaired control and increased alcohol tolerance are developed, but withdrawal symptoms followed by relief drinking are not yet observed. Forty-six out-patients (31 men and 15 women, mean age 38 ± 7 years) were studied by means of audit and clinical interview.

The average duration of alcohol abuse was $8,7 \pm 5$ years, the mean daily dose of alcohol was 10 ± 4 standard drinks. Most of the patients were drinking alcohol from several times a week to several times a month.

The decision to seek treatment in most cases was pushed by patients' family members because of the recurrent interpersonal problems caused or exacerbated by the effects of alcohol – 70% ($n = 32$). Other triggers included: job instability – 35% ($n = 16$); alcohol blackouts – 26% ($n = 12$); exacerbations of symptoms of existing physical conditions – 24% ($n = 11$); legal problems – 7% ($n = 3$). Alcohol consumption in early stages of alcohol addiction can affect nearly every aspect of a patient's life. The triggers which promote treatment-seeking behaviour should be addressed in the course of the treatment in order to encourage recovery and prevent transition to more severe stages of the disease.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Misuse of pregabalin: Case series and literature review

N.E. Suardi, M. Preve*, M. Godio, E. Bolla, R.A. Colombo, R. Traber

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Pregabalin is widely used in neurology, psychiatry and primary healthcare, and recently in literature different studies explain the possible misuse [1,2]. Pregabalin has shown greater potency in preclinical models of epilepsy, pain and anxiety, and may

have potential in the treatment of cocaine addiction [3]. The purpose of this report is to review the clinical evidence for the potential of abuse and misuse of pregabalin. We propose ten different cases and literature review.

Method Ten inpatients with misuse of pregabalin were assessed with: the SCID-P, Anamnestic Folio, HAM-A and DAST. We conducted a systematic review of the literature (PubMed, Embase, PsychInfo), using the terms “pregabalin”, “misuse”.

Results All our patients present: cocaine, alcohol and/heroin positive in drugs urine screening at admission; a significant high level of total anxiety at the HAM-A Tot ($P < .001$), and especially at the item 7 ($P < .001$); the misuse of pregabalin is made for sniffing; the predominant symptoms assessed were euphoria, psychomotor activation and sedation.

Discussion and conclusion Schifano F et al., [1,2] suggest that pregabalin should carefully prescribe in patients with a possible previous history of drug abuse. Our result identifies a particular population the misuse pregabalin that are abuser of cocaine, alcohol and/or heroin. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Quetiapine XR reduce impulsivity and dissociation in a sample of alcoholic patients

M. Godio, M. Preve*, N.E. Suardi, E. Bolla, R.A. Colombo, R. Traber

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Alcohol dependence (AD) is a major public health problem. Currently, three drugs for the treatment of AD have been approved: acamprosate, disulfiram and oral naltrexone. Quetiapine XR is an atypical antipsychotic has been shown to be a promising medication for the treatment of alcoholism [1,2]. The aim of our study is evaluate quetiapine efficacy on impulsivity in a sample of alcoholic patients.

Method A sample of alcoholic patients ($n = 40$) was assessed at the entrance and 2 months with: SCID-P, Brief-Temps, BIS-11, GSR, BPRS, SCI-DER, and CGI. The medium dosage of quetiapine is 300 mg.

Results Using the last observation carried forward, the mean total BIS score decreased from 60.8 at baseline to 40.2 at the final visit ($P = .03$). More pronounced improvement was observed in motor impulsiveness ($P < .03$) and attentional impulsiveness ($P < .05$) compared with non-planning impulsiveness ($P = .09$). We observed an improvement in SCI-DER total score ($P = .02$), in particular in derealization ($P = .03$) and autopsychic depersonalization ($P = .04$). A mean weight gain of 4.8 kg was observed. There is not significant different related to the different affective temperament.

Discussion and conclusion Analyses revealed a significant effect of Quetiapine XR in improving impulsivity and dissociation, in particular motor and attentional impulsiveness, derealization and autopsychic depersonalization. Moreover, an improvement of dissociative symptoms is probably connected with the blockade of postsynaptic 5-HT_{1A} receptors [3]. Methodological limitations,

clinical implications and suggestions for future research directions are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Methylphenidate is a CNS stimulant approved for treatment of ADHD. It is generally considered well tolerated and exhibiting low dependence potential, although diversion for recreational use has been described. Provided that its effects are comparable to those of more popular drugs of abuse, such as cocaine and amphetamines, we hypothesized that it could be sold as such.

Objective The aim of this study was:

- to describe the presence of methylphenidate from the samples handled to, and analyzed by, Spanish harm-reduction service energy control between August 2009 and August 2015;
- to determine whether it is being sold as other drugs.

Materials and methods All samples presented to energy control (EC) were analyzed. EC is a Spanish harm-reduction non-governmental organization that offers to users the possibility of analyzing the substances they intend to consume.

Samples in which methylphenidate was detected using Gas Chromatography–Mass Spectrometry were selected for this study.

Results From a total of 20062 samples, 17 contained methylphenidate (0,09%), with no clear variations among the years studied. The samples were mostly sold as amphetamine (29%), methylphenidate (23%) and ethylphenidate (18%).

Conclusion Presence of Methylphenidate in the Spanish illegal drug market seems anecdotic and stable over the studied time-frame. Moreover, it was sold as substances with similar dosages, lowering potential for life-threatening intoxications. Therefore, our results suggest that diversion of methylphenidate into the drug market as adulterant is not a concerning phenomenon.

The role of buprenorphine maintenance therapy in opioide recidive prevention: Experiences from Croatia

K. Radic^{1,*}, D. Bosnjak¹, A. Korpar², A. Puljic¹, A. Bagaric¹

¹ University Psychiatric Hospital Vrapče, Addictions Treatment Department, Zagreb, Croatia

² General Hospital Varaždin, Department of Psychiatry, Varaždin, Croatia

* Corresponding author.

Introduction Buprenorphine, a partial agonist of mu opioid receptors and an antagonist at kappa opioid receptors, is widely used in the treatment of the opioid addiction, as it reduces cravings and effects of opioid withdrawal, decreases opioid consumption and diminishes rewarding effects of it. In University Psychiatric Hospital Vrapče, the oldest psychiatric hospital in Croatia, buprenorphine maintenance therapy is a standard and important part of integrative psychiatric treatment offered to opioid drug users.

Aims To show potential benefits of buprenorphine maintenance therapy as a pharmacological agent in psychiatric care for opioid drug users.

Objectives To describe series of clinical cases in which the introduction of buprenorphine in therapy of opioid drug users lead to reduced number of their hospitalizations.

Methods Clinical cases from University Psychiatric Hospital Vrapče Addictions Treatment Department were identified and the course of patients' treatment was analyzed. Summaries of cases, with the emphasis on protective factors for stabile maintenance, are presented.

Results After switching patients from various opiates to buprenorphine in a controlled in-patient environment, our patients became more functional and their integrative psychiatric treatment could then start. After discharge, an improvement was visible in different dimensions of their lives, and the re-admittance was the exception, since recidives were rare. They continued their treatment actively, in outpatient programmes of our clinic.

Conclusions Drug-seeking behaviour of presented opioid users was avoided by buprenorphine maintenance therapy provided with intermittent psychotherapeutic interventions or usual psychiatric support in aftercare. In our experience, such integrative psychiatric care prevents re-admittances and recidives.

New drugs: Use of everyday substances as substances of abuse

M.D.L.C. Ramirez Dominguez*, I. Prieto Sánchez, M. Nuñez Caro, L. Hernandez Gonzalez

Complejo Hospitalario de Huelva, Psiquiatria, Huelva, Spain

* Corresponding author.

Introduction Emerging drugs are a growing problem, of which we have little information and clinical experience and pose a challenge in everyday clinical practice because many are not detectable with the test at our disposal and its effect on cognition and behavior are not well known.

Methods Conduct a thorough literature review of all the material in this regard has been published both in high impact journals and in the last International Congress of Dual Pathology.

Results There are many and varied new substances used for harmful/abuse consumption mainly for their sedative effects

and/or hallucinogens, easily accessible since many are easily purchased online or can even be easily obtained at any pharmacy without a prescription.

Conclusion There are more and more often consumed new substances with high harmful potential and very easy to obtain. It is therefore essential knowledge to identify, treat and educate not only our patients but to the general population.

Introduction The most common psychiatric disorders associated with substance use in patients with dual diagnosis, personality disorders are followed by schizophrenic disorder. Among the substances used in patients with dual diagnosis, stands cocaine, followed by cannabis and alcohol.

Objectives Evaluate the differences in the frequency of sex for cocaine and cannabis consumed in a sample of patients undergoing follow Mental-Health Center for Drug Dependency Unit.

Material and method We conducted a cross-sectional study and analyze the differences by gender for the frequency and pattern of cocaine and cannabis, in a sample of patients in treatment at the Mental-Health Center for a year to present dual pathology.

Results There are significant differences in the frequency of cocaine use among men and women. Eight percent of men use cocaine compared to 0% of women. This monthly cocaine use is more common in women than in men at 45.5% versus 21.8%. Of women, 27.3% use cocaine fortnightly, which is not typical for men (0% of men in the sample). The weekly use of cocaine represents 55.2% among men compared to 27.3% of women.

There are no significant differences in the frequency of cannabis use among men and women. Both sexes consume cannabis daily.

Conclusions The monthly cocaine use is more common in women. In men the most common is the use of cocaine weekly.

In both sexes cannabis use is more common daily.

Introduction Cocaine use is prevalent in mental health consultations in both sexes. However, in men and women there are differences in the frequency of use of substances and on the employment situation.

Objectives Show the differences for the use of cocaine and employment status of men and women, in a sample of patients followed at the Mental Health Center in Drug Dependency Unit.

Material and methods We conducted a cross-sectional study and analyze the differences according to sex for cocaine use and the employment situation, in a sample of patients who are undergoing treatment at the Mental Health Center for a year diagnosed with dual pathology.

Results In men in active employment status, the percentage of cocaine use is 19.5% and if we compare with women in the same job situation, the percentage of cocaine use is 0%.

Men who are unemployed use more cocaine than women in the same job situation. For retirees, the highest percentage of cocaine is found in women.

Hundred percent of women use cocaine by sniffing. Men use different ways of cocaine consume.

Snorted way 67.7%, 14.9% smoked and snorted, smoked 8% and 2.3% intravenous.

Conclusion Men use cocaine more frequently unemployed while women do more it often being retired.

The route most used cocaine consume in both sexes is snorted.

Introduction Alcohol use is a common behavior in most people in our society. A first episode of alcoholism can be fully recovered through specialized treatment and other protective factors and need not become a relapse later.

Objectives Whether there are differences in alcohol use after 1, 3 and 6 months after the administration of paliperidone palmitate extended-release injectable suspension in a sample of patients.

Material and methods This is a descriptive study that analyzed the differences observed with respect to alcohol use after administration of paliperidone palmitate in a sample of 98 patients attending in a Mental Health Centre, in the Unit for drug dependency to present pathology dual.

Results The percentage of alcohol use at baseline is 56.1% of the total sample.

One month after treatment with paliperidone palmitate the percentage of use is reduced to 31.6%. At 3 months of treatment the reduction is more significant assuming only the 6.1% of the total sample. Finally after 6 months of treatment the percentage of patients maintaining alcohol use is 4.1%, which represents a 52% reduction compared to the initial rate of use.

Conclusions The data reflect a 92% reduction in alcohol use after 6 months of the administration of paliperidone palmitate.

We can say that paliperidone palmitate is effective in reducing alcohol use in patients with dual diagnosis.

Chronic ketamine use increases serum levels of brain-derived neurotrophic factor

V. Ricci^{1,*}, G. Martinotti²

¹ Department of Psychiatry, Aosta, Italy

² University "G.d'Annunzio", Department of Neuroscience – Imaging – and Clinical Sciences, Chieti, Italy

* Corresponding author.

Rationale Ketamine is a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist which interferes with the action of excitatory amino acids (EAAs) including glutamate and aspartate. The use of ketamine at subanaesthetic doses has increased because of its psychotomimetic properties. However, long-term ketamine abuse may interfere with memory processes and inhibit the induction of long-term potentiation (LTP) in the hippocampus, an effect probably mediated by its NMDA antagonist action. Neurotrophins such as brain-derived neurotrophic factor (BDNF) and nerve growth factor (NGF) serve as survival factors for selected populations of central nervous system neurons, including cholinergic and dopaminergic neurons. In addition, neurotrophins, particularly BDNF, may regulate LTP in the hippocampus and influence synaptic plasticity.

Objectives The purpose of this study was to test the hypothesis that ketamine use in humans is associated with altered serum levels of neurotrophins.

Methods We measured by enzyme-linked immunosorbent assay the NGF and BDNF serum levels in two groups of subjects: frequent ketamine users and healthy subjects.

Results Our data show that BDNF serum levels were increased in chronic ketamine users as compared to healthy subjects, while NGF levels were not affected by ketamine use.

Conclusion These findings suggest that chronic ketamine intake is associated with increases in BDNF serum levels in humans. Other studies are needed to explore the pharmacological and molecular mechanism by which ketamine, and/or other NMDA antagonists, may induce modification in the production and utilization of BDNF and alter normal brain function.

Intro Substance use disorder is a growing phenomenon among the elderly. It is undervalued, misidentified, underdiagnosed and poorly treated.

Aim Study prevalence, characteristics and risk factors associated with drug use among the elderly.

Method A 6-month prospective study of substance use in elderly patients (65+) who attended the addiction and dual diagnosis unit, Vall d'Hebron University Hospital.

Results Fifty-nine patients evaluated, mean age 70.04 years, 60% men. A total of 49.1% are married, 35.8% divorced and 53.8% live with a partner and/or children. A total of 67.3% have basic studies and 78.8% are pensioners. A total of 82.7% have no criminal record. Medical comorbidity presents in 90.4% of the sample, psychiatric and addictive family background in 42.3% and 37.3%. A total of 67.3% have comorbid Axis I (mainly affective disorders) and 25% Axis II (cluster B most). A total of 7.7% attempted suicide at least once.

The main substance is alcohol (76.9%), followed by prescription drugs (19.3%). A total of 28.8% are multi-drug users. A total of 67.3% have used tobacco in their life and 63.5% are currently dependent. The average age of onset for a disorder for any substance consumption is 28.19, being lower for alcohol and illegal substances and higher for prescription drugs.

A total of 61.5% have gone through treatment before but only 32.7% has been admitted because of addiction. The adherence rate is 90.4% and the relapse rate 8.3% at first month and 13% at 6 months.

Conclusions Old adults present differences compared to overall drug user population: prevalence by gender is almost equal, lower Axis II, less multi-drug consumption and both dropout and relapse rate are drastically lower.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dual diagnosis patients at first admission in an acute psychiatric ward. Trend over a decade

A. Rossi^{1,*}, A. Lombardi¹, C. Gramaglia¹, M. Cavanna¹, F. Bert², R. Siliquini², P. Zeppego¹

¹ Università del Piemonte Orientale, Traslatonal Medicine, Novara, Italy

² Università degli Studi di Torino, Scienze della Sanità Pubblica e Pediatriche, Torino, Italy

* Corresponding author.

Introduction Dual diagnosis (DD) is the coexistence of a Psychiatric Disorder (PD), and Substance Use Disorder (SUD). The increase of DD observed in recent years has caused serious problems to both public and private services organization.

Aims Our aim is to assess the prevalence and features (including clinical and sociodemographic ones) of DD over a decade, comparing the period 2003–2004 and 2013–2014.

Methods We performed a retrospective study retrieving the medical records of DD patients at their first admission to the Psychiatry Ward AOU "Maggiore della Carità", Novara, Italy. Sociodemographic and clinical features were recorded. The two groups of patients (2003–2004 vs. 2013–2014) were compared.

Results In both periods DD patients are usually Italian male, aged 19–40, single. They have usually attended middle school, live with parents, have two or more brothers and/or sisters but no kids. DD patients in 2003–2004 and 2013–2014 showed differences as far as employment and diagnosis are concerned. The first were more frequently employed than the latter: moreover the 2003–2004 patients were more frequently diagnosed with a personality disorder while the 2013–2014 patients had mixed diagnoses. We have found differences in the possible predictors of substance abuse in the two periods, as well.

Conclusions The identification of changes in the prevalence of first admission DD patients and their clinical and sociodemographic features may help to highlight an evolving pattern of substance use

and to identify possible risk factors which may be the target of prevention and treatment approaches.

Prevalence of substance use among Russian, Somali and Kurdish migrants in Finland: A population-based study

E. Salama^{1,*}, S. Niemelä², A. Castaneda³

¹ University of Turku, Psychiatry, Turku, Finland

² University of Oulu, Department of Clinical Neurosciences, Rovaniemi, Finland

³ National Institute of Health and Welfare, Helsinki, Finland

* Corresponding author.

Introduction Although substance use is a well-known public health risk factor, European population-based studies reporting the substance use among adult migrant populations are scarce.

Objectives We aim to: (1) determine the prevalence of alcohol use, cigarette smoking and consumption cannabis and intravenous drugs in Russian, Somali and Kurdish migrants in Finland and compare them to those of the Finnish general population; (2) determine if socio-economic and migration-related factors are associated with substance use in migrants.

Methods We used data primarily from the Finnish migrant health and well-being study. Alcohol use was measured with the AUDIT-C questionnaire, smoking habits and the lifetime cannabis and intravenous drug use were recorded. Age-adjusted prevalence rates were determined by ethnicity and sex. The associations between background factors and substance use were analysed using logistic regression analysis.

Results The prevalence rate of risky drinking is lower and the proportion of abstainers is higher in migrants than in the general population. Current smoking is more common in Russian (31%, $P < 0,05$) and Kurdish (31%, $P < 0,05$) migrant men than in the general population (21%). Younger age was associated with risky drinking, socioeconomic disadvantage increased the odd for the daily smoking among migrants, and migration-related factors were associated with substance use.

Conclusions Migrants report less substance use than the general population, but acculturation-related factors seem to be associated with higher levels of substance use among migrants. Substance use seems to be a gendered phenomenon in migrant populations in comparison to the general population, where lately the alcohol and tobacco consumption of women have been growing.

Before and after nalmefene, a case report

N. Salgado^{1,*}, S. Benavente², B. Macías¹, C. Sanchez¹

¹ Hospital Dr. Rodríguez Lafora, Psiquiatria, Madrid, Spain

² Hospital Universitario 12 de octubre, Psiquiatria, Madrid, Spain

* Corresponding author.

Introduction Clinical and social improvement after treatment with nalmefene in an alcoholic 41-year-old male, with history of dependence during 20 years.

Case report Our patient had been abusing alcohol for almost 20 years with short breaks of abstinence (one month). Before treatment he made a consumption of 105 g of alcohol per day. Serological examination showed hepatic alterations (GGT 2115, ALT 229) and a low amount of platelets (61,000). He also had no

other relevant medical history and other possible clinical diagnoses were excluded. After a week detoxification program and alcohol consumption cessation during one month, the analytical values drastically changed: ALT 35, GGT 275, platelets 222,000.

Discussion Nalmefene is an opioid system modulator with antagonist activity at the μ and δ receptors and partial agonist activity at the κ receptor. Nalmefene as-needed has been shown to reduce the total amount of alcohol consumption and number of heavy drinking days and to improve liver function. The aim of this treatment is centered in decreasing consumption rather than achieving a total abstinence.

Conclusions Against other pharmacologic approaches such as disulfiram an acamprostate, the options that allow acute consumption help patients in controlling drinking rampage and make them realize they will be able to afford alcohol cessation.

Alcohol use disorder following traumatic brain injury: Lessons learned from bench to bedside

G. Santos^{1,*}, C. Lima², J. Vitória²

¹ Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal

² Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal

* Corresponding author.

Introduction and objectives Traumatic brain injury (TBI) can result in a variety of neuropsychiatric disturbances ranging from subtle deficits to severe intellectual and emotional disturbances, including cognitive impairments, mood and psychotic disorders and behavioral disturbances. Alcohol use disorder (AUD) and TBI are closely related. The reward-mediated behaviors central to alcohol addiction seem to interact with the cognitive dysfunction of TBI. First, a significant proportion of patients with TBI have a history of alcohol abuse. Second, AUD might jeopardize TBI recovery and trigger or lower seizures threshold. Third, both AUD and TBI share a negative impact on mental functioning (from memory and cognitive performance to mood impairment). Finally, there is some limited and recent evidence that TBI can increase AUD in patients with no history of substance use prior to the injury, by disrupting incentive-motivation neurocircuitry.

Methods We aim to present a 27-year-old Portuguese male patient without prior psychiatric history who developed AUD and epilepsy after TBI (from a work-related fall).

Results After 3 years of treatment, the patient's hasn't achieved abstinence. His treatment included pharmacological therapy with mood stabilizers, flufenazine injections and naltrexone, psychotherapy and rehabilitative interventions.

Conclusions Given the sparse knowledge about this dual diagnosis, the approach of AUD after TBI is still challenging and the best treatment remains to be determined. Monitoring alcohol consumption should be considered in all patients presenting with TBI.

Gender differences in the use of prohibited substances in prison

O. Sanz Garcia^{1,*}, M.P. Ibañez², A. Muro²

¹ Barcelona, Spain

² Parc Sanitari Sant Joan de Deu, Uhp-p.c.P. Brians 1, Sant Esteve de Sesrovires, Barcelona, Spain

* Corresponding author.

Objectives The aim of this study is to evaluate the use of both legal and illegal substances, and see the difference in consumption patterns that occur in both men and women.

Methods Surveys have been conducted on consumer habits in the past year among 84 inmates (60 women and 24 men) at the prison Brians 1, interrogating both the consumption of illegal drugs and consumer recreational drugs and routes of administration. Data were analyzed using SPSS program.

Results A total of 57.1% had used illegal drugs. The most frequent was cannabis, with 54.8% (62.5% men and 51.7% women), followed by heroin, with 23.8% (29.2% in men and 21.7% in women) and cocaine, with 14.3% (20.8% in men and 11.7% women).

Use of legal drugs was 45.2% (50% in men and 43.3% women). In this case, the greatest differences were obtained in the use of bupropion (26.7% women versus 0% men), new generation anticonvulsants such as gabapentin and pregabalin (31.7% women and 12.5% men) and the use of intranasal route of administration (31.7% women versus 0% for men). At the other extreme we find more abuse benzodiazepines abuse in men (45.8 versus 20% in women) and sedative antipsychotics (37.5% vs. 8.3%)

Conclusions Although there is a serious problem with the misuse of legal psychotropic drugs by inmates in prisons, there is still greater consumption of illegal substances.

Men's consumption pattern is more "traditional" (predominance of illegal substances and "classical" legal substances orally).

Women's consumption pattern is more experimental at both the use of new psychoactive drugs and the use of alternative routes of administration.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Calcium as a treatment option for alcohol dependence

R. Schuster*, A. Koopmann, F. Kiefer

Central Institute of Mental Health- University Heidelberg, Department of Addictive Behavior and Addiction Medicine, Mannheim, Germany

* Corresponding author.

In the last couple of decades anti-craving drugs have been developed. Acamprosate was described as an effective treatment option to support alcohol abstinence with a low side effect profile. Moreover its molecular mode of action is highly controversial. Recently, calcium salt was described to be the active part of Acamprosate. Using a clinical sample of placebo ($n = 10$) vs. Acamprosate-treated ($n = 19$) abstinent alcohol-dependent patients, we measured calcium plasma concentrations after the 1st, 2nd and 3rd month after the treatment commenced. Before treatment, the same physiological calcium concentration of about 2.4 mmol/l was found in both groups respectively. We found significant correlations in the Acamprosate group while no correlations in the placebo group were observed.

The very well regulated extracellular calcium serum concentration seems to get out of balance in association with the severity of alcohol dependence in inpatients during withdrawal.

Accordingly, in another clinical sample ($n = 57$) we found a negative correlation between calcium serum concentration and craving ($r^2 = 0.125$; $P = 0.011$) on day 1 of detoxification. The measurement of craving was carried out by a self-rating scale, the Obsessive Compulsive Drinking Scale (OCDS). Furthermore a low calcium level correlated with high breathalyser readings and the number of alcohol inpatient detoxification's.

* Corresponding author.

Introduction Neurobiological research describes one of mechanisms overlap in the Cortico-Striatal-Limbic Circuit (CSLC), which can be disrupted due to chronic stress and alcohol abuse that primarily modulated by the hypothalamic-pituitary-adrenal (HPA) axis, from which cortisol is an end-product.

Objectives To investigate the effects of chronic stimulant abuse on the CSLC. This was examined by relating cortisol levels with grey matter volume in brain structures associated with addiction and stress.

Aims We hypothesized that stimulant-dependent individuals show increased cortisol levels and abnormalities in the CSLC. We further hypothesized relationships between altered grey matter volume and increased cortisol levels in the patients.

Methods Twenty-two alcohol-dependent individuals, men only and 21 healthy volunteers (matched for age and gender) underwent an assessment session. Cortisol, DHEA and DHEA-S was assessed in blood plasma. Mood, impulsivity and compulsivity were measured by clinical instruments.

Results Alcohol-dependent individuals showed higher levels of cortisol in blood plasma, and decreased levels of progesterone and its metabolites DHEA and DHEA-S, which were associated with distinct expression in impulsivity and compulsivity in alcoholic patients. Indices of these steroids were changed compared with healthy persons. Plasma cortisol was positively correlated with the duration of alcohol use. The relationships observed between cortisol, progesterone and its metabolites: DHEA and DHEA-S may be explained by abnormal functioning of HPA axis.

Conclusions Optimizing of disrupted homeostasis during chronic ethanol consumption being provided with specific mechanism by manipulation of endogenous neurosteroids activity may prove a beneficial pharmacotherapeutic strategy in the intervention of alcohol abuse.

Introduction The problem of the treatment of alcohol addiction is very difficult due to the reoccurrence of relapses. One of the major concepts of the formation of alcohol addiction is the concept of epileptic origin of compulsive craving for alcohol.

Objective We investigated therapeutic efficacy of long-term dosing of original anticonvulsant (m-ch-BHU) on symptoms of alcohol withdrawal syndrome (AWS) in patients with a compulsive craving for alcohol.

Methods Sixty-eight male alcoholic patients aged from 24 to 53 years with different levels of alcohol abuse were examined. Type of course of alcoholism in examined patients was of middle-progressing character. Clinical evaluation of state of patients was carried out with traditional clinical description. Quantitative characterization was conducted according to Hamilton Anxiety Scale and Hamilton Depression Scale. m-ch-BHU was administered to alcoholic patients at dose from 300 mg a day during 21 days against the background of conventional medication as well as in post-withdrawal period under various degrees of severity of affective disorders.

Results Among affective disorders dysphoric symptoms have a marked tropism for m-ch-BHU. Of the other clinical manifestations in the structure of AWS cerebral diencephalic paroxysms, cardiovascular and myofascial symptoms have the most pronounced sensitivity to the drug. In patients with complicated forms of alcoholism application of m-ch-BHU is effective also in phase of remission in spontaneously arising symptom complex of neurovegetative manifestations of primary pathological craving for ethanol called "dry abstinence".

Conclusions Our data allows recommending the use of m-ch-BHU under outpatient conditions as an anti-recurrent and preventive agent.

Chronic psychiatric changes in a severe post-traumatic brain injury patient

J. Silva^{1,*}, J. Mota², P. Azevedo¹

¹ Magalhães Lemos Hospital, Inpatient C Unit, Porto, Portugal

² Magalhães Lemos Hospital, Inpatient C Unit – Electroconvulsive therapy Unit, Porto, Portugal

* Corresponding author.

Introduction Severe traumatic brain injury (TBI) causes neuropsychiatric disturbances. Emotional and personality disturbances seem to cause much more seriously handicap than residual cognitive or physical disabilities. The prognosis may be poor associated with marked social impairment, so a multidisciplinary approach team is required in order to

improve patient's quality of life and reintegration in family and society.

Objectives To summarize the latest literature about this field and to present a case report.

Aim To explore and learn more about chronic psychiatric changes in severe post-traumatic brain injury and share with the scientific community how challenging the approach of this entity can be.

Methods A brief review of the latest literature was performed, using PubMed and the keywords "traumatic brain injury" and "psychiatric changes". A case report is presented.

Results Although SSRI, benzodiazepines, mood stabilizers and antipsychotics are commonly used, new options are reported such as methylphenidate and cholinesterase inhibitors. The presented patient, a 27-year-old male, began with neuropsychiatric disturbances after a work-related fall from 9 meters high: convulsions and alcohol compulsive drinking. Three years have passed and his changes are still difficult to approach. Besides other medication, such as benzodiazepines and mood stabilizers, flufenazine injections and naltrexone seemed to be determinant in his behaviour and mood stabilization. He is also on a long-term alcoholism programme.

Conclusions Although the understanding of TBI-associated neuropsychiatric disorders has improved in the last decade, further research is needed, such as randomized-controlled studies to study new pharmacological and non-pharmacological approach.

Clinical and demographic characteristics of treatment seeking online video game players

O. Simon^{*}, R. Chebbi, A. Ochoa Godall, J. Eicher, C. Zumwald, C. Dickson

Centre du jeu excessif, Department of Psychiatry, Lausanne, Switzerland

* Corresponding author.

Background and aim Within Switzerland, video game players seeking specialised treatment are usually referred to gambling addiction services. The Centre for Excessive Gambling (CJE) is a specialised gambling addiction unit in Lausanne University Hospital. Between 2003 and 2015 the service offered also support to 64 adults seeking treatment for videogaming-related disorders.

According to international literature, Internet disorder treatment programmes have been developed. However, little is known about clinical profile of users seeking treatment. Studies into Internet or gaming disorders typically employ Internet survey methods or use student samples. The current presentation will outline demographic and clinical features of video gamers receiving treatment at the CJE.

Method Data were collected from the medical records of 57 video gamers seeking treatment at the CJE between 2003 and 2015.

Results The sample includes 93% men, mostly single (91%), with an average age of 25 years \pm 7. On average the sample spent 9 hours \pm 5 per day playing video games. A disorder had emerged an average of 3 years ago \pm 3. The crisis preceding the first consultation was familial (50%), emotional (29%) or professional (16%). Sixty-five percent of the sample had a mood disorder and 20% reported suicidal ideations.

Discussion Treatments should address comorbidities and family problems associated with video game disorders. Offering consultations for parents could be useful, even in absence of the young player.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Causes of psychoactive substance use by cannabis users with schizophreniaK. Simonienko^{1,*}, M. Kwiatkowski¹, U. Cwalina², N. Wygnał¹, K. Wilczynska¹, B. Konarzewska¹, N. Waszkiewicz¹¹ Medical University of Białystok, Department of Psychiatry, Białystok, Poland² Medical University of Białystok, Department of Statistics and Medical Informatics, Białystok, Poland

* Corresponding author.

Introduction Psychoactive substance use (PSU) in patients with schizophrenia can affect the course of the disease and causes many side effects. There is no clear evidence whether cannabis use can trigger the first episode of schizophrenia. The main causes of cannabis use in patients with schizophrenia are also still not defined.

Objectives Determine causes of PSU in cannabis users with schizophrenia.

Aims The aim of this study was to find out the causes of PSU in patients with schizophrenia.

Methods Thirty-five cannabis users with schizophrenia (28 males, 7 females) were asked to complete 15-item questionnaire about the reasons of psychoactive substance intake. Eighteen of them used also stimulants. Additional information if PSU or schizophrenia occurred first was also taken.

Results The results indicated that regardless of stimulants use PSU occurred before schizophrenia in 83% of patients. Main reasons of substance intake were: need for relaxation (86%) which was more often in marijuana group (100%) than in marijuana and stimulants group (73.7%) and this difference was statistically significant ($P=0.049$), curiosity (80%), self-regulation of well-being (74%), shyness, need for altered states of consciousness, expectation that psychoactive substances could help them in problem solving, relationships and sleep disorders (49–54%).

Conclusions PSU usually occur before the first episode of schizophrenia. Anxiety, curiosity and looking for unprofessional help are the most common reasons. The results may indicate an increased need of psychoeducation and social support in many areas of life. Future research should be considered.

EV103

The relationship between dimensions of impulsivity and alcohol consumption in heavy drinkersS.Y. Sohn^{1,*}, S. Kim¹, S.Y. Lee^{2,2}¹ Yonsei University College of Medicine, Department of Psychiatry and Institute of Behavioral Science in Medicine, Seoul, Republic of Korea² Dankook University College of Medicine- Cheil General Hospital & Women's healthcare center, Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction Impulsivity has been studied as underlying mechanism among addictive disorders such as alcohol use disorder. Several authors have suggested that impulsivity is not a unitary construct and consist of several subconstructs such as response inhibition, risk taking.

Objectives This study conceptualized impulsivity as a multidimensional construct and those subconstructs of impulsivity can predict alcohol use differentially.

Aims Our aim was to identify the specific component of impulsivity that explained the greatest variance in heavy and problem drinking among a sample of alcohol use disorder.

Methods Participants with alcohol use disorder ($n=170$) completed a behavioral test battery comprising response inhibition tasks (Stop signal task), the Balloon Analogue Risk Task (BART) as measures of subconstruct of impulsivity. Participants also completed the UPPSP as a measure of general impulsivity.

Results In a multiple regression model, impulsivity measured by UPPSP and risk-taking was identified as the measures that predicted alcohol use and problems.

Conclusions Results suggest that among patients with alcohol use disorder, a behavioral measure of risk-taking predicts alcohol consumption and alcohol problems, even when individual differences in trait impulsivity are statistically controlled. However, behavioral measures of response inhibition do not predict unique variance in alcohol use in patients with alcohol use disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV104

Problem-solving appraisal as mediator, moderator and predictor of smoking-abstinence effects

A. Soliman

Qatar University, Social Sciences, Doha, Qatar

Introduction There are extensive investigations explaining smoking abstinence effect, yet little is known about the cognitive and metacognitive mechanisms that underlie the severity of smoking abstinence effects. Several studies reported that that problem-solving appraisal is associated with psychological maladaptive behaviors, such as depression, anxiety.

Objectives Examining the role of problem-solving appraisal as mediator, moderator and/or predictor of the severity of withdrawal symptoms and probably relapse.

Aims Studying the role of problem-solving appraisal in the severity of smoking abstinence withdrawal symptoms.

Methods The present study utilized a two-group pretest and posttest design to examine the mediating, moderating and predicting role of problem-appraisal of smoking-abstinence effects. A total of 92 adult men smokers were administered the problem-solving inventory (PSI-Ar) as well as several self-report measures of most reported smoking abstinence effects (pre-test), and then were asked to stop smoking for 48 h and administered again the same measures except the PSI-Ar (post-test).

Results The results revealed that problem-solving appraisal acts as a possible mediator and predictor but not moderator of the severity of smoking-abstinence effects. The individuals with who appraised themselves as ineffective problem solvers have shown more severe abstinence effects i.e. somatization, depression, general anxiety, panic, mood states, smoking urges, insomnia and habitual sleep duration.

Conclusions Problem-solving appraisal plays a key role in severity of smoking-abstinence effects by means of mediating the relationship between abstinence effects before and after smoking abstinence. The findings are discussed in the context of future research and possible intervention recommendations.

Keywords Appraisal; Problem-solving appraisal; Problem-solving inventory; PSI-Ar; Smoking abstinence effects

Sociodemographic characteristics and clinical outcomes among patients with comorbid alcohol dependence and depressive spectrum disorders

E. Solodkaia^{1,*}, I. Loginov¹, V. Sergina¹, A. Zhurbuck¹, S. Savin², H. Jian³

¹ Far Eastern State Medical University, Psychiatry and Narcology, Khabarovsk, Russia

² Computer Center of FEB RAS, Laboratory of medical information, Khabarovsk, Russia

³ Harbin Medical University, Psychiatry, Harbin, China

* Corresponding author.

Introduction The accelerated development of substance dependence with social disadaptation and delinquent behavior, which is associated with the integration of pathological processes addictive and mental pathology, is observed in most patients with comorbid mental disorders.

Aims We evaluated the association of sociodemographic characteristics with clinical outcomes among patients with comorbidity of alcohol dependence and depression.

Objectives To study the structure and clinical features of depressive spectrum disorders with comorbid alcohol dependence among males aged 18–60. Data were collected at the Khabarovsk territorial psychiatric clinic, and all participants provided written informed consent prior to participation. Participants in the current study consisted of 89 males with comorbid alcohol dependence and depression (ICD-10 criteria).

Methods The present study based on clinical examination and interview, including data of demographic characteristics, family background and remission. Logistic regression was used to evaluate the associations of interest.

Results Analyses showed that risk of relapse was higher among males with low education and income level ($r=0.65$; $r=0.55$), family destruction until puberty ($r=0.76$), parental alcohol misuse ($r=0.74$), authoritarian parenting style in childhood ($r=0.55$), conflict relationships with spouse ($r=0.80$), “conflict” dominant motivation for abstinence ($r=0.77$), mood swings ($r=0.74$) and absence of treatment for depression ($r=0.80$).

Conclusions Integrative approach to treatment of patients with comorbid alcohol dependence and depressive spectrum disorders should take into consideration sociodemographic characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Integrated approaches to the treatment of pain syndrome in the patients with drug addiction

I. Sosin*, Y. Chuev, O. Goncharova

Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

* Corresponding author.

Introduction Pain syndrome is integral acute sign of drug addiction at psychoactive substance deprivation and is a severe urgent state.

Objectives and aims To work out integrated approaches to pain syndrome cessation with combined pharmacotherapy and non-pharmaceutical methods. To study dynamics of pain syndrome reduction at application of the developed methods.

Methods One hundred and eighty-nine opioid addicts (cessation state) were examined. The treatment efficiency was evaluated with

visual analogue scale; Roland-Morris questionnaire; pain numeric rating scale.

Results Four innovative options of modified therapy for pain authorized with the patents of Ukraine were proposed (with membrane plasmapheresis, medical electrophoresis, laser therapy and standard pharmacotherapy):

– pain syndrome cessation in opioid addicts is provided with Tramadol (up to 600 mg i/m), at intravascular laser hemotherapy (wavelength 0.63 mcm, power 2 mW, 30–40 min exposure, 3–4 days course);

– recurrent deprivation pain syndrome cessation is realized by membrane plasmapheresis with intravascular laser blood irradiation and i/m 1.0 mL Ketanov solution 2–3 days;

– pain syndrome treatment in drug and alcohol addicts is provided with Analgin and Sibazon by electrophoresis, current 1.5–5 mA, exposure 25–30 min, 1–2 procedures daily;

– pain syndrome cessation in drug addicts is performed by injection of 0.5% Seduxen solution (up to 4.0 mL), paracetamol – (up to 0.4 g), 10% solution of sodium caffeine benzoate – 1.0–2.0 mL subcutaneously, at night – 0.5% seduxen 2.0–4.0 mL, paracetamol – 0.2–0.4 g.

Conclusions Monitoring and statistical processing data proved that the proposed methods give 1.5–2-fold growth in efficiency of treatment for pain syndrome in drug addicts.

EV107

Clinical and biological predictors of the resistance to anti-smoking therapy of tobacco dependent patients

O. Speranskaya

Serbsky National Research Centre for Social and Forensic Psychiatry, tobacco dependence, Moscow, Russia

Objectives The treatment resistance to anti-smoking drugs (NRT, varenicline) remains one the most important problems of the efficacy of antismoking programs.

The role of biological signs (EEF profile, genetic changers) in the possibility of forthcoming resistance to anti-smoking drugs needs investigation.

Aims Thirty-one tobacco dependent patients, age 47–61, male, smoking period more than 25 years, had the resistance to NRT (15) ore varenicline (16) appeared after several successful quits. The number of cigarettes was 28–60 per day.

Thirty male patients, age 42–59, smoking period 20 years without therapy resistance were in the control group. The number of cigarettes per day was 22–35.

EEG indices and genetic polymorphism of COMT were identified in both groups of the patients.

Results The patients with therapy resistance had special clinical features of tobacco dependence: the prevalence of ideatory component of tobacco craving. The maximum intensity (up to 4 points in special scale) symptoms of craving to smoke, correlated with high (82.7 ± 0.1) level of alexithymia ($r = .759$, $P < 0.01$), low values of alpha index of EEG ($P < 0.05$), the presence of double valin allele of COMT ($P = 0.0741$).

Conclusion The presence of at least one valin polymorfism allele of *rs4680* COMT gene might be the predictor of pharmacological resistance to anti-smoking therapy, as well as low values of alpha index of EEG and clinical signs.

Metacognitive factors in a sample of Greek alcohol dependent patients

P. Stefanatou^{1,*}, E. Giannouli¹, P. Tsellos¹, Z. Antonopoulou²,
T. Paparrigopoulos¹, V. Ermiliou¹, M. Typaldou¹

¹ Athens University Medical School, First Department of Psychiatry, Eginition Hospital, Athens, Greece

² Panteion University of Social and Political Sciences, Department of Psychology, Athens, Greece

* Corresponding author.

Introduction The harmful use of alcohol causes a large disease, social and economic burden in societies. Metacognition is a complex concept referring to the cognitive control and regulation of many types of cognitive processes.

Objectives Metacognitions are considered to be an important factor in the development and continuance of psychological disorders.

Aims The purpose of this study is to examine the probable relations between alcohol abuse and Metacognitions with the Metacognitions Questionnaire – 30 (MCQ-30).

Method Twenty-three men and 16 women, aged between 22 and 64 years, inpatients in Eginition Hospital, due to alcohol dependence, completed the Greek-Version of the MCQ-30.

Results The mean total scores of alcoholics were higher than the ones of the healthy subjects. Namely, the group of the alcohol abused patients presented a higher score in comparison with the normal group in three of the five metacognitive dimensions. Additionally, alcoholic men outscored alcoholic women in two of the five factors. Specifically, alcoholic men appeared to be less confident about their memory and attention than alcoholic women. Furthermore, alcoholic men, compared to alcoholic women claimed in a significant greater level that worrying helped them to function.

Conclusions The above findings suggest that metacognitions could play a role in the orientation and maintenance of alcoholic abuse behavior. Moreover, these results may pose the question of whether these metacognitive beliefs could be seen as an indicator of differentiating alcoholic men from women. Overall, further research could provide additional information concerning the relation between Metacognitions and alcoholic dependence.

Transformation of social networking sites' usage patterns – a threat to health?

A.R. Szczegieliński*, K. Palka, K. Krysta

Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

* Corresponding author.

Introduction Internet as a vast global network, consisting of commercial, educational, informational and communicational facilities, has a huge impact on human behavior. Designed simultaneously by the needs of users and technical capacity, has become an addictive medium thanks to low cost of usage and broad availability. Social networking sites (SNSs) have a special place in the cyberspace. Due to the wide range of services, additionally differing on latitude, age and other variables, SNSs' impact on a life of an average user is difficult to assess.

Aim The study assess the changes between 2013 and 2015 in usage patterns and impact of the social networking sites on users with focus on possibility of dependence development and emphasis on gender differences.

Materials and methods Anonymous questionnaire, available online, was prepared solely for the purpose of the study. Questions were related to the types and frequency of specific activities

undertaken by the private profiles of users and based on pilot study conducted in January 2013.

Results The first stage (March–April 2013) consisted of 1248 respondents, the second stage (August–September 2015) gathered 1112 respondents. Research showed changes in age of users, type of information looked for and tools used to browse SNSs.

Conclusions Private profiles are no longer used only for communication or personal expression; it is a new way of getting to know what is happening and sharing voices of communities. As a tool of making money, which is more and more visible, SNSs interfere with previous patterns of portals' usage.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effectiveness of aripiprazole in remission from borderline personality disorder associated with multiple drug use – case report

A. Teixeira*, J. Jaber, R. Fernades, J. Veríssimo

Clinica Jorge Jaber, Addictions, Rio de Janeiro, Brazil

* Corresponding author.

The essential feature of borderline personality disorder is pervasive pattern of instability of interpersonal relationships, self-image, and affects, and marked impulsivity beginning by early adulthood and present in a variety of contexts. These individuals may show performance in school or work situations unstructured. Impulsivity exhibits at least two potentially harmful to themselves. They can play, make irresponsible spending, overeating, abusing psychoactive substances, engage in unsafe sex, or recklessly. People with borderline personality disorder have recursively behavior, gestures, or threats of suicide or self-mutilating behavior.

Methodology The following case features a patient whose characteristics meet the diagnostic criteria for borderline personality disorder, with positive family history of psychiatric illness (parent drug addict and bipolar disorder patients) and user of multiple drugs, particularly cocaine, marijuana and alcohol. The same has been treated with the same professional team between 2011 and 2013, with an average of 2.3 psychiatric hospitalizations per year and with signs unchanged until the last year, and these intervals between hospitalizations patient had outpatient care when introduction of drug aripiprazole caused the remission of some symptoms and attenuating others, with significant improvement in quality of life of the patient, as the scope of complete abstinence from drug use and school progress.

Conclusions Although this is only one case, the excellence of result with aripiprazole in mood stabilization and improvement of impulsive behaviors, especially in the cessation of compulsive use, makes our attention turns to the substance so that it remains subject of further studies.

Combined use of varenicline and cognitive behavioral treatment for nicotine dependence in patients admitted to a psychiatric clinic in Rio de Janeiro – Brazil

A. Teixeira^{1,*}, J. Jaber², R. Elias², J. Veríssimo Junior², A. Tomé²

¹ Rio de Janeiro, Brazil

² Clinica Jorge Jaber, Addictions, Rio de Janeiro, Brazil

* Corresponding author.

Objective Nicotine dependence is a worldwide health problem and the second cause of death worldwide. This article aims to present the improvement in the technique used by us. The results of the implementation of the treatment program with the use of varenicline as a specific medicine for nicotine dependence during admission to a clinic for chemical dependency treatment. We also demonstrate that this treatment is possible and safe for patients with comorbid psychiatric disorders and drug use disorders.

Methods Between August 2012 and August 2013, 98 patients were evaluated in a clinic for psychiatric and drug use treatment in Rio de Janeiro, Brazil. The treatment consisted of a smoking cessation therapy concurrently with the psychiatric treatment. These patients had used pharmacological therapy associated with intensive cognitive behavioral therapy, occupational therapy and moderate physical activity. In addition to the associated therapy, smoking was limited to three cigarettes daily beginning the first day of hospitalization. The drug use disorders and psychiatric illnesses were treated as usual.

Results The patients adhered to the treatment. Hundred percent of the treatment group were discharged from the clinic such as tobacco abstainers. The percentage of abstinence in patients after discharge according to previous assessments (2008–2009) with follow-up of 18 months was 51%. Results of the current study are still under evaluation.

Conclusions Behavioral group therapy and physical activities can be important allies for varenicline. Behavioral changes also exert great influence in the maintenance of abstinence.

Hereditary influence in alcohol dependence

J. Teixeira^{1,*}, G. Pereira², T. Mota², J. Cabral Fernandes²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Lisbon, Portugal

² Lisbon's Psychiatric Hospital Center, UTRA, Lisbon, Portugal

* Corresponding author.

Introduction Alcohol dependence is one of the psychiatric disorders for which hereditary influence is strongest. In fact, the importance of genetic factors in transmission of vulnerability to alcohol dependence was first described in literature many years ago by psychiatrists who dedicate to its study. That vulnerability may be explained by an epigenetic model in which biological hereditary factors associate with environmental factors to cause alcohol dependence.

Objectives Study the influence of genetic factors on alcohol dependence.

Methods During 4 consecutive months a sample of alcoholic patients was collected from the Alcohol Treatment Unit of CHPL (inpatients and outpatients). Biographic data, patient's psychiatric diagnosis and family history of alcohol dependence or of dependence of other drugs were recorded.

Results Initial sample included 122 patients. After exclusion of patients who were also hospitalized in that period, the final sample included 102 patients (26% female), with a mean age of 48 years old. Main patients' diagnosis was alcohol dependence but most of them (52%) presented psychiatric comorbidity. Most patients (55%) had family history of alcohol dependence or dependence of other substances, 26% did not have and 19% did not know. For 61% of patients, the father and/or mother were the affected relative. Most patients (61%) who had a family history of alcohol dependence or dependence of other substances had 2 or more affected relatives.

Conclusions Most patients with alcohol dependence have family history of alcohol dependence or dependence of other substances, usually in more than 1 relative, which must be taken in account during treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment of tobacco dependence in Romanian women – a vulnerable population that needs a more personalized approach

L. Trofor^{1,*}, R. Gherghesanu¹, R. Chirita¹, A. Trofor²

¹ Clinic of Psychiatric Diseases, Psychiatry I, Iasi, Romania

² Clinic of Pulmonary Diseases, Pulmonology I, Iasi, Romania

* Corresponding author.

Background Women face unique and greater health risks from smoking than men and have a different nicotine dependence pattern.

Aim To design a personalized approach for women addressing Romanian tobacco dependence treatment centers to quit smoking.

Material and methods A group of 68 smoking women received a 3 months tobacco dependence treatment intervention, consisting of 3 DVD educational sessions, 20 minutes each and a face to face cognitive – behavioral counseling intervention, emphasizing particularities of tobacco dependence in women (pregnancy risks, passive smoking, female hormones configuration, nicotinic receptors interactions, efficacy of nicotine dependence therapy according to gender, etc.).

Results Females under study were heavy smokers (17.16 ± 8.03 SD packs cigarettes/years) with high nicotine dependence scores (6.52 ± 6.03 SD).

Abstinence rate evaluated in end of treatment (3EOT) phase by an office visit (self-declared abstinence and exhaled carbon monoxide validation) was 38% and increased at 44.1% at 6 months follow-up when evaluated by a telephone contact visit (6TCV).

Conclusions Personalized tobacco dependence treatment approach, focusing on specific women tobacco use concerns increased abstinence rates, comparatively to previous data in women not benefiting educational DVD and face to face sessions [1].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive factors in social adaptation of opium addicts in remission

L. Tursunkhodjaeva^{1,*}, L. Muzaffarova²

¹ Tashkent, Uzbekistan

² Tashkent Institute of Physicians' Post-Graduate Study, Academic Department of Addiction Medicine and Adolescent Psychopathology, Tashkent, Uzbekistan

* Corresponding author.

Given significant influence of factors contributing or preventing social adaptation of drug addicts after termination of drug abuse on the stabilization of remission, their study is quite a challenge. To study cognitive factors in social adaptation of opium addicts in remission, a patient's ability to predict people's behavior in various everyday situations, to discern intentions, feelings and emotional states of a person by non-verbal and verbal expression we used M. Sullivan's method in examination of 75 opium addicts at the Republican Tertiary Detox Center.

More than 80% of the patients demonstrated low scores in a number of subtests, such as “a story to be completed”, “a verbal expression” and “a story to be extended”. That was the evidence for the patients' poor understanding association between behavior and its consequences, which can cause them to get into conflict or dangerous situations. The patients had poor ability to understand changes in initial meanings of verbal reactions by the context of the situation caused. They poorly discerned various meanings one and the same verbal messages may have by the character of relationships between people and peculiarities of communication. Even during the period of prolonged withdrawal, the patients are found to poorly discern associations between behavior and outcomes, to misunderstand character of social relationships, and find it difficult to predict people's behavior. All above makes difficult the process of interaction with the persons surrounding them, reduces possibilities for social adaptation, prevent stabilization of remission and poses the risk of the addiction recurrence.

* Corresponding author.

Aims To describe the case and management of a patient with marchiafava bignami disease (MBD) with frontal cortical lesions,

no specific symptoms at first referral to the emergency room, and late onset of atypical psychiatric symptoms.

Methods We report the case of a 44-year-old patient with a history of chronic alcohol abuse, eventually diagnosed with MBD.

Results Magnetic resonance showed lesions in the splenium and in the body of corpus callosum and bilateral lesions of the frontal cortex. The patient showed late-onset atypical psychiatric symptoms, which were drug resistant.

Conclusions The case we describe seems to support the existing few ones describing cortical involvement in MBD, which suggest that this is associated with a poorer prognosis. Psychiatric symptoms may be challenging to treat because of drug resistance. The involvement of psychiatrists together with neurologists and radiologists, with a consultation–liaison approach has proved important for the achievement of diagnosis and of the most appropriate management and treatment for this patient.

³ Maastricht University, Department of Psychiatry and Neuropsychology, Maastricht, Netherlands

⁴ University of Hertfordshire, School of Life and Medical Sciences, Hatfield-Herts, United Kingdom

* Corresponding author.

Introduction Alexithymia represents a personality construct, characterized by an inability in identifying and verbally describing own and others' emotions. According to the recent research on emotional dysregulation and the alexithymic construct, it has been described a positive correlation between alcoholism and alexithymia. The present study aims to evaluate the presence of alexithymia in a sample of alcohol dependant patients and, therefore, analyze how the presence of these alexithymic traits may influence/interact with a range of cognitive processes such as the anger rumination, metacognitive capabilities and dissociative experiences.

Methods A sample of 40 alcohol dependant inpatients affected with alcohol dependence and alcohol-related issues were recruited, evaluated and compared with a sample of 40 healthy controls. A clinical evaluation and a complete clinical and psychological assessment were carried out in order to investigate alcohol-related clinical patterns, alexithymia construct, anxiety and depression symptomatology and cognitive pattern.

Results Subjects with alcohol addiction show higher total scores in all tests except the scale that evaluates anxiety, compared to healthy controls. Finally, a factorial ANOVA analysis demonstrated that alcoholism seems to be determined by the lack of emotional recognition from which derives a dissociative state, which consequently generates a depressive rumination.

Conclusions According to the recent literature, the present study identifies a significant proportion of alexithymic patients within the sample of subjects affected by alcohol-related disorders. Other clinical variables (i.e. depression, pathological anxiety-related worry, anger rumination, dissociation and metacognitive capabilities) mirror a specific cognitive pattern in the sample of alcoholics rather than the healthy group.

Gender characteristics: Behavioral and socio-demographic profile of crack users

T.V. Vernaglia^{1,*}, M.S. Cruz², T.L. Henriques³

¹ Federal University of Rio de Janeiro State, UNIRIO, Medical-Surgical Nursing Department, Rio de Janeiro, Brazil

² Psychiatric Institute IPUB/UFRJ, Street Drug Program, PROJAD, Rio de Janeiro, Brazil

³ State University of Rio de Janeiro, UERJ, Institute of Social Medicine, Rio de Janeiro, Brazil

* Corresponding author.

Background The increase of crack use has been a challenge for public health in Brazil. In this context, few studies focus on difference in abuse of this substance between women and men.

Aims To compare socioeconomic, family relationship and service use characteristics crack users in both sexes in out-treatment patients in Brazil.

Methods A multicentric cross-sectional study was conducted in 6 Brazilian cities. A total of 900 crack users were selected. A Addiction Severity Index – 6 (ASI-6) questionnaire was applied. It was made a Chi² test to identify differences in frequency.

Results The most areas of ASI showed difference. The women have poor safety conditions than men: unemployment (69.2% × 49.0%); no money for housing or clothing (74.64% × 57.56%); without income (66.89% × 40.56%); most illiterate (23.27% × 13.55%); live with their children (31.21% × 14.33%); difficulty of dealing with their children (18.25% × 5.09%); are investigated by Council of Guardianship (33.33% × 7.45%); sexual abuse (33.97% × 8.71%).

Conclusion The woman crack user is more vulnerable than man. These difficulties could decrease the success rate of rehab. The knowledge about this vulnerable situation in woman user could help the health professional to offer support in this fields.

Changes in qualified detoxification treatment of inpatients with multiple substance use: Impacts on key figures, a pre-post-study in an open door unit in Saxony, Germany

B.S. Voigtlaender*, J. Schneider, H. Groß, T. Barth

Klinikum Chemnitz gGmbH, Psychiatry-Behavioural Medicine and Psychosomatics, Chemnitz, Germany

* Corresponding author.

Introduction Detoxification treatment of adults at younger ages suffering from polysubstance dependence on our department pursues an integrative therapeutic concept. In addition to addiction-specific, topic-centred group and talk therapy orientation also behavioural therapy elements are included: a penalty points system provides negative sign stimuli for undesirable behaviour.

Objectives Since 2010, both rate of psychotic disorders and number of N-methylamphetamine consumers ($P < 0.001$) have been growing impressively while the proportion of repeated admissions

amounted to >55%. Dissatisfying trends were identified by longitudinal measurement, e.g. regarding ALOS, kind of discharge, bed occupancy.

Aims Targeted changes in treatment were established in the 2nd half of 2014. In particular, the penalty point system was adapted towards less restrictive rules, combined with slightly reduced therapeutic intensity in order to come better on the disorder-related needs of the patients. Staffing level and structure remained stable.

Methods Key figures including quality criteria and performance data such as LOS, kind of admission and discharge, service intensity, and bed occupancy were evaluated by a pre-post study (pre: 1st half of 2014, $N = 76$ /post: 1st half of 2015, $N = 77$) using descriptive and test statistics.

Results Socio-demographic patient data remained stable. Regarding selected key figures there were significant changes (LOS > 21 days: $P < 0.05$; bed occupancy: $P < 0.001$; therapeutic contacts < 25 min: $P < 0.001$) and positive trends, e.g. decreased ratio of non-regular discharges.

Conclusions Our data suggest that punishment-oriented interventions impede addressing specific needs of inpatients with multiple substance use whereas more need-oriented interventions may lead to improvements. Further evaluation including patient satisfaction is indispensable.

Decrease of velocity and acceleration of fast eye movement after the administration of methadone

P. Walecki^{1,*}, E. Gorzelanczyk², J. Feit², M. Kunc³

¹ Jagiellonian University Medical College, Department of Bioinformatics and Telemedicine, Kraków, Poland

² Nicolaus Copernicus University in Torun, Collegium Medicum, Bydgoszcz, Poland

³ Airedale NHS Trust, Faculty of Medicine, Steeton, United Kingdom

* Corresponding author.

Aims The goal of this study is to assess the differences in peak and medium velocity, peak and medium acceleration of eyeball movements after the administration of methadone.

Materials and methods Twenty-eight opioid addicts were examined. Patients admitted oculomotor impaired were excluded.

In this study, we made use of the Saccadometer Advanced (Advanced Clinical Instrumentation, Cambridge, UK), allowing the measurement of eye position with the time resolution of 1 msec (1000 Hz). The eye movement measurement is automated and synchronised with stimuli presentation. Before and after the administration of methadone two saccadic tests were carried out: Prosaccades Test (PT) and Antisaccades Test (AT).

Results The average of peak and medium velocity and the average of peak and medium acceleration of eyeball movements in the test AT were lower than in the PT test. After administration of a single dose of methadone the peak and medium velocity, peak and medium acceleration decreased in both tests (PT and AT). After administration of methadone prolonged the duration of saccades, and prolonged the duration of rising and falling slope of saccades.

Conclusion It was found that methadone (μ -opioid receptor agonist) is associated with change of velocity and acceleration of eyeball movements.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV121

Effects of BF-HRV of opioid-dependent persons with pathological gamblingE. Gorzelanczyk¹, J. Feit¹, K. Pasgreta¹, E. Laskowska¹, P. Walecki^{2,*}¹ Nicolaus Copernicus University in Torun, Collegium Medicum, Bydgoszcz, Poland² Jagiellonian University Medical College, Department of Bioinformatics and Telemedicine, Kraków, Poland

* Corresponding author.

Introduction It is necessary to search for and to carry out effective treatments for chemical dependency – including behavioral addictions. One of the methods used in various disorders is a biofeedback HRV (BF-HRV). The aim of the study is to examine the impact of BF-HRV on people addicted behaviorally to gambling and chemically dependent patients on opioids.

Material and methods Twenty-four opioid addicts were examined. We used emWave (HeartMath) with a heart rhythm monitor to learn stress reduction and emotional management skills. For a detailed analysis of the HRV data was used Kubios 2.0 software (Biosignal Analysis and Medical Imaging Group).

Results The average value of the three components of HRV, i.e. low (LF), medium (MF) and high (HF) frequencies of spectral energy FFT recorded during six consecutive sessions of BF-HRV were the following: 1st session LF 63%; MF: 17%; HF: 19%. Changing parameters in the next sessions: 2nd session LF –9.27%, MF: +0.50%, HF: +6.19%; 3rd session LF –11.11%, MF: +1.00%, HF: –10.07%; 4th session LF –14.27%, MF: –4.17%, HF: +18.77%; 5th session LF –15.02%, MF: –2.04%, HF: +17.07%; 5th session LF –15.02%, MF: –2.04%, HF: +17.07%; 6th session LF –20.86%, MF: –4.04%, HF: +24.90.

Conclusions After the BF-HRV training decrease low and medium frequencies (LF-MF) and increase high frequency (HF). Recent studies suggest that LF-HRV is an index of cardiac sympathetic control and the LF/HF ratio is an index of sympathovagal balance.

EV122

Relationship between severity of tobacco dependence and personality traits, insomnia and impulsivity in male and female individuals entering alcohol treatmentA. Wnorowska^{1,*}, P. Serafin¹, A. Topolewska-Wochowska¹, A. Klimkiewicz¹, A. Jakubczyk¹, K. Brower², M. Wojnar¹¹ Medical University of Warsaw, Psychiatry, Warsaw, Poland² University of Michigan, Psychiatry, Ann Arbor, USA

* Corresponding author.

Introduction Tobacco dependence (TD) often coexists with alcohol dependence. Previous research documented that both biological and environmental factors influence simultaneous development of the two disorders. However, it has not been determined whether the same psychological and psychopathological factors affect TD in alcohol-dependent males and females.

Aim The objective of the study was to assess risk factors for high severity of TD in alcohol-dependent individuals considering gender differences.

Methods The study entailed two groups: male ($n=284$) and female ($n=102$) subjects entering alcohol addiction treatment programs in Warsaw, Poland. Standardized instruments were used to assess: severity of TD – Fagerstrom Test for Nicotine Dependence, personality traits – NEO-Five Factor Inventory to assess, consequences of drinking – Short Inventory of Problems, impulsivity – Barratt Impulsivity Scale, and Sleep Disorder Questionnaire-7 as a measure of insomnia.

Results In the studied sample, current smokers comprised 79.1% ($n=225$) of male and 79.4% ($n=81$) of female participants. Multivariate regression model showed that high negative consequences of drinking ($P=0.001$) and low NEO Openness score ($P=0.009$) were associated with high risk of TD in female alcoholics (corr. $R^2=0.223$; $P<0.0005$). Bivariate analyses showed that TD was associated with impulsivity, openness, agreeableness and neuroticism in male alcohol-dependent subjects. Insomnia was the only significant predictor for high severity of TD in the males (corr. $R^2=0.068$; $P=0.002$).

Conclusions Different factors contribute to severity of tobacco dependence in male and female alcohol-dependent individuals entering addiction treatment.

Social anxiety in medical students: A five-year follow-upS. Ak^{1,2,3,*}, C. Kılıç^{1,3}¹ Hacettepe University, Faculty of Medicine, Psychiatry, Ankara, Turkey² Kastamonu University, Faculty of Medicine, Psychiatry, Kastamonu, Turkey³ Hacettepe University, Stress Assessment and Research Center STAR, Ankara, Turkey

* Corresponding author.

Introduction Social anxiety is known to interfere with academic attainment. Its negative effects may be more pronounced in medical students, since symptoms may prevent acquisition of necessary skills for appropriate medical examination or procedures.

Objectives Medical education in Turkey lasts six years. Clinical internship (6th year) is qualitatively different from other years, since the student assumes the responsibilities similar to those of resident physicians. The transformation involved in this process may have an effect on the social anxiety levels of students.

Aims Our aim was to examine how medical education effects social anxiety level, focusing on the change from start to graduation.

Methods This was a pooled, time series cross-sectional study. Independent samples of students from same group were assessed for demographic information and social anxiety at three time points: at the first year of medical school ($n=152$), at the beginning of 6th year of medical school ($n=153$), and at the end of the 6th year ($n=130$).

Results Social anxiety levels declined from Time 1 (Liebowitz Social Anxiety Scale [LSAS] = 44.3) to Time 2 (LSAS = 30.6), and was stable after that (LSAS at Time 3 = 30.7). Social anxiety was predicted by “having another phobia” at Time 1; and by “psychiatric history in family” at Times 2 and 3.

Conclusions Our study shows that medical education probably has a positive effect on social anxiety, but this effect does not continue into the last year, i.e. internship. This is unexpected, because internship requires the acquisition of new social and professional skills. Findings will be discussed in the light of relevant literature.

Low vitamin D, and bone mineral density with depressive symptoms burden in menopausal and post-menopause women

A. Bener

Istanbul University, Biostatistics & Public Health, Istanbul, Turkey

Objective The objective of current study was conducted to determine whether low vitamin D level and BMD are associated with depressive symptoms as burden in Arab women during the menopausal and post-menopausal period.

Design and setting A cross-sectional descriptive study.

Subjects A multi-stage sampling design was used and a representative sample of 1436 women aged 45–65 years were included.

Methods Bone mineral densitometry measurements [BMD] (g/m^2) was assessed at the BMD unit using. Data on body mass index (BMI), clinical biochemistry variables including serum 25-hydroxyvitamin D were collected. The Beck Depression Inventory (BDI) was administered for depression purposes.

Results Of the 1436 women living in urban and rural areas, 1106 women agreed to participate (77.0%). There were statistically significance differences between menopausal stages with regards to ethnicity, education level, systolic and diastolic blood pressure, parity, sheesha smoking and depressive symptoms. Overall, 30.4% of women were affected with osteopenia/osteoporosis in menopause and postmenopausal (24.4% vs. 35.7%; $P=0.0442$). Osteopenia in menopause and postmenopausal (18.7% vs. 29.3%; $P=0.030$) and osteoporosis (9.9% vs. 15.9%; $P=0.049$) were significantly higher in post-menopausal women than in pre-menopausal women ($P=0.046$). Similarly, vitamin D deficiency was more prevalent among postmenopausal women than menopausal women. The study revealed that vitamin D level, hemoglobin level, serum iron fasting plasma glucose, calcium, triglycerides, HDL cholesterol, LDL cholesterol, alkaline phosphate and magnesium were considerably lower in postmenopausal compared to menopause women ($P<0.001$).

Conclusion The study confirmed strong association between vitamin D level and BMD in Arab women during the menopausal and post-menopausal period.

⁴ University of Genoa, UNESCO CHAIR "Anthropology of Health – Biosphere and Healing system", Genoa, Italy

⁵ Iowa State University, School of Education, Ames, USA

⁶ Iowa State University, Human Computer Interaction Graduate Program, Ames, USA

* Corresponding author.

Introduction Nomophobia is the fear of feeling disconnected and is considered a modern situational phobia.

Objectives No psychometric scales in Italian are available investigating nomophobia. Therefore, we planned a translation and validation study of the Nomophobia Questionnaire (NMP-Q) by Yildirim and Correia.

Aims Subjects were recruited via an online survey using a snow-ball approach.

Methods NMP-Q was translated from English into Italian. To explore the factor structure, exploratory factor analysis (EFA) was carried out. A principal component analysis (PCA) approach with varimax rotation was performed.

Results Four hundred and three subjects volunteered to take part into the study. Age was 27.91 ± 8.63 y, 160 were males (39.7%) and 243 females (60.3%). 45 subjects used to spend less than 1 hour on their mobile (11.2%), 94 between 1 and 2 hours (23.3%), 69 between 2 and 3 hours (17.1%), 58 between 3 and 4 hours (14.4%), 48 between 4 and 5 hours (11.9%), 29 between 5 and 7 hours (7.2%), 36 between 7 and 9 hours (8.9%) and 24 more than 10 hours (6.0%). Eigen values and the scree-plot supported a 3-factorial nature of the translated questionnaire. NMP-Q showed a Cronbach's alpha coefficient of 0.95 (0.94, 0.89 and 0.88 for the three factors). The first factor explained 23.32% of the variance, the second and the third 23.91% and 18.67%, respectively. Further, the total score of NMP-Q correlated with the number of hours spent on the mobile, the age (beta-coefficient -0.33 , $P=0.016$) and sex (being higher among females).

Conclusions The Italian version of NMP-Q proved to be reliable.

The relationship between sensory processing disorder and temperament on emotional functioning and self-efficacy in childhood

S. Buchris Bazak

Qiryat-Gat, Israel

My study presents and explores the emotional functions and the sense of self-efficacy among school-age children (6–10) with sensory processing disorder manifested in sensory processing disorder (SPD) while addressing their temperament. Central questions in this study involve the element of temperament, which determined the emotional functioning of children who suffer from SPD and examined whether temperament explaining the variance in these children's self-efficacy. The SPD was the independent variable. Emotional functioning and the sense of self-efficacy were the dependent variables and temperament served as the mediating variable. The study focused on 209 students (129 boys, 80 girls) between the ages 6–10 ($M=8$, $SD=1.13$), studying in schools in different geographical areas in Israel. The Short Sensory Profile (SPS) Questionnaire was administered to the students in order to characterize their sensory profiles and served as a tool for screening and identifying the children with SPD and children who will be included in the control group. The questions raised in this study, have both educational and clinical research importance. They can be used as the basis for educational interventions for children with SOR and may be useful in supporting the building of an integrated intervention and treatment program.

Introduction Test anxiety is a multidimensional phenomenon, including concerns about conflicts lead to negative emotional and behavioral responses in academic scores.

Aim Current study examines the influence of educating time management on decreasing exam anxiety and educational negligence of conditioned university students on Tehran.

Methods The method of doing study is of testing in which statistical society includes conditioned university students of Tehran. Of general statistical society, we have selected 20 persons by in access sampling method. Gathering information instrument in this study is Solomon and Roth bloom's educational negligence questionnaire and Sarason test anxiety in which has been in access of studied sample after testing its stability and narration.

Result After education, the result of *t*-test dependent and covariance analysis has shown time management education does have meaningful influence on decreasing test stress and conditioned university students negligence on Tehran universities.

Conclusion Dropped students compared to other students, provided a significant contingent of students had less time management and procrastination.

Keywords Time management; Test anxiety; Educational negligence

Feasibility randomized controlled clinical trial of mindfulness and acceptance based therapy for females with social anxiety in Karachi, Pakistan

Z. Batool, B. Fatima*, Z. Zadeh

Bahria University, Institute of Professional Psychology, Karachi, Pakistan

* Corresponding author.

Background Anxiety and depressive disorders are becoming the major psychological issues among women in Pakistan. Social anxiety is one of the emerging psychological disturbances observed in young women. Since other therapeutic approaches for social anxiety have not shown significant positive outcomes in terms of symptom reduction and relapse prevention, further studies that focus on improving post-functional recovery is needed. Mindfulness and acceptance-based group therapy for social anxiety has shown to significantly reduce symptoms of social anxiety in the western world.

Aim The present study aims to test the feasibility of mindfulness and acceptance-based group therapy for females with social anxiety in Karachi, Pakistan.

Methods This trial is a feasibility study of a randomized controlled clinical trial in which 32 female participants will be recruited and randomized to a therapy group and the waiting list control

group. A mini social phobia inventory (SPIN-mini) will be administered for screening and recruitment of participants.

Discussion This is the first randomized controlled trial study in Pakistan for assessing the feasibility and usefulness of a culturally-adapted manualized intervention for social anxiety.

Treatment of general anxiety disorder by using of pregabalin – case report

M. Hajda*, D. Kamaradova, J. Prasko

University Hospital Olomouc, Klinika psychiatrie, Olomouc, Czech Republic

* Corresponding author.

Introduction Pregabalin is a chemical analog of the neurotransmitter gamma-aminobutyric acid (GABA). Its anticonvulsive, anxiolytics and analgetic effect is based on reducing of quantity of several neurotransmitters – especially glutamate, noradrenaline and substance P.

Objective Generalized anxiety disorder is a quite common psychiatric disorder, affecting approximately 8% of the population. Pregabalin is effective in the treatment of GAD. Its efficacy is comparable to sertraline. The first positive effects on symptoms of anxiety are described after one week of an administering. Anxiolytic dose of pregabalin varies from 450 to 600 mg per day. Pregabalin could be used potentially in patients with benzodiazepines addictions. There is hypothesis that pregabalin moderates withdrawal symptoms.

Aims This poster presents a case report of the patient who suffers from generalized anxiety disorder with comorbid somatoform disorder and severe hypnotic (zolpidem abuse)

Methods Short-termed hospitalisation at the detoxification unit to reduce doses of zolpidem. The attempt to use pregabalin to treat an anxiety and to decrease withdrawal symptoms.

Results Patient who has been treated by antidepressants without any effect so far, is now showing a good response to pregabalin.

Conclusion Decreasing symptoms of anxiety and somatoform pain compared to the beginning of the treatment. Complete discontinuation of using zolpidem without the withdrawal symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-stigmatization, adherence to treatment and discontinuation of medication – comparison between patients with severe mental disorders and anxiety spectrum disorders

D. Kamaradova*, K. Latalova, J. Prasko, M. Ociskova, A. Grambal, M. Hajda, R. Kubinek, K. Vrbova

University Hospital Olomouc, Psychiatry, Olomouc, Czech Republic

* Corresponding author.

Introduction Aim of our study was to found connection between self-stigmatization, adherence and discontinuation of drug treatment in two broad categories of the disorders:

– severely disorders patients (schizophrenia spectrum disorders, bipolar affective disorder, unipolar depression);

– anxiety spectrum disorders; and compare them each other.

Methods It is a cross-section study of ambulatory patients of Department of psychiatry, University hospital Olomouc. Patients were diagnosed according ICD-10 research diagnostic criteria. There were used ISMI, DAI-10 and demographic questionnaire for the assessment of the self-stigmatization, treatment adherence and

to collecting demographic data including self-report about discontinuation of the treatment in past.

Results We examined data from 99 patients (54 males) suffering from severe mental disorders and 86 patients (41 males) suffering from anxiety spectrum disorders. There were no statistically significant differences between these two groups in gender, age, education or marital status. In both groups, we proved significant correlation between level of self-stigmatization and adherence to treatment ($r = -0.320$, respectively $r = -0.432$). Up to our results, there were no statistically significant differences between both groups in level of self-stigmatization ($P = 0.656$), adherence to treatment ($P = 0.474$) and discontinuation of medication ($P = 0.231$).

Conclusions Level of self-stigmatization proved to be an important factor in influencing both level of adherence and discontinuation of drugs in both subgroups of patients. There were no differences between self-stigmatization or adherence between subgroups. More attention should be paid to issue of self-stigmatization throughout whole diagnostic spectrum of psychiatric patients.

Gender differences in anxiety among secondary school in Kuwait

S. Kareemi

Kuwait University, Faculty of Social Sciences, Psychology, Kaifan, Kuwait

Introduction Anxiety disorders are the most common mental disorders, and their prevalence is substantially higher in women than in men. Research has confirmed the existence of gender differences in several types of anxiety disorders.

Objectives The current investigation sought to determine whether any observable gender differences existed in anxiety for a nonclinical sample.

Methods the sample consisted of 300 males and 300 female students from a secondary school in Kuwait. The genders were matched in age (males = 16.52 ± 0.90 & females = 16.37 ± 0.96 , $t = 1.93$, $P > .05$). The inclusion criteria for all participants: sample of the population of Al-Jahra city, aged between 15 and 18 years old, school grades 10, 11, 12, and the social status of the parents (married). The Arabic version of Beck Anxiety Inventory (BAI) was administered to participants. BAI reliabilities ranged from .88 to .87 with a mean .87 (alpha) denoting good internal consistency. The convergent correlations in eight samples between BAI and Kuwait University Anxiety Scale KUAS (mean $r = .52$) for validity coefficients.

Results The results revealed that females (18.67 ± 11.11) had significantly higher mean anxiety than their male (14.52 ± 10.37) counterparts ($f = 22.27$, $P < .000$).

Conclusion Therefore, we can conclude that female preponderance of anxiety has been a consistent finding within literature.

Disclosure of interest The author has not supplied his declaration of competing interest.

EV132

A research on anxiety disorder prevalence and severity among vestibular migraine and migraine patients

Ö. Kutay Yüksel^{1,*}, G. Akdal², T. Alkın³, B. Dönmez Balcı¹

¹ Dokuz Eylul University, Clinical Neuroscience, Izmir, Turkey

² Dokuz Eylul University, Neurology, Izmir, Turkey

³ Dokuz Eylul University, Psychiatry, Izmir, Turkey

* Corresponding author.

In this research, anxiety, depression symptoms and severity were compared between healthy controls (HC), vestibular migraine (VM) and migraine patients without history of vertigo (MO).

Method Thirty-five definite vestibular migraine patients (according to Neuhauser criteria), 35 MO patients and 32 healthy controls were included. All patients were evaluated for their lifetime psychiatric disorders with Structured Clinical Interview for DSM-IV/Clinical version (SCID-I/CV). All three groups evaluated by:

– Hamilton Anxiety Rating Scale (HARS);
– State-Trait Anxiety Inventory (STAI), (STAI-X1) and the other trait anxiety STAI-X2);

– Beck depression inventory (BDI);

– Lifetime Panic Agoraphobic Spectrum Scale (PAS-SR);

– Penn State Worry Questionnaire (PENN);

– Separation Anxiety Symptoms Inventory (SASI);

– Adult Separation Anxiety Questionnaire (ASA).

Psychiatric diagnosis history (SCID-I); comparison of VM and MO did not indicate a significant difference ($P < 0.05$). VM and MO patients were significantly different than HC in terms of anxiety symptoms in "HAM-A, PENN, ASA, PAS-SR and PAS-SR subscales ($P < 0.05$)". VM was significantly different than MO patients in BDI and PAS-SR (overall; separation anxiety, agoraphobia, reassurance seeking) ($P < 0.05$). The longer the history of migraine the higher was the anxiety points in both in VM and MO patients ($P < 0.05$). Headache and vertigo severity in VM patients were significantly correlated with the elevated anxiety and depression points ($P < 0.05$).

Conclusion VM and MO patients significantly different in anxiety and mood disorder when compared with healthy controls. Our findings showed that VM patients were more vulnerable to psychiatric disorders. For that reason, multidisciplinary approach for the treatment of VM may facilitate the treatment process.

The Balkan region preferences for the treatment of anxiety disorders

M. Latas^{1,*}, D. Bonevski², A. Andromahi Naumovska²

¹ Belgrade, Serbia

² Психијатриска болница "Скопје", Центар за ментално здравје "Центар", Скопје, The Former Yugoslav Republic of Macedonia

* Corresponding author.

The most countries from West Balkan region do not have the official guidelines for the treatment of patients with anxiety disorders (AD). We have done the survey on preferences of treatment of patients with AD. We have collected data from sample of 221 psychiatrists from Croatia (41 psychiatrists), Macedonia (81 psychiatrists) and Serbia (99 psychiatrists). They give us information about their preferences for treating patients with AD.

The results indicate that the vast majority of psychiatrists report that almost all patients with AD receive benzodiazepines prior to first psychiatric visit. The majority of psychiatrist would opt for SSRI/SNRI antidepressants (91–97%) as the monotherapy or in combination with benzodiazepines (53–59%) or in combination with cognitive-behavior (25–35%) or psychodynamic psychotherapy (12–16%).

The most indicative difference between psychiatrists from different countries is result about the use of pregabalin – almost half of Serbian subsample would opt for pregabalin, but only a quarter of Croatian subsample and no psychiatrist from Macedonian subsample would choose pregabalin. Also, much more Macedonian and Serbian psychiatrist would opt for CBT treatment, but, in contrast, much more Croatian psychiatrist would opt for psychodynamic

psychotherapy versus CBT. There is the dissimilarity between preferences for patients' treatment and preferences for psychiatrists himself/herself treatment:

- more than half of the sample would opt for benzodiazepines in their patients but only the third of the sample would prefer benzodiazepines for himself/herself treatment;
- more psychiatrists would prefer to receive psychotherapy treatment than they would prefer to give it to their patients.

Relationship between cognitions and perceived self-efficacy with the severity of panic disorder with agoraphobia

L. Leon-Quismondo^{1,*}, G. Lahera²

¹ "Principe de Asturias" University Hospital, Psychiatry, Alcalá de Henares, Spain

² University of Alcalá, Ircys-Cibersam, Psychiatry, Alcalá de Henares, Spain

* Corresponding author.

Introduction The influence of cognitions and the perceived self-efficacy on mental health has been studied for a long time. Some studies have linked the perceived self-efficacy and apprehensive cognitions with the severity of panic disorder with agoraphobia.

Objectives To study the relationship between self-efficacy and dysfunctional beliefs of patients with panic disorder with agoraphobia and severity of the disorder.

Method A systematic review of the literature was performed to examine the evidence of relationship between self-efficacy and cognitions with the severity of panic disorder. PubMed and PsycInfo databases were searched.

Results The studies conclude that a higher level of self-efficacy decreases anticipatory anxiety and negative emotional states in panic disorder with agoraphobia, reducing the severity of panic disorder. There is a temporal relationship between dysfunctional beliefs, self-efficacy and fear of a panic attack: changes in fear are preceded by changes in beliefs, changes in efficacy or changes in both beliefs and self-efficacy. Therefore, a higher level of self-efficacy and positive beliefs have been studied as a significant predictor of lower severity of the disorder and a greater improvement during treatment.

Conclusions These results support the hypothesis that cognitive changes precede improvement and the importance of cognitive appraisals for anticipatory anxiety and severity of the panic disorder with agoraphobia.

The system prevention of adjustment disorders in medical students

I. Leshchyna

Kharkov National Medical University, Psychiatry, narcology and medical psychology, Kharkov, Ukraine

The problem of consolidation and strengthening of the mental health of students can be solved by the active use of complex systems of psychoprevention mental disorders in students.

The purpose of investigation was development of the scientifically determined system prevention of adjustment disorders in medical students.

In this research, were determined and systematized clinical-anamnestic, clinical-psychopathological, psychodiagnosical aspects of mental health and state of disadaptation medical students.

Adjustment disorders were diagnosed in 107 people (12.86%). In the structure of mental pathology are dominated by prolonged and short-term depressive reaction (38.6% and 31.2%) and mixed anxiety-depressive reaction (22.3%).

Primary psychoprevention was aimed at identification and elimination markers of risk of adjustment disorder among healthy students, followed by complex use of measures aimed at potentiation of resistance to mental disorders, increased socialization, optimization way of living, learning, relaxation. Secondary psychoprevention was directed to early diagnosis and prognosis of adjustment disorder using screening for mass examination. Measures of tertiary psychoprevention based on qualitative assessment of clinical picture of adjustment disorder aimed at making optimal clinical decision and included the integrated use of psychocorrection and psychopharmacotherapy. Their goal was clinical recovery and prevention of aggravation psychopathological symptoms and psychosocial disadaptation.

The effectiveness of proposed psychoprevention was significant decrease (more than twice) frequency of manifestation new cases mental disadaptation disorders in students.

The development and active implementation in practice psychoprevention of adjustment disorders in students is one of the priority areas preserving the health of young person under conditions professional education and should be complex, maximally approached to the students.

Body dysmorphic disorder and psychosis: A case report and review of literature

H. Maatallah*, H. Ben Ammar, M. Said, A. Aissa
Razi Hospital, F, Tunis, Tunisia

* Corresponding author.

Introduction Patients with body dysmorphic disorder (BDD) are concerned about a slight or non-existent defect on their appearance, causing significant stress and interfering on their social and professional life.

Despite its prevalence and psychosocial impact, this disorder remains unknown by many clinicians.

Methods and objective Through a review of literature and illustration in our case report we will define: the symptomatology of this pathology, psychopathological models of the disorder and the etiopathogenic assumptions associated with it, in terms of risk factors and neurobiological correlations.

Case report Patient 33 years old unmarried having been the victim of an AVP at the age of 25 years causing him a head injury above right eye for which he undergoes cosmetic surgery three times but the patient still not satisfied with installation of psychotic and delusional disorders requiring the use of antipsychotics.

Conclusion The complexity of body dysmorphic disorder should not discourage clinicians to confront this disease. The management requires more than putting under medical treatment associated to psychotherapy, we also need a good relationship of trust and maintain effective working alliance.

² Faculty of Medicine of Porto University, Department of Clinical Neurosciences and Mental Health, Porto, Portugal

³ Faculty of Medicine of Porto University, Department of Pharmacology and Therapeutics, Porto, Portugal

* Corresponding author.

Introduction Illness anxiety disorder, or hypochondriasis, is one of the most difficult and complex psychiatric disorders to treat.

Objectives To describe a case of a patient with illness anxiety disorder and summarize the most important aspects on this theme.

Methods Interviews with the patient and literature review searching the PubMed/MEDLINE were performed.

Results A 42-year-old married man, dentist, Angolan citizen, who had recently arrived in Portugal, was referred to psychiatry assessment during his hospitalization in medicine service, after an exhaustive medical evaluation. He was excessively anxious and worried about having a severe heart disease because he has gradually become more aware of palpitations and chest pain. Although negative results of the examinations he was worried that “something has been missed”. After he had consulted several medical providers in Luanda, he decided to seek medical advice in Portugal. Patient believed that his symptoms exacerbated with activity and intake food, so he gradually restricted them. Due to his health anxiety, he stopped his work and lost 36 kilos. Shortly before the onset of the clinical picture, his daughter was hospitalized for the first time.

Conclusion Illness anxiety disorder often begins in early to middle adulthood. Its core feature is the fear or idea of having a serious disease, based on the misinterpretation of bodily signs and sensations as evidence of disease, which persists despite appropriate medical evaluations and reassurance. This patient fulfills the DSM-5 criteria of illness anxiety disorder and has a clinical profile similar to those found in literature.

Psychogenic astasia-abasia: A case report and a review of the literature

A. Mota

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

Introduction Psychogenic movement disorders are the result of a psychiatric rather than a primary neurological disorder. Astasia-abasia refers to the inability to stand or walk despite having good motor strength and conserved voluntary coordination.

Objectives Starting from a case report of a patient with an unusual gait disturbance the author intends to discuss the history and knowledge evolution on psychogenic gait disorders until the present time.

Aims To debate the nosology, clinical features, diagnosis and treatment of psychogenic movement disorders.

Methods Non-systematic review of the literature. Case presentation with the exhibition of a video showing the patient's gait.

Case presentation A 48-year-old female was admitted to a psychiatry ward after attempting to commit suicide by cutting her throat. On day 3, she suddenly could not walk or stand without help. The neurological examination revealed some inconsistencies and all laboratory, electroencephalogram, and imaging studies performed

were normal. After 2 weeks of treatment she started gradually getting better until the full recovery.

Discussion The gait disturbance presented might be regarded as a form of astasia-abasia. This term was first coined by Paul Blocq (1888) when he described a group of patients who showed inability to maintain an upright posture. Similar movement disorders were previously described as hysteria by authors like Charcot. Nowadays, these case descriptions would be likely considered cases of conversion or psychogenic gait disorder.

Conclusion The etiology of these disorders is still not very well understood. These patients usually benefit from a multidisciplinary approach that includes psychiatry, neurology, physiotherapy, among others. Pharmacological and non-pharmacological treatments should address the underlying psychiatric condition.

Disclosure of interest The author has not supplied his declaration of competing interest.

Psychotherapy anxiety and phobic disorders

T. Chorna

Kharkov Medical Academy of Postgraduate Education, Psychotherapy, Kharkov, Ukraine

The aim of the study: the development of a comprehensive system of psychotherapy and psychocorrection of anxiety disorders of neurotic case, based on the study of their clinical structure and peculiarities of emotional damages.

Methodologies Spielberger, Eysenck Personality Questionnaire (EPQ), the Hamilton Rating Scale for Depression (HRSD), the study of accentuation of personality by K. Leonhard.

Scope and contributing research One hundred patients with diagnostic categories: F41.0 – Panic disorder (episodic paroxysmal anxiety), F41.1 – Generalized anxiety disorder, F41.2 – mixed anxiety-depressive disorder who are on the examination and treatment at the psychiatric unit. A control group included 40 patients. We performed the exploration of the peculiarities of clinical anxiety and patterns of therapeutic effect, based on the influence of short-term group and individual psychotherapy in the treatment of anxiety disorders, and evaluation the effectiveness of its recognition.

The development of the methodology of applying a short-term group and individual psychotherapy in the treatment of anxiety disorders based on combination relaxation, hypnosis, cognitive-behavioral techniques in combination with short-term group therapy.

In fact, this is a new real model psychotherapy based on integrative principles. The high efficacy was shown in 82% patients, compared with 54% efficacy in control group patients.

We will offer a new comprehensive methodology in the treatment of anxiety disorders of neurotic case that will improve the therapeutic efficacy of the treatment process, reduce the time of treatment, reduce the period of drug therapy.

Respiratory panic disorder in acute clonazepam treatment and long-term follow-up

A. Nardi*, R.C. Freire, S. Machado, R. Amrein

Federal University of Rio de Janeiro UFRJ, Institute of Psychiatry, Rio de Janeiro, Brazil

* Corresponding author.

Objective to describe with prospective methodology the therapeutic response to clonazepam in the respiratory panic disorder (PD) subtype versus the non-respiratory subtype in a long-term follow-up.

Methods A total of 67 PD outpatients (DSM-IV) were previously divided into respiratory ($n=35$) and non-respiratory ($n=32$) subtypes and then openly treated with clonazepam for 8 weeks. Those who responded were then treated for 3 years. Demographic and clinical features were compared in the two groups. The instruments used to evaluate response were the Clinical Global Impression, the Sheehan Panic and Anticipatory Anxiety Scale, and the Panic Disorder Severity Scale.

Results In the first 8 weeks of treatment (acute phase), the respiratory subtype had a significantly faster response on all the major scales. During the follow-up and at the end of the study (week 156), there was no difference in the scale scores, and the reduction in panic attacks from baseline to end-point did not differ significantly between the two groups. After the acute phase treatment, the patients could undergo psychotherapy. In the respiratory subtype, the disorder had a later onset, was associated with a high familial history of anxiety disorder. The non-respiratory subtype had significantly more previous depressive episodes. Clonazepam had a safe adverse event profile during both phases of treatment.

Conclusion The respiratory PD subtype had a faster response to treatment with clonazepam at 8 weeks than did the non-respiratory subtype and an equivalent response after 6 months of treatment. The response of clonazepam is clearly maintained during the long-term follow-up.

Psychiatric factors in alopecia areata: A case report

E. Palha Fernandes*, J. Maciel, P. Pina, A. Fonte
Unidade Local de Saúde do Alto Minho, Psychiatry and Mental Health Department, Viana do Castelo, Portugal

* Corresponding author.

Introduction Alopecia areata is a recurrent nonscarring type of hair loss that can affect any hair-bearing area and can manifest in many different patterns. The influence of psychological factors in the development, evolution and therapeutic management of alopecia areata is well-documented. Life events and intrapsychically generated stress can play an important role in triggering of some episodes. Besides that, alopecia itself can cause psychosocial distress.

Objectives/aims The authors will present a case of a 47 years old woman who developed alopecia areata after a big fight with her sister-in-law and after the death of her father-in-law.

Methods Literature review of alopecia areata and correlation between alopecia areata and psychological factors. The patient has been followed in psychiatry ambulatory consultation, for a period of one year, and in dermatology outpatient consultation, for a period of four years.

Results Stressful life events played an important role in the development of alopecia areata. The illness itself had an impact on the patient's life, with subsequent deterioration of psychological condition and social withdrawal during the exacerbations. Treatment with antidepressants positively affected the patient's adaptation to the disease and even lead to a better dermatological evolution of the alopecia.

Conclusions There is a well-established correlation between psychological factors and alopecia areata. Therefore, these patients should be examined through multidisciplinary approach. The psychological aspect of alopecia areata must be taken in consideration,

as it can be implicated in both pathogenesis and consequence of the disease.

EV142

Clinical staging in panic disorder and agoraphobia

A. Pavlichenko

Moscow State University of Medicine and Dentistry n.a. Evdokimov, Psychiatry, Narcology and Psychotherapy, Moscow, Russia

There is an increasing literature about the implementation of the staging model in many mental disorders. According to this approach, there are four stages of a psychiatric disorder: prodromal stage, acute manifestations, residual phase, chronic. In this study, we empirically investigate whether additional clinical variables such as clinical manifestations and comorbid disorders may be useful to modify the staging model to panic disorder (PD).

We distinguished inpatient sample ($n=79$) with a diagnosis of "panic disorder" according to the DSM-IV criteria. We propose that the inclusion of prodromal stage of PD does not make clinical sense since the different unspecific neurotic symptoms may proceed to a variety of anxiety and depressive disorders. First stage was characterized by the situationally predisposed panic attacks (PA) with both somatic and cognitive symptoms. Comorbid disorders included somatoform disorders and generalized anxiety disorder (GAD). During second stage individuals experienced agoraphobic avoidance until traveling in public transport. On the other hand, spontaneous PA were accompanied by the only somatic but not cognitive symptoms. The most common patterns of comorbidity were GAD and alcohol misuse. Third stage was associated with the absence or limited symptom attacks and chronic agoraphobia. Major depression and obsessive-compulsive disorder might be an integral part of the clinical manifestations. This study supports that the staging model in PD might be updated by the detailed description of clinical manifestations and comorbid disorders at each stage that may help the practitioners to choose the best strategy for the treatment of a particular patient.

EV143

Pregabalin – mono- or adjuvant therapy for somatoform disorders

D. Popovic^{1,*}, D. Pavicevic²

¹ Petrovac na Mlavi, Serbia

² Clinic of Psychiatry "Dr L. Lazarevic", Daily Hospital, Belgrade, Serbia

* Corresponding author.

Somatoform disorders (SD) represent complex interaction between mind and body, where physical symptom is a symptom of a mental disorder.

The efficacy estimation of pregabalin (PG) versus combination of PG and antidepressants (AD) in patient with SD after long-term treatment with partial response to various AD therapies (SSRI, SNRI, MAOI, TCAs, SARIs, SNDIs).

These nine months, prospective, open-label study involved 31 patients diagnosed by standard clinical interview as F45 and comorbid diagnosis F41, F32, F33 or F34 according to ICD-10 criteria. There were two groups: experimental group (EG) on PG-15 patients and control group (CG) on PG + AD-16 patients. The assessment was made by 100 mm Visual Analogue Scale (VAS) and Clinical Global Impression Scale (CGI) on the baseline and follow ups were

made on seventh day, after one, two and nine months. Daily PG dose ranged from 150–300 mg.

Within both groups there was highly significant difference in the decline of scores on the VAS and CGI in all repeated measurements, except for CGI in both groups between second and ninth month: there was no statistical difference, Wilcoxon Signed Ranks Test: $CGI_{EG} P=0.102$, $CGI_{CG} P=0.317$. Comparing results between CG and EG on both scales, there were no statistically significant differences in all measurements. At the end of the study, Mann-Whitney test for CGI $P=0.560$ and VAS $P=0.705$ and no difference in the effects of the drugs between EG and CG on both scales CGI $P=0.467$, VAS $P=0.860$.

Efficacy of PG is equal as PG + AD combinations in SD treatments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Anxiety, depression and perceived health status in patients with epilepsy

F. Smaoui^{1,*}, E. Turki¹, N. Halouani^{2,*}, M. Turki¹, I. Bouchhima¹, N. Bouzidi¹, M. Ben Amar¹, O. Amami², C. Mhiri¹

¹ Habib Bourguiba Hospital, Neurology, Sfax, Tunisia

² Hedi Chaker, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Epilepsy is a chronic disease often disabling, source of stigma and poor quality of life.

Objectives Determine the prevalence of anxiety and depression in patients with epilepsy and the associated factors.

Methods We conducted a prospective, descriptive and analytical study among 20 patients followed for epilepsy in our department of neurology. The study was conducted from February to April 2015. We used a preestablished form to collect the socio-demographic and clinic profile of the patients. The assessment of anxiety and depression was made via the HADS "Hospital Anxiety and Depression Scale" and the perceived health status via GHQ scale "General Health Questionnaire".

Results The average age of our patients was 35.9 years. The average GHQ score was 27.7. It was higher in women without a statistically significant difference. It was positively correlated with the number of attacks during the last 12 months ($P=0.042$), poor treatment adherence ($P=0.007$), the feeling of disability ($P=0.021$) and the feeling of stigma ($P=0.008$). Anxiety was estimated in 35% of cases and 45% were depressed. Depression was significantly associated to the celibacy ($P=0.012$), the feeling of stigma ($P=0.038$) and the GHQ score ($P=0.016$). Anxiety was correlated with the absence of hobbies ($P=0.02$) and the GHQ score ($P=0.008$).

Conclusion It is important to detect these psychiatric disorders and to manage generators factors to ensure a better quality of life and social integration for these patients with epilepsy.

EV145

The psychological impact of melasma. A report of 30 Tunisian women

F. Fatma¹, I. Baati¹, M. Mseddi², R. Sallemi^{1,*}, H. Turki², J. Masmoudi¹

¹ Hedi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

² Hedi Chaker University Hospital, Dermatology, Sfax, Tunisia

* Corresponding author.

Introduction Melasma is a common disorder of acquired hyperpigmentation characterized by tan or brown macules and patches localized to photo-exposed areas of the face.

Objective To study the psychological impact of melasma on Tunisian women.

Methods We conducted a cross-sectional study on thirty patients with melasma who attended the dermatology department of the University Hospital in Sfax (Tunisia).

The questionnaire included socio-demographic and clinical data. We used four measurement scales:

- MELASQOL questionnaire;
- Rosenberg Self-Esteem Scale;
- Hospital Anxiety and Depression Scale;
- Body Image Questionnaire.

Results The mean age was 34.6 years. The majority was living in urban areas (90%), was married (56.7%) and had a profession (80%). Sixty percent of patients were anxious and 16.7% were depressed. Both self-esteem and body image were respectively altered in 43.3% and 36.6%. The average score of MELASQOL was 31.77%. It was higher in single woman (36.8 vs. 28.4), younger than 40 years old (31.5 vs. 21.7), having a low socioeconomic status (45.2 vs. 29) and working in private sector (40 vs. 24).

The quality of life was more damaged in patients with disease duration less than five years ($P=0.024$).

Anxious patients had higher MELASQOL scores than non-anxious (38.17 vs. 22.17; $P=0.008$), as well as depressed patients (49 vs. 28.32; $P=0.009$).

High MELASQOL scores were correlated with low self-esteem ($P=0.05$) and altered body image ($P=0.04$).

Conclusion Although benign, melasma causes an important psychological impact such as anxiety, depression, low self-esteem and poor body image. These effects should be considered in the care plan.

EV146

Efficacy of antidepressants in post-traumatic stress disorder

H. Snene

Military Hospital of Tunisia, Psychiatry, Tunis, Tunisia

Introduction The treatment of post-traumatic stress disorder (PTSD) has several aims such as reducing the severity of symptoms, minimizing the functional impact and improving the quality of life. Antidepressants are considered as the first line pharmacological treatment for PTSD. However, recent reports concluded that current evidence to determine their efficacy is at best suggestive.

Aims The purpose of this study was to evaluate the efficacy of antidepressant treatment in PTSD.

Methods This was a prospective and descriptive study concerning patients who consulted from August to October 2013 in the psychiatry department of military hospital of Tunis and were then diagnosed as having a PTSD according to the DSM-IV-TR criteria ($n=28$). All patients had an antidepressant treatment. An evaluation by the Clinician-Administered PTSD Scale (CAPS) was performed at diagnosis and after 12 weeks. The most common definition of therapeutic response for patients with PTSD is a decrease of 30% or more in the CAPS score.

Results Tables 1 and 2.

Conclusion Antidepressants have shown efficacy in the treatment of over half of PTSD cases. However, these results confirm that a large proportion of patients do not respond to this therapeutic class. Other options are needed to overcome these shortcomings in order to improve the prognosis of this particularly disabling disease.

Table 1

Response to treatment	53.6%
No response to treatment	46.4%

Table 2

	Average CAPS score
At baseline	92
After 12 weeks	63

Dissociative disorder – unraveling the mystery

L. Sousa*, A. Antunes, S. Oliveira

Hospital de Santa Maria, Lisbon Academic Medical Center, Psychiatry and Mental Health, Lisbon, Portugal

* Corresponding author.

Introduction Dissociative disorders are among the most enigmatic and controversial psychiatric pathologies. In the last decades, great interest has emerged in understanding its pathophysiology, nonetheless, problems in recognition and management of these disorders are still challenging the psychiatric community.

Objectives We describe a paradigmatic case of a dissociative disorder illustrating the “choice” of dissociation as a strategy for coping with a traumatic reality.

Aim Call attention to problems that interfere with the recognition, diagnosis and management of dissociative disorders.

Methods Bibliographic research was conducted through the PubMed in the Medline library and clinical information was obtained through medical records and clinical interviews with the patient.

Results A 51-year-old Brazilian woman with no psychiatric history presented to the psychiatric outpatient care with apparent dissociative symptoms, these consisted of amnesia for episodes of agitation and aggressive behavior that occurred mainly at bed time. She had been previously on general practice and neurology consultations but none organic diagnose was made. Already in psychiatry, it was recognized that those symptoms developed together after a car accident and the beginning of a romantic relationship. It was also recognized that she has sexual dysfunction and a history of sexual abuse by a family member during her childhood, a known risk factor to dissociative disorders.

Conclusions Skepticism and lack of understanding might be the reason for late psychiatric referral after the realization of various expensive and time-consuming medical exams. Improving the recognition of dissociative disorders will conduce not only to better clinical outcomes but also improve cost effectivity of medical interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Burnout and neurotic symptoms among medical students

A. Tereszko^{1,*}, K. Drozdowicz², M. Szymura¹, A. Tuleja¹, W. Korzeniowski¹, A. Kozłowska¹, M. Siwek², D. Dudek²

¹ Jagiellonian University Medical College, Students' Scientific Association of Affective Disorders, Kraków, Poland

² Jagiellonian University Medical College, Department of Affective Disorders, Kraków, Poland

* Corresponding author.

Introduction Medical studies are considered one of the most stressful majors and the medical profession is one of the most at risk of burnout. Some studies indicate the presence of symptoms of burnout already in the early stages of career, or even before it started, i.e. during studies preparing for the profession. Medical studies may be such a case and it can affect the mental health deterioration and cause the occurrence of both burnout and neurotic symptoms.

Objectives Assessment of the impact of the course of studies on mental health of students and the risk of rapid burnout.

Aim Estimation of the prevalence and severity of burnout and neurotic symptoms among medical student depending on the year of study.

Methods Seven hundred and eighty-one medical students participated in the study. We used translated version of Maslach Burnout Inventory-Student Survey and Polish questionnaire – Symptom checklist S-III – for neurotic symptoms assessment.

Results There was no significant difference in MBI-SS subscales and symptoms checklist between first and last year of studies. Difference turned out to be significant when 1st and 6th year students with 3rd year – in Symptom checklist ($P < 0.01$ and $P < 0.05$, respectively), MBI-SS emotional exhaustion subscale ($P < 0.01$ for both) and depersonalization subscale ($P < 0.01$, significant only when compared with 1st year students).

Conclusions Study revealed interesting pattern of burnout and neurotic symptoms, with their greatest severity at the beginning and the end of studies.

Virtual reality therapy for agoraphobic outpatients in Lima, Peru

M.I. Vásquez Suyo*, P. Núñez-Torres

Arzobispo Loayza National Hospital, Mental Health, Lima, Peru

* Corresponding author.

Virtual reality (VR) is an effective treatment for anxiety and phobias, including agoraphobia, close the gold standard (in vivo exposure) with less cost and logistical problems. In our country, Peru, experience of VR use or research in phobia treatment with objective measures of anxiety and anxious manifestations in the body are not found.

Objective The aim of the study is to determine whether treatment of agoraphobia with RV is effective in patients from Arzobispo Loayza National Hospital 2015 (symptom reduction: 50% or less), comparing its effectiveness with other studies and determine whether patients have side effects (cibersickness) as other realities.

Method The sample consisted of 8 patients of both sexes with clinical diagnosis of agoraphobia. Subjects were exposed to virtual reality environments generated by Psious Virtual Reality application for agoraphobia treatment and skin conductance (measured in microsiemens) and scale of subjective units of anxiety (SUDS) were recorded while the patient was exposed to virtual environment that provoke anxiety; they was measured by 5 sessions.

Results All patients had clinical improvement and reduction in microsiemens conductance measurement and SUDS: six patients improved more than 50%, with statistically significant results. There was only cibersickness in a patient. The results correspond to findings in other countries about the effectiveness. It is suggested that new studies expanding the sample and including other phobias.

Nonlinear electroencephalogram analyse cortical functional activity in patients with generalized anxiety disorder

Y. Wang

Guiyang Medical University, Department of Psychiatry, Guiyang, China

Background The neurological correlates of generalised anxiety disorder (GAD) are not well known, however there is evidence of cortical dysregulation in patients with GAD. The aim of the study was to examine cortical functional activity in patients with GAD using nonlinear electroencephalogram (EEG) analysis, and to evaluate the contribution of anxiety severity.

New method The sample consisted of 64 outpatients diagnosed with GAD, anxiety severity was assessed using the Hamilton Rating Scale for Anxiety (HAMA) severity score, with 7–17 scores indicating mild anxiety as A group and 18 and above indicating moderate-severe anxiety as B group. EEGs were conducted, and between-group differences on non-linear parameter Correlation Dimension (D_2) were analyzed. The association between D_2 value and HAMA scores was analysed.

Results Compared with the control group, D_2 values were increased in anxiety groups. For those with mild anxiety, this difference occurred only in the left prefrontal regions. For those with moderate-severe anxiety, significantly greater D_2 values were observed in all of the cerebral regions, especially in the left and right temporal and other left cerebral regions. When compared with those with mild anxiety, D_2 values were significantly greater for those with moderate-severe anxiety in the left and right temporal lobe and all other left cerebral regions.

Conclusions GAD was significantly associated with dysfunctional cortical activity in the majority of cerebral regions, GAD severity was associated with involvement of a larger number of cerebral regions. This analysis method is suggested as a complementary tool to examine dysfunctional cortical activity in GAD.

Do bipolar II and bipolar I disorder have different genotypes and why do we observe unipolar depression converting to bipolar II and then bipolar I?

M. Agius^{1,*}, M. Fawcett², R. Zaman¹

¹ University of Cambridge, Psychiatry, Cambridge, United Kingdom

² University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom

* Corresponding author.

We review the recent literature in order to establish the importance of a spectrum for bipolar affective disorder, and that unipolar depression, bipolar II and bipolar I are discrete entities that may however evolve in sequence. We discuss clinical, genetic and neurobiological data which illustrate the differences between bipolar I and bipolar II. To fit the data we suggest a series of multiple mood disorder genotypes, some of which evolve into other conditions on the bipolar spectrum. Thence, we discuss the nature of the bipolar spectrum and demonstrate how this concept can be used as the basis of a staging model for bipolar disorder.

Use of lithium in acute mania in adolescents

C. Aksoy Poyraz^{1,*}, A. Özdemir², G. Günay², B.Ç. poyraz¹, S. Enginkaya², G. Karaçetin², N. Tomruk²

¹ Istanbul University Cerrahpaşa Faculty of Medicine, psychiatry, Istanbul, Turkey

² Bakırköy Mazhar Osman Mental Health and Neurological Diseases Education and Research Hospital, psychiatry, Istanbul, Turkey

* Corresponding author.

The aim of the present study was to investigate whether the use of lithium followed recommended practice in acutely manic adolescent inpatients. This study was a 12-month retrospective review of patients with manic episode admitted to Bakırköy Mazhar Osman Mental Health and Neurological Diseases Education and Research Hospital. Length of stay, medication data, serum levels and adverse effects were recorded for patients who started lithium treatment within average of 7 days of admission ($n = 52$). Average length of stay was 23.63 (SD = 17.6). The maximum dose prescribed within 24 h of starting treatment was 721.15 mg (SD = 239.5). The maximum daily dose was reached in an average of 7 days to 1136.5 mg (SD = 336.4). The average time after starting treatment until the first recorded serum level was 5 days. The average serum level reached was 0.5 mEq/L (SD = 0.22), which was raised to 0.6 mEq/L (SD = 0.3) at discharge with an average daily dose of 1038.46 mg (SD = 460). In 8 admissions (15.4%), one adverse effect was recorded that could have been related to lithium treatment but adverse events did not lead to discontinuation of drug. The literature supports that rapidly attained high serum levels are associated with positive outcomes. In this current study, clinicians used a relatively slow dose titration and lower serum levels were obtained suggesting that lithium was not considered as a primary agent for treating mania. Taking advantage of lithium especially for the maintenance treatment of bipolar disorder and tolerability may have driven these findings.

* Corresponding author.

Introduction Bipolar disorder (BD) is often associated with various comorbidities. It is substance use disorders (SUD) one of the most frequent comorbidities.

The ECA study (Epidemiologic Catchment Area) observed a prevalence over the life of the 56, 1% for any TUS in the total sample of patients with bipolar disorder. In subjects with bipolar I disorder prevalence was 60.7%, and those of type II 48.1.

In the OMS study conducted in America, Europe and Asia, the results confirm the high rates of disorders in patients diagnosed with bipolar disorder regardless of the country of study.

Case This is a male, 32, who came first to the Provincial Drug Addiction Service of Huelva in 2009 for cocaine, cannabis and alcohol.

In his personal history, he relates a convulsive episode at 14 years and one manic episode associated with consumption of cocaine in 2002 which began to be treated by a team of Mental Health and Provincial Center for Addictions.

He entered twice in a therapeutic community in 2009 for treatment for their disorder dependence on cocaine, alcohol and cannabis.

It has required admission to the Unit Hospitalization twice in 2012, with the discharge diagnosis of manic episode secondary to drug consumption.

Conclusions Most epidemiological studies in recent decades note the high prevalence of comorbidity BD + SUD.

BD-SUD comorbidity is particularly complex because each disorder affects the evolution of the other and they are frequently multiple comorbidities. In addition, it implies a worse clinical and functional outcome as well as poorer therapeutic response.

Objectives Analysis of the treatment alternatives for patients diagnosed with a bipolar disorder of torpid evolution. Revision of the possible adverse effects of lithium and its impact on the adherence to treatment.

Methods We revise the clinical evolution of a patient diagnosed with Bipolar disorder type I, with the following characteristics: at least two manic episodes per year, consumption of toxic substances and high sensibility to antipsychotics and euthymics.

Results We will describe the case of a 23-years-old patient diagnosed with bipolar disorder type I. During the course of the illness, benign intracranial hypertension is diagnosed and the treatment with lithium must be stopped. We replace lithium treatment by Asenapine monotherapy. The evolution of the patient was very positive. Taking account of the adverse effects of lithium and reducing them can facilitate the adherence to treatment and also benefit early remission and less deterioration in each episode.

Conclusions It is fundamental to promote a comprehensive approach to each patient, including psychotherapy, psychoeducation as well as appropriate medication. The knowledge of the described effects helps us to determinate the appropriate medication for each patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Unipolar mania: Prevalence, socio-demographic and clinical correlates

A. Baatout^{1,*}, U. Ouali², F. Nacef²

¹ Hôpital Razi, Avicenne, Maamoura Nabeul, Tunisia

² Hôpital Razi, Avicenne, Tunis, Tunisia

* Corresponding author.

The concept of unipolar mania (UM) arose from the observation that some patients with bipolar disorder (BD) presented manic episodes in the absence of depressive episodes. The frequency of UM ranges from 4 to 52% in bipolar populations. The aim of our study was therefore to add to existing research by establishing the prevalence of UM in a sample of patients with BD and by studying their socio-demographic and clinical characteristics.

Of the 100 patients, 67 had been diagnosed with MD phases and 33 with UM. The mean age of the MD group was 43.21 years whereas it was 39.36 years in the UM group. Males represented 41.8% of the MD group and 72.7% of the UM group. The two groups were similar with regards to marital status, level of education and work activity. Age of illness onset was lower in the UM group (mean = 24.45) compared to the MD group (mean = 26). UM group patients had more relatives with affective illness (42.4% versus 32.8%).

The type of first affective episode was manic in 46.3%, mixed in 11.9%, depressive in 31.3% and not specified in 10.4% of the MD group whereas it was manic in 93.9% and not specified in 6.1% in the UM group.

The two groups were similar with regards to the presence or the absence of psychotic features.

The results of our study show that patients with UM were distinct from patients with a bipolar course of the illness in a range of clinical aspects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Behavioral disturbances are common in psychiatric patients. This symptom may be caused by several disorders and clinical status.

Case report We report the case of a 40 year-old male who was diagnosed of nonspecific psychotic disorder, alcohol dependence, cannabis abuse and intellectual disability. The patient was admitted into a long-stay psychiatric unit because of behavioral disturbances consisted in aggressive in the context of a chronic psychosis consisted in delusions of reference and auditory pseudohallucinations. During his admission the patient received the diagnosis of bipolar disorder type 1, presenting more severe behavioral disturbances during these mood episodes. It was necessary to make diverse pharmacological changes to stabilize the mood of the patient. Finally, the treatment was modified and it was prescribed clozapine (25 mg/24 h), clotiapine (40 mg/8 h), levomepromazine (200 mg/24 h), topiramate (125 mg/12 h), clomipramine (150 mg/24 h) and clorazepate dipotassium (50 mg/24 h). With this treatment, the patient showed a considerable improvement of symptoms, presenting euthymic and without behavioral disturbances.

Discussion In this case report, we present a patient with severe behavioral disturbances. The inclusion of bipolar disorder in the diagnosis of the patient was very important for the correct treatment and management, because of depressive and manic mood episodes the behavioral disturbances were exacerbated.

Conclusions Patients with behavioral disturbances could present psychotic and affective symptoms as cause of them. It is necessary

to explore these symptoms and try different treatments to improve them.

The influence of treatment modality on long-term neurocognitive functioning in treatment resistant bipolar depressed inpatients treated with pharmacotherapy or electroconvulsive therapy

J. BJORKE-BERTHEUSSEN^{1,*}, B. AUESTAD², U. KESSLER³, H. SCHOYEN¹

¹ Stavanger University Hospital, Psychiatry, Stavanger, Norway

² Stavanger University Hospital, Research Department, Stavanger, Norway

³ Haukeland University Hospital, Psychiatry, Bergen, Norway

* Corresponding author.

Introduction Bipolar depression is difficult to manage, and causes considerable disability and distress for patients and their surroundings. Electroconvulsive therapy (ECT) is an effective treatment, but there are concerns regarding long-term neurocognitive impairment, and in particular autobiographical memory.

Objectives To compare the long-term effects of algorithm-based pharmacologic treatment (APT) and ECT in treatment-resistant bipolar depression as measured with standard neurocognitive tests and autobiographical memory interview.

Aims To examine the long-term neurocognitive effects of ECT.

Methods In this multicenter randomized controlled trial 73 in-patients with treatment resistant bipolar depression were randomized to either APT or unilateral ECT. Patients were assessed at baseline and at 6 months. Neurocognitive functions were assessed with the MATRICS Consensus Cognitive Battery (MCCB), Wechsler Abbreviated Scale of Intelligence (WASI) and the Autobiographical Memory Inventory – Short form (AMI-SF). At 6 months, neurocognitive data were available for 26 patients (APT $n = 11$, ECT $n = 15$).

Results There were no group-differences at baseline.

At 6 months, there was no group-difference in MCCB-score (APT 44.9 vs. ECT 46.0, P -value: 0.707), or WASI total IQ-score (APT 103.9 vs. ECT 107.2, P -value: 0.535). There were indications of (P -value: 0.109) poorer AMI-SF consistency score in the ECT group (APT 72.3% vs. ECT 64.3%).

Conclusions This study does not find that ECT causes long-term impairment in neurocognitive function as measured with standard neuropsychological tests. We find a trend towards poorer autobiographical memory in the ECT-group, and there needs to be further research regarding this.

Discontinuation of antipsychotic therapy in severe mania: A six months follow-up study

S. BRIOSCHI, D. DELMONTE, C. DE SANTIS*, L. FRANCHINI, C. COLOMBO

Scientific Institute and University Hospital San Raffaele, Clinical

Neurosciences, Milan, Italy

* Corresponding author.

Introduction Independently of the drug choice, antimanic treatment has to be continued at least until full remission. Most guidelines recommend continuation therapy for 6–12 months but controlled studies are lacking.

Objectives A six months follow-up study on a sample of 57 inpatients affected by mania at Mood Disorder Unit.

Aims To evaluate a timeframe for the discontinuation of the antipsychotic therapy.

Methods Fifty-seven bipolar inpatients affected by a manic episode according to DSM-5 criteria. Patients treated according to our pharmacological protocol with a mood stabilizer (lithium or valproate) and an antipsychotic (haloperidol or risperidone). Course of illness assessed with Young Mania Rating Scale (YMRS) scored at week 0, 1, 2, 4, 8, 24. Remission defined as YMRS < 12.

Results Twenty men (35.09%) and 37 women (64.91%); mean age 43.18 ± 12.71 years. Mean YMRS basal score 38.55 ± 8.08 . At 4th week, remission rate was 54.39% (31 patients); at 8th week was 80.70% (46 patients). At 8th week, 39/57 patients (68.42%) discontinued the antipsychotic. Relapse rate after 6 months was 26.32% (12 depressed, 3 manic). Multiple regression, t -test and χ^2 analysis were performed: older patients ($P = 0.01$) and with higher number of episodes ($P = 0.04$) tend to relapse earlier. Neither severity of the episode ($P = 0.3$), nor delusional symptoms ($P = 0.6$) nor discontinuation of the antipsychotic ($P = 0.3$) correlate with relapse time.

Conclusions Our experience suggests that an early discontinuation of antipsychotics, usually 4–8 weeks after remission, does not worsen the short-term course of illness. This approach could minimize the risk of side effects. Evidence is lacking about the duration of this therapy, long-term studies are still necessary.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between suicide attempts and insight among patients with bipolar disorders

A. CARDOSO^{1,*}, P. AGUIAR², M. BYRNE³, M. XAVIER¹

¹ Faculty of Medical Sciences, Mental Health, Lisbon, Portugal

² School of Public Health, New University, Public Health, Lisbon, Portugal

³ University of Wollongong, Clinical and Forensic Psychology, Wollongong, Australia

* Corresponding author.

Introduction Insight is an important factor associated with non-compliance and poor outcome. Poor level of insight has been described as a characteristic in patients with acute bipolar disorder with more unawareness in social consequences. In contrast, awareness of having a mental disorder, of its symptoms, of its consequences, and/or of the need for treatment is associated with a number of positive prognostic indicators. Insight is also linked, however, to depression and suicidal ideation in bipolar disorder.

Objectives (1) Assess the illness perception. (2) Assess the impact of insight in suicidal tendencies.

Aims Contribute to development measures to improve the insight in bipolar disorders.

Methods In this cross sectional study we use a convenience sample of patients with bipolar disorder attending in the mental health departments of three general hospitals in Lisbon great area. We have applied clinical and socio-demographic questionnaire and additional measures to assess symptom severity, treatment adherence and illness perception.

Results A samples was composed by 64 patients with bipolar disorder (mean age = 38.7; SD ± 10.1). A total of 48.4% patients ($n = 31$) had made a suicide attempted and 23.4% ($n = 15$) of this patient done 5 or more attempted suicide. We found a significant correlation with symptoms and insight ($r_s = 0.56$; $P < 0.01$).

Conclusion Mental health professionals often utilize insight as an indicator of prognosis, because of its association with treatment adherence. The findings of the current study suggest that having

intact or good insight may be an indicator for suicidal ideation among patients with bipolar disorders. A brief psychoeducational approach could potentially be effective. We recommend a combined approach to improve clinical insight in bipolar disorder.

Introduction Emotional intelligence is defined as the ability to process, understand and manage emotions. In bipolar disorder seem to be more conserved, with less functional impairment than other severe mental disorders as schizophrenia. So far, there are few studies analyzing emotional intelligence in bipolar disorder.

Objective The objective of this research is to better understand the different characteristics and the factors affecting these social-cognitive dysfunctions in bipolar disorder.

Aims To explore possible factors related to emotional intelligence in these severe mental disorders: symptoms, cognitive functioning, quality of life and psychosocial function.

Material and methods Twenty-six adults bipolar type I patients were examined using MSCEIT (the most validated test for emotional intelligence), BPRS, YMRS, HDRS, WAIS-IV, TMT and Rey Figure in order to determine the level of emotional intelligence and factors relate.

Results Bipolar patients show lack of emotional intelligence when compared with general population. Cognitive impairment and age are the principal factors related.

Discussion Results are discussed and compared with recent literature.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Psikids, Psychiatry, Madrid, Spain

⁴ Hospital del Henares, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Severe mental disorders have deficits in different aspects of social cognition, which seem to be more pronounced in patients with schizophrenia compared to those with bipolar disorder. Emotional intelligence, defined as the ability to process, understand and manage emotions, is one of the main components of the sociocognition. Both in schizophrenia and bipolar disorder have been described changes in emotional intelligence, but only few studies compare both disorders.

Objectives The objective of this research is to increase knowledge about the differences between schizophrenia and bipolar disorder.

Aims To compare emotional intelligence in patients with schizophrenia versus bipolar patients.

Methods Seventy-five adult patients with schizophrenia and bipolar disorder were evaluate.

The assessment protocol consisted of a questionnaire on socio-demographic and clinical-care data, and a battery of assessment scales (BPRS, PANSS, SCID-I-RV, YMRS, HDRS, CGI-S, EEAG, MSCEIT). Among the assessment tools of emotional intelligence, we select MSCEIT as the most validated.

Statistical analysis was performed using SPSS 23 version. After the descriptive analysis of the data, we compare the results of the scales.

Results Both disorders show a deterioration of emotional intelligence compared to the general population. There were no statistically significant differences in the comparison of emotional intelligence between schizophrenia and bipolar disorder.

Conclusion Schizophrenia and bipolar disorder have deficits in emotional intelligence, while it is difficult to show differences between them. These changes in emotional intelligence are part of a set of cognitive, social and non-social skills, which are altered in these severe mental disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Hospital Universitario Araba. Cibersam, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction The bipolar disorder (BD) has an important effect over the lives of patients and families. The attitude of the family is a modifiable factor through specific interventions and it has been related with BD prognosis.

Objectives Study a sample of families and patients with BD.

Aims Compare between two groups its course of burden of caring for family members with BD. Also, we will see the course of the functionality in patients.

Methods Sample of 148 individuals who caring a familiar with BD. Seventy-six of these followed psychoeducation session are going to be experimental group (EG), and the others 72 did not followed any session are going to be control group (CG). There is a follow-up at 6 months and one year. To see the course of the burden and the functionality it will be used mixed models.

Results At baseline, there were not significant differences between CG and EG in objective and subjective burden and functionality. But over time there were significant results in the three cases. For objective burden ($b = -0.016$; $P = 0.0001$) EG presented a drop ($b = -0.014$; $P = 0.0062$), while CG did not show changes ($b = 0.002$; $P = 0.4691$). For subjective burden ($b = -0.014$; $P = 0.0058$) without significant results for CG ($b = -0.352$; $P = 0.3203$) and a significant decrease in EG ($b = -0.017$; $P = 0.003$). For the functionality ($b = 1.474$; $P = 0.000$) there was a significant increase in EG ($b = 1.349$; $P = 0.000$) but not for CG ($b = -0.125$; $P = 0.3828$).

Conclusions Two groups did not differ at baseline however after the psychoeducation sessions appear clear differences, decreasing the burden for EG group and the functionality also improved for EG.

* Corresponding author.

Introduction Cognitive functions are known to be impaired both in schizoaffective and bipolar patients during the acute manic episode, but also in euthymia.

Objectives The purpose of the study was to identify differences in neurocognitive functioning of schizoaffective and bipolar patients.

Methods The study was conducted between 2012 and 2015. It included inpatients from the Timisoara Psychiatric Clinic, diagnosed with either bipolar disorder ($n=45$) or schizoaffective disorder ($n=43$), according to ICD-10 criteria, and a healthy control group ($n=85$). The Rey verbal memory test and the d2 Test of Attention were used to assess cognitive functions.

Results Statistically significant differences ($P<0.0001$) were found between the control group and the patients group in regard to “total number of items processes” (TN), “percentage of errors” (E%) and in “concentration of performance” (CP). No significant differences were found concerning neurocognitive functions between the two patient groups during the acute manic episode. However, cognitive functions were significantly more impaired in schizoaffective than in bipolar patients during euthymia (lower mean scores in bipolar patients regarding all the aforementioned parameters).

Conclusions The severity of cognitive deficits is similar in both bipolar and schizoaffective disorder during the acute manic episode. During euthymic periods, schizoaffective patients have a poorer neurocognitive functioning than bipolar patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Victor Babes University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Empathy is described as the ability to infer or share the feeling state of another person. Despite knowledge of impairments in cognitive and social functioning, to date, little work has been conducted concerning empathic response in bipolar and schizoaffective patients.

Objectives Finding potential differences regarding the empathic response of manic bipolar and schizoaffective patients.

Methods Inpatients from the Timisoara Psychiatric Clinic, diagnosed with either bipolar disorder ($n=50$) or schizoaffective disorder ($n=45$), according to ICD-10 criteria, and a healthy control group ($n=80$) were included in the study. The study was conducted between 2011 and 2015. To assess the empathic response we used Empathy Quotient (EQ).

Results We found statistically significant differences ($P<0.0001$) between the patient groups and the control group (lower mean for empathy scores than the control group in both bipolar and schizoaffective patients). During the acute manic episode, no significant

differences were found concerning the empathic response between the two patient groups. In euthymia, however, patients with schizoaffective disorder had significantly lower EQ mean scores than bipolar patients ($P=0.03$).

Conclusions Bipolar and schizoaffective patients seem to have similar lower levels of empathy during the acute manic episode, but schizoaffective patients have a poorer empathic response than bipolar patients during euthymic periods.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mixed states – hallmark characteristics and controversial nosologic evolution

D. Durães*, J. Martins, R. Borralho

Centro Hospitalar Barreiro-Montijo, Mental Health and Psychiatry Department, Barreiro, Portugal

* Corresponding author.

Introduction Classically described as the contemporary presence of affective symptoms of opposite polarity during a manic or major depressive episode, mixed states (MS) still remain a controversial topic and a diagnostic challenge, remaining many times undiagnosed and mistreated.

Objectives/aims This work aims to review the conceptualization and definition of MS over the years, their main characteristics and the controversy around the latest diagnostic criteria.

Methods A review of relevant literature was conducted alongside online database research (PubMed and Medscape) using the keywords “mixed state”, “bipolar” and “depression”.

Results Since their first description, by Johann Heinroth, the conceptualization and diagnostic features of MS have been largely contested. Subsequently, Emil Kraepelin systematized several subtypes of MS, being the first to introduce the term, and Wilhelm Weygandt published the first book on the subject (1899). Since then, largely due to Kurt Schneider disbelief, their study was neglected for several years.

MS definition suffered numerous changes through the different DSM editions, which clearly reflects the difficulty in their correct understanding. Recently DSM-5 introduced a broader definition that seems to better depict their nature and will certainly impact the known epidemiology, diagnosis and treatment.

Conclusions Accurate identification and prompt diagnosis of MS are crucial for clinical practice since these patients appear to show a more severe form of disease and a worse prognosis, with longer, more frequent relapses, substance use comorbidities and higher suicide risk with poorer response to treatment. Further investigation seems necessary to clarify the validity of the DSM-5 diagnostic criteria.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Subthreshold symptoms in bipolar disorder

R. Feki*, D. Trigui, I. Feki, I. Baati, J. Masmoudi
CHU Hédi Chaker, Psychiatrie A, Sfax, Tunisia

* Corresponding author.

Introduction Bipolar disorder is a severe mental illness characterized by intermittent episodes of mania, depression and mixed states. The presence of residual symptoms, seems to be the common factor in many studies assessing functioning in BD patients.

Objective To evaluate the prevalence of residual symptoms (both depressive and manic) in euthymic patients with bipolar disorder and seek for associated factors.

Methodology A total of 30 patients with bipolar disorder were enrolled for this study. They were in remission for at least two months. The patients answered the Hamilton Depression Rating Scale and the Disorder Questionnaire Mood Hirschfeld (the MDQ scale).

Results The average age of our patients was 43 ± 13 years. Most patients were from a rural area (70%), married (60%) and did not go beyond secondary school level (93.3%).

Forty percent (40%) had organic personal history. Social dysfunction was found in 40% of cases, and professional difficulties in 30% of patients.

Depressive residual symptoms were found in 33.3% in cases and hypomanic ones in 26.6%.

Residual depressive symptoms were significantly more frequent among married patients and having organic personal history ($P=0.025$).

The professional difficulties were associated with male gender ($P=0.025$) and the poor quality of free interval ($P=0.03$).

Conclusion These results illustrate that the “intercritical phase” in bipolar disorder is not really euthymic. These findings are in favour of developing interventions to manage subthreshold symptoms to reduce their impact on social and professional functioning.

* Corresponding author.

Introduction Recent studies have focused on the imbalance in inflammatory and antioxidant pathways as possible causes of the underlying neurodegenerative processes in bipolar disorder. Thus, the study of these pathways in first episodes of mania (FEM) can increase knowledge about this issue.

Aim To compare plasma concentrations of pro-inflammatory (MCP-1, PGE2, TNF α) and oxidative parameters (TAS, NO₂ and TBARS) between controls and FEM patients and to analyze the evolution of these parameters in patients from baseline to 6 months assessment time.

Methods This study included 44 FEM patients and 79 healthy controls, aged 18 to 40. Blood samples were available for controls at baseline and for patients at baseline and 6 months after. TAS and TBARS were measured using non-EIA assay kits, NO₂ was measured with Griess method and PGE2, MCP-1 and TNF α with ELISA kits.

Results At baseline, TAS was significantly lower in patients than in controls and TBARS, MCP-1 and TNF α were significantly higher in patients. Among patients, TAS and MCP1 were lower at 6 months than at the illness onset and PGE2 and NO₂ were significantly higher than at baseline.

Conclusion Patients presented an increased oxidative damage and also a higher activation of pro-inflammatory pathways than healthy controls at baseline. After 6 months their level of oxidative stress continue increased. Pro-inflammatory parameters decreased overtime (MCP-1 and TNF α) but PGE2, increased surprisingly. This can be due to the fact that antipsychotics are not able to completely reverse baseline inflammation.

Treatment of bipolar patients in manic phase: A comparison between asenapine and aripiprazole

L. Girardi*, S. Gili, E. Gambaro, E. Di Tullio, E. Gattoni, E. Grossini, S. Farruggio, L. Mora, C. Gramaglia, P. Zeppego
Università del Piemonte Orientale, Translational Medicine, Novara, Italy

* Corresponding author.

Introduction Agitation is the most evident symptom in an acute manic episode. It can be defined as excessive motor or verbal activity that can degenerate into aggressive behaviour. Both aripiprazole and asenapine are indicated for the treatment of agitation in patients with manic episode.

Aims To retrospectively evaluate the acute effects of drug therapy on psychomotor agitation rated with the PANSS-EC, the change in manic symptoms through the YMRS, the QoL with the SF-36v2 and the cardiometabolic effects of the new oral APS.

Methods We administered the following tests to 13 patients with DBI at T0 (baseline), T1 (after 1 week), T2 (after 4 weeks), T3 (after 12 weeks) and T4 (after 24 weeks): PANSS-EC, YMRS, SF-36v2, CGI-BD, CGI-S, HAM-D, BPRS. We also considered weight, height, BMI, ECG and complete blood count.

Results Patients recruitment and statistical analyses are still in progress. Our preliminary results suggest that there is not a marked difference between the two drugs. We highlighted that there has been a noticeable decrease in results at PANSS as well as at YMRS from T0 to T4 and patients showed an improvement in QoL. Only one patient treated with asenapine showed an increase in the results of HAM-D.

Conclusions Results suggest the efficacy of the two new APS but further recruitment and data collection are needed to better understand their impact on agitation and QoL, including the metabolic profile, with the aim to help clinicians to make a more accurate choice of drug for each specific patient.

* Corresponding author.

Introduction Recently, depot aripiprazole was approved as a maintenance treatment for schizophrenia. However, long-acting antipsychotics has not been established efficacy in manic episode or maintenance treatment of bipolar disorder.

Aims Describe a clinical case of multiresistant bipolar disorder.
Methods Thirty-nine years old male, diagnosed since 8 years ago with bipolar disorder, current episode manic with psychotic symptoms, admitted to Acute Psychiatrist Unit. It was his seventh internment. He was dysphoric, had insomnia, and showed many psychotic symptoms like grandiose delusions and delusions of reference. He thought he was a famous painter from nineteenth century.

His disorder was refractory to mood stabilizers monotherapy and to many neuroleptic and, like olanzapine 30 mg/day, depot risperidone, zuclopenthixol, haloperidol, palmitate paliperidone, He was on treatment with lithium 1200 mg/day (lithemia 0.62 prior to admission) and oral aripiprazole 15 mg/day that he was not taking regularly. Poor compliance to oral treatment. No awareness of illness.

Results during the patient admission, we started long-acting aripiprazole 400 mg per 28–30 days. First 3 days he persisted dysphoric, hostile, and showing delusions of mind being read. From the fourth day, delusions disappeared and later he was calmer and more friendly, He was discharged 9 days later fully euthymic.

For 6 months follow-up, the patient came once a month to community center for aripiprazole injection and he was taking lithium regularly. Last lithemia 0.65 mEQ/L.

Conclusion Long-acting antipsychotics, like depot aripiprazole could be a useful alternative to oral medication, specially when there is no awareness of illness and there is low adherence to oral treatment.

Dementia or mania? A case report

C. Gomez*, V. Rodriguez, B. Pecino, E. Tercelan, C. Gomis, L. Gonzalez, C. Ortigosa, M. Anibarro
Hospital de Sant Joan de Alicante, Psiquiatry, Alicante, Spain

* Corresponding author.

In the clinical practice, we encounter situations that require precise differential diagnosis and special treatment. This poster reviews diagnosis and pharmacotherapy of two cases that point out how likely is to confuse the diagnosis of two apparently different pathologies: bipolar disorder and frontotemporal dementia. The first case presents a 75-year-old man that presented behavioural changes and insomnia without previous known psychiatric history other than alcoholism. The family explained a history of episodes of mood changes going from depression to mania, compatible with a bipolar disorder never diagnosed, and the neuropsychological exam performed did not show any cognitive impairments, finally receiving a diagnosis of bipolar disorder after good response to lithium treatment. The second case presents a 58-year-old man with behavioural disturbances and mood fluctuation that changed from short periods of hypomania with disinhibition and insomnia to a predominance of hypothyria, apathy and self-care negligence, which received at the beginning a diagnosis of bipolar disorder and after the proper complementary tests was shown to be a frontotemporal dementia.

When facing behavioural and mood changes in advance age, we should take into account the considerable percentage of patients with a final diagnosis of frontotemporal dementia that received previously a mistaken diagnosis of bipolar disorder and vice versa. Even though in our practice age can point to a disorder, we should not forget the importance of a good clinical history and anamnesis

to reach a correct diagnosis as well a organized and carefully planned treatment approach for each individual patient.

Interferon alpha is a cytokine with antiviral and antineoplastic action, which is commonly used for treatment of Hepatitis C and B, malignant melanoma, Kaposi's sarcoma, kidney cancer and certain hematologic diseases. It is well-known some of its neuropsychiatric symptoms such as depressive symptoms, cognitive impairment, chronic fatigue, dysphoria and anxiety, but there are also other less common like mania, psychotic symptoms and suicide risk that have been reported. These symptoms interfere in the quality of life very significantly, which at the end can affect treatment adherence.

We report a case of a 33-year-old man who was taken to the emergency department by his family referring nervousness, irritability, verbose, and insomnia during the last 5 days. The patient had not psychiatric history. He was diagnosed with a malignant melanoma stage III A a year ago which required to start interferon alpha treatment.

Patient and family tell that symptoms began after forgetting last interferon dose. In the psychopathology exploration, we could observe mood lability, delusion ideas of prosecution, which includes his entire family and autorreferentiality. In the emergency room the blood test, urine drug test and CT were normal.

During the admission, and in collaboration with the Oncology service, it was agreed the reintroduction and maintenance of interferon combined with olanzapine up to 30 mg/day and clonazepam up to 6 mg/day, which resulted in the resolution of symptoms in two weeks.

Sexual behavior in women with bipolar disorder

F. Guerhazi*, F. Charfeddine, K. Mdhaffer, L. Aribi, W. Bouattour, E. Elleuch, J. Aloulou, O. Amami
Hedi Chaker University Hospital, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Women with bipolar disorder warrant special consideration with regard to sexual health. The impairment in sexual function would be frequent but underestimated and contributes to non-compliance with treatments.

Aims (1) Evaluate sexuality among a population of women affected by bipolar disorder.

(2) Determine the factors associated with impaired sexual function.
Methods This is a cross-sectional and descriptive study during the period ranging from 1st September to 15 October 2015.

It was conducted in 40 women suffering from bipolar disorder.

The exclusion criteria were: relapse period in sick, age over 60 years or severe somatic comorbidity.

The evaluation of sexual function was made using the "Sexual Behavior Questionnaire" (SBQ).

Results The mean age was 30 years. Bipolar disorder type I accounted for 72.5%.

According to the SBQ, 37.5% of patients had a desire disorder, 57.5% had a frequency less than 3 times per week sexual intercourse, 45% had a drop in excitation and 42.5% were not satisfied with their sex life.

Sexual problems are positively correlated at an early age of onset of bipolar disorder ($P=0.001$).

The lack of desire, the sexual excitation disorder and the decrease in the frequency of sexual intercourse are positively correlated with the depressive phase of bipolar disorder.

Conclusion A better understanding of sexual behavior in women with bipolar disorder and the early screening of the sexual disorders must be integrated into the management of the disease. It can improve their quality of life and adherence to therapy.

Dealing with bipolar disorder

H. Guillen Rodrigo*, R. Remesal Cobreros, R. Alonso Díaz

Hospital Juan Ramon Jimenez, Salud Mental, Huelva, Spain

* Corresponding author.

The psychoeducational group therapy program for patients diagnosed with bipolar disorder is carried out in the Hospital Vazquez Diaz in Huelva. The objectives of the group therapy are: provide an adequate patient awareness of the disease, improve the drugs adherence, facilitate early detection of new episodes, stress management, avoid the use and abuse of illegal substances, achieve a consistency in their lifestyle, prevent suicidal behavior, increase understanding and coping with the psychosocial consequences of the past and future episodes, improve social activity, cope with the subsyndromal residual symptoms and the following deterioration and increase the welfare and the quality of life.

The group consists of patients diagnosed with bipolar disorder I, II and cyclothymia. The psychiatrist has to establish if it is convenient for the patient to attend the group and has to communicate, if it has been detected, lack of knowledge about the disease, distorted beliefs, lack of awareness of the disease, unhealthy habits and poor adherence to the treatment.

The group was a closed group consisting of 10 to 12 patients. It was carried by a clinical psychologist with the help of the clinical psychology residents. The psychoeducational program we developed in our hospital consisted in 9 bimonthly sessions of 90 minutes.

As a result, we can say that the psychoeducation was very useful in improving the course of bipolar patients and in reducing the number of episodes and hospitalizations. Patients who received psychoeducation and pharmacotherapy have suffered significantly fewer relapses. Therefore, there is a prophylactic efficacy of psychoeducation in bipolar disorders.

² All India Institute of Medical Sciences, Nuclear Magnetic Resonance, New Delhi, India

* Corresponding author.

Introduction There is a lack of consensus on the dysfunctional brain areas underlying mania.

Aims and objectives The study was carried out to understand the various brain networks implicated in active mania.

Methods After obtaining ethical clearance from the Institute Review Board, we recruited 30 subjects with active mania and 15 healthy controls using purposive sampling, and applying SCID. A computerized cognitive test (Verbal N-Back) was used.

Results Mania group took significantly longer time while making correct responses. They (Fig. 1C) showed activation in bilateral frontal lobe, and bilateral superior temporal gyrus during verbal 1-Back task, whereas, the control group (Fig. 1A) showed left middle frontal gyrus, and right superior frontal gyrus activation. On verbal 2-Back task, the mania group (Fig. 1D) had bilateral frontal lobe, and bilateral superior temporal gyrus activation, whereas the control group (Fig. 1B) had activation in the bilateral frontal lobe.

Conclusions It was clearly visible that the mania group was significantly slower in giving correct responses on N-Back task as compared to the controls. On the 2-Back task, there was under-activation in left frontal lobe in the mania group with respect to the control group (Fig. 1E). This implies that the mania group may have deficits in information processing speed.

Self-stigma, treatment adherence, and medication discontinuation in patients with bipolar disorders in remission – a cross-sectional study

M. Hajda*, D. Kamaradova, J. Prasko

University Hospital Olomouc, Klinika psychiatrie, Olomouc, Czech Republic

* Corresponding author.

Introduction Self-stigma is a gradual process during which a stigmatized person uncritically accesses and integrates negative societal stereotypes towards persons with mental disorders.

Objective It has been repeatedly shown that fear of stigma and self-stigma is associated with lower adherence to various medical procedures.

Aims The aim of study is to investigate the relationship between current adherence, discontinuing of medication in the past and self-stigmatization by stable patients with bipolar disorder.

Method Until now 33 outpatients with bipolar disorder completed The Drug Attitude Inventory-10 items (DAI-10) scale used to estimate adherence to treatment, the Internalized Stigma Mental Inventory scale (ISMI) measuring self-stigma and The Clinical Global Impression (CGI), which assesses current severity of mental disorders. Demographic and clinical data were also obtained.

Results Current results show that, the level of adherence to pharmacotherapy positively correlated with age and negatively with self-stigma. Nineteen (57.6%) patients discontinued medication at least once in the past. The patients, who discontinued medication in the past, were significantly younger and more often single

when compared to the patients who did not discontinue medication. There were no other differences between the groups in the clinical and demographical data. There was also no difference in the level of adherence in patients treated by different drugs.

Conclusions More than half of bipolar patients discontinued medication in the past. The risk of the discontinuation of medication is higher in patients who are young and single. The rate of current adherence significantly negatively correlated with self-stigma.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Study of the impulsivity in bipolar parent

G. Hamdi^{1,*}, M. karoui², L. robbana², F. elouze², F. mrad²

¹ Razi Hospital, F, Mannouba, Tunisia

² Razi Hospital, G, Mannouba, Tunisia

* Corresponding author.

Introduction Impulsivity, as defined by Barratt in 1983, is the inability to associate a behavior to context or consequences. It refers to a variety of risky behaviors, inappropriate to the situation and can lead to undesirable consequences. It is well-established that impulsivity is strongly related to bipolar disorder. Currently, we speak of impulsivity trait present even in bipolar patients in euthymia given the hereditary nature of bipolar disorder. In this study, we are interested in assessing impulsiveness in healthy relatives of bipolar patients.

Methodology Impulsivity was measured using BARRAT scale [the Barratt impulsiveness Scale-11 (BIS-11)] in 30 healthy subjects who are first degree relatives of bipolar patients treated in Razi hospital; and comparing the results to 30 subjects, witnesses matched for age and sex with no personal or family history of psychiatric disorders.

Results The impulsivity score among parents of bipolar patients was significantly higher compared to controls especially for motor impulsivity with average scores 19.15 versus 16.94, respectively. The general impulsivity score among parents of bipolar patients was 61.53 ± 13.83 versus an average score in controls of 47.20 ± 18.26 .

Limits The small sample size did not allow conclusive results. The difficulties in determining the mental history of the control group (to check the absence of a family history of bipolar disorder).

Disclosure of interest The authors have not supplied their declaration of competing interest.

The recognition of facial emotions in bipolar disorder

G. Hamdi*, Dr. H. Ben Ammar, Z. Hechmi

Razi Hospital, F, Mannouba, Tunisia

* Corresponding author.

Introduction Bipolar disorder is a common chronic psychiatric disorder, marked by the severity and frequency of mood episodes and their impact on the psychosocial functioning of these patients. Even during inter-critical periods, these patients' cognitive functions are altered. Patients diagnosed with bipolar disorder, by definition, have problems with emotional regulation. However, it remains uncertain whether these patients also have a deficit in processing emotions of others.

The main objective was to assess social cognition (recognition of facial emotions) in euthymic bipolar subjects by comparing them to a control group.

Methodology This is a transversal case-witness study, conducted in consultation with the post-treatment, of 30 euthymic bipolar patients and 30 healthy volunteers matched for age, sex and

educational level, with the help of a questionnaire targeting socio-demographic and clinical data, as well as a facial expression recognition test to measure social cognition.

Results Our study showed that bipolar patients had deficits in social cognition compared to the volunteers' group. Bipolar patients have more difficulties than healthy subjects to recognize facial emotions of fear, anger and disgust, and assign intentions to others from images. These deficits are even more accentuated in the early onset forms.

Conclusion This study shows a disturbance of perception of emotions in bipolar patients. These cognitive deficits could participate in behavioral and social disorders present in bipolar disorder.

Childhood trauma in bipolar disorder

G. Hamdi*, H. Ben Ammar, Z. Hechmi

Razi Hospital, F, Mannouba, Tunisia

* Corresponding author.

Introduction Bipolar disorder is a multi-factorial disease and has a heterogeneous clinical presentation. Currently, the negative impact of stress on the evolutionary course of the disease is increasingly being recognized. However, studies exploring the childhood trauma in bipolar disorder are, so far, few and inconclusive.

Objectives We sought to compare injury rates during childhood in adults with bipolar disorder compared with a healthy control group to study the impact of childhood trauma on the clinical evolution of bipolar disorder.

Methods A retrospective assessment of childhood trauma was conducted using the Childhood Trauma Questionnaire (CTQ) with 30 patients with bipolar disorder who are stabilized and who following post treatment in the psychiatric unit "F" Razi hospital and 30 healthy subjects matched based on age and sex.

Results Significantly higher rates of childhood trauma were observed in bipolar patients compared to the control group. The scores for sexual abuse and emotional neglect differ significantly between the two groups. Psychological violence was predictive of early onset bipolar disorder. Associations with clinical severity were less clear.

Conclusion Emotional deprivation in early childhood appears to be significantly associated with bipolar disorder. More thorough studies especially on the neurobiological consequences of childhood trauma would be necessary.

Psychosocial functioning impairment in euthymic patients with bipolar disorder II: The role of clinical factors

R.S. Ilhan^{1,*}, V. Senturk-Cankorur²

¹ Dr. Nafiz Korez Sincan State Hospital, Ministry of Health, Psychiatry, Ankara, Turkey

² Ankara University School of Medicine, Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction Growing body of evidence have showed that euthymic bipolar patients have poor psychosocial functioning. Most of the studies have focused on the psychosocial functioning in euthymic bipolar disorder (BD)-I patients. On the contrary, there have been limited researches investigating psychosocial functioning in euthymic BD-II patients. Moreover, the factors associated with psychosocial functioning in euthymic patients with BD II have been also understudied.

Objectives/aims Aim of our study was to investigate the association between clinical variables and poor psychosocial functioning in euthymic BD-II patients. Hypothesis of this study was that euthymic BD-II patients would have low level of psychosocial functioning compared with healthy individuals.

Methods BD-II ($n=37$) and healthy subjects ($n=35$) were compared in terms of their psychosocial functioning which were assessed by Functional Assessment Short Test (FAST). The euthymic state was confirmed by low scores both on the Hamilton Depression Rating Scale (HDRS) and the Young Mania Rating Scale (YMRS). Anxiety symptoms were also assessed by Hamilton Anxiety Rating Scale (HARS) in both groups. Clinical variables were taken as independent variables and FAST scores were taken as dependent variable in order to run correlation analysis in BD-II group.

Results No socio-demographic differences were found between two groups. Euthymic BD-II patients had significantly higher FAST, HARS, HDRS YMRS scores compared with healthy individuals. Only HDRS scores correlated with FAST scores of BD-II patients.

Conclusions This study indicated that euthymic BD-II patients had poorer psychosocial functioning. And subclinical depressive symptoms were associated with poor psychosocial functioning.

² Istanbul University, Cerrahpasa Faculty of Medicine, Department of Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Insight is a well-documented phenomenon for psychotic disorders. It has been studied extensively in schizophrenia and its association with clinical outcomes has drawn increased attention. Although less is known for affective disorders, recent studies point out that impaired insight in bipolar disorder may take part in patients' overall well-being.

Aims Exploring the main components of insight in psychiatry, particularly in bipolar disorder.

Objectives With this study, we wanted to examine how clinical and cognitive insights change in patients with bipolar disorder through their hospitalization period and how they correlate with symptom severity and neuropsychological functioning.

Methods In this prospective study, inpatients with bipolar I disorder who were presented by manic episode with psychotic features were included. The patients were assessed with Young Mania Rating Scale, Beck Cognitive Insight Scale, Schedule for the Assessment of Insight-Expanded Version (SAI-E) and a neuropsychological test battery both at the time of admission and discharge.

Results As of October 2015, a total number of 20 patients with bipolar I disorder participated in the study. Preliminary results revealed a significant improvement in the total score of clinical insight, which was measured with SAI-E by the time of discharge ($P=0.001$). This transition was strongly correlated with the decrease in symptom severity ($P=0.006$, $r=-0.61$). Improved clinical insight exhibited significant correlation with the increase in patients' memory span ($P=0.007$, $r=-0.596$).

Conclusion The preliminary results suggest that changes in symptom severity and working memory might be the determinants of improvement in clinical insight of inpatients with bipolar disorder through manic episode.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Decrease in prolactine levels after treatment with aripiprazole during a maniac episode: A case report

J.M. Coll^{1,*}, G. Martínez-Alés¹, N. Salgado²

¹ Hospital Universitario La Paz, Psychiatry, Madrid, Spain

² Hospital Dr. Rodríguez Lafora, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Hyperprolactinemia can produce clinical symptoms affecting the patient's quality of life and therefore limiting therapeutic approaches to bipolar disorder.

Case report We report a case of a 46-year-old woman, with a 10 year history of type I bipolar disorder and a microprolactinoma, who was admitted to a psychiatry inpatient unit due to a maniac episode. Current symptoms at the moment of admission included hyperthymia, verbiage, flight of ideas and insomnia. Menstrual changes and galactorrhea had been present previously. Aripiprazole was introduced, reaching a dose of 30 mg/day, in addition to her usual treatment with lithium and gabapentin. Response to treatment was good and euthymia was reached within 10 days. Moreover, gabapentin was substituted by Valproic acid, and the patient was discharged once therapeutic levels were attained. Prolactin levels were measured at the moment of admission (128.75 ng/mL) and after 11 days of treatment (92.93 ng/mL).

Discussion Choosing an adequate antipsychotic agent can reduce the risk of iatrogenesis and thus enhance adherence to treatment and quality of life. Aripiprazole had previously shown a high potential at decreasing levels of prolactine. In this case, clinical practice supports scientific evidence.

Conclusions Aripiprazole is an effective treatment for type I bipolar disorder. Especially, it can be a treatment of choice in patients suffering from symptoms related to high levels of prolactine, even using a high dosage.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Razi Hospital, Psychiatry C, Mannouba, Tunisia

* Corresponding author.

Introduction The bipolar disorder (BD) is a chronic and severe disease which diagnosis and treatment are still raising the issues.

Aims To show a potential clinical and socio-demographic profile in BD patients.

Objective We hypothesized that BD patients have a particular clinical and socio-demographic characteristics.

Methods This was a descriptive and retrospective study which assesses 49 BD's outpatients. The diagnosis was accorded to DSM-IV criteria. The enrollment was conducted from January 2010 to August 2015. The socio-demographic and clinical data were collected by a preestablished railing.

Results The mean age was 39.7 years with a sex ratio of 1.33. Six patients (12.2%) lived in urban zones and 61% ($n=30$) patients have a lowly socioeconomic conditions. Celibacy was the prevailing civil status in 57.1% ($n=28$) among which 17 lived in family home. Thirty-four (69.4%) patients were unemployed.

A primary school level was found in 34.7% of the cases ($n=17$). Nineteen patients (38.8%) were schooled until the secondary level and 9 patients (18.4%) followed a university program.

Addiction to smoking was found at 26 patients (53%) whose half of them had moreover an alcoholic poisoning. The mean age at the diagnosis was 35.6 years with an inaugural manic episode in 63.4% ($n=31$) of the cases. The average number of relapse was 1.23 and the mean duration of follow-up was 3.2 years.

Conclusion The knowledge of the profile of the consultants, their socio-demographic and clinical characteristics would allow to adapt the offer of care to the request.

Association between the 5-HTTLPR genotype and childhood impulsivity in subjects with bipolar II disorder

E.J. Kim

Eulji General Hospital, Department of Psychiatry, Seoul, Republic of Korea

Objective It has been suggested that the features of childhood ADHD are significantly associated with adult mood disorders. Some genetic factors may be common to both ADHD and mood disorders underlie the association between these two phenotypes. The present study aimed to determine whether a genetic role may be played by the serotonin transporter-linked polymorphic region (5-HTTLPR) in the childhood ADHD features of adult patients with mood disorders.

Methods The present study included 232 patients with MDD, 154 patients with BPD, and 1288 normal controls. Childhood ADHD features were assessed with the Korean version of the Wender Utah Rating Scale. The total score and the scores of three factors (impulsivity, inattention, mood instability) from the WURS-K were analyzed to determine whether they were associated with the 5-HTTLPR genotype.

Results In the BPD II group, the 5-HTTLPR genotype was significantly associated with the total score ($P=0.029$) and the impulsivity factor ($P=0.004$) on the WURS-K. However, the inattention and mood instability factors were not associated with the 5-HTTLPR genotype, and the MDD and normal control groups did not exhibit any significant associations between the WURS-K scores and the 5-HTTLPR genotype.

Conclusion The present findings suggest that the 5-HTTLPR genotype may play a role in the impulsivity component of childhood ADHD in patients with BPD II. Because of a small sample size and a single candidate gene, further studies investigating other candidate genes using a larger sample are warranted to more conclusively determine any common genetic links.

Keywords 5-HTTLPR; ADHD; Bipolar II disorder; Childhood; Impulsivity; WURS-K

Thyroid dysfunction in inpatients with affective disorders

A.M. Leitão Moreira^{1,*}, R. Pacheco Alves², M. Lazaro², A.M. Mota², M.A. Nobre²

¹ Hospital de Dona Estefânia, Centro Hospitalar de Lisboa Central-EPE, Área de Psiquiatria da Infância e Adolescência, Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5 - Perturbações Afetivas e Obsessivo-Compulsivas, Lisboa, Portugal

* Corresponding author.

Introduction Thyroid dysfunction has been linked to psychiatric disorders, particularly to affective disorders. Moreover, aging of the population receiving mental health care leads to an increased epidemiological risk of thyroid disease.

Objectives Assess the prevalence of abnormal thyroid function, and its correlations to clinical factors, in an acute psychiatric inpatient ward dedicated to affective disorders.

Aims Reflect on the clinical relevance of thyroid function screening on admission in mental health care.

Methods Retrospective, descriptive study, concerning inpatient episodes from a 12 month period (January to December 2015) in a ward dedicated to affective disorders, in a tertiary psychiatric hospital.

Results The prevalence of thyroid dysfunction across all psychiatric diagnostic groups was 11%. Preliminary data has shown higher prevalence in non-elderly women with personality disorder as a main diagnosis (30%, $P=0.017$). Only women were under thyroid replacement therapy, which was significantly more prevalent in those diagnosed with bipolar disorder.

Conclusion The relatively high prevalence of thyroid dysfunction underlines the relevance of its screening in mental health inpatients. Our results were consistent with the known epidemiology of thyroid disease. Correlations with bipolar and personality disorder were noted, which can contribute to improve the understanding of clinical-epidemiological relationships between thyroid disease and specific psychiatric disorders.

Recognition and treatment of bipolar mixed states

F. Leite^{1,*}, H. Salgado², C. Olga², P. Carvalho²

¹ Matosinhos, Portugal

² Hospital de Magalhães Lemos, Serviço de Psiquiatria, Porto, Portugal

* Corresponding author.

Introduction Mixed features refers to the presence of high and low symptoms occurring at the same time, or as part of a single episode, in people experiencing an episode of mania or depression. In most forms of bipolar disorder, moods alternate between elevated and depressed over time. A person with mixed features experiences symptoms of both mood “poles” – mania and depression – simultaneously or in rapid sequence.

Aims and objectives To review the nosological status of bipolar mixed states and its treatment.

Methods Online search/review of the literature has been carried out, using Medline/Pubmed, concerning “mixed states”, “affective disorder”, “bipolar disorder”.

Results The presence of depressive symptomatology during acute mania has been termed mixed mania, dysphoric mania, depressive mania or mixed bipolar disorder. Highly prevalent, mixed mania occurs in at least 30% of bipolar patients. Correct diagnosis is a major challenge. The presence of mixed features is associated with a worse clinical course and higher rates of comorbidities. There is ongoing debate about the role of antidepressants in the evolution of such states.

Conclusions Clinical vigilance and careful evaluation are required to ensure mixed states are not missed in the clinical context. Atypical antipsychotics are emerging as the medications of choice in the pharmacological management of mixed states.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The late-onset bipolar disease: A case report

A. Lopes*, P. Sales

Hospital Garcia de Orta, Psychiatry, Almada, Portugal

* Corresponding author.

The prevalence of bipolar disorder after 65 years is 0.1 to 0.4%. Mania represents 4.6% to 18.5% of all psychiatric admissions in geriatrics in the USA. It has some specificity in terms of clinical presentation, evolution, prognosis and treatment.

We report the case of a patient who presented a first manic episode after 65 years. E.H, AP, 67 years old, single, without personal and familial psychiatric history, addressed to psychiatric emergencies for psychomotor agitation and euphoric mood. He presented two months ago a manic access with almost total insomnia, euphoria, psychomotor agitation and delusions of grandeur. The balance sheet reveals no incorrections (blood count, thyroid balance, serology: TPHA, VDRL, hepatitis B and C, HIV). The cerebral CT was normal. The patient has been received a quetiapine 200 mg/day, olanzapine 10 mg/day and valproate 1000 mg/day. The evolution after three weeks was favorable.

The late-onset bipolar disorder is characterized by: a less intense euphoria, replaced by anger and irritability, a more elements of persecution, disinhibiting and impulsivity. Respecting to that, this case is an exception. The most common confounding symptoms and behavioral disorders. A higher frequency of neurological diseases is noted in elderly subjects with a bipolar disorder and, so, a neuropsychiatric rigorous evaluation is fundamental to exclude the possibility of an organic pathology for the manic access. The prescription of psychotropic drugs in the elderly must be under monitoring.

* Corresponding author.

Bipolar disorder (BD), along with schizophrenia, is one of the most severe psychiatric conditions and is correlated with attentional deficits and emotion dysregulation. Bipolar patients appear to be highly sensitive to the presence of emotional distractors. Yet, no study has investigated whether perceptual load modulates the

interference of emotionally distracting information. Our main goal was to test whether bipolar patients are more sensitive to task-irrelevant emotional stimulus, even when the task demands a high amount of attentional resources.

Fourteen participants with BD I or BD II and 14 controls, age- and gender-matched, performed a target-letter discrimination task with emotional task-irrelevant stimulus (angry, happy and neutral facial expressions). Target-letters were presented among five distractor-letters, which could be the same (low perceptual load) or different (high perceptual load). Participants should discriminate the target-letter and ignore the facial expression. Response time and accuracy rate were analyzed.

Results showed a greater interference of facial stimuli at high load than low load, confirming the effectiveness of perceptual load manipulation. More importantly, patients tarried significantly longer at high load. This is consistent with deficits in control of attention, showing that bipolar patients are more prone to distraction by task-irrelevant stimulus only when the task is more demanding. Moreover, for bipolar patients neutral and angry faces resulted in a higher interference with the task (longer response time), compared to controls, suggesting an attentional bias for neutral and threatening social cues. Nevertheless, a more detailed investigation regarding the attentional impairments in social context in BD is needed.

Clinical overlap between behavioral variant of frontotemporal dementia and bipolar disorder: A case report

P. Oliveira¹, C. Roque², V. Santos¹, N. Madeira^{2,*}

¹ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

² Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

* Corresponding author.

The behavioral variant of frontotemporal dementia (FTD) often begins with psychiatric symptoms, including changes in personal conduct and/or interpersonal behavior. Prior to developing cognitive impairment, differentiating FTD from primary psychiatric disorders might be challenging.

This work presents a case of a manic episode with psychotic features in a 61-year-old man, whom personality changes and daily life difficulties arouse and persist after optimal management of the active manic and psychotic symptoms. Neuropsychological assessment detailed severe deficits among visuospatial and planning performances. Structural neuroimaging (CT-scan) primary revealed a global pattern of brain volume reduction. Severe perfusion deficits on frontal and both parietal lobes were shown on 99mTc-HMPAO single-photon emission computed tomography (SPECT). The hypothesis of probable FTD (behavioral variant) was established.

The present case highlights how putative atypical and late-onset forms of bipolar disorder (BD) might instead progress to FTD. Several links are being advanced between the BD and FTD, for instance the close involvement of the C9ORF72 gene in a group of BD patients which progresses to dementia. These relations have actually been on focus recently. The field is however still relatively unexplored.

Significant response to amantadine in a patient with malignant catatonia: A case report

M. Maki^{1,*}, O. Kato², J. Kunimatsu¹, T. Sato¹, S. Fujie¹

¹ National center for global health and medicine hospital, general internal medicine, Tokyo, Japan

² National center for global health and medicine hospital, psychiatry, Tokyo, Japan

* Corresponding author.

Purpose Catatonia is a complication of bipolar disorder, which is a constellation of symptoms such as catalepsy, mutism, and stupor. Standard therapy for catatonia contains benzodiazepines and electroconvulsive therapy. An uncomplicated catatonia is usually a benign condition. On the other hand, malignant catatonia is a life-threatening condition that is complicated with fever, autonomic instability, delirium, and rigidity. The syndrome is typically fulminant and progresses rapidly within a few days without appropriate intervention. Several previous reports suggested that some catatonias are associated with the overstimulation of N-methyl-D-aspartate (NMDA) receptor, and that amantadine may have an effectiveness for catatonia, as a NMDA receptor antagonist. We report a case of successful treatment for malignant catatonia refractory to benzodiazepines, by using amantadine.

Materials and methods/case A 64-year-old Japanese woman with bipolar disorder was referred to our hospital because of 8-week prolonged fever. On admission, she was in febrile and stuporous states. Severe rigidity was observed in her extremities. Blood tests, lumbar puncture, and blood cultures were all negative. Brain MRI was normal. Consequently, we reached a diagnosis of malignant catatonia, and thus we gave additional benzodiazepines for her catatonic symptoms. However, there was no improvement, and we finally add a 50 mg/day amantadine for her malignant catatonic state.

Result Her fever resolved in a few days. Gradual dose-titration of amantadine led her clinical manifestation to completely disappeared.

Conclusion Amantadine can be a potential option as one of the pharmacological therapies for refractory malignant catatonia.

Social functioning and social cognition in bipolar disorder: Is there a connection?

V. Maria Iulia^{1,*}, R.C. Delphine^{1,2,3}, H. Audrey^{2,3}, K. Arthur^{1,2,3,4}

¹ Department of Psychiatry, University Hospital of Reims, Reims, France

² University Hospital of Reims, Reims, France

³ Cognition, Health, Socialisation Laboratory, EA 6291, Reims Champagne-Ardenne University, Reims, France

⁴ Faculty of Medicine, Reims Champagne-Ardenne University, Reims, France

* Corresponding author.

Introduction The research interest in social cognition in bipolar disorder has increased in a significant way in the last decade showing major impairments, especially in mental state reasoning, even during euthymia (Samamé et al., 2012; Samamé et al., 2015). Social cognitive processes in humans describe the ways individuals draw inferences about other people's beliefs and the ways they weigh social situational factors in making these inferences (Green et al., 2008). A causal relationship between social cognition deficits and global functioning has been already established in schizophrenic populations (Green et al., 2015). But there is still little information

regarding the relation between social cognition and social functioning in bipolar disorder.

Aims To review the relationship between general/social functioning and social cognitive impairments in bipolar patients.

Methods A systematic review of literature was conducted. Relevant articles were identified through literature searches in PubMed/Medline, EBSCOHost and Google Scholar databases dating from 2000 to 2015 using the keywords "bipolar", "social cognition", "theory of mind", "mentalizing", "emotion recognition", "emotion processing", "functioning" and "quality of life".

Results The findings of the review will be discussed, regarding the specificity of the thymic state of the patients and the social cognition instruments used.

Conclusions To the best of our knowledge, the present review is the first to explore specifically the relation between the social cognition deficits and the general/social functioning of bipolar patients. This exploration is of interest for a better comprehension of this disorder to improve the outcome of the patients.

Keywords Bipolar disorder; Social cognition; Functioning

First episode of bipolar depression and suicide attempt after bariatric surgery in a 45-year-old woman

E. Muniz Magalhaes^{*}, R. Gois Campos, L.M. Sarin, J.A. Del Porto
Universidade Federal de São Paulo, Psychiatry, São Paulo, Brazil

* Corresponding author.

Introduction Weight loss positively influences mental health but findings are mixed in patients undergoing bariatric surgery. The permanent changes in body image, diet-related stress, and unmet expectations could increase mental health problems such as major depression and self-harm behaviors. Mixed symptoms during major depressive episode were often misdiagnosed as agitated depression, and should be regarded as a risk factor for suicide and rapid cycling course of illness.

Method Single case report.

Results A 45-year-old woman, initially diagnosed as a unipolar depressive episode after bariatric surgery, did not show improvement after SSRI treatment. She had no history of previous episode but her temperament was described as hyperthymic. Antidepressant worsened irritability, racing/crowded thoughts, heightened anxiety and aggressive impulses, mood instability, impaired concentration, insomnia and she had a suicide attempt (antidepressant overdose). After mood stabilizer and atypical antipsychotic, symptoms fully remitted and she is stable in the last year.

Conclusion Self-harm emergencies after bariatric surgery are higher than before surgery. Intentional overdose is considered the most common self-harm mechanism. Psychiatric follow-up after bariatric surgery and early recognition of bipolar depression with mixed features as a distinct condition among the variety of depressive syndromes is essential to reduce the risk of self-harm behaviors and improve treatment outcomes. Premorbid temperamental features, especially hyperthymic and cyclothymic temperaments, are often responsible for such mixed depressive presentations.

Mood disorder in epilepsy: A case report

R.A. Baena^{1,*}, I. Mesían², L. Mendoza¹, Y. Lázaro¹

¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

² Hospital Niño Jesús, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction A lot of studies have described that up to 50% of patients with epilepsy develop psychiatric disorders: depression, anxiety and psychotic symptoms. We can classify these symptoms according to how they relate in time to seizure occurrence, i.e. pre-ictal/prodromal, ictal, post-ictal or inter-ictal. In this case, we have a 76 years old woman that develops a maniac-episode previously that she has an episode.

Objectives Make a review about the prevalence, risk factors of psychiatric problem in epilepsy (biological, psychosocial and iatrogenic) and report of clinical case.

Methods Review the bi-directional associations between epilepsy and bipolar disorder (epidemiological links, evidence for shared etiology, and the impact of these disorders) with an integrated clinical approach.

Results Theoretically, epilepsy and bipolar disorder share an important number of clinical and neurobiological features. Classic neuropsychiatric literature focused on major depression with data on bipolar disorder remains limited. However, actually there are many evidences that mood instability, mixed irritability even mania is not uncommon in patients with epilepsy.

Conclusions It is important develop more sensitive and specific screening instruments to identify mood disorder in epilepsy's patients. Future research becomes decisive for a better understanding of the similarities between epilepsy and BD, and the treatment of both.

A case of a varenicline-induced mania in a patient with the history of depression

O. Onur*, G. Teksin, C. Karsıdag

Istanbul Bakırköy Research and Training Hospital for Psychiatry Neurology and Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Varenicline is an alpha 4 beta 2 nicotinic receptor partial agonist with dopaminergic effects, approved for smoking cessation. The complex interactions and modulations of serotonin and nicotine receptors caused by varenicline may cause mania by its serotonin agonist activity and by its release of dopamine in the striatum. We report a case of a varenicline-induced mania with the history of depression.

Case A 38-year-old female, with the history of depression and have been using sertraline 50 mg/day for a year, admitted for grandiose delusions, decreased need for sleep, increased amount and rapid speech, and agitation. These symptoms began 1 week after she started taking varenicline as prescribed for smoking cessation. Young Mania Score (YMS) was 32. She discontinued sertraline and varenicline after 1 week of use but symptoms of mania continued. The patient smoked about 20 cigarettes a day for more than 10 years. She had a positive history of depression in her family. Her lab work up was unremarkable; including negative urine toxicology and brain CT scan. The patient met DSM-5 criteria for a manic episode and was started on olanzapine 10 mg/day and quetiapine 100 mg/day. The patient's symptoms gradually improved within 1 week with attainment of euthymic mood, improved sleep, and resolution of grandiosity. YMS was 7.

Conclusion Based on this case it might be suggested that patient's and family's psychiatric history should be assessed cautiously before prescribing varenicline for smoking cessation due to development of mood symptoms.

* Corresponding author.

Introduction Immune alterations are believed to be an important part in etiopathogenesis of affective disorders. However, it is not clear if the altered immune mediators are related to distinct disorders or particular psychopathology.

Aims The aim of our study was to explore the differences in C-reactive protein levels (CRP) between euthymic BD patients and healthy controls, as well as to explore the relationship between CRP and lifetime presented psychopathology within BD.

Methods The study group consisted of 83 patients diagnosed with BD, compared to the healthy control group ($n = 73$) and matched according to age, gender, and body mass index (BMI). Lifetime psychopathology has been assessed according to predominant polarity as well as previous history of suicide attempts and psychotic episodes.

Results The CRP levels were significantly higher in BD patients when compared to healthy controls. After covarying for confounders, we observed that CRP levels, in euthymic BD patients, were related to number of previous suicide attempts, but not other indicators of lifetime psychopathology.

Conclusions BD patients per se, and particularly those with more suicide attempts, are more likely to present with proinflammatory state, even when in remission. Previous history of suicide attempts could bear specifically vulnerable endophenotype within BD. Systemic, longitudinal monitoring of the course of illness, and potential inflammatory mediators that underlie its systemic nature is warranted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² University of Belgrade, School of Medicine, Belgrade, Serbia

* Corresponding author.

Introduction Oestrogen fluctuations may be an important factor in the etiology of bipolar disorder and age at menarche is associated with the clinical course of BD. Moreover, it is associated with traits related to mood.

Aims The aim of our study was to explore the differences in age at menarche between euthymic BD patients and healthy controls, as well as to explore the relationship between age at menarche and lifetime psychopathology within BD.

Methods The study group consisted of 83 patients diagnosed with BD, compared to the healthy control group ($n = 73$) and matched according to age, gender, and body mass index (BMI). Lifetime psychopathology has been assessed according to predominant polarity as well as previous history of suicide attempts and psychotic episodes.

Results Age at menarche in BD patients was similar to that in controls. After covarying for confounders, we observed that age at menarche is negatively related to number of previous depressive episodes in euthymic BD patients, but not other indicators of lifetime psychopathology.

Conclusions BD patients with earlier age at menarche are more likely to present with more depressive episodes in the course of illness. Systemic, longitudinal monitoring of the course of illness, and potential hormonal fluctuations within particular groups of patients are warranted.

⁴ University of Medicine and Pharmacy, Targu Mures, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction In present, bipolar disorder and unipolar depression are accepted as distinct nosological entities, still there are authors who describe bipolar disorders as a comorbidity between depression and mania.

Objectives The comparative assessments of socio-biographical and evolutive aspects in two samples, some of them diagnosed with bipolar affective disorder (BAD) and the others with recurrent depressive disorder (RDD), according to ICD 10.

Aims To highlight significant differences between these two types of pathologies regarding socio-demographic and evolutive aspects.

Methods We have selected two samples which comprise 30 subjects, one with subjects with BAD and the other subjects with RDD. We have assessed the following features of these subjects: the age, educational level, professional and marital status, the existence of triggers at the onset, the period of time until the first readmission into hospital, the period of hospitalization for the depressive episodes, the total number of hospital admissions during the first 5 years of evolution.

Results We have found significant differences regarding the age of onset, the existence of triggers before the onset of the disease, the period of time until the first readmission into hospital, the period of hospitalization of depressive episodes, the marital status at the onset, the marital and professional status after 5 years of evolution.

Conclusions Although these studied disorders are periodic affective disorders which have in common depression, the existence of the manic pole changes the bipolar disorder into a disorder which is different from a unipolar disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ The Zucker Hillside Hospital, North Shore, Long Island Jewish Health System, Psychiatry Research, New York, USA

* Corresponding author.

Diagnosis plays a key role in identification of a disease, learn about its course, management and predicting prognosis. In mental health, diseases are often complex and coalesce of different symptoms. Diagnosing a mental health condition requires careful evaluation of the symptoms and excluding other differential disorders that may share common symptoms. Diagnose hastily can lead to misdiagnosis. A premature diagnosis or misdiagnosis has clear negative consequences. This is one of the problems related to mental health and one needs to optimize the diagnostic process to achieve a balance between sensitivity and specificity. Currently, the diagnosis of bipolar disorder (BD) is one of the major mental health conditions that is often misdiagnosed.

To differentiate BD from unipolar depression with recurrent episodes or with personality disorder (PD), especially type Cluster B – with features shared with mania/hypomania like mental instability or impulsivity, it is important to differentiate between a diagnosis and its comorbidity. BD is often misdiagnosed as personality disorder and vice versa specially when both are coexisting (almost 20% of patients with bipolar disorder type II are misdiagnosed as personality disorders). This is common especially with borderline PD, although in some cases the histrionic PD may also be misdiagnosed as mania.

Due to the inconsistency in patient care involving different psychiatrists combined with difficulty in obtaining a precise patient history and family history leads to loss of key information which in turn leads to misdiagnosis of the condition. The time delay in making the correct diagnosis cause by such inconsistencies may worsen the prognosis of the disease in the patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Bipolar mood disorder (BMD) is the result of ambiguity between master and slave circadian oscillator

K. Pirkalani^{1,*}, Z. Talaeead²

¹ Mehr Medical Group, Internal Medicine, Tehran, Iran

² Mehr Medical Group, Gynecology, Tehran, Iran

* Corresponding author.

Introduction Derangement of the circadian system is a generally accepted theory for the pathogenesis of BMD but its mechanism is unclear.

Objectives A series of genes are up or down regulated in BMD.

Aims We present an algebraic model that incorporates multiple genes in the pathogenesis.

Methods The suprachiasmatic circadian gene CLOCK/BMAL1 heterodimer is regarded as the master oscillator with a curve of $y = a \sin x + b$.

Light/darkness events (noise <5%) changes it into a more broken curve; hence $y = \Omega (ne^x + b) + a \sin x$. Superimposition of oscillating (but not non oscillating) functions can change the pattern of periodicity or even abolish it. The master oscillator, just like the cardiac pacemaker has suppressing effect on 3 slave oscillators.

Alternating reigning of the master and slave oscillators can cause a dying curve in the form of $Y = f(e^t) g(\sin 1/t) + \zeta(b)$ where t is time and f and g are functions typical for master and slave oscillators and $\zeta(b)$ the effect of light/darkness (not negligible anymore). This causes the disease course unpredictable. Alternate reigning of master and slave oscillators is due to:

- mutation in the master with longer periodicity or no suppressing effect on slaves;
- mutation in the slave with shorter periodicity than the master or less sensitivity to the suppressing effect of the master.

Combination of the above in the form of genetic polymorphism.

Results Incorporation of many genes can explain many items in BMD with good predictions of its course.

Conclusions This model can predict the course of BMD disease spectrum.

Disclosure of interest The authors have not supplied their declaration of competing interest.

General results of personality scores of bipolar patients studied by MCMI-III during inter-attack periods and relevance to clinical course

K. Pirkalani^{1,*}, Z. Talaeerad²

¹ Mehr Medical Group, Internal Medicine, Tehran, Iran

² Mehr Medical Group, Gynecology, Tehran, Iran

* Corresponding author.

Introduction Physicians and patients' relatives regard patients with BMD during inter attack periods with suspicion.

Aims Evaluation of relevance of personality tests for BMD and finding correlations in addition to risk factors

Methods Thirty-three patients were evaluated by way of the MCMI-III during inter attack interval. They were apparently without prominent signs and symptoms, slept well and were under treatment with Lithium. They were compared with 45 examinees that were evaluated for unrelated reasons.

Results (1) There were overall higher scores in schizotypal, borderline, narcissistic, histrionic and self destructive personalities among BMD patients compared to the control group. $P < 0.03$.

(2) With the BR score of 72, all patients fulfilled the diagnosis of at least one of the personality disorders. $P < 0.1$.

(3) Borderline personality had the highest correlation with BMD and after scheduled interview 22 of 33 patients fulfilled the criteria for it. $P < 0.1$.

Presence of high scores in apparently contradicting personalities such as obsessive compulsive and histrionic or narcissistic and dependent or avoidant and histrionic were also encountered. $P < 0.2$.

Conclusions Though apparently normal functioning during inter attack intervals BMD patients fulfill the criteria of some personality disorders. This is in concordance with our idea that BMD spectrum has correlation with personality disorders in a subgroup that has mutations in the downstream genes to CLOCK/BMAL1 [glycogen synthase kinase3-b (GSK3-b), casein kinase I epsilon, NCAN, PER1,

2, 3 or CRY1, 2...]. They do not show full-blown symptoms but remain aberrant with subclinical attack like fluctuations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of medical condition in perplexity inside psychotic mixed states in bipolar disorder: Case series and literature review

M. Preve*, E. Bolla, M. Godio, N.E. Suardi, R. Traber, R.A. Colombo

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction In literature Leonard introduce, after Wernike (1900) and Kleist (1928), the concept of cycloid psychoses, and he gives again a weight to the mixed forms in affective disorders [1–4]. A lot of different medical conditions cause psychiatric problems, like hyperammonemia, hyponatremia, thyroid dysfunction, urinary infections and still others. The aim of our study is to evaluate the role of a medical condition in perplexity inside psychotic mixed states in bipolar disorder (BD). We propose three different cases and literature review.

Method Three patients with perplexity in BD were assessed with: the SCID-P for axis I diagnosis, HRSD, YMRS, internist examination, blood test exams and urinalysis, and first level brain imaging (CT and/or MRI). We conducted a systematic review of the literature (PubMed, Embase, PsychInfo), using the terms “bipolar disorder”, “mixed states”, “perplexity” and “medical condition”.

Results All our patients present: hyperammonemia, reduction of TSH and presence of infection at the urinalysis, and a resolution of perplexity with the normalization of the blood test and urinalysis.

Discussion and conclusion To our knowledge there are not studies that confirm the relationship between thyroid and hepatic dysfunction, and urinary infection with perplexity in psychotic mixed states in BD, and the resolution with the normalization of blood and urinary exams. Further research is warranted to replicate our clinical observations and to confirm our results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychotic mixed state in bipolar I disorder due to neurosyphilis: Case report and literature review

M. Preve*, M. Godio, N.E. Suardi, R. Traber, R.A. Colombo

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction The presence of mixed features in bipolar disorder (BD) has been associated with a worse clinical course and high rates of comorbidities including anxiety, personality, alcohol and substance use disorders and head trauma or other neurological problems [1]. A recent study reports the connection of neurosyphilis and mania [2]. The aim of our study is to evaluate an

inpatient with a psychotic mixed state due to a medical condition (neurosyphilis).

Method An inpatient with psychotic mixed state in BD was assessed with: SCID-P, HRSD, YMRS, and a complete internistic examination, blood test exams, urinalysis, electrocardiogram and ecocardiogram, as well as a first level brain imagin (CT and/or MRI). We conducted a systematic review of the literature (PubMed, Embase, PsychInfo), using the terms “bipolar disorder”, “neurosyphilis” AND “mixed state”.

Results A comprehensive diagnostic and laboratory screening was unremarkable except for a positive venereal disease research laboratory (VDRL). Treatment for syphilis was started and we used olanzapine to control the psychiatric symptoms.

Discussion and conclusion The estimated annual incidence of non-HIV STIs (sexually transmitted infections) has increased by nearly 50% during the period 1995–2008 [3]. Our case report underly, like Barbosa et al., the need to evaluate neurosyphilis as a potential cause of behavioural and psychiatric symptoms that simulate a psychotic mixed state of bipolar disorder. Olanzapine control and improve the psychiatric symptomatology in neurosyphilis. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Monitoring of biochemical changes in antipsychotics and anti-depressive therapy

A. Prifti¹, V. Qemalli^{2,*}, L. Zikaj¹

¹ Polyclinic of Specialty Nr.3, Laboratory, Tirana, Albania

² The Regional Health Authority, Tirana, Albania

* Corresponding author.

Objective Biochemical changes in treatment of schizophrenic and bipolar disorders, in Albanian patients, with atypical antipsychotic and anti-depressive drugs. Some of the adverse effects related to their use are hyperlipidemia, hepatic enzymes, type 2 diabetes and CK level, which may result in development of metabolic syndrome. This study aimed to investigate a possible increase of biochemical parameters, in patients with schizophrenia and bipolar disorders treated with atypical antipsychotic and antidepressive drugs (Olanzapin, Risperidon, Clozapin, Antidepressiv triciclik, SSRI, SNRI).

Methods Forty subjects with schizophrenia and bipolar disorders were evaluated, 12 women and 28 men, aged between 17 and 72 years. Blood collection of the patients was taken in our laboratory and this values were measure in long treatment patients, after years of treatment. Analyses were perform in our laboratory with autoanalysator SAT 450.

Results Evaluation after measurements showed significant differences when comparing the mean values obtained in each patients. The biochemical indicators of development of metabolic syndrome measured in our study, show that is an increasement of lipids panel, specially triglycerides and total cholesterol, also in glucose, CK level and hepatic enzymes, presenting statistically significant changes ($P < 0.05$) for prolong treatment.

Conclusion We conclude that the treatment with atypical antipsychotic and antidepressive drugs, promoted a substantial increasing of biochemical blood parameters. Lipids panel, hepatic enzymes, type 2 diabetes, CK levels are observed in among subjects evaluated.

Manic episode secondary to maca

P. Quandt^{1,*}, M. Puga²

¹ Hospital Universitario de Canarias, Psiquiatría, La Laguna, Spain

² Hospital Universitario Nuestra Señora de Candelaria, Psiquiatría, S/C de Tenerife, Spain

* Corresponding author.

Introduction Maca (*Lepidium meyenii*) is a plant grown in the Andes Mountains, formerly used for nutritional purposes. Nowadays is used as a nutritional supplement and energizing.

Objectives To describe a case of manic episode secondary to maca consumption, as an ingredient of an energizing product.

Aims To report on antidepressant properties of maca, based on a clinical case.

Methods X. is a 27-years-old male without any psychiatric history. He came to the emergency service because of the presence of sudden onset behavioral disorders, presenting a manic-like episode of seven hours of evolution. His symptoms consisted in psychomotor restlessness, hyperactivity, insomnia, verbose and loud speech, hyperthymia, megalomaniac verbalizations, and unsuitable future plans. The patient had self-awareness of his symptoms and was self-critical with his behavior. He reported he was consuming an energizing supplement containing maca from about two weeks ago. Treatment with olanzapine 20 mg was initiated, and the patient remained under observation for 24 hours.

Results Symptomatology subsided completely after 24 hours. The patient is discharged from the hospital with diagnosis of manic episode secondary to maca, without any treatment. He was advice to not take stimulants.

Conclusions There are studies reporting that maca plant has antidepressant properties, associated with the activation of noradrenergic and dopaminergic systems, as well as the attenuation of oxidative stress. However, more studies are needed to identify specific compounds that produce these effects.

First manic episode in a patient with a frontal meningioma

M. Queirós^{1,*}, J. Caseiro²

¹ Hospital de Magalhães Lemos, Psiquiatría, Porto, Portugal

² Centro Hospitalar do Porto, Pedopsiquiatria e Saúde Mental da Criança e Adolescente, Porto, Portugal

* Corresponding author.

Introduction Psychiatric symptoms are common among brain tumor patients. Meningiomas are the most common benign brain tumors accounting for 13 to 26% of all intracranial tumors and might present exclusively with psychiatric symptoms. To diagnose a manic episode according to DSM-5 criteria the episode must not be attributable to the physiological effects of a substance or to another medical condition.

Objectives/aims Describe a case of first manic episode with a frontal meningioma along with a brief review of available literature.

Methods The case we report is based on information collected from interviews with the patient and the family members as well as from the clinical files. The literature review was performed using the PubMed database.

Results We describe the case of a 58-year-old woman presenting with symptoms of a first manic episode with psychotic features. There were no previous hypomanic or major depressive episodes.

In order to exclude organic causes a brain CT scan was performed that revealed a possible frontal lesion. A brain MRI confirmed the presence of a frontal meningioma with an approximate diameter of 1.4 cm.

Conclusions The majority of the cases described in the literature refer to large tumors presenting with major depressive symptoms. Given the absence of similar cases in the literature, it seems unlikely that such a small benign lesion may cause a manic episode with psychotic features. Nevertheless, we cannot exclude that possibility.

Background In the previous studies, the relevance of inflammatory processes to disorders of the brain and body may serve as an important touchstone for increasing integration of psychiatry and medicine. Until recently, few studies had examined the potential role of inflammation in bipolar I disorder. We aimed at comparing C-reactive protein (CRP) serum levels as a marker of systemic inflammation between bipolar disorder (BD) patients in different affective phases and matched healthy controls and investigating the possible effects of CRP elevations on the cognitive impairment in BD remitted patients group.

Methods Forty-two patients with bipolar I disorder subdivided into (manic, depressive, full remitted) groups were examined. We measured the circulating levels of high-sensitivity C-reactive protein (hs-CRP). The results were compared with 42 age- and sex-matched healthy control. Then the neuropsychological function for the full remitted group only was assessed using the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) test and examine the correlation between the neuropsychological function and hs-CRP levels in this group.

Results It showed that hs-CRP levels were significantly higher in BD patients than healthy controls. By comparing each group (manic, depressed and remitted) separately with healthy controls, the difference was still statistically highly significant ($P < 0.001$). There was statistically significant positive correlation between hs-CRP levels and poorer performance on the RBANS total and four of its five subscales ($P < 0.05$) except for visuospatial/constructional subtest ($P > 0.05$).

Conclusion Our finding adds to the growing evidence that inflammation has a role in mood disorders psychopathology.

Introduction Endocannabinoid System (ECS) has been highlighted as one of the most relevant research topics by neurobiologists, pharmacists, basic scientists and clinicians (Skaper and Di Marzo, 2012). Recent work has associated major depressive disorder with the ECS (Ashton and Moore, 2011). Despite the close relationship between depression and bipolar disorders, as far as we know, there is no characterization of ECS and congeners in a sample of patients with bipolar disorders.

Aims and objectives The objective of this work is to characterize the plasma levels of endocannabinoids and congeners in a sample of patients with bipolar disorders.

Method The clinical group was composed by 19 patients with a diagnosis of bipolar disorders using SCID-IV (First et al., 1999). The control group was formed by 18 relatives of first- or second-degree of the patients.

The following endocannabinoids and congeners were quantified: N-palmitoleylethanolamide (POEA), N-palmitoleylethanolamide (PEA), N-oleylethanolamide (OEA), N-stearolethanolamide (SEA), N-arachidonylethanolamide (AEA), N-dihomo- γ -linolenylethanolamide (DGLA), N-docosatetraenylethanolamide (DEA), N-linoleylethanolamide (LEA), N-docosahexaenylethanolamide (DHEA), 2-arachidonoylglycerol (2-AG), 2-linoleoylglycerol (2-LG), and 2-oleoylglycerol (2-OG).

Results The result showed statistically significant lower levels of AEA, DEA and DHEA in clinical sample. Previous research also identified lower levels of AEA in depressed women (Hill et al., 2008, 2009). Until date, it is unknown if DEA and DHEA have some effect on EC receptors, and whether they have some direct effects on endocannabinoids.

Conclusions It would be necessary to carry our other research with a larger sample, which could allow the control of potential confounding variables.

* Corresponding author.

Introduction Decreased quality of life can be observed in both bipolar and schizoaffective disorder, more so in the acute episode, but also during remission.

Objectives To assess the quality of life of bipolar and schizoaffective patients after at least 6 months of euthymia.

Methods Eighty-nine outpatients diagnosed with bipolar disorder and 74 outpatients diagnosed with schizoaffective disorder, according to ICD 10 diagnostic criteria and 90 healthy subjects were selected for this study. The assessment of the subjects took place during remission (present for at least 6 months), between 2009 and 2015. As work instruments we used the SF-36 Scale for assessing quality of life and the HAMD Scale (Hamilton Depression Rating Scale) and YMRS Scale (Young Mania Rating Scale) to confirm remission.

Results The schizoaffective group scored lower regarding quality of life when compared to the bipolar group. Both affective disorder groups showed significantly lower quality of life scores when compared to the healthy control group.

Conclusions Both affective disorders have a significant negative impact on quality of life even during remission. Schizoaffective patients seem to have a lower quality of life than bipolar patients. Interventions regarding education, care planning, social interventions and interventions towards improving physical health should aid in the improvement of the quality of life.

* Corresponding author.

Introduction Religious delusions have regularly been reported throughout history in patients with schizophrenia, affective psychoses, complex partial seizure disorders and drug-induced psychoses.

Objectives The purpose of the study was to identify potential differences regarding demographic and clinical features of bipolar and schizoaffective patients presenting religious delusions.

Method Thirty-five inpatients diagnosed with bipolar disorder and 32 inpatients diagnosed with schizoaffective disorder, according to ICD 10 diagnostic criteria, were selected for this study. The assessment of the subjects took place between 2012 and 2015. We divided the subjects into two samples: with and without religious delusions. Socio-demographic (age, sex, education, marital status) and clinical data were analysed. The Brief Psychiatric Rating Scale (BPRS) and the Global Assessment of Functioning Scale (GAF) were used to assess current psychopathology and global functioning.

Results Among the schizoaffective patients, 17.8% and 16.9% of bipolar patients presented religious delusions. Similarly, in both samples, patients with religious delusion were older, more frequently unmarried women, had graduated high school, had higher BPRS total scores and higher BPRS psychotic cluster scores and had lesser global functioning.

Conclusions Religious delusions were not related to any of the two diagnostic groups but were associated, in both bipolar and schizoaffective patients, with an increased severity of psychotic positive symptoms and had worse global functioning.

Efficacy of electroconvulsive therapy (ECT) in the first trimester of pregnancy: A case of manic patient

M. Sahin*, O. Sahmelikoglu Onur, N. Fistikci, C. Karsıdag
Bakirkoy Research and Training Hospital for Psychiatry Neurology and Neurosurgery, Psychiatry, Istanbul, Turkey

* Corresponding author.

Women with bipolar disorder have a risk for symptom exacerbation during pregnancy. ECT is an appropriate option for psychiatric symptoms during pregnancy although it is often neglected. We report a case of bipolar, week 6 of gestation woman who discontinued medication in the second week of pregnancy but resumed pharmacotherapy with ECT due to manic episode that recurred during the first trimester.

Case A 23-year-old female, with a history of one psychiatric hospitalization (a manic episode three years ago) and lithium 900 mg/day, olanzapine 5 mg/day use for three years until week 2 of gestation admitted to clinic with complaints of decreased need for sleep, increased speech, lability of emotions, religious delusions and irritability for the last two weeks. Young Mania Score (YMS) was 32. ECT, which was considered as the first-line treatment, was not carried out due to low pseudocholinesterase (2401). Therefore, olanzapine was reinstated with a dose of up to 20 mg/day. Although olanzapine, irritability still continued. Therefore, medication was switched from olanzapine to haloperidol 15 mg/day and quetiapine 25 mg/day. Due to persistent symptoms, after necessary consultations and family approval taken, she was administered 6 sessions of ECT with oral haloperidole, although low pseudocholinesterase. Since 7 YMS, she was discharged with haloperidol 15 mg/day, biperiden 4 mg/day and quetiapine 25 mg/day.

Conclusion This case highlights the effectiveness of ECT in mania during the first trimester of pregnancy. We suggest that ECT might be considered as a valid option for manic episode during pregnancy.

Evolution of bipolar disorder in dual pathology

C.F. Silvia*, M.D. Sánchez García, A. Gómez Peinado, P. Cano Ruiz
HNSPS, PSIQUIATRIA, Albacete, Spain

* Corresponding author.

Introduction The substance use is common among people with a diagnosis of bipolar disorder. In addition, alcoholism and bipolar disorder coexist with a high frequency. This association is higher in men than in women, and this consumption is the factor that most strongly influences the hospitalization.

Objectives To analyze the clinical, epidemiological, diagnostic approach and evolution of bipolar disorder and alcoholism.

Methods Review of the subject on recent articles of alcoholism in bipolar disorder.

Results The stages of mania associated with alcohol consumption up to 40% of cases and are more common at this stage than in depressive. This association is greater than that which occurs between alcoholism and schizophrenia or depression. Patients with bipolar disorder who have mixed and irritative states and those with rapid cycling have a prevalence of alcohol consumption and substance use higher than those who do not use substances. It has also been observed that the consumption of alcohol and substance use

can change the symptoms of mania and turn them into a mixed state symptoms. It also states that rapid cycles can be precipitated by increased alcohol consumption during rotation from mania to depression.

Conclusions The association of bipolar disorder with addictive behaviors is a factor that worsens the prognosis and comorbid alcohol itself is associated with a poor prognosis. Close monitoring of bipolar patients and especially in those who consume alcohol is very important.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical vignette – aripiprazol long acting injection monotherapy as long-term treatment for bipolar disease

M. Solana^{1,*}, J.M. Oliveira¹, A. Sousa²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

² Centro Hospitalar Barreiro-Montijo, E.P.E, Psychiatry, Barreiro, Portugal

* Corresponding author.

Introduction Over the last decade a number of effective maintenance treatments for bipolar disorder (BPD) have been developed. Lithium remains the best-established option, but valproic acid, lamotrigine, olanzapine, and quetiapine are also effective maintenance drugs. However, oral administration contributes to lower adherence rates with these drugs. In the United States and Europe, aripiprazole is approved for the acute management of manic and mixed episodes and maintenance in BPD. It presents the advantage of a low risk of metabolic side effects, sexual dysfunction, and sedation, which can facilitate treatment adherence and help improve clinical outcomes.

Objectives/aims The authors present an illustrative case on which aripiprazol long acting injection monotherapy was effective as maintenance treatment in a patient with long history of BPD with several hospital inpatient admissions and very poor therapeutic adherence.

Methods Case report based on the patient's file. Narrative review of articles available in PubMed about the use of aripiprazol in BPD.

Results For this patient, aripiprazol long acting injection has proved to be an excellent choice for long-term treatment of BPD. The once-a-month injection promotes therapeutic adherence, which in this case was combined with involuntary outpatient treatment, ensuring therapeutic compliance.

Conclusions Aripiprazol has been shown to be safe and effective in the maintenance treatment in BPD. It shows similar efficacy and a superior tolerability profile when compared with other well-established treatments. Further studies are needed, warranted by its potential advantages, particularly on patients with poor insight and adherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessing risky sexual behavior among patients with bipolar disorder in euthymic period

N. Staali

Tunis, Tunisia

Introduction Risky sexual behaviors are typically seen in patients with bipolar disorder, especially during the manic phases.

Disinhibition, impulsivity and risk taking expose these patients to unplanned pregnancies and sexually transmitted infections.

However, there is a lack of studies regarding these behaviors in stabilized bipolar patients during euthymia.

Objectives The objective of this study was to look for a risky sexual behavior by evaluating sexual knowledge and sexual behavior of patients with bipolar disorder in the euthymic phase.

Methods We conducted a descriptive cross-sectional study including 30 patients diagnosed with bipolar disorder I or II (DSM-IV).

Data were obtained through a semi-structured interview evaluating the following: sexually transmitted infections, condom use, multiple sexual partners, sex under the influence of drugs or alcohol, and prostitution.

The Young Mania Scale and the Hamilton Depression Scale were used for clinical assessment.

Results The preliminary results suggest a lack of knowledge leading to a tendency to risky sexual behavior in both male and female, married and unmarried patients.

Conclusions Patients with bipolar disorder are exposed to risky and unsafe sex because of the clinical features of their disease and associated comorbidities.

Prevention and awareness of sexual risks are unavoidable in the management of these patients.

Disclosure of interest The author has not supplied his declaration of competing interest.

¹ University of Naples Sun, Department of Psychiatry, Naples, Italy

² University of Salerno, Neurosciences Section-Department of Medicine and Surgery, Salerno, Italy

* Corresponding author.

Introduction Bipolar disorder (BD) is associated with high morbidity and mortality. Patients are symptomatic almost half of their lives and experience significant disability. One subtype of BD is associated with a more chronic course, refractoriness to treatment and poor outcome. Diabetes mellitus type 2 (T2D) and insulin resistance (IR) have been identified as risk factors for this more severe form of BD.

Objectives and aims We investigated the rates of IR and T2D in patients with BD and whether this comorbidity is associated with specific clinical features of BD such as rapid cycling or treatment resistance.

Methods IR and T2D were screened in patients with BD types I or II, who were on stable treatment with mood stabilizers. The response to treatment was assessed by means of the Alda scale.

Results In a preliminary sample, we made a new diagnosis of IR in 40% of patients. The 1% of this sample had a diagnosis of T2D. The treatment response was worse in BD patients with comorbid IR or T2D as compared to those without metabolic abnormalities.

Conclusions These findings show that IR and T2D have high prevalence in BD patients and have negative impact on treatment response.

First episode of bipolar depression after systemic lupus erythematosus in a 51-year-old woman

V. Tardelli*, L. von Nielander, L. Sarin, J.A. Del Porto
Unifesp, Psychiatry, São Paulo, Brazil

* Corresponding author.

Introduction Systemic lupus erythematosus (SLE) is a multi-system disease with a broad spectrum of clinical features and neuropsychiatric manifestations that occur in up to 60% of patients. Disease activity and treatment with corticosteroids may contribute to this higher risk. It is also known that 36% of patients with SLE and comorbid Bipolar Disorder (BD) have had their psychiatric onset after they had been diagnosed with SLE.

Method Single case report.

Results A 51-year-old woman received a diagnosis of SLE 24 months before the beginning of depressive symptoms. After her diagnosis of SLE, seven years ago, she had three suicide attempts, being diagnosed with major depressive disorder. From then on, she had crises characterized by well-defined periods of 7 to 10 days with sadness, reduced need for sleep, social isolation, irritability, anger outbursts, impulsivity, racing thoughts and suicidal ideation. After treatment with mood stabilizers (quetiapine 300 mg/day and lithium 600 mg/day), she had a substantial reduction of symptoms intensity and frequency.

Conclusion The link between immune dysregulation, autoimmunity and bipolar disorder may be closer than previously thought. Even if the autoimmune disease is not directly etiologically related to the psychiatric presentation, its detection is important due to the high morbidity and mortality, considering the current understanding that Bipolar Disease is strongly related with inflammation in central nervous system.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A 41-year-old woman is diagnosed with a major depression after a few weeks of having been operated of a stomach reduction (bariatric surgery). She goes into old antidepressant medication for a few weeks with an increasing worsening of her state, at the point she is sent to the emergency room with high irritability, intense agitation, suicide thoughts as the highlight symptoms of what we think to be a mixed episode of a bipolar disorder and how we orient the case during hospitalization. The patient follows both public and private psychiatric services and after discharge from acute hospitalization, still with residual depressions symptoms, her private psychiatrist substitutes the given treatment, including mood stabilizers, by only antidepressants. Two weeks after discharge from the hospital, the patient is relocated to our partial hospitalization

resource. During her stay in our resource, we decide to keep the new treatment and diagnosis and increase the dosage of one of the antidepressants, which immediately yields to hypomania symptoms, at what we conclude that our patient is better treated as a bipolar type II with a mood stabilizer and low doses of an SRI. We find this to be an interesting case in the both psychopathological and psychophysiological point of view. To understand the case beyond clinical diagnosis, we discuss profoundly whether the bariatric surgery may have a role as a trigger.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction It is known the relationship between mental disorders such as bipolar disorder and metabolic disorders such as dyslipidemia, and therefore, increasing comorbid pathologies such as heart disease.

Objectives Determine in patients diagnosed with bipolar disorder and dyslipidemia, which are the epidemiological characteristics, the diagnostic subtype and drug treatment prevalent.

Aims Determine the profile of patients with bipolar disorder and dyslipidemia.

Methods Creation of a database and conduction of a descriptive study with statistical analysis of the data extracted from the medical records of 100 patients from a public hospital.

Results Higher prevalence of diagnosis of bipolar disorder type I on II (74% and 26%) over female (54%) (46%), the age range of 40–50 years, treated with antipsychotics more mood stabilizers (62%) compared to mood stabilizer monotherapy (38%) (Fig. 1).

Conclusions Interventions should be conducted screening character and in patients with a diagnosis of bipolar disorder type I, male, age between 30–50 years, treated with mood stabilizers plus antipsychotics (with a preference for lithium association with olanzapine).

Educating, implementing and auditing nice standards for bipolar disorder

M. Tremblay*, S. Palin

Cheshire and Wirral Partnership NHS Foundation Trust, Mental Health, Winsford, United Kingdom

* Corresponding author.

Introduction The National Institute for Health and Care Excellence (NICE) sets standards of clinical practice in the UK. An extensive update on guidance regarding bipolar disorder was released in September 2014. Practitioners face the challenge of translating this guidance into practice. NICE suggests that interventions might be better delivered by bipolar specialist clinics. Updated NICE standards were integrated into a Bipolar Clinical Effective Practice Screen (BICEPS), allowing existing community psychiatric teams to deliver these revised clinical standards in bipolar care.

Purpose To assess the effectiveness of the BICEPS in delivering interventions aligned with NICE clinical standards.

Method Three psychiatric community teams were audited; two teams (1 and 2) used the BICEPS to support their interventions whilst a third team provided management as usual. Team 1 was previously familiarized with the concept.

Results Table 1.

Conclusion The teams using BICEPS show better concordance to NICE standards. Superior outcomes by the team previously acquainted with the concept suggest longer-term benefits and adaptability. Using BICEPS may offer a cheaper alternative to developing specialist clinics.

Psychological experiences reported by offsprings of mothers with bipolar disorder: A clinical-qualitative study in a Brazilian university outpatient service

L.K.S. Campos, A. Santos Jr, C. Garcia Jr, E.R. Turato*

University of Campinas, Laboratory of Clinical-Qualitative Research, Campinas SP, Brazil

* Corresponding author.

Introduction Children of patients with bipolar disorder are at increased risk of developing psychopathology and psychosocial difficulties.

Objectives To understand the emotional experiences of adult children of mothers with bipolar disorder.

Method Qualitative study, using in-depth semi-directed interviews with open-ended questions, sample closed by saturation information criteria, content analysis, discussion under psychodynamic concepts.

Results From interviewees' reports, it can be seen that offspring's experiences emotional vulnerability, such as directions given by early exposure to self injurious behaviour, psychiatric hospitalizations, routine absences from home and consequent perception of helplessness, especially in periods of the mother's crisis. The findings suggest that for the children the insecurity to assume the precociously inverted responsibility regarding the need of care to mother seems to experience by them as an entrapment to the care of the mother, for the effort they make to keep them alive, with an emotional burden due to both impaired childhood and adolescent.

Conclusion It was analyzed the assumption that the evolution of reactive psychological stages regarding the mother affected by a mental illness marked by bipolarity manifestations, alternating with phases of the normality of psychic manifestations, would follow the evolution of the oscillating psychological stages of his/her own mother, which minimizes often both the disease and the treatment during the phases of remission of manifestations.

Introduction Fertility and fecundity are usually considered signs of social and emotional well-being. Bipolar disorder (BD) is a prevalent psychiatric disease that influences the individual's life style and behaviours. Some studies have addressed the issue of fecundity among women with bipolar disorder but few have focused on determining the differences between disease subtypes, which is expected, taking into account the studied differences in demographic measures.

Objectives To examine the fecundity of a population of women with bipolar disorder.

Aim The aim of this study is to compare the fecundity among women diagnosed with subtypes I to IV of BD, according to Akiskal's bipolar spectrum disorder classification.

Methods A total of 108 female outpatients were divided into four groups. We analyzed number of offspring and demographic

features between patients with different subtypes of BD using multivariate analyses.

Results Our results showed a significantly higher average number of children for BD IV patients when compared with BD I patients. Although not reaching statistical significance, BD I patients had less offspring than BD II and BD III patients. BD I patients had lower marriage rates compared to the other groups.

Conclusions Our results suggest that the subtype of bipolar disorder influences fecundity and behaviours, as is expressed by the lower number of marriages seen in BD I patients. We found that fecundity is significantly impaired among BD I patients, which may imply that female with more severe disorders are less likely to become parents. Fecundity is higher among BD IV patients, which makes a way to speculate about the adaptive role of hyperthymic temperamental traits.

Role of traditional healers in the pathway to care of patients with bipolar disorder in Egypt

N. Zaki

Institute of Psychiatry, Neuropsychiatry Department, Cairo, Egypt

Background A large number of mentally ill patients prefer to visit non-medical practitioners such as traditional healers because of the confidence in the system, affordability and accessibility of the service. This may lead to delay in seeking psychiatric services and has prognostic impact.

Aim To assess the rate of bipolar affective disorder (BAD) patients seeking traditional healers, the sociodemographic and clinical correlates of those patients.

Methods We assessed 350 patients with BAD after confirmation of diagnosis with Structured Clinical Interview for DSM-IV Axis I Disorder (SCID-I) research version and assessment of functioning with Global Assessment of Functioning scale. They were assessed for percent, rate and timing of seeking traditional healers.

Results In all, 40.8% sought traditional healers, with 34.9% more than four times. Of those, 62.2% were before seeking psychiatric services and 37.8% after. Lower educational level, less impairment of functioning and presence of hallucinations were significant correlates.

Conclusion This study shows that most of the patients suffering from mental illness prefer to approach faith healers first, which may delay entry to psychiatric care and thereby negatively impact the prognosis of BAD. This highlights the importance of mental health education and developing a positive collaborative relationship with traditional healers.

Introduction The symptoms and behavior of children with ADHD impose demands and difficulties on part of their caring parents, which may cause the latter group to suffer psychological stress.

Objectives The study of the suffering and symptomatic expression of psychological stress in parents of children with ADHD.

Aims To study type and severity of symptoms in children with ADHD and the effect of that on the stress response of their parents.

Methods Thirty-seven children with ADHD diagnosed clinically and with Conner's Test were studied using Child Behavior Check List (CBCL). Available parents for each child were interviewed and studied with Symptom Check List 90 Revised (SCL90R). Two control groups were used for both ADHD children and their parents.

Results The mean age of the children with ADHD was 7.1 ± 1.6 , they were 22 males and 15 females. Parents of these children scored highly on total and subscales of SCL90R, they were significantly higher than their control group on total and some of these subscales including somatization, interpersonal, depression, paranoid ideation and hostility domains. Depression and paranoid ideation of ADHD children parents were positively and significantly correlated with most of the sub-items of Conner's test of their children. In addition, somatization, depression and hostility of parents were positively and significantly correlated with most of the sub-items of CBCL of their ADHD children.

Conclusions The symptoms, behavior and severity of illness of children with ADHD have a great impact on their parents' psychological state of suffering and stress.

Behavioural sleep interventions that can be used for children with attention deficit hyperactivity disorder: A Delphi study

H. Alammam*, A. Weighall, I. Kellar, H. Nash

University of Leeds, School of Psychology, Leeds, United Kingdom

* Corresponding author.

Children who are diagnosed with Attention Deficit Hyperactivity Disorder ADHD are at high risk of many difficulties that could affect them and their families. Sleep related problems are one of the most significant difficulties observed in around 25 to 50% of children with ADHD. The aim of this study is to identify research priorities for behavioural interventions that can be used to manage such sleep problems in children with ADHD from the perspective of professionals and primary caregivers. A Delphi method will be used to identify research priorities in two rounds. In the first round, professionals who work with children with ADHD and primary caregivers of ADHD children in Saudi Arabia will be asked to rank the most important behavioural interventions for children who experience sleep problems. The panel members will be asked to suggest other behavioural interventions that are not included in round one in order to include these in round two. They will also be asked how

many sessions they would recommend for the programme. After receiving their views and analysing the results, the expert panel will be presented with the results and they will be asked to rank the interventions again. The expected results for the Delphi will be available in February 2016. This study is part of a PhD study that is funded by Shaqra University. It will help the researcher to design an intervention that will be conducted in April 2016 using a randomised controlled trial design in the same population in Riyadh, Saudi Arabia.

* Corresponding author.

Unit Mental Health Day Hospital Child and youthful, is a device of tertiary health care, integrated into the UGC Mental Health, led to intensive treatment of children and young people in the province of Huelva, with severe mental illness and who need specialized medical care.

To first access to this unit, the person should be referred for specialized Pediatrics; by your psychiatrist or psychologist benchmark for mental health teams; or from the Hospitalization Unit, as it is a third-level device.

When a patient was diagnosed with eating behavior disorder (TCA) is derived, an initial consultation with the child and parents, a first psychiatric evaluation, also by nutritional and Endocrinology Nursing is performed. After evaluation of these professionals, you can take the decision to begin an intensive outpatient treatment in which the patient would have frequent consultations with the psychiatrist, the nurse and endocrine.

They may also decide inpatient hospitalization and this could be partial, to be held in the Day Hospital; or all, if the patient is under 14 years and hospitalization for psychiatric criteria indicated; the patient would enter Pediatrics. If he is over 14 years old, would join Hospitalization Unit.

In Child and Adolescent Hospitalization Unit of Huelva patient it is included in a specific program for TCA where a psychiatric, endocrine, educational approach in the classroom is done. Coordination meetings with education, social services and early care centers that are also in contact with that child are also conducted.

Learning disorders and ADHD

E. Cortázar Alonso*, H. Guillén Rodrigo, R. Alonso Díaz

Hospital Juan Ramos Jimenez, Salud Mental, Huelva, Spain

* Corresponding author.

The term learning disorders alludes to problems in reading, calculate, writing and spelling. The prevalence of these disorders ranges from 5 to 15 percent of all the children in school age. As for sex distribution, men tend to have these problems often than women. This summary is about a 9-year-old male with multiple eye tics and suspected of having ADHD. He was referred by her general pediatrician. The patient did not have a history of mental illness, although he had a diagnosis of migraines.

J. is an only child, who lives with his parents in a district of the city of Huelva, where he was born. His psychomotor and social

developments are within normal limits. His parents define him as an introverted child, sensitive, with low self-esteem and very attached to his mother.

The patient has a history of underperforming at school since he was in third grade, without being associated with external factors. He is going to support classes since then. He was evaluated by the guidance team from his school and they decided to do a curricular adaptation for him. Currently, he is repeating 4th year and he is going to educational support.

The patient's assessment consisted in clinical interviews with the patient and their parents and the implementation of additional tests like WISC-IV, D2, CDI, TALE, SNAP IV and a review of his clinical report.

The results showed us a specific development disorder comorbid with a deficit of attention so we decided to start with the psychopharmacological treatment and psychotherapy.

Early interventions practices in ASD – Maternal behavior in spontaneous interaction with their children

C. Amato^{1,*}, M.E. D'Antino¹, M. Rocha¹, F. Fernandes²

¹ Mackenzie Presbyterian University, Developmental Disorders

Program, Centre for Health and Biological Sciences, São Paulo, Brazil

² Universidade de São Paulo, School of Medicine, São Paulo, Brazil

* Corresponding author.

Recent studies point out that the occurrence of Autism Spectrum Disorders (ASD) is up to 1%. In Brazil, providing services of medical diagnosis for children with ASD takes precious time. The time spent waiting for the conclusion of the diagnostic process would be extremely important to the child's development. In this context, the parent–children interaction is an important aspect to be considered as a factor that has a positive impact in this process. The aim of this study was to explore maternal behavior during a spontaneous play situation with their children. All subjects were filmed for 30 minutes during a spontaneous play situation with their mothers that did not receive any special instructions. The subjects were 30 normal children, 3 of each age (respectively 9, 12, 15, 18, 21, 24, 27, 30, 33 and 36 months) and 20 autistic children with ages varying from 2:10 to 10:6 (not expected any chronological association). The whole corpus was analyzed considering of each subject, of each group and the possible associations between the groups. The analysis of the maternal behavior provides data about the importance of mother–child interaction and how everyday life activities and routines can be used to increase the opportunities to improve the ASD child's communicative abilities and their creative use as an important part of the whole development. These findings provide further evidence that families should be included in any plan for intervention designed towards ASD children.

Kasr Al Ainy, Psychiatry, Cairo, Egypt
* Corresponding author.

The development of language and communication may play an important role in the emergence of behavioral problems in young children. A cross-sectional relationship between language and ADHD were examined in 30 ADHD children and 30 healthy matched controls. We applied the modified preschool language scale, Stanford Binnet test and Conner's parent rating scale. ADHD children showed more language and behavioral difficulties and spent less time in communication than controls. Also, they showed more impairment in academic, social, and behavioral abilities.

Practices of Tunisian professionals in the diagnosis of autism

S. Amina*, C. Leila, A. Hela, K. Khawla, H. Imen, W. Adel, M. Yousr, G. Farhat
Hedi Chaker hospital, CHU Hédi Chakar Sfax, Sfax, Tunisia
* Corresponding author.

Introduction The diagnosis of autism spectrum disorders is complex. Recommendations for good medical practice in the diagnosis exist. The objective of this study is to evaluate the practices of Tunisian professionals in the diagnosis of autism.

Methodology We conducted a cross-sectional, descriptive study of 40 professionals involved in the diagnosis of autism, in all of Tunisia. Participants were recruited by e-mail, and received questionnaires. The anonymity was respected. This questionnaire was used to collect information about the practices of professionals in the diagnosis of autism.

Results Participants were child psychiatrists in 69.2% of cases, pediatric neurologists in 12.9% of cases, psychiatrists in 10.3% of cases, psychologists in 5.1% of cases, and speech therapists in 5.1% of cases. For the diagnosis of autism, professionals use diagnostic scales in 87.2% of cases with use of CARS in 53.8% of cases and the ADI-R in 7.7% of cases. Prescribing para-clinical investigations was noted in 94.9% of participants. It was systematic in 61.5% of cases. It was auditory evoked potential in 87.2% of cases, electroencephalogram in 66.7% of cases, a complete physical examination in 51.3% of cases, a genetic examination in 30% of cases, a brain MRI in 15.4% of cases, a specialized neurological examination in 12.8% of cases, and an ophthalmological examination in 2.6% of cases.

Conclusion The results of this study point out that the use of scales, testing and prescription of not para-clinical investigations is not done systematically. This can be improved by familiarizing professionals with the recommendations of the literature.

Parents' of adolescent children with attention deficit hyperactivity disorder (ADHD) perception about their children exposure to violence

E. Scherer^{1,*}, J. Stefanini², Z. Scherer²

¹ Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, Brazil

² University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences Department, Ribeirão Preto - São Paulo, Brazil

* Corresponding author.

Introduction People with ADHD can expose themselves to violence in different environments. ADHD typical behaviors can provoke inadequate behaviors of parents in their children's education, as physical and emotional maltreatment.

Objectives We carried out a qualitative study using the oral thematic history to identify the perception of parents of children with ADHD about their exposition to familial or extrafamilial violence.

Aims Understanding the ADHD adolescents' exposure to violence.

Method Nine parents of adolescents with ADHD taken care of in a Brazilian public university hospital participated. The thematic interview was carried through in their homes.

Results The narratives' analysis allowed identifying the occurrence of "Conflicts in the familiar conviviality" and "Conflicts in the context of the school and the community" in all cases. The violence identified was of physical and psychological nature. The communication between areas, sectors, professionals and family was harmed, problem that is reflected in the social relations established with the adolescents.

Conclusion The difficulty of the individuals with ADHD in adjusting to effective social behavior standards takes them to be labeled, suffering social intolerance and discrimination, producing consequences in their interpersonal relationships in the family, school and community. The addition of violent actions as educative methods and other inadequate family behaviors allied to social and school difficulties can bring harmful consequences with repercussions on adolescents' development and adaptation in their different contexts of conviviality.

Adjunctive aripiprazole for treatment of antipsychotic induced hyperprolactinemia in adolescents: A series of illustrative case reports

B. Ay*, S. Turan, A. Ozbek, O. Gencer Kidak
Dokuz Eylul University Faculty of Medicine, Child and Adolescent Psychiatry, Izmir, Turkey

* Corresponding author.

Objective Atypical antipsychotic agents are frequently used in pharmacological treatment of Schizophrenia and Bipolar disorders. Although hyperprolactinemia is a common side effect of many antipsychotic drugs, it has received little attention in comparison to extrapyramidal side effects, especially in younger population. Aripiprazole is reported to be associated with the lowest rates around 5% or less. Moreover this agent is reported to lower PRL levels induced by first and second generation antipsychotic use in adults.

In this study we aimed to present and discuss six adolescents who had received aripiprazole treatment aiming to reduce PRL levels induced by various second generation antipsychotics.

Methods Six patients were aged between 14 and 17 years. Five of them were diagnosed as early onset schizophrenia and the remaining one was diagnosed as bipolar 1 disorder. Risperidone, amisulpride, olanzapine and in some cases combinations of these agents were responsible for hyperprolactinemia as displayed by basal and fortnightly measurements of serum prolactin levels. Aripiprazole were added to current antipsychotics and serum PRL levels obtained every two weeks were recorded.

Results Aripiprazole was used between 2.5–15 mg's initially and reached up to 10–30 mg per day within 3 weeks. In all six cases serum, PRL levels decreased by 9.1–88.76 percent.

Conclusions Aripiprazole seems to be promising in the treatment of antipsychotic induced hyperprolactinemia in adolescents. Randomized controlled studies necessitate.

Psychiatric symptoms induced by montelukast: A case report

E. Aydın Aşık^{1,*}, Ş. Yalın Sapmaz²

¹ Celal Bayar University Faculty of Medicine, Psychiatry, Manisa, Turkey

² Celal Bayar University Faculty of Medicine, Child and Adolescent Psychiatry, Manisa, Turkey

* Corresponding author.

Introduction Montelukast is a leukotrienes receptor antagonist, which is used, in chronic asthma, exercise induced bronchoconstriction and allergic rhinitis treatment. Montelukast inhibates the proinflammatory cytokines and leukotriene is released from the specific cells. Leukotrienes cause mucus secretion, vasodilatation, bronchoconstriction and eosinophilia. This case is about an asthma-diagnosed child who had acute disturbing behaviour and sleeping problems after using montelukast treatment.

Case A 5 year-old boy assessed because of symptoms like breaking the rules, disturbing friends, self-harming, hyperactivity, distractability, insomnia and nightmares. In his history, when he was 9 months old acute hyperactivity, yelling, naughtiness, insomnia, disturbing and self-harming behaviours occurred suddenly 24 hours after intravenous montelukast treatment due to asthma crisis. While he was still using oral montelukast, his parents had cut off the treatment. After about 2 months, there was decrease in the symptoms. After using montelukast, these kinds of misbehaviour occurred again in a week. The montelukast treatment was terminated controlled way under a pediatrician consultation. Turgay DSM-IV Based Destructive Behaviour Disorders Screening and Rating Scale were completed by both of the parents in the first interview and after 2 months of cutting off montelukast treatment. While comparing 2 scales and parents' anamnesis, we found that impulsivity, oppositional defiant, hyperactivity, distractability, breaking off the rules, irritability, insomnia and having nightmares reduced.

Conclusion Montelukast can cause many psychiatric symptoms. In that case we found sleeping problems and disturbing behaviour caused or induced by montelukast treatment. As in that case, other drugs also can cause or enhance psychiatric symptoms. So it is important to assess the other drugs while assessing the diagnosis and the treatment.

Affective symptoms and emerging psychotic disorder in adolescents

X. Benarous

Hôpital Pitié-Salpêtrière, Child and adolescent psychiatry department, Paris, France

Depressive symptoms are frequently reported during the period preceding the onset of schizophrenia in adolescents when such symptoms can be mistaken for those of mood disorder. However, it is unclear which emotional symptoms should be considered predictive of schizophrenia onset.

The types of emotional disturbances that may precede schizophrenic disorder were sought through a review of historical descriptive studies and seminal works using a phenomenological approach. Five main types of emotional disturbances have been found as prodromal symptoms of a schizophrenic disorder: (1) increased sensitivity to stress, (2) poor or incomplete expression of emotions, (3) reduced emotion sharing, (4) emotional detachment, and (5) disconnection between the perception and expression of emotions. Studies based on phenomenological views of schizophrenic disorders stressed the chronological sequence of these symptoms in the same person. For example, the term “delusional mood” (Wahnstimmung) coined to describe changes in the perceived atmosphere encompass mood disturbances from subtle emotional overreactivity to more severe symptoms that could evoke athymhormia.

Analysis of recent studies among subjects at high-risk for psychotic transition showed that the presence of mood symptoms at a very early stage of the disorder is common. While these symptoms predict a lower level of general functioning, they were not associated with a higher risk of developing a schizophrenic disorder at follow-up.

The RDoC roadmap to explore neurocognitive difficulties of youths with severely dysregulated mood: Current findings and prospects

X. Benarous

Hôpital Pitié-Salpêtrière, Child and adolescent psychiatry department, Paris, France

The Research Domain Criteria (RDoC) has been developed as a multilevel approach to study neurocognitive impairments in psychiatry. Considering the high prevalence and the functional impairment associated with disruptive mood dysregulation disorders (DMDD) in youths, a better understanding of the neurobiological mechanisms underlying such emotional difficulties could help guide therapeutics.

So far, three key difficulties in the socio-emotional neurocognitive process have been documented in youths with DMDD:

- a deficit in the recognition of facial emotions has been found (systems for social process/social communication construct). Functional imagery has shown that such impairment is associated with a hypoactivity of limbic neural structures, especially the amygdala. Such findings are in line with those found in adults with depressive episodes;

- poor flexibility during cognitive tasks (cognitive systems/cognitive effortful control construct). In particular, these youths score poorly in neuropsychological tasks associated with response reversal paradigm measuring the capacity to change cognitive strategy when the rules of the game change implicitly. These results partly explain the difficulties facing DMDD youths in a frustrating context;

– higher level of emotional arousal. Such youths would present specific impairments in the initial stages of attention; reflected by lower N1 event-related potential amplitude during Posner affective tasks.

Ongoing studies are being conducted to explore other RDoC domains such as abnormalities in circadian rhythms; in metacognition and perspective-taking tasks; and in the non-facial communication process (such as prosody or postural expressions). A computational model of interactive behaviors is a promising field to study difficulties of DMDD youths in regulating moods during social interaction.

Childhood adversities and emergency room visits

B. Samsó^{1,*}, L. Alba¹, V. Chavarría¹, B. Sanchez², M. Pardo²

¹ Hospital Del Mar, INAD, Barcelona, Spain

² Hospital Sant Joan de Deu, psiquiatria infanto juvenil, Barcelona, Spain

* Corresponding author.

Introduction Institutionalized children and adolescents who reside in foster centres are a subgroup of population that use mental health resources. This group of population has an increased risk of physical and psychopathology health problems. That translates into a greater number of emergency visits. This is the same perception presented by different professionals.

Objectives The aim of the study is to analyse visits to emergency child and adolescent psychiatry service from a pediatric hospital. Also ask for a point of view of the professionals about it.

Methods We select all the patients attended the emergency psychiatry child and adolescent care that were institutionalized. The sample was collected for 4 months in a pediatric hospital.

Results $n=66$ (51.5% male; mean age 14.09 ± 1.95 years old), 31.8% was the first time at the emergency room, 31.8% had consulted between 2–4 times and 36.4% over 4 times. The main reason for consultation was aggressiveness (66.7%). The three main discharge diagnoses were conduct disorder (50%), adjustment disorder (25.7%) and TDAH (7.5%) The 45.5% had a history of drug use and the 24.2% of self-harm. Asking professionals 80% responded perception of increased emergency consultations and the 90% think inadequate value between 50–70% of queries.

Conclusions The boys institutionalized perform a high use of paediatric and psychiatric emergencies. There are a significant number of re-consultations. Professionals have the perception that their emergency visits are increasing. Since patients are at high risk of suffering mental disorders and high use of emergency would be interesting to develop specific protocols for emergency care for these groups.

EV235

Continuity of attachment in children with disruptive behavior disorders and in their parents: A pilot study

F. Bizzi*, R. Castellano, D. Cavanna

University of Genoa, Department of Educational Sciences, Genoa, Italy

* Corresponding author.

Introduction The quality of adult–infant attachment plays an essential role in influencing the children's well-being (Groh et al., 2012). Disruptive Behavior Disorders (DBD) has been found as

particularly influenced by the presence of unavailability in the parental caregiving. It is widely attested that parents' attachment states of mind predict the attachment patterns of their children. Nonetheless, the investigation of the attachment organization during the middle childhood shows inconsistent data. Moreover, a paucity of studies focused on the role of father's attachment in this period still remains.

Objectives This pilot study investigates the attachment patterns of children with DBD and those of their parents.

Aims The aims are to verify the presence of: (1) an over-representation of Disorganized attachment in these children; (2) an over-representation of Irresolution with respect to abuse or loss in one or both their parents.

Methods The sample consists of 33 subjects: $n=11$ children with DBD and $n=22$ parents. The children completed the Child Attachment Interview (Shmueli-Goetz et al., 2000) and the parents completed the Adult Attachment Interview (George et al., 1985).

Results Findings showed: (1) a significant presence of Disorganized attachment with respect to both parents in the children; (2) an over-representation of Insecure states of mind in their parents; (3) a more significant presence of Disorganization in the fathers than in the mothers.

Conclusion This focus on the topic of intergenerational transmission of attachment in a specific clinical sample enriches the research, underlining the more pronounced role of fathers' attachment configuration.

Disruptive behavior disorders and somatic symptoms disorders: Which strategies of emotion regulation children and their parent's use?

F. Bizzi*, R. Castellano, D. Cavanna

University of Genoa, Department of Educational Sciences, Genoa, Italy

* Corresponding author.

Introduction Emotion regulation (ER) is defined as the processes through which emotional awareness and experience are monitored, evaluated, maintained, and modified (Thompson, 1994). Difficulties with these processes have been proposed to increase risk for psychopathology. Disruptive behavior disorders (DBD) and somatic symptoms disorders (SSD) are characterized by an inability to express and modulate emotional states. Research aims to understand how ER influences mental health.

Objectives We focus on two strategy of ER: Cognitive Reappraisal, involves changing the way one thinks about a situation in order to change its emotional impact; Expressive Suppression involves suppressing or hiding external expressions of emotion from others (John and Gross, 2004)

Aims We assess ER in order to examine the relation with SSD and DBD in childhood and with their parents.

Methods The sample consists of 188 subjects divided in four groups: $n=41$ children with DBD ($M=10.78$ years, $SD=2.11$); $n=50$ parents (36 mothers and 14 fathers) of children with DBD; $n=44$ children with SSD ($M=11.98$ years, $SD=2.04$); $n=53$ parents (40 mothers and 11 fathers) of children with SSD. Were administered the ERQ (Balzarotti et al., 2010) for parents and ERQ-CA (Gullone and Taffe, 2012) for children.

Results DBD children reported higher levels of Suppression than SSD subjects; high levels of Suppression were reported in mother SSD and in father DBD.

Conclusion This study extended previous research in childhood, including both mothers and fathers. The findings contribute to a greater understanding of the development of ER, which has important implications for psychological wellbeing.

The evolution of cognitive functioning in adolescents with early onset psychosis

A. Bohus

Cluj-Napoca, Romania

Introduction Cognitive deficits (executive functions, verbal and spatial learning and memory, visual processing and attention) are a fundamental trait of schizophrenia.

Objective The main objective of this study is to compare the cognitive functioning in psychotic adolescents at the psychosis onset and after one year, using psychological tests.

Methods This is a longitudinal study, during a period of two years and a half. Twenty-eight patients with first psychotic episode agreed to participate to this study and were assessed during their hospitalization in a university clinic for child and adolescent psychiatry in Cluj-Napoca, Romania. The diagnosis was based on DSM-IV criteria. All the patients were initially assessed for intelligence level using Raven Test and those with mental retardation were excluded. After one year, sixteen adolescents from the initial group were reassessed. The cognitive functioning was assessed with Trail Making A and B, verbal fluency tasks, Wisconsin Card Sorting Test and Rey Auditory Verbal Learning Test. The results from patients group were compared with those from healthy controls.

Results The results show weaker global cognitive performance from adolescents with early onset psychosis, initially and at one-year evaluation, than the healthy adolescents from the control group.

Conclusions This results are consistent with those of previous studies. The adolescents with early onset psychosis show multiple cognitive impairments initially and one year after the psychosis onset.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The start of Child and Adolescent attention to gender dysphoria is very recent. In our Unit, it has objectified a growing increase in such demand over recent years.

As a typical example would be a patient of 13 years following gender dysphoria begins to present school failure and behavior problems at home with emotional instability.

According to the recommendations of the Group Identity and Sexual Differentiation (GIDSEEN) after early detection is to guide parents towards a comprehensive treatment at a specialized

interdisciplinary teams and a psychosocial approach to improve the quality of life, decrease mental comorbidity and gender dysphoria own. Having no such care in our community has been necessary to make a referral to another community to attend this demand.

Currently it is giving adequate attention to these cases, but except for referral to another community. However, as we are seeing progression care in our area in the future could be feasible. Therefore, we consider as a first step dysphoria quantify each case in our area.

Wernicke-Korsakoff syndrome with psychotic symptoms in a severe case of anorexia nervosa: A case report

D. Brigadeiro^{1,*}, C. Ferreira², J. Magalhães², J. Nunes¹, P. Santos³, E. Santos², A. Pissarra¹

¹ Hospital Sousa Martins - ULS - Guarda - EPE, Psiquiatria, Guarda, Portugal

² Centro Hospitalar Tondela - Viseu - EPE, Pediatria, Viseu, Portugal

³ Centro Hospitalar Tondela - Viseu - EPE, Pedopsiquiatria, Viseu, Portugal

* Corresponding author.

Introduction The Wernicke-Korsakoff syndrome comprises a complex of symptoms including Wernicke's encephalopathy and the Korsakoff's syndrome. While the former is characterized by a classic clinical triad of ataxia, ophthalmoplegia and a global confusional state; the Korsakoff's syndrome is characterized by memory impairment and confabulation. These two entities are now considered as a clinical spectrum of a same disease caused by deficiency of thiamine (vitamin B1).

Objective To describe a case of Wernicke-Korsakoff Syndrome with psychotic symptoms in a 13-year-old female patient with anorexia nervosa.

Method The patient and family were interviewed. Literature relevant to the case was reviewed.

Results A 13-year-old Caucasian female was admitted to the emergency department with bradycardia (38 bpm) and a two-month history of weight loss totaling 6 kg. This loss of weight was a result of dietary restriction and over-exercise because she "felt too fat". On admission she has a body mass index of 12.17. She was diagnosed with anorexia nervosa and was hospitalized. On day 11 after hospitalization, patient initiated alteration in behavior, fluctuating mental state with periods of lucidity and periods of confusion, memory impairment and psychotic symptoms, with paranoid delusions and auditory hallucinations. The classic triad of Wernicke's encephalopathy was not present. The treatment with thiamine was initiated and the symptoms including psychotic symptoms improved.

Conclusion Wernicke-Korsakoff syndrome should be considered in cases of anorexia nervosa with a confusional state and memory impairment even if the classic symptoms are not present.

Disturbed sleep and activity as early signs of ADHD in preschool children

A.K. Bundgaard^{1,2,*}, N. Bilenberg³, J. Asmussen³, P. Munk Jørgensen²

¹ Psychiatric Hospital and University of Southern Denmark, Research Unit - Child - and Adolescent Psychiatry - Region of Southern Denmark, Odense C, Denmark

² Psychiatric Hospital - Region of Southern Denmark, Psychiatric Research Academy Odense, Odense C, Denmark

³ Psychiatric Hospital and University of Southern Denmark, Child and Adolescent Psychiatry, Odense C, Denmark

* Corresponding author.

Introduction Attention-deficit-hyperactivity-disorder (ADHD) is the most frequent psychiatric disorder present in childhood, and sleep-problems are a prominent, pervasive and clinically important feature of ADHD. Our understanding of whether sleep-problems mimic or exacerbate daytime ADHD-symptom expression remains insufficient. Furthermore we lack knowledge about the connection between objective measuring and subjective observations in children with early symptoms of ADHD.

Objective Future research that examines sleep-problems and daily activity in very young children with and without ADHD-like symptoms might help us identify early risk factors and achieve a better understanding of the importance of sleep in ADHD.

Aims To investigate if sleep-problems and activity level during day time is associated with early signs of ADHD.

Methods A sample of 50 preschool children ages 2–3 and their parents recruited in a birth cohort are invited to participate and divided into two groups of 25 cases and 25 controls based on ADHD-symptom score. An actigraph on the child's non-dominant wrist measures sleep and daily activity. Sleep-latency, total sleep time and awakenings are examined. Moderate-to-vigorous-activity (MVPA) is the measure for daily activity. Subjective observations from parents are provided through questionnaires. Furthermore we examine the stability of the sleep problem score from child behavior checklist, which parents fulfilled when their child was 27 months old and again at the age of 5.

Results The results will be presented at the EPA March 2016 in Madrid.

Conclusion Results from this study together with other findings of risk factors in the cohort may lead to a preschool ADHD risk-index, which can guide future early intervention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relationship between coping and anxiety in young university population

K. Cabas-Hoyos*, N. German-Ayala, E.D.L. Nadia, M.B. Loreina, U.U. Alicia

Grupo CAVIDA, Facultad de Psicología, Universidad Pontificia Bolivariana, Sede Montería, Cra. 6 No. 97A, 99, Montería, Colombia, Cordoba, Montería, Colombia

* Corresponding author.

In Latin American countries the University Entrance occurs before 17 years of age, in adolescence. The literature proposes some tasks of this stage as the search for identity and definition of the plan of life (Casullo et Fernández-Liporace, 2001). This stage is characterized by changes that may lead to stress (Frydenberg et Lewis, 1991) and strategies and styles should be deployed to deal with situations surpluses. The aim of this paper is to explore the relationship between coping styles and anxiety in young university students. The total sample consisted of $n=216$ university students (53.2% female, $n=115$, 46.8% male, $n=101$; between 16 and 18 years of age: $m=17.32$, $SD=0.70$). The subjects answered the ACS (Frydenberg, 1997) which assesses coping styles in young people and the AMAS-E (Reynolds, 2007) assessing anxiety. The design was correlational, the data were analyzed using SPSS 21.0 statistical program.

Results and discussion As used style Troubleshooting reduces test anxiety, the tendency of these two variables is negative ($P=0.01$). Implement the style Relating to others it will decrease test anxiety,

the tendency of both variables is negative and statistically significant ($P>0.05$). Stress in young people increases as gets underway unproductive type ($P=0.00$). The results are consistent with the literature that suggests that late adolescents in academic challenges cause such hardship (Marote et Martínez, 2001).

Strange behavior as defense mechanism related to sensorial impairment in autism

M.C. Cancino Botello*, A. Peña Serrano, M.D.L.A. Canseco Navarro, J.M. Hernández Sánchez, F. Molina López

Consorcio Hospital General Universitario, Psychiatry, Valencia, Spain

* Corresponding author.

Introduction So far, autism etiology is not known yet, it is believed that is due a combination of neurobiological, structural, genetic and environmental factors. This disorder is characterized by social interaction and communication impairments and presence of restricted and repetitive behaviors. Some authors have spoken about Sensorial Perception Theory that tries to explain how sensorial impairment of people with autism causes "strange" conducts, as a protective mechanism to stimuli they perceive as disturbing.

Objectives To highlight the role of sensorial perception in people with autism in their way of interacting over the environment.

Method systematic review of the literature in English (PubMed), with the following keywords: "Autism", "sensory perception", and "Asperger syndrome".

Results According to Sensorial Perception Theory, people with autism perceive sensorial information from environment in different ways. It is believed that each sense operates as a hyper or hyposensitive sense, according to the intensity and the moment the stimulus is produced. This fact provokes "abnormal" responses as repetitive or restricted behavior, in order to protect themselves from the disturbing stimuli.

Conclusions Sensorial hyper or hyposensitive may be related to the strange behavior that can be present in people with autism. If we could interpret such conducts, we will be able to imagine how patients are perceiving the world and then we could help them to develop strategies in order to function more properly.

ADHD and bipolar disorder challenge in diagnosis in children and adolescents

P. Cano Ruiz^{1,*}, A. Gómez Peinado¹, S. Cañas Fraile¹, P. Sanmartín Salinas²

¹ HNSPS, Psiquiatría, Albacete, Spain

² Universidad de Alcalá, Systems Biology, Alcalá de Henares, Spain

* Corresponding author.

Introduction The professionals in charge of children and adolescents with attention deficit disorder and hyperactivity disorder (ADHD) should be prepared to treat a wide variety of psychiatric symptoms, as most have at least one comorbid psychiatric disorder. Sometimes the differential diagnosis between ADHD and bipolar disease is difficult because of overlapping symptoms between the two disorders (Geller et al., 1997; Biederman et al., 2000; Singh et al., 2006).

Methodology A literature review about the comorbidity between ADHD and bipolar disorder in children and adolescents was performed.

Results According to different studies, between 60 and 90% of children and adolescents with ADHD have comorbid bipolar disorder. However, the percentage of children and adolescents with ADHD that has comorbid bipolar disorder varied from 10 to 22% (puedes poner from 60 to 90% si no quieres repetir el and).

Conclusions The prevalence of bipolar disease, particularly among adolescents, is between 1 and 7%. This percentage is higher if all forms of bipolar spectrum are included. Some personal and family factors increase the probability of a patient having ADHD present bipolar disease: decreased IQ, delayed development, family history of ADHD or bipolar disease, and the combined subtype.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Acute psychosis in an adolescent with cerebral palsy

C.A. Moreira^{1,*}, A.R. Soares², G. Maia²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

² Centro Hospitalar Lisboa Ocidental, Child and Adolescent Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Cerebral Palsy is a movement, posture or muscle toning disorder caused by an insult to the immature, developing brain, most often before birth. It is a leading cause for serious disabilities in childhood and a risk factor for the development of psychiatric disorders, particularly in adolescents. Moreover, according to DSM-5, a Brief psychotic disorder is a short-term illness with psychotic symptoms, which arise suddenly, but last for less than one month, after which the person recovers completely.

Objectives/Aims The authors aim to present a case of an adolescent with cerebral palsy who has developed secondary psychotic symptoms, a rare and sparsely understood phenomenon.

Methods A non-systematic review of English scientific literature was conducted through research in the PubMed search engine, using the keywords “Cerebral Palsy” and “Brief Psychotic Disorder”.

Results A 16-year-old female adolescent with history of Cerebral Palsy (due to neonatal anoxia) was admitted in the paediatric ward due to behaviour disorder characterized by incoherent speech, full insomnia, agitation and auto/alo-aggression. A complete clinical investigation was performed, in which trauma, organic brain injury, degenerative and inflammatory diseases, infection or toxic ingestion were all excluded. The hypothesis of an acute psychotic disorder was considered and after antipsychotic treatment, a total remission of the symptoms was obtained.

Conclusions Although rare, the association between cerebral palsy and psychotic disorders should be considered in the diagnostic investigation of behavioural changes. Early identification allows a proper therapeutic intervention and a better quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric antiepileptics side effects: A case report

C.A. Moreira^{1,*}, A.R. Soares², G. Maia²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

² Centro Hospitalar Lisboa Ocidental, Child and Adolescent Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Psychiatric disorders in epilepsy have a multifactorial etiology, being pharmacotherapy only one of many risk factors, which can be both biological and psychosocial. The adverse effects of antiepileptics (AEDs) embrace all categories of psychiatric symptomatology, including disturbances of consciousness, psychotic state, neurotic state, behaviour and character disorder. In fact, Psychotropic effects of AEDs require further research because many relevant parameters related to pathological mechanisms, frequency, psychopathology, and prognosis are not well understood.

Objectives The authors aim to present a case of an adolescent with epilepsy who has developed secondary psychiatric symptoms.

Aims To understand and deal with the most common Psychiatric side effects of AEDs.

Methods A non-systematic review of English scientific literature was conducted using keywords “Epilepsy” and “antiepileptic side effects”.

Discussion A 14-year-old female adolescent with history of seven years of Epilepsy (usual medication: carbamazepine 45 mg/kg/day, Lamotrigine 8 mg/kg/day; pregabalin 8 mg/kg/day) was admitted in the paediatric ward due to behaviour disorder characterized by agitation, anxiety and seizures-like symptoms. A therapeutic adjust was made (Fenetoína and Levetiracetam). After this medication change, the adolescent presented psychotic symptoms namely auditory and tactile hallucinations. A complete clinical investigation was performed and the hypothesis of drugs side effects was considered. After AEDs reduction, a total remission of the symptoms was obtained.

Conclusion Psychiatric disorders in epilepsy have a multifactorial etiology and are not yet well understood. Behavioural side-effect profiles of AEDs (both negative and positive effects) should be considered in the choice of the optimal drug for each patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Drawing can be a tool to complete the psychodiagnose process, especially in children with expression and verbal problems. The Autistic Spectrum Disorder (ASD) children have problems to describe their feelings and emotions, they can provide us many information drawing their own world.

Objective The purpose of this study was to discover the psychopathology of children with ASD through their drawings.

Methods A4-sized booklets were given for ASD children from 6 to 16 years to draw an imaginary family (L. Corman), a human figure (Buck) or a free drawing.

Results In most of the drawings of ASD children we could find at least one of the three criteria of ASD: social deficits, communication difficulties and restricted interests.

Conclusions A projective technique as drawing could help us to discover additional information about our patients, specially children and mainly the ones who had problems with the expression of feelings like ASD children. The act of drawing can be used to understand children's struggles, their internal world. Moreover it could also help the children gain insight and review progress through drawing records.

Introduction Anti-NMDA encephalitis normally appears as a characteristic syndrome with typical symptoms that undergoes with multiphase evolution. However, it sometimes develops atypical symptoms so we must perform a careful differential diagnosis. **Objectives** To conduct a current review of detection and management of anti-NMDAr encephalitis, and psychiatric manifestations. **Method** Systematic review of the literature in English (PubMed), with the following keywords: "Autoimmune encephalitis", "psychosis", and "NMDA receptor".

Results We present the case of a 15-year-old boy referred to evaluation for a first psychotic episode. He had no past history of psychiatric illness or substance abuse. The only relevant antecedent is multiple sclerosis in a first degree relative. For the last months, he presented high levels of anxiety symptoms apparently related to college stressful events and fluctuating hypoesthesia of left cranial side. Days later, it appeared autolimited gastrointestinal symptoms, headache and fever. During the next days it appeared psychomotor retardation, choreic movements, suicide ideation and mood-congruent paranoid and nihilistic ideation, auditory and visual hallucinations, perplexity and catatonic symptoms so he was hospitalized. We observed cognitive functions impairment, unsteady gait, dysarthria, dysphasia, clonus and left babinsky sign. EEG showed slow waves on right frontal area. CFS showed protein elevation and immunologic study revealed positive anti-NMDA antibodies. Treatment with methylprednisolone and gammaglobuline was started with partial response, needing addition of rituximab.

Conclusions In this case, we highlight the importance of early detection and a detailed differential diagnosis, to determine whether the etiology of psychiatric symptoms in order to achieve an accurate and early treatment.

* Corresponding author.

Introduction There is currently a resurgence of handwriting difficulties in school-age children. Researches in literature focus on kinematics temporal and spatial measures of letters in the writing process and on clinical performances such as the handwriting scale (BHK). This assessment doesn't consider the organization and the maturation of the handwriting gesture.

Objectives We aim to study the developmental organization of the handwriting gesture to provide developmental standards of reference in order to complete performances measures allowing a better understanding of handwriting disabilities.

Methods Healthy children of elementary school aged between 6 and 11 years old are eligible for inclusion. All children are assessed with neuropsychological and neuropsychomotor evaluations and with handwriting assessment (BHK). Two groups are established, the one with handwriting difficulties and the other one (control group) without writing disorder or learning disabilities. The children were matched for age, gender and school level. All children are filmed with a camera suspended over to observe with specific handwriting tasks, the upper limb gesture about segmental organization of fingers, hand, forearm, arm, shoulder and postural organization. **Results** Preliminary findings show significant differences of the segmental organization of the writing gesture between the two groups. We will discuss the identified causes of the handwriting disorders with the analysis of neuropsychomotor and neurological assessments data in correlation with gesture segmental organization.

Conclusion Developmental organization of the writing gesture is a possible underlying mechanism of handwriting disabilities. Practically, it appears important to improve news tools of evaluations with gestural writing consideration and to implement it in intervention process.

EV249

The moderating effect of irrationality on the relationship between callous-unemotional traits and conduct problems in teenagers

C. Costea

Universitatea Babeş-Bolyai- Facultatea de Psihologie si Stiinte ale Educatiei, Psihologie Clinica si Psihoterapie, Cluj Napoca, Romania

The main objective of this study was the investigation of the moderation effect of irrationality on the relationship between callous-unemotional traits and conduct problems in youths, this last association having been demonstrated before in scientific research. The data was collected from 40 patients of a pediatric psychiatry clinic, during the last 18 months.

We used the following instruments for measuring the main variables of the study: The Youth Self-Report (YSR, Achenbach, 1991) for the conduct problems, The Inventory of Callous-Unemotional Traits (ICU, Frick, 2004) and The Child and Adolescent Scale of Irrationality (CASI, Bernard and Cronan, 1999).

The acquired data was analyzed with the SPSS 20 statistical software. First, we performed the descriptive statistics and then we conducted the hierarchical multiple regression analysis. The research design is predictive, moderation type.

The results showed a significant positive association between callous-unemotional traits and conduct problems, a significant positive association between irrationality and conduct problems, no significant statistical association between callous-unemotional traits and irrational beliefs and no significant moderating effect of irrational cognitions on the relationship between callous-unemotional traits and conduct problems. Nonetheless, callous-unemotional traits and irrationality explain 49.5% of the variance of behavior problems.

The results confirm the need of adapted individualized therapeutic strategies for children and adolescents with conduct problems, to address both their callous-unemotional traits and their irrational beliefs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Conversion disorder (CD) is an uncommon but highly disabling condition. Affected children and adolescents are often severely impaired and at risk of serious long-term physical and psychosocial complications. Despite the enormous personal suffering and health resource implications of CD, little research has been done.

Objectives To update our knowledge about CD in adolescents, with a comprehensive review of the literature with special focus in prevalence, psychosocial factors, diagnosis, treatment and outcome.

Aims To present the most relevant data of our review with a clinical illustration that provides a practical vision of this disorder.

Methods A systematic literature review was performed in MEDLINE, with particular interest in papers published in the last 10 years. Clinical illustration is provided by a case selected from an outpatient child and adolescent mental health service.

Results Few reliable prevalence data are available; the range goes from 0.2 in a German study to 31% in non-western clinical settings. Diagnosis is based on a constellation of features and treatment should involve several health care professionals. CD has a favourable outcome in children and adolescents. However, mood and/or anxiety disorders are encountered at a considerable rate even after recovery from conversion symptoms. Long clinical follow-up seems appropriate.

Conclusions The expression of emotional distress in the form of physical complaints is common in children. Nevertheless, the most severe presentation of physical symptoms is not a common topic in literature. More research should be done to improve our understanding of this disabling disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Hoarding disorder is described in the DSM-5 as a new clinical entity whose essential characteristic is the persistent difficulty discarding or parting with possessions, regardless of their actual value, arguing reasons of utility, aesthetics, attachment or strong fear of losing information.

Objectives We present the case of an 11-year-old male patient brought to the Health Mental office when his mother found in the school bag debris that he had collected from the garbage, and useless objects in a bedroom drawer. The patient recognizes the nonsense of his behaviour but is unable to get rid of these objects but he allows his mother to do it. He had lowered school performance and showed irritable, shy and solitary, difficulties to sleep and cried often without apparent reason. They also noted since six months before, strange movements with the neck and eyes.

Methods After ruling out, underlying organic pathology, we started treatment with sertraline 50 mg, aripiprazole 2.5 mg and cognitive behavioural therapy, with complete disappearance of symptoms including the movement disorder.

Results Obsessive compulsive disorder 300.3 (F42); Hoarding disorder 300.3 (F42); Provisional Tic disorder 307.21 (F95.0).

Conclusions Hoarding behaviour of strange objects is very unusual in Hoarding Disorder but more common in the Obsessive-Compulsive Disorder. In this case report, we consider the possibility of both disorders.

EV252

Early attachment trauma and the impact on child's development

D. D'Hooghe

Traumacentre Belgium, Brugge, Belgium

It is important to broaden our vision on attachment trauma, by pointing out the importance of the quality of parenting as an indicator to develop a secure attachment relationship.

This quality mainly depends on the caregivers' ability to mentalize, regulate, contain, play, . . .

The absence of these features causes traumatic stress in the child and impacts his psychological and neurological development and the possibility to attach. Thus, it is important that we are aware of the relationship between early attachment trauma (EAT) and affect dysregulation and dissociation.

The seriousness depends on the early age of the child, an immature coping mechanism, the child's different experience of danger, the stress level of adverse experiences and the caregiver as the source of trauma.

We can consider dissociation and affect dysregulation as complex adaptation to trauma.

In addition, when the child is not able to manage distress, it lacks the capability to integrate the experiences.

Dissociation and inadequate self-regulation interfere with one another and impact the development of the sense of self.

By raising awareness amongst caregivers and clinicians about EAT and the severe consequences, new therapeutic opportunities could be developed.

When Ockham razor's principle is not applicable: Differential diagnosis of a rare case of child and adolescent psychosis

F. Dinamarca*, A. Palma, M. Grifell, L. Galindo, L. Gonzalez, M.T. Campillo, V. Perez
Hospital Del Mar, Psychiatry service, INAD, Barcelona, Spain

* Corresponding author.

Introduction The diagnosis of schizophrenia in children is rare. Less than 4% of schizophrenic patients begin before age 15 being much less stable than in adults as an entity in time. It is estimated that only 50% of diagnoses of schizophrenia in patients under 15 years are maintained over time. The most frequent differential diagnoses are bipolar disorder, post-traumatic stress disorder and dissociative disorder.

Objective and methods A case of a patient of 18 years old admitted in our service with diagnosis of paranoid schizophrenia due to the presence of delusional symptoms at age of 14 and due his evolution with impaired overall performance is presented. Upon arrival he presented delusions, self-referentiality and a strange phenotype with a pitched voice. Clinical history included presence of sexual abuse prior to debut of psychotic symptoms and rare medical comorbidity (diagnosed at age 15 of hypertension and paroxysmal sinus tachycardia). A kariotipe was done in a previous admission with normal results.

Results During hospitalization symptomatic remission was achieved in just two days by decreasing antipsychotic potency of the treatment, he also presented elevated metanephrines and also elevated plasma aldosterone and renin in blood tests.

Conclusions We discuss the differential diagnosis including schizophrenia, post-traumatic stress disorder with dissociative symptoms and endocrine pathology (pheochromocytoma and hyperaldosteronism).

Introduction One of the main challenges facing the fact that every society has always called divorce. Phenomenon in modern societies is growing at a rapid rate and adverse effects of economic, social and especially psychological, parents and children.

Aim This study pays to determining the influence of game treatment on decreasing divorce children's stress.

Methods The method of study is of testing in which statistical society of study includes all children (girl and boy) of divorced

parents. From all statistical society, we have selected a sample about 26 persons by randomly sampling. The instrument for gathering information in this study includes children stress test (SCARED) in which has been studied sample after measuring its narration and stability.

Result The result of dependent *t*-test and covariance analysis showed game treatment has meaningful and positive influence on children stress.

Conclusions The amount of its interference on decreasing divorce children stress is about 83%. It means 83% of the whole remained score's variance is related to game treatment interference.

The increase in prevalence of Autism Spectrum Disorders (ASD) demands that new strategies for delivering speech-language therapy services to them are tested and improved. Including families and familiar situations may be a way to provide more intensive stimulation. The aim of this study was to identify strategies to stimulate communication development of children with ASD that can be suggested to parents and followed-up systematically. Participants were 67 children with diagnosis within the autism spectrum that attended weekly speech-language therapy at a specialized service of a large university in São Paulo (Brazil). The study was conducted in four phases: planning of activities; four face-to-face meetings with the parents to suggest and discuss activities that should be conducted at home daily; during six weeks the parents continued to conduct the proposed activities at home, with systematic weekly follow-up by the child's therapist finally, individual the parents reported their impressions about the proposal and the outcomes regarding their child's development during individual interviews. Activities involved the main areas of disorders in ASD. They suggested that the parents used familiar situations as opportunities for games and plays involving language, cognitive and social demands. Parents reported difficulties in implementing the proposed routine of playing with their child for at least a few minutes every day. They mentioned "lack of time" and "being tired" as the main reasons for it. Nevertheless they all reported that they were more able to understand their child's needs and demands and that their child responded well to the suggestions.

² Centro Hospitalar e Universitário de Coimbra, Serviço de Pedopsiquiatria, Coimbra, Portugal

* Corresponding author.

Introduction Cystic fibrosis (CF) is an autosomal recessive disease characterized by abnormal airways secretions, chronic endobronchial infection, and progressive airway obstruction. In Portugal is estimated 30–40 born children with CF per year. The prognosis of CF has changed over the last decade, death in childhood is now rare, and children born today are likely to have a mean life expectancy of over 40–50 years. An understanding of the psychiatric aspects of CF is more important than ever.

Methods Review published and referenced scientific articles on MedLine/PubMed.

Results Researchers found CF can affect the patient and their family in many ways. Physical and social restrictions, the rigorous medical regimen, hospital admissions, concerns about illness, and uncertainties of the future can create anxiety and depression in patients and parent alike. They also may have problems with interpersonal relationships resulting in isolation and social maladjustment. Some studies also reported an increased risk of develop an insecure attachment and less adapted eating behaviors. The essential responsibilities of psychiatrist are: evaluating the psychiatric effects of living with CF, comprehensive assessment and intervention when emotional, behavioural and psychological difficulties arise and providing support.

Conclusions Awareness of types of emotional strain experienced by these children and their families can be of use to avert potential problems which may seriously impair therapeutic effectiveness and the patient's well being. Management requires an interdisciplinary team to maximise longevity and quality of life. All patients and their families must be offered the opportunity to meet with a Child and adolescents psychiatrist.

Psychosocial predictors in adolescent's non-suicidal self-injury: Preliminary results

J. Ferreira*, V. Leite, L. Veiga, J. Garrido

Hospital pediátrico, centro hospitalar e universitário de Coimbra, child and adolescence psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Non-suicidal self-injury (NSSI) have their typical onset during adolescence. Although a growing body of research has been dedicated to this subject, little is known about the relation between psychosocial factors (PF) and NSSI in adolescence.

Objectives To identify the main PF associated with the occurrence of NSSI in adolescence and potential relations between them.

Methods The authors used a convenience sample of 50 outpatient adolescents from Coimbra's Child and Adolescent Psychiatry Service, with identified history of NSSI. Each patient was evaluated regarding the presence/absence of the PF contemplated in the Axis V (Associated Abnormal Psychosocial Situations) of the Multiaxial Classification of Child and Adolescent Psychiatric Disorders, (ICD-10, WHO).

Results Sixty-seven factors were evaluated within this sample, with 50% of the subjects showing the 3 most prevalent PF (the 5 most prevalent PF are displayed on Table 1). Statistical significance between pairs or triads of PF (selected within the 10 most prevalent PF) was evaluated, with results showing 14 significant correlations between pairs and 20 significant correlations between selected triads among the most prevalent PF.

Conclusions PF are highly prevalent within adolescents with NSSI. Identification of specific associations of PF may be useful to identify high-risk patients and promote early intervention and prevention programs.

Table 1

PF	n	%
Intrafamilial discord among adults (both parents)	37	74
Inadequate or distorted intrafamilial communication	37	74
Events resulting in loss of self esteem	36	72
Loss of a love relationship (removal)	34	68
Lack of warmth in parent-child relationships (father)	32	64

Social media modulation of mood and anxiety in adolescents with chronic visible skin conditions

J. Gagnon*, A.M. Duchemin

Ohio State University, Psychiatry, Columbus, USA

* Corresponding author.

Chronic skin diseases are often associated with psychiatric disorders, and psychological factors such as stress can affect the management of skin conditions. In adolescents, skin diseases can have a profound impact on body image, self-esteem and social interactions. Social media is a mode of communication increasingly used, especially among adolescents. It has been shown to have detrimental effect by the negative influence of peers through social network interactions as well as positive effects by allowing support and access to care. The posting of pictures of individuals by others in social media may make this mode of communication particularly distressful for teens with a visible skin condition; they cannot control the photos being shared with the group and are reminded of the visibility of their skin condition through these postings. To determine how social media may impact mental health and skin disease management in adolescents' with chronic visible skin conditions, we conducted a survey of patients in the ambulatory setting. This cross-sectional study is based on an anonymous survey in teens, age 12 to 19, with various levels of chronic visible skin conditions. It explores the influences of social media on incidence and or severity of both psychiatric and dermatological health status as self-reported by patients. Acne, psoriasis, and atopic dermatitis are often associated with poor quality of life even with moderate skin disease. Taking in account the impact of social media on these pathologies is especially critical among adolescents due to their wide use and relevance in this population.

Parental group therapy & conduct disorders

E. Garcia*, E. Guerrero, I. Vicente, R. Martinez

Hospital General de Ciudad Real, USMJJ, Ciudad Real, Spain

* Corresponding author.

Conduct disorders are common between ADHD, some series has shown that even almost 40% of patients develop some of the two main diagnosis: ODD or CD.

That comorbidity between ADHD and ODD or CD has made that treatment become complex and requires different interventions. One field of treatment has been parental functioning.

It has been common that reward or punishment as two effective strategies modulate familiar interactions when they are referred to AHD sons.

However, in a long time, they failed to improve functioning, and frustration appears.

Attachment somehow is been hidden behind diagnosis and treatment, and family stop its evolution repeating wrong strategies.

Group therapy is a well-known tool that may help with this dysfunction in two ways: psychoeducation and debriefing.

The aim of this work is to resume our experience working with parents in a group therapy model.

We have found that affective symptoms are common between parents, and that they difficult parenting strategies.

Taking that into account, we promoted emotional expression using debriefing groups as model, before introducing psychoeducational issues.

Our hypothesis is that change is not possible if there is not a corrective attachment experience that let parents recover their role.

We use it as a complementary tool to family and individual therapy.

We will explain this model and its results based in therapists' and patients' experiences using open interviews.

First-episode psychosis: Ongoing mental health service utilization during the stable period for adolescents

R. Gearing^{1,*}, K. Brewer², K. Moore², M. Irfan³, P. Fisher⁴

¹ University of Houston, GCSW, Houston, USA

² Columbia University, Columbia, New York, USA

³ The Hospital For Sick Children, Psychiatry, Toronto, Canada

⁴ New York State Psychiatric Institute, Division of Child and Adolescent Psychiatry, New York, USA

* Corresponding author.

Introduction The importance of timely identification and treatment of psychosis are increasingly the focus of early interventions, with research targeting the initial high-risk period in the months following first-episode hospitalization. However, ongoing treatment and service utilization after the symptoms have been stabilized over the initial years following first-episode has received less research attention.

Objectives (1) To model the variables predicting continued service utilization with psychiatrists for adolescents following their first-episode psychosis, and (2) examine associated temporal patterns in continued service utilization.

Methods This study utilized a cohort design to assess adolescents (age 14.4 ± 2.5 years) discharged following their index hospitalization for first-episode psychosis. Bivariate analyses were conducted on predictor variables associated with psychiatric service utilization. All significant predictor variables were included in a logistic regression model.

Results Variables that were significantly associated with service utilization included: diagnosis with a schizophrenia spectrum disorder rather than major mood disorder with psychotic features (OR = 24.0; *P* = 0.02), a first degree relative with depression (OR = 0.12; *P* = 0.05), and months since last psychiatric inpatient discharge (OR = 0.92; *P* = 0.02). Further examination of time since last hospitalization found that all adolescents continued service utilization up to 18 months post-discharge.

Conclusions Findings suggest the importance of early diagnosis, that a first degree relative with depression may negatively influence the adolescent's ongoing service utilization, and that 18 months post-discharge may a critical time to review current

treatment strategies and collaborate with youth and families to ensure that services continue to meet their needs.

The other 25%: Autistic girls and women

M. Gill

Madera, USA

Autism spectrum disorder (ASD) is a pervasive developmental disorder characterized by impairments in social and communicative abilities, along with the presence of ritualistic and/or repetitive behaviors. One of the under-researched areas in the ASD literature is the large gender difference in the diagnosis rates. On average, the male to female ratio stands at 4.3:1, increasing to 9:1 in the absence of comorbid intellectual impairment. It has been evidenced that compared to boys, ASD is diagnosed later in cognitively able girls, despite there being no difference in the number of visits to a health-care professional during the diagnostic process and the age at which parents first express concern. The suboptimal identification of the disorder in cognitively able girls causes a large magnitude of gender discrepancy. These statistics may not be accurate since females may camouflage their difficulties and may be undetected due to their ability to disguise their symptoms better than males. The other hypothesis of under diagnosing ASD in girls is how we quantify and diagnose it. It is based on a male-centric presentation, which does not accurately reflect the disorder in girls. Altogether, these differences may make it more challenging for medical professionals and clinicians to identify potential early signs of the disorder in girls. Hence, there is a need to develop programs to mentor girls and women on the autism spectrum in schools, colleges and industry. And there should be an insistence on inclusion of females on the autism spectrum in pharmacological research and other research projects.

Anxiety and loss experiences during pregnancy and postpartum and anxious children

M.J. Güerre^{1,*}, O. Santesteban², L. Hernandez¹, D. Rentero¹

¹ Hospital 12 De Octubre, Psiquiatría y salud mental, Madrid, Spain

² "Fundación Alicia Koplowitz", Unidad Infanto-Juvenil, Hospital Universitario 12 de Octubre, Madrid, Spain

* Corresponding author.

Anxiety disorders in children are very prevalent in youth. They are associated with poor psychosocial functioning and predict later psychopathology in individuals. Environmental and genetic factors and their interaction are involved in the genesis of anxiety disorders.

Stress, depression or anxiety during pregnancy are considered risk factors for development of psychopathology in children. We aimed to know its relationship with anxiety disorders in young people.

Patients recruited for this study were the participants of our CBT group based in the coping cat model of treatment. All of them were children between 8 and 13 years old and meet criteria for Generalized Anxiety Disorder, Separation Anxiety Disorder or Social Phobia. Children and their parents assessed different anxiety and socio-demographic questionnaires. For this study we only analyzed the risk factors of pregnancy, delivery and breastfeeding of the

socio-demographic interview. SPSS v-21 was the statistical instrument.

We found out that mothers of our patients had reported anxiety symptoms, loss experiences or stress during pregnancy or postpartum period more than we expected.

Stress, anxiety or depression during pregnancy is related with anxiety disorders in children. Helping mothers to cope with stressors during pregnancy and postpartum period will contribute to a better mental health in their children. The findings of this study match with previous researches.

Objectives Review the multidisciplinary approach of ADHD and its relationship with self-injurious behavior. Expose the use of projective techniques in the diagnosis and treatment of psychiatric disorders.

Introduction Aggressive, opposition, defiant and disobedience behavior are becoming more frequent in the child population. There have been an increase number of adolescents, who self-harm, since 1960.

Material and methods A 17-year-old girl, with the following psychiatric history: consultations since 2009; one income in the Day Child Hospital; and two incomes in the Inpatient Childhood and Youth Unit. This year, the patient has gone to the emergency room twice by self-harm episodes the days before concerts at the conservatory. Her schoolteachers refer concentration problems. She behaves with contempt for the rules at home. The family relationships are mismatched.

Results The multidisciplinary intervention was based on personal, family and group therapies, cognitive behavioral therapy and pharmacotherapy (Methylphenidate). We are currently working on the control of self-injurious behavior with: strategies to regulate emotions, which are based on troubleshooting ("brain storming"), social skills training (role-playing), recognition and anger management.

Conclusions ADHD is a major health problem in children. The combination of pharmacotherapy, psychotherapy, social interventions with educational guidance, self-training activities achieves better results when performed independently. The prevalence of self-harm behavior is greater in young people with psychiatric disorders. Self-harm behaviors are often strategies to regulate the emotional pain. The graphic techniques express emotions, feelings and fantasies. They can help resolve conflicts, develop interpersonal skills and reduce stress. The pictures allow only formulate hypothesis, we must contrast them with other tests.

Fears in anxious children

L. Hernandez Arroyo*, O. Santesteban Echarri, M.J. Güerre Lobera, J.C. Espin Jaime, M.Á. Jimenez-Arriero
Hospital 12 de Octubre, Child and Adolescent Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Fear is a distressing emotion aroused by a risk or a damage, real or imaginary. Fears have a warning function against dangers. Nevertheless, fear can also become in one of the most limiting elements of a person's life.

Objectives To characterize the profile of fears presented in a sample of 19 children, aged between 8 and 13 years old, who had previously been diagnosed with one of the following: Generalized Anxiety Disorder, Separation Anxiety Disorder or Social Phobia.

Material and methods The sample was taken from patients who participated in a cognitive-behavioral group therapy. The Spanish version of the Fear Survey Schedule for Children-Revised (FSSC-R) questionnaire was employed. The FSSC-R asks children to indicate on a 3-point scale ('none', 'some', 'a lot') how much they fear 80 specific stimuli or situations. Five basic categories of fears can be established: failure and criticism (17 items); the unknown (17 items); minor injury and small animals (13 items); danger and death (16 items); medical fears (5 items).

Results The sample includes 19 children: 12 boys (63.2%) and 7 girls (36.8%). The median age is 10.74 years. The sample shows 15 excessive fears on average (those scored as 'a lot'). Girls show higher rates of excessive fears than boys: 19 versus 13. The most common fears were 'being hit by a car or truck', 'bombing attacks. Being invaded', 'a burglar breaking into our house' and 'falling from high places'.

Conclusions Most common excessive fears belong to danger and death category. Females report more fears than males.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The problem of rehabilitation of children and adolescents with mental disorders in Russia

I. Iakovleva
Bekhterev Psychoneurological Institute, Medical Faculty of St. Petersburg University, Saint-Petersburg, Russia

Introduction Assistance to children and adolescents with mental health disorders is very acute problem in Russia today.

Objectives A team approach is the most effective method (Koren, 2011; Popov, Iakovleva, Semenova, 2012).

Aim To examine the problem of rehabilitation of children with mental disorders.

Methods Eighty parents of mental disease's children and 86 were examined by special questionnaires were developed in the department of Adolescent Psychiatry of St. Petersburg Bekhterev Research Institute.

Results A total of 41.9% (36) of the teachers believed that children and adolescents with mental disorders may attend mass child garden and the school, 32.6% (28) did not agree with that. 37.2% (32) of the teachers believed that intercourse with a sick child is unlikely to be useful and pleasant for children. Therefore, following an acute problem is the fear of parents to contact a psychiatrist: 28 parents (35%) took their children to psychiatrist by their own initiative, some other professionals (pediatrician, general practitioner, neurologist or psychologist) encouraged applying to a psychiatrist in 44 cases (55%), 8 parents (10%) asked for advice after strong recommendations from teachers. One of the main signs of psychiatrist's competence for 64 parents (80%) was the appointment of additional

medical research techniques. 53 parents (66.3%) were convinced that a doctor for a diagnosis of mental disorder had to examine the child several times.

Conclusions Interaction of parents, teachers and psychiatrist is need for improving the effectiveness of children rehabilitation.

⁵ University of Ilorin, Behavioural Sciences, Ilorin, Nigeria

* Corresponding author.

Introduction Adolescents in Nigeria tend to report feelings of mental, physical and general fatigue without having correspondingly exerted themselves to trigger this. This tiredness has been observed to also affect their sleep habits.

Aim We set out to investigate how the report of tiredness by in-school adolescents tends to affect their sleep habits both on weekdays and weekends.

Methods The Tripartite Fatigue Scale (TFS) and a modified version of the School Sleep Habits Survey (SSHS) were administered on 606 (272 males and 334 females) secondary school adolescents in Lagos and Ogun states of Nigeria aged between 12–19 years ($\chi^2 = 15.24$; $SD = 1.42$) in their classrooms.

Results A multivariate analysis of variance (MANOVA) was used to analyse the effect of fatigue on the sleep habits of adolescents. The result shows that fatigue significantly affects the sleep habits of adolescents during weekends and weekdays, $F(3, 602) = 20.068$, $P \leq 0.01$; Pillai's Trace = 0.91, partial $\eta^2 = 0.91$. The adolescents also reported general inadequate sleep ($\chi^2 = 6.29$ $SD = 2.32$), less than the required amount of adequate sleep their age. Additional Analysis of Variance (ANOVA) result showed that fatigue significantly affected the students self-reported grade $F(3, 605) = 5.32$, $P = 0.01$.

Conclusions The present study has empirically highlighted that the consistent complaint of tiredness by secondary school adolescents in Nigeria emanates from fatigue marked mostly by insufficient sleep.

From ADHD to psychosis. . . executive functions and time

C.D.M. Isabel

Jaen, Spain

Introduction Cognitive impairment is present from the early stages of psychotic disorders. Alterations are found mainly in areas of attention, memory work and executive functions. During adolescence, ADHD patients often suffer from secondary disorders to lack of efficient procurement processes information by the poor development of executive functions.

Objective Evaluation of a patient whose diagnosis of ADD evolve to acute psychotic episode.

Method Review by clinical and psychometric tests developments in executive functions disorders.

Results Twelve years old patient who comes to the hospital since 2012, was initially diagnosed with literacy difficulties and low academic performance, after MFF-20 speaks of Learning Disabilities. It presents lack of motivation, apathy, difficulty in scheduling and organization and adherence to schedules, so they diagnosed ADD. It is given treatment with methylphenidate and atomoxetine, presenting erratic path.

After a year without treatment and the presence of a major stressful life event, at 17, has a first episode, consisting in mutiste attitude, phenomena of self-referenciality, experiences of control, enforcement and dissemination of ideas and auditory hallucination imperative type.

Conclusions The presence of emocional dysregulation and alterations in the executive functions atribuyen to ADD, in this case, were premorbid symtomatology of a first psychotic episode. The presence of positive symptoms allows to clarify the diagnosis.

The body image and psychopathology in children

M. Ivanov*, N. Platonova, G. Kozlovskaya

Mental Health Research Center of the Russian Academy of Medical Sciences, Department of Child Psychiatry, Moscow, Russia

* Corresponding author.

Introduction The body image development begins at an early age. Children with psychopathology may have body image disturbances. It is important to determine nosological specificity of body image disturbances in children.

Objectives To reveal body image disturbances in: 20 people (12 boys, 8 girls) having schizophrenia; 18 people (8 boys, 10 girls) with detected fact of sexual abuse (catamnesis study over a 5-year period); control group – 5 boys, 5 girls with normal psychophysical development.

Aims To reveal body image disturbance in children in case of psychopathology.

Methods All the children were examined clinically and paraclinically by psychiatrist and clinical psychologist (projective techniques; standardized personality questionnaires and semantic method [analysis of statements]).

Results and conclusions In children having schizophrenia specific disturbances of proprioceptive self-awareness in the form of senestopathy (feelings of compression, deformation, size loss or size gain of the body) and the idea of physical defect, are considered as the early symptoms of the body dysmorphic disorder. In this group of children disturbances of body scheme, difficulties in right/left orientation were detected. In the group of children with detected fact of sexual abuse the following disturbances took place: the body dysmorphic disorder (self-disgust, considering body to be tainted by the abuser, feeling dirty, compulsive body washing, sensitivity to touch) and senestopathy below one's waist, in the area of genitals, feeling dirtiness of the skin and clothes. In the pictures drawn by the children, they represented themselves older, grotesquely painted their faces, pictured strange haircuts, preferring bright and extravagant clothes.

An audit of melatonin prescribing in a community-based child and adolescent mental health service (CAMHS)

A. Javed*, M.F. Moosa, T. Sandhu

Birmingham Children's Hospital NHS foundation Trust, Community Child and Adolescent Psychiatry, Birmingham, United Kingdom

* Corresponding author.

Introduction Melatonin is widely prescribed in the United Kingdom for the treatment of sleep difficulties and disorders in children. Licensed and unlicensed products are available. A prolonged-release form, licensed for use in older adults, is used 'off-label' in children.

Aims and objectives To ensure evidence-based, cost effective prescribing of melatonin.

Methods Retrospective data was collected over a 3-month period. Prescriptions for all forms of melatonin issued to patients under 16 years of age with sleep disorders were included. A case note audit was conducted. Standards were measured based on evidence-based 'advice' and generic prescribing guidelines. Main outcome measures were, forms of Melatonin used, timing of its use (before or after sleep behaviour therapy), documentation, and cost to the service.

Results The licensed prolonged-release product was prescribed in 92% of cases ($n=59$), and for the great majority (93%) it was below or within the recommended dose range (4–6 mg). Melatonin was used more often as first line (69%) therapy as compared to the recommended sleep behaviour therapy. There was lack of documentation, relating to its 'off-label' use and shared decision-making with patients. Overall cost of prescribed Melatonin was £1800 per month.

Conclusions A licensed product of melatonin was used, cost-effectively. However, a question remains about the timing if its use and relevant discussion with patients. A local guideline is needed to guide clinicians on appropriate use of melatonin and to improve documentation.

Olfactory reference syndrome – a case report

C. Kapugama

National Hospital of Sri Lanka, Department of Psychological Medicine–Ward 59–, Colombo, Sri Lanka

Introduction Olfactory reference syndrome (ORS) is a condition characterised by persistent preoccupation about body odour with feelings of embarrassment, shame, distress, avoidance and isolation. There is often referential thinking.

Case description A 16-year-old male was referred to Child and Adolescent Mental Health Services. He believed that 'everyone thought I smelt bad' for the past 3 years. He avoided going out with friends, sitting at restaurants, going to the cinema, and playing games. He sprayed himself with deodorant between every lesson. He insisted his laundry to be done by hand using special products. He asked his mother how he smelled before going to school. He spent his time in isolation in his room. When asked, he accepted that his concerns were excessive. He was commenced on cognitive behaviour therapy (CBT) with his mother as a co-therapist.

Discussion There has been much debate over whether ORS warrants a separate entity in the current classificatory systems. At present it is placed between delusional disorders, social phobia, body dysmorphic disorder and obsessive compulsive disorders. Our patient did not experience hallucinations. His conviction was

derived from referential thinking and did not reach the level of a delusion. Literature on management of ORS is scarce. Our patient was offered CBT and he showed improvement from first session onwards. By the end of therapy he rated his improvement as 80%. He stopped avoidance behaviours and reassurance seeking and used techniques to combat automatic thoughts.

CBT seems a promising option in the management of ORS.

Implementation of British tool for the evaluation of outpatient child-adolescent mental health services (CAMHS) in Attica-Greece

A. Katideniou^{1,*}, K. Kavalidou²¹ Athens University of Economics and Business, Counselling Service, Athens, Greece² University of Glasgow, Suicidal Behaviour Research Laboratory, Glasgow, United Kingdom

* Corresponding author.

Introduction The development of child-adolescent mental health services (CAMHS) is a necessity for each country. Based on evidence-based findings the provision of specific quality standards in regard to mental health services, maximizes the patients' health care outcomes and satisfaction.

Objectives A British tool adapted in the Greek context assesses the services against the British standards. For the current study, we used the part of the tool referred to the areas of:

- referral and access;
- assessment & care planning;
- care & intervention.

Aims Promotion of evaluation and quality assurance of Greek CAMHS.

Methods Due to the fact that Greek services are based on the British model, we chose the British self-review questionnaire of Quality Network for Community CAMHS (QNCC). The tool was translated, adapted and posted to services. Twelve out of twenty outpatient CAMHS of Attica (includes Athens) responded. Data collected was computed in SPSS taking a highest and a lowest score of meeting the standards.

Results Based on a scale of "not meeting the standards", "moderately meeting the standards", and "meeting the standards", ten out of twelve services moderately met the British Standards on all three areas examined. It should be noted that the "assessment and care" section was found to have a higher quality of replies among services reaching the 75%–100% of "meeting the standards" for two services.

Conclusions Greek CAMHS show a satisfactory function in Attica prefecture, taking into consideration the extremely difficult political/financial circumstances. Strengths and weaknesses between different domains were also identified.

Symbolic development in TD, DS and ASD

M. Kékes Szabó

University of Szeged, Department of Applied Pedagogy and Psychology, Szeged, Hungary

This study is about symbolic processes in atypical populations, which is presumed to lead to a deeper understanding of the

ontogenesis of normal symbolic development. Exactly, we aimed to explore the emergence of symbolic play in children with Down syndrome (DS) and in children with autism spectrum disorder (ASD). A typically developing (TD) control group was also involved in the study. Fundamentally, we applied the qualitative method and focused on the replica play of the children that could be observed during their dyadic interaction with their parents. The activity of the individuals was recorded on video. The data were analysed with Noldus Observer XT 8.0 program software. The results confirmed atypical patterns of replica play in DS and ASD. Although both of these children groups demonstrated impairments in representational abilities, the autistic children seemed to have a basic cognitive defect. While children with DS were more often able to demonstrate coherent play activity, children with ASD could not use replica toys in the appropriate context verifying impairments in the social-communicative system. However, further studies are needed to cover the characterizations of psychopathological-specific disorders, to plan new diagnostic tools and more effective interventions.

Virtual sexuality of the Tunisian teenagers

R. Khemakhem*, W. Homri, D. Karoui, M. Mezghani, L. Mouelhi, N. Bram, I. Ben Romdhane, R. Labbane

Razi Hospital, Psychiatry C, Mannouba, Tunisia

* Corresponding author.

Introduction The digital boom and the media coverage of the sexuality urge the youngest to expose itself more and more via the social networks and other digital applications.

Aims/objective To explore the virtual sexuality of the Tunisian teenagers.

Methods It's a cross-sectional study made in August 2015, including 104 Tunisian teenagers from different social backgrounds and living in Tunis, chosen aimlessly. An auto-railling drafted in Arabic, anonymous and carrying on various items was distributed.

Results We included 52 boys and 52 girls. Seven of them (6.1%) was not schooled and 68.3% ($n=71$) were at high school. Ninety-one of the teenagers (87.5%) reported not have sexual education at school and 74% ($n=77$) have already turned to web sites to inquire about sexuality. A regular practice of cybersex at the rate of at least once a week, was founded at 36.5% ($n=36$) and 41 teenagers (39.4%) have reported to have already undressed in front of their webcam. The candidates have already consulted a pornographic site at least once in their life in 76.9% ($n=80$) of the cases. The allocated time for these virtual activities is made to the detriment of the sleep in 75% of the cases ($n=27$). The connection was accompanied with a masturbatory activity in 38.9% ($n=14$).

Conclusion Contrary to preconceived ideas, the computer screen does not protect from sexual risk behaviors. Therefore, a sexual education for the youngest is more than ever necessary to avoid such drift.

Delayed memory in ADHD children

O. Lvova

Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

Introduction It is known that children with ADHD have deficit in cognitive abilities. However there are different opinions about

the nature of this deficit. It is necessary to conduct researchers for revealing specific profile of impairments in different cognitive domains in ADHD children to better understanding the nature of this disorder.

Aims The aim of this research was to examine the hypothesis that children with ADHD have a specific deficit in memory – weakness in delayed memory.

Methods The experimental group included 15 Russian-speaking children with ADHD at age 7–8 years. The control group included 15 typically developing children. The children from experimental and control group were matched for IQ, gender and age. Children from both groups were assessed with NEPSY using memory for names subtest. This subtest is designed to assess the ability to learn the names of children in immediate and delayed conditions. Two-way ANOVA was used to reveal group differences in reproducing the names in two conditions.

Results We have not revealed significant differences between children from experimental and control group in the reproducing the names in immediate condition.

However, the interaction of condition type and group was significant ($P \leq 0.05$). ADHD children were less successful in reproducing the names in delayed condition.

Conclusions In view of the obtained results, it can be assumed that children with ADHD have specific deficit in memory domain – weakness in delayed memory. It is necessary to confirm this result using different memory tasks.

The possible role of mothers' thrombophilic predisposition as a risk factor mental and motor delay in toddlers

D. Baranov^{1,*}, O. Lvova²

¹ Ural State Medical University, Pediatrics, Ekaterinburg, Russia

² Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

* Corresponding author.

Introduction Inherited thrombophilia is described as a risk factor for burdened obstetrical history. But the relationships between mothers' thrombophilic predisposition (MTP) and mental status in their children is not investigated thoroughly.

Objectives To investigate the mental and motor neonates' status, born from MTP.

Methods Case-control study. Thirty-seven children born from MTP were assessed at 1, 3, 6 and 12-month (1st group). MTP carried more than 5 thrombophilic single nucleotide polymorphisms and had burdened obstetrical history; 47 neonates with clear mothers' obstetrical history and 2 and less SNPs (2nd group); informed consent form. The quantity of term and preterm neonates were equal in groups.

Results We found the neonates from both group were comparable under the 6-month age (table). But in year-old children mental and/or motor delays were more frequent in 1st group despite on comparable level of paresis and brain ultrasound data. There were no thrombotic episodes in children in 1st group.

Conclusions There were no direct link between MTP and neurological outcomes in children: paresis and ischemic lesions in brain were not differ in groups. Confirmed MTP can cause mental and motor delays to year-old period, milestones must be supervised thoroughly until 3 y.o.

Differential diagnosis of recurrent hypersomnia. Case report of primary narcolepsy and acute transient psychotic attack

J. Kiyak*, S. Köse, B. Özbaran

Ege University, Child and Adolescent Psychiatry, İzmir, Turkey

* Corresponding author.

Introduction We report a case of 17-year-old boy with excessive daytime sleepiness.

Objectives Case presented in our study is an example of atypical narcolepsy with coexistence of psychotic symptoms that were especially prominent during the first attack. Excessive daytime sleepiness period was followed by psychotic symptoms including delusions of reference and persecution, as well as visual and acoustic hallucinations. However, during the second attack, negative psychotic symptoms were more prominent.

Aims Clinicians should not forget that child and adolescent patients, which demonstrate psychotic symptoms and excessive daytime sleepiness component, should be evaluated for a diagnosis of primary hypersomnia.

Method Patient did not exhibit any comorbidities that would match with secondary hypersomnia. The initial sleep study did however reveal increased REM sleep latency (43% of total sleep time). The result of polysomnographic study was abnormal and suggestive of narcolepsy. In multi-sleep latency test mean REM latency was 1.7 min, sleep-onset REM (SOREM) was observed 3 times. Between the tests he had no episodes of cataplexy.

Result Patient was diagnosed with primary hypersomnia-narcolepsy without cataplexy. We found that mixed symptoms of narcolepsy and psychotic attack improved with anti-psychotic agent treatment.

Conclusion Child and adolescent patients, which demonstrate psychotic symptoms and excessive daytime sleepiness component, should be evaluated for a diagnosis of primary hypersomnia following a multidisciplinary cooperation of neurologists, pediatricians and psychiatrists.

Different expressions of conduct disorders – childhood versus adolescent onset type

J. Kostić*, M. Stankovic, L. Milosavljević, N. Ilić

Health Centar-Nis, Department for Child and Adolescent Psychiatry, Nis, Serbia

* Corresponding author.

Introduction Conduct disorder is a heterogeneous disorder in terms of etiology, course and prognosis, and currently, there is no singular model that would describe the development of the disorder. The results of empirical research on males confirm this heterogeneity, as they point out that two possible developmental pathways: childhood-onset and adolescent-onset type.

Aim This paper presents two clinical picture of conduct disorders: a boy aged ten years with early onset conduct disorder and a boy aged sixteen years with adolescent onset conduct disorders. Our emphasis is placed on a different etiology, risk factors for the development of the disorder, clinical picture and the course of disorder. Special attention was focused on therapeutic intervention and possible prognosis in the two described cases.

Conclusion Advanced typologies of conduct disorders, as postulated in DSM V classification, is important from the standpoint of a better understanding this disorders and more effective therapeutic interventions.

The role of parental bonding for self-harm adolescents

A. Kotsopoulou*, A. Melis

Synchronous Support Center, Psychology, Athens, Greece

* Corresponding author.

This study explores how the Greek adolescents understand self-injury and whether they have self-harm episodes. For the purpose of this study the questionnaire of the CASE study and the parental bonding instrument was used. The main research question is to explore the reasons that lead an adolescent to self-harm. More specifically if the relationship with their parents and the function of the family plays a role for leading a teenager to self-harm. One hundred Greek 14–17 years old participated in the study. The results show that 71% adolescents state that there is high mother care and 62% high mother protection and 63% high father care and 50% high father protection. Significant associations were made for self-harmers and the rest of the sample. There are statistically significant differences between those participants who self-harm and their parental bonding ($\chi^2(2, n = 100) = 7.59, P < 0.05$) regarding their mother protection. It seems that those with low mother protection are self-harming. Similarly, there are statistically significant differences between low father care and self-harm behavior ($\chi^2(4, n = 100) = 10.35, P < 0.05$). It is interesting to see what they perceive about this parental bonding and how the engage into this type of self-harming behavior, but also to explore whether their parents are aware of this behavior.

How stressful life events influence adolescents to self-harm

A. Melis¹, A. Kotsopoulou^{2,*}¹ Synchronous Support Center, Psychology, Athens, Greece² Athens, Greece

* Corresponding author.

This study explores how 100 Greek adolescents both males and males deliberately harm themselves and how the stressful life events they experience influence their decision. The CASE study (2008) questionnaire was given 14–17 years old adolescents to self-report on the situations they are experiencing and the episodes of self-harm. There were statistically significant differences for those stressful life events and students who reported to self-harm. It seems that “having problems keeping up with school work” is statistically significant between those who self-harm and those who do not ($\chi^2(2, n = 100) = 14.3, P < 0.05$), “having any serious arguments or fights with either or both of their parents” ($\chi^2(2, n = 100) = 8.5, P < 0.05$) with 44% of self-harmers reporting having problems in the past 12 months. Furthermore, statistically significant differences were found for been “physically abused” ($\chi^2(2, n = 100) = 8.4, P < 0.05$) with adolescents who self-harm being 21% of the sample. Regarding deaths and suicides they have experienced many questions were statistically significant: In reporting a death of someone close to them the results were statistically significant between those who self-harm and the rest ($\chi^2(2, n = 100) = 3.9, P < 0.05$), as well as the suicide attempt or deliberate self-harm of a close friend ($\chi^2(2, n = 100) = 0.2, P < 0.05$), the worries of the sexual orientation ($\chi^2(2, n = 100) = 12.2, P < 0.05$), the “force to engage in sexual activities against their will” ($\chi^2(2, n = 100) = 10.6, P < 0.05$) and finally their report of having experiences a distressing event

involving them, their family or close friends ($\chi^2 (2, n = 100) = 19.8, P < 0.05$).

Cognitive and functional outcomes after a trial of an mTOR inhibitor in an adolescent with neuropsychiatric sequelae of TSC

A. Lachman^{1,*}, C. van de Merwe², P. De Vries³

¹ Tygerberg, Psychiatry, Cape Town, South Africa

² Stellenbosch University, Psychology, Cape Town, South Africa

³ University of Cape Town, Psychiatry, Cape Town, South Africa

* Corresponding author.

Tuberous sclerosis complex (TSC) is a genetic autosomal dominant condition with multi-organ involvement and highly variable clinical manifestations. Neurological manifestations (subependymal nodules, cortical tubers, and subependymal giant cell astrocytomas [SEGAs]) are a leading cause of morbidity and mortality leading to cognitive impairment, behavioural disturbances and refractory seizure disorders. Experimental and human evidence suggest that the use of mTOR inhibitors may induce regression of TSC tumor types and provide an alternative to surgical resection of SEGAs. In the EXIST-1 trial everolimus (mTORi) was associated with clinically meaningful increases in the time to progression of subependymal giant cell astrocytomas and skin lesion response rate compared with placebo. We present a case of a 16-year-old girl (MM) referred with neuropsychiatric sequelae including disruptive and dangerous behaviours not responding to outpatient management. Multiple trials of anti-convulsants and antipsychotic treatments achieved poor responses. During admission to a state facility, MM had several seizures followed by aggressive outbursts, inappropriate behaviour and confusion. Her intrusiveness, sexual disinhibition and lack of response inhibition suggested frontal lobe dysfunction impacting on executive functioning. Despite seizure control being optimized to an acceptable rate with anticonvulsants, improvement in social or cognitive functioning was limited. She required individual constant supervision for personal safety and independent functioning. A trial of mTOR inhibitor was initiated, and achieved an improvement in cognitive, social and psychiatric functioning. This report will discuss the challenges in this complex case, and report on baseline as well as 6month post medication outcomes measured by radiological, functional and cognitive testing.

* Corresponding author.

Introduction Anorexia nervosa is a serious illness associated with a chronic course and high mortality. Follow-up studies in this population show great variability in prognosis, and inpatient treatment is frequently needed.

Objectives This study aimed to examine association between different clinical variables of patients with anorexia nervosa and the need of inpatient treatment, as a way to investigate possible predictors of severity of illness.

Methods Descriptive, longitudinal, retrospective study of all patients with a diagnosis of anorexia nervosa, with a first psychiatric appointment in a Child and Adolescent Psychiatry Department at a major university hospital, between 2009 and 2013. Clinical variables were compared based on the need of inpatient treatment in the first year after initial psychiatric appointment. Clinical data were collected from individual medical records. Statistical analysis was performed using Statistical Package for the Social Sciences, version 21.

Results Eight-five patients with anorexia nervosa were evaluated. In the first year after the initial psychiatric appointment, 47.1% of the sample received inpatient treatment. There were no statistical significant differences between groups for any of the clinical variables assessed: gender, age at onset of disease, body mass index at first psychiatric appointment, duration of illness at first psychiatric appointment, personal history of obesity, psychiatric comorbid conditions and family history of an eating disorder.

Conclusions No associations were found between the clinical variables assessed and the treatment setting. Further investigation is needed in order to identify other variables that may play a role in the course of anorexia nervosa in adolescent patients.

Background There are many causes of behavioral disorders in children investigating the causes and efforts to reduce them are useful for children.

Methods This causal-comparative research is cross-sectional study among of the children born with assisted reproductive technology and natural fertility methods in the Afzalipour hospital in Kerman city. A sample of 30 children were born with assisted reproductive technology and 30 children were born with natural methods of fertility chooses randomly and two groups matched on the basis age, sex, education, father's occupation, and family members. For two groups completed Czech list revision Quay-Peterson and Data were analyzed by SPSS software version 16.

Findings The results showed that differentiation between behavioral disorders (0.002) and its components, including attention-immaturity (0.008) and anxiety-recluse (0.000) in two groups were significant (increased in children born with infertility treatments), but between the elements of aggression (0.911) and conduct disorder (0.066) were not a significant difference.

Conclusion This study showed that the kind of fertilization effective on behavioral disorders in children.

Be yourself in a connected world: A challenge for the digital natives teenagers

G. Mottet

Psychiatre libéral, Romans sur Isère, France

The Digital Revolution has radically changed the relationship to the body of the other in a connected world. The classic balance between appresentation/presentation (L. Binswanger) has been destroyed in the new digital matrix. Three clinical examples illustrate the consequences of this phenomenon for three digital natives teenagers in the structuration of their ipseity: Maximus the gifted giant that draws trolls, Léa “monstrous”, Thomas the DJ who never went clubbing. It leads to the wider question of a new way of seeing mannerism.

The effect of exercise therapy on symptoms of hyperactivity/attention deficit disorder in elementary school students in Rafsanjan

M. Nazer

Rafsanjan University of Medical Sciences, Psychiatry, Kerman, Iran

Background and objective Children with attention deficit/hyperactivity disorder are the first victim of emotional, behavioral and educational neglect. So it is necessary to treat these children. The purpose of this study was to investigate the effectiveness of exercise therapy on hyperactive, impulsivity and distraction of children with ADHD.

Material and methods Eighty elementary school age children with attention deficit/hyperactivity disorder by using of Conners scale and clinical interview selected and divided into experimental and control groups randomly. The experimental group received 10 sessions of exercise therapy with Tatami Therapy method. Post-test and follow-up tests performed in both groups and finally, data analyzed by using repeated measures.

Results Data indicate a significant reduction of hyperactivity, impulsivity and Distraction in the experimental group ($P < 0.05$). This difference was also significant at follow-up.

Conclusion Finally, can be concluded that exercise therapy or play therapy can be used as an alternative or complementary treatment for children with attention deficit/hyperactivity disorder.

Keywords Attention deficit; Hyperactivity disorder; Exercise therapy; Elementary school

Relationship between sensory processing patterns and behavioral regulation in autistic children

A. Nesayan*, R. Asadi Ganomani

University of Bojnord, Psychology, Bojnord, Iran

* Corresponding author.

Introduction In recent years, autism has been under consideration in public and research area. Autism spectrum disorders are a variety of related disorders that affect a child's social development

and ability to communicate and that included unusual behavioral manifestation such as repetitive motor movements. Autistic children have dysfunction in communication, socialization, repetitive and stereotyped behaviors. In addition, they clinically suffer from difficulty in attention, challenge with familiar behaviors and sensory processing problems. The aim of this study was to investigate the relationship between sensory processing patterns and behavioral regulation in children with autism.

Method This study has categorized in correlational research methods. After determining of entry criteria, according to purposive sampling method, 50 children were selected. Sensory profile Dunn school component for assessment of sensory processing patterns and rating inventory of executive functions (Brief) for assessment of function of working memory were used.

Result The results showed that there is significant negative correlation between sensory processing patterns (low Registration, sensory sensitivity, sensory avoiding and sensation seeking) and behavioral regulation. According to the findings, there is significant relationship between the patterns of sensory processing and behavioral regulation, so children with sensory processing difficulty are weak in behavioral regulation.

Keywords Sensory processing; Behavioral regulation; Autistic children

Introduction Adoption constitutes a discontinuity in child care trajectory, that falls into a separation and a lost of reference figures, and therefore, the need to set up new attachment figures into a suitable familiar atmosphere.

Objectives This case is a review of how a child adoption process, that can be something positive at first, can also produce many problems in the future, added to difficulties in order to regulate stressing situations and also solving problems.

Methods The clinical case consists in a 25-year-old woman, who suffers from anxiety and self-injure behaviour. She has a diagnosis of non-specified personality disorder with limit characteristics. The patient was adopted a few months after her birth. At the moment she's living with her adoptive father, her adoptive mother passed away when she was 4. At the age of 21, the patient meets her biological mother and since that moment she spends most of the weekends with her. After a few medical appointments, she admits that she has allowed sexual relationships with her biological mother since six months ago.

Results It's important to appreciate the value of familiar atmosphere, and in addition, the attachment between child and his parental figures. The quality of the attachment is going to have influence in emotional regulation.

Conclusions Children who have suffered neglect from their biological parents and have been adopted develop attachment behaviours characterized by negative experiences. In spite of being in a good familiar environment, they feel vulnerable and insecure. Early and appropriate attachment experiences can improve relationships between children and their new family.

How does psychotropic medication consent work for youth in foster care

C. Pataki^{1,2,*}, C. Thompson^{3,4}, G. Crecelius², J. Tesoro^{2,5}, G. Polsky², P. Kambam²

¹ David Geffen School of Medicine at UCLA, Psychiatry & Biobehavioral Science, Los Angeles, California, USA

² Department of Mental Health, Juvenile Court Mental Health Service, Monterey Park, California, USA

³ David Geffen School of Medicine at UCLA, Psychiatry & Biobehavioral Science, Los Angeles, California, USA

⁴ Department of Mental Health, Juvenile Justice Mental Health Program, Los Angeles, California, USA

⁵ University of Southern California School of Pharmacy, Pharmacy, Los Angeles, California, USA

* Corresponding author.

Introduction It is well known that youth in foster care are at high risk for psychiatric disorders, recently reported in up to 89%, with over 55% exhibiting ADHD in one sample (Linares et al., 2013). Psychotropic medication use was reported in 59% of foster care youth within a 2-month period (Brenner et al., 2013). The psychotropic medication consent process in Los Angeles for dependent children is multidisciplinary, starting with the treating psychiatrist's written authorization request to Children's Dependency Court. Once received, it is distributed to the child's attorney, social worker, and Juvenile Court Mental Health Service (JCMHS). JCMHS reviews and provides recommendations to the judicial officer who ultimately approves, modifies, or denies consent.

Objectives To present the steps and reasoning in the process of review, consultation, recommendations and decisions in psychotropic medication consent for dependent youth.

Aims To provide an understanding of the multidisciplinary review process involved in determining psychotropic medication consent in foster care youth.

Method Presentation of a timeline, forms and guidelines used in the process including the "Psychotropic Medication Authorization Form" (PMA) (Judicial Council of California, 2008).

Results Categories of recommendations and approvals provided to the judicial officer will be presented and rationales for in-person consultations.

Conclusion The psychotropic medication consent process for foster care youth is a complex multidisciplinary process which includes a clinically significant set of recommendations from JCMHS to the judicial officer to aid in making informed decisions regarding psychotropic medication.

Catatonic features in adolescence: Interfaces with affective disorders

I. Peixoto^{1,*}, C. Santos¹, M. Sousa², S. Pimenta¹

¹ Hospital Dona Estefânia, Child Psychiatry, Lisbon, Portugal

² Centro Hospitalar Lisboa Norte, Child Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Catatonia is a potentially life-threatening but treatable neuropsychiatric syndrome. The prevalence of catatonia in children and adolescents is probably underestimated since investigation on this matter is still lacking. Different studies have led

to the recognition of catatonia as a separate psychiatric entity, as reflected in DSM-5, renewing interest on this subject. While in the adult population there is evidence highlighting the strong association between catatonia and affective disorders, this has been poorly reflected in child and adolescent psychiatry literature. In fact, most of the research in this population focuses on associations with organic, psychotic or developmental disorders.

Objectives We aim to illustrate the diagnostic challenges when facing an adolescent with catatonia encompassing psychiatric, neurologic and immunologic factors known as possible causes for this condition. We aim to explain the diagnostic procedure and the possible clinical results of this workup, as well as raise the discussion around treatment options.

Methods We used a clinical case vignette of a 14-year-old adolescent, presenting with a stress-induced catatonic syndrome and depressive symptoms without any prior organic or psychiatric condition. We reviewed the most relevant literature in order to contextualize our clinical case.

Results and conclusion Catatonia is an under-recognized condition in children and adolescents without a prior medical or psychiatric condition, especially when associated with affective disorders. The inclusion of catatonia as a specific syndrome in the psychiatric nosography may help its recognition. Case reports on this matter are therefore especially important as a way of pushing clinical investigation on this matter forward.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Autism-plus spectrum disorders: Interfaces with psychosis

I. Peixoto^{*}, R. Velasco Rodrigues, C. Marques

Hospital Dona Estefânia, Child Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Despite categorical differentiation, autistic and psychotic disorders are historically related diagnostic entities and there is still much controversy regarding their limits and developmental course. Particularly in children, the presence of idiosyncratic fears, difficulties in the social sphere and thought disorder are important factors in the differential diagnosis. There are some research-derived clinical constructs that operationalize symptomatology aiming to highlight the interfaces and the overlap between such disorders. Their clinical implications can be extremely relevant in the face of the limits of current nosology.

Objectives To phenomenologically describe differentiating parameters and high-risk clinical profiles for the development of psychosis in children with autism spectrum disorder.

Methods Selective review of the literature in PubMed (MEDLINE). Illustration with a clinical case vignette.

Results The clinical case reflects well the difficulties posed in the differential diagnosis due to the multiple interfaces between autism and psychosis. Constructs such as "multiple complex developmental disorder" or "multidimensionally impaired syndrome" allow a clearer and more practice-friendly characterization of such individuals.

Conclusion The constellation of symptoms identified in these criteria may become useful through the definition of subgroups of autism spectrum disorder individuals with complex psychopathology. Studies in this regard are still scarce, but the validation and reproduction of the positive results observed in the near future can help optimize the clinical approaches in these children.

Age as a hidden aspect in pediatric obsessive-compulsive disorder

I. Peixoto*, C. Marques

Hospital Dona Estefânia, Child Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Pediatric obsessive-compulsive disorder (OCD) is a multifaceted clinical entity. Rage attacks have been repeatedly described in the phenotype of anxiety disorders in children and adolescents. It has been acknowledged that anxious youth who display rage have more severe clinical profiles and increased levels of dysfunction in most domains, consistent with the notion that rage is a marker of more severe psychopathology. However, this matter remains largely underappreciated in pediatric OCD. Namely, the role and functions of rage in pediatric OCD in relation to family accommodation and illness severity have highly relevant clinical management and treatment implications.

Objectives We aim to discuss how does rage look like in pediatric OCD, what are its associated features and its contributions to additional functional impairment. We examine the central role of family accommodation mediating clinical outcomes and review highly relevant diagnostic and treatment challenges.

Methods Selective review of the literature in PubMed (MEDLINE). Illustration with a clinical case vignette.

Results and conclusions Rage attacks are relatively common in pediatric OCD, have a negative impact on illness presentation, and contribute to functional impairment above and beyond obsessive-compulsive symptom severity. We hereby illustrate that rage may contribute to family accommodation of symptoms, which may further affect and perpetuate obsessive-compulsive symptom severity and impairment. There is a need to avoid misdiagnosis and to prioritize psychotherapeutic interventions and psychopharmacological treatment approaches. This provides important insights regarding the clinical validity of this component of OCD, aiming to capture further the attention of the clinical and research community.

Encopresis: A medical and family approachI. Peñuelas Calvo^{1,*}, J. Sevilla Llewellyn-Jones², L. Poggio Lagares³, C. Cervesi⁴, A. Sareen⁵, A. Gonzalez Moreno¹¹ *Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain*² *Hospital Universitario Virgen de la Victoria, Psychology, Málaga, Spain*³ *Universidad Complutense de Madrid, Facultad de Psicología, Social Psychology, Madrid, Spain*⁴ *Institute for Maternal and Child Health- IRCCS "Burlo Garofolo", Psychiatry, Trieste, Italy*⁵ *The Zucker Hillside Hospital - North Shore - Long Island Jewish Health System, Psychiatry Research, New York, USA*

* Corresponding author.

Introduction Encopresis is a not very common disorder. The prevalence of this disorder is about 1.5% after the age of 5 years old and decreased even more as age increased, being very rare in adolescence.

Aim Here we present a clinical case of an 11-year-old girl, with a diagnosis of functional encopresis with constipation and overflow incontinence for 4 years.

Method In this case, we followed a program consisted of 12 sessions combining different techniques that are on experimental phase. The program we designed consist of toilet training, establishment-token economy- of a diet high in fiber with a

progressive remove of laxative medication and a family intervention with both parents that got divorced 4 years ago.

Results Having both parents the same frame the patient's problem easily started to decrease. In follow-up (6 and 12 months), we observed good toilet habits and not constipations episodes.

Conclusions Even though all the techniques used were in experimental phase, we considered that because of the chronicity of this problem a multidisciplinary approach was the best option.

Brain development in attention deficit hyperactivity disorder: A neuroimaging perspective review

V. Pereira*, P. de Castro-Manglano, C. Soutullo Esperon

Clinica Universidad de Navarra, Psychiatry and Medical Psychology, Pamplona, Spain

* Corresponding author.

Introduction Attention deficit hyperactivity disorder (ADHD) is a challenge in child and adolescent psychiatry. In the recent decades many studies with longitudinal designs have used neuroimaging with ADHD patients, suggesting its neurodevelopmental origin.

Objectives Study the findings of neuroimaging (MRI, fMRI, DTI, PET) techniques on ADHD patients from a longitudinal point of view, looking also for the potential influence of treatments and other predictors (i.e. genetics).

Aims To provide a global perspective of all the recent findings on ADHD patients with the neuroimaging technics, focusing on longitudinal measurements of the changes in brain development.

Methods We conducted a review of the literature in the databases Pubmed and ScienceDirect (terms ADHD, neuroimaging, MRI, fMRI, DTI, PET, functional connectivity, methylphenidate and cortical thickness). We focused on studies using neuroimaging techniques with ADHD patients, looking at their populations, methodologies and results.

Results The studies found abnormalities in the structure of grey matter, activity and brain connectivity in many neural networks, with particular involvement of the fronto-parietal and Default Mode Network. There is also convergent evidence for white matter pathology and disrupted anatomical connectivity in ADHD. In addition, dysfunctional connectivity during rest and during cognitive tasks has been demonstrated.

Conclusions This evidence describe ADHD as a brain development disorder, with delays and disruptions in the global development of the central nervous system that compromises grey and white matters, most evident in the prefrontal cortex, parietal and posterior cingulate cortices, as well as basal ganglia, damaging activity and structural and functional connectivity of various brain networks, especially the fronto-striato-parietal and default mode network.

Emotion regulation strategies in adolescents with mitral valve prolapse

E. Pervichko*, Y. Zinchenko

Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

* Corresponding author.

Introduction Two thirds of adolescents with mitral valve prolapse (MVP) show signs of anxiety disorders. They display difficulty in emotion regulation (Van Der Ham et al., 2003; Scordo, 2007).

Objective To investigate into emotion regulation strategies in MVP adolescents.

Methods A projective study of emotion regulation was undertaken with our modified version of Rosenzweig Picture–Frustration Test (Zinchenko, Pervichko, 2014). Thirty-six adolescents with MVP (mean age was 17.1 ± 0.8 years) and 40 healthy adolescents (mean age was 16.7 ± 0.6 years) took part in the study.

Results MVP adolescents significantly more frequently ($P < 0.001$) would mark Rosenzweig's situations as potentially traumatizing. Ego-defence (E-D) and extrapunitive (E) reactions appear to be significantly ($P < 0.05$) more frequent among MVP adolescents. MVP adolescents are more than healthy subjects prone to avoid open verbal revelations of their thoughts and feelings that emerge in the situation of frustration. Content analysis of responses conditioned by cognitive control (when the task was to taper off arbitrarily the traumatizing effect of the situation) revealed that suppression of emotions was displayed by MVP adolescents in 52% of answers, and for healthy participants - 29% of answers ($P < 0.001$). Cognitive reappraisal strategy was displayed by MVP adolescents in 27% of answers, and for healthy participants - 38% of answers ($P < 0.05$). Twenty-one percent of answers of MVP adolescents and 33% of answers of healthy participants suggested cognitive transformation of emotional experience and actualization of new meanings in traumatic situations ($P < 0.05$).

Conclusions MVP adolescents appear to be more sensitive of frustrations and differ from healthy peers in more frequent use of the strategy of suppression of emotions.

Adolescent prostitution: Which role plays psychopathology?

C. Petrocchi^{1,*}, M. D'Aguzzo¹, R. Carafa¹, P. Velotti²

¹ Sapienza - Università di Roma, Dynamic and Clinic Psychology, Roma, Italy

² University of Genoa, Department of Educational Sciences, Genoa, Italy

* Corresponding author.

Introduction The characteristics and the mental functioning of adolescent prostitutes were examined in several studies. Literature associates externalizing problems (i.e. impulsivity) with high rates of sexual activity and high rates of prostitution (Donenberg et al., 2005). Research has identified a link between psychopathology and high rates of health-risking sexual behavior and conduct problems. Despite the identification of psychopathology as a risk factor for the development of health-risking sexual, its role in prostitution has not been well examined.

Objectives Although the association between psychopathological disease and engagement in health-risking sexual behavior is documented, the specific nature of the cause or mechanism for the link between psychopathological disease and the development of these behavior problems is not known.

Methods An extensive literature search for relevant published and unpublished studies was conducted on Medline, CINAHL Plus with Full Text, Psycinfo and PsycArticle from inception through September 21, 2015. Additionally, we performed a search in Google Scholar and manually searched by the reference lists of included articles. Comprehensive search strategies were developed using the controlled vocabularies of each database. We systematically searched for relevant studies using a combination of Medical Subject Headings (MeSH) terms and corresponding free-text terms. Search term and keywords were altered as per specification of individual database.

Results Adolescent prostitution is one of the major public health problems and psychopathology plays an important part in it.

Adolescent prostitutes' shown elevated level of psychopathological disease that may reflect the possibility that their psychological functioning leads them to this particular environment.

* Corresponding author.

About a third of children are described as overactive by their parents, and up to a fifth of schoolchildren are described in this way by their teachers. Diagnosis of ADHD can be exhibited in 3–7% of children reached school age. It is not surprising that in children with ADHD as a result of such symptoms develop low self-esteem and emotional problems, often observed a variety of neurotic symptoms and behavioral disorders. The aim of our work was to investigate effectiveness of GABA-ergic medications in complex correction of ADHD children. It is investigated and treated 69 children with ADHD in age from 6 to 12 years. All the children were assigned GABA-ergic medications in doses that depended on the age of the child within three months. Besides medication, parents with their children carried out psychological adjustment, first of all it was a psychological training of parents based on system model of psychotherapy and appropriate recommendations for changes in behavioral strategies in relation to children. After treatment 100% of parents noted improvement of children's state. However, symptoms significantly smoothed in 51 children, children were more attentive, calmer, and more reflective. It was made significant changes in the relationships of parents with children that manifested itself in improving mutual understanding, increased positive reinforcement, reducing cases of different methods of punishment and expression of dissatisfaction with the behavior of children. Therefore, GABA-ergic medications can be successfully used in complex correction in children with ADHD.

Art-therapeutic approaches in the diagnosis of depressive disorders in children

E. Mykhailova^{1,*}, T. Proskurina¹, T. Matkovska¹, N. Reshetovska¹, A. Matkovska²

¹ State Institution "Institute for Children and Adolescents Health Care of the NAMS of Ukraine", psychiatry, Kharkov, Ukraine

² Kharkov V. Karazin National University named, medical, Kharkov, Ukraine

* Corresponding author.

Background and aims To study diagnostic and rehabilitation significance of projective drawing tests in children with depression.

Materials and methods Multidisciplinary study of pediatric patients with depression (48 children in the prepuberty and 164 children in puberty) was carried out in the psychiatric department of the SI "Institute for Children and Adolescents Health Care of the NAMS of Ukraine" for the period 2012–2015.

The study design Clinical and psychopathological, somatoneurological, and psychological (CDRS-R depression scales, “I and my illness”, “House-Tree-Person”, “I am in this world”, “Me and my family” projective drawing tests as well as “My sorrows” and “My dreams” topical mini-compositions).

Results Graphic signs reflecting anxiety, depression, fatigue, algia, aggression, low self-evaluation, isolation, hypochondria and phobias have been registered in the projective drawn tests of all our patients. In cases of suicidal behavior and aggression, art-therapy sessions enabled the experts to convert the problem and make it a stimulus for the exit from the psychological crisis. In dysmorphic fixation on the bodily problems therapeutic intervention was aimed at restoring the adoption of a child of his “ego”. Regardless of the specific psychological problems with depression of each patient art-therapy sessions made it possible to restore the emotional homeostasis and compliance, which contributed to more effective therapeutic interventions.

Conclusion The differentiation of somatic, emotional and behavioral patterns of depression by art-diagnosis provides concentration on psychopathologic symptoms and psychosocial stressors, which is effective in the rehabilitation of children with depressive anxiety disorders.

Antipsychotic in children and adolescents: Metabolic effects

M.D.L.C. Ramirez Dominguez*, I. Prieto Sánchez, L. Hernandez Gonzalez, S. Fernandez Leon, M. Reina Dominguez
Complejo Hospitalario de Huelva, Psiquiatria, Huelva, Spain
* Corresponding author.

Introduction The use of antipsychotics in children is controversial, one of the considerations to take into account is the possible effect on the values of fasting glucose, prolactin or weight gain are very important.

Objectives To study the effect of these drugs on metabolic rate in children.

Methods We measured the weight, waist circumference, fasting glucose and basal prolactin in 6 children at Children’s Hospital in the province of Huelva, diagnosed with bipolar disorder and early schizophrenia, atypical antipsychotics before starting treatment and 6 months later.

Results In the provisional results it is found that there is not a significant weight gain (less than 3%), no impairment of glucose and only in one case basal prolactin was elevated.

Conclusions The use of atypical antipsychotics in children should be reserved when strictly necessary. Once established, keep tight control of metabolic parameters, although the data of our study coincide with the literature, do not produce significant alterations.

The importance of multiple-family group therapy in treatment of psychosomatic pathology

C. Sanahuja^{1,*}, A. Suarez²
¹ Hospital Universitario de Fuenlabrada, Mental Health, Fuenlabrada, Spain

² Instituto Psiquiatrico Jose Germain, Mental Health, Leganes, Spain

* Corresponding author.

Introduction The “parental multiple-family school” was developed in Buenos Aires (Argentina) by E. Rotenberg, based on the theory and practice of J. García Badaracco’s multiple-family psychoanalysis (which further expands on the classical psychoanalysis’ frame), applying it to the kids and their relatives. We will focus on the therapeutic group treating psychosomatic pathology, with the collaboration of the Dermatology department of the Hospital de Niños Dr. Ricardo Gutiérrez.

Objective To highlight the importance of creating spaces to modify the psychic mechanisms and resources of the psychosomatic patient at an infant age.

Methods We describe the “multiple-family parents school”, an open, weekly group, coordinated by two psychologists and assisted by a dermatologist, in which the theories of J. García Badaracco’s multiple-family group analysis are applied. We also discuss the importance of applying this system in our clinical practice.

Results We observed, according to the Dermatology department, very positive and significative changes in every post-group, which could lead to the disappearance of dermatological diseases in different patients without a pharmacological treatment which was previously given as first option. Single-session groups had many advantages, including the removal of waiting lists, a better development of the emotional connection between kids and their families, and a reduction of the therapeutic and professional costs.

Conclusion We think that starting interventions in multiple-family group therapy in Madrid in order to treat psychosomatic diseases in kids and teenagers should be encouraged after the very positive clinical experience in other cities.

⁴ La Paz University Hospital. IdiPAZ Health Research Institute, Psiquiatría, Madrid, Spain

* Corresponding author.

Objective This study examined the emotional and behavioral functioning among 10–14 year-old children who were born with very low birth weight (VLBW, <1500).

Method Prospective and cross-sectional study of 90 VLBW (<1500g) survivors born at the Hospital Universitario la Paz in Madrid, Spain, from 2000 to 2005 who were assessed by interviewers using the Strengths and Difficulties Questionnaire (SDQ). Parents also reported on their children’s functioning. Children who showed an abnormal SDQ score on the total difficulties subscale or who had psychiatric history were also assessed using the K-SADS-PL.

Results The proportion of children with abnormal-self-rated-SDQ scores was as follows: almost 25% of children showed an abnormal score on hyperactivity, nearly 15% on emotional problems, 15% on conduct problems and 10% on peer problems. Overall, 15% of children showed an abnormal score on the total difficulties subscale. Most children (99%) showed a normal score on the prosocial subscale. These proportions were higher when the questionnaire was rated by parents. Thirty-eight percent of children

were assessed using the K-SADS and very few of them meet the criteria for at least one psychiatric disorder. Biomedical variables were associated in the expected direction to children's SDQ scores such as birth weight, head circumference and Apgar scores.

Conclusion To conclude, being born with very low birth weight seems to be related to the emotional and behavioral functioning that these children appear to show between 10 and 15 years later.

School refusal: Idiom of distress and/or Babel tower?

J. Sibeoni*, A. Moscoso, A. Revah-Levy

Hospital de D. Estefânia Department of Child and Adolescent Psychiatry, Rua Jacinta Marto, Lisbon, Portugal

* Corresponding author.

Across Europe, school absenteeism is an increasing problem on the crossroad between educational and public-health political matters. This issue underlies socio-economical, sociological and school-related factors as much as it questions individual psychopathology and family functioning. Indeed, school refusal behavior among adolescents has become a very frequent reason to seek for psychiatric consultations. A recent review about this topic has shown that around 90% of these adolescents met the criteria for a psychiatric diagnosis, mostly anxiety disorders [1]. It appears to be a very complex and heterogeneous phenomenon which raises many questions, to date still unsolved: terminology confusions (truancy, school phobia, school refusal), lack of a concise definition, contradictory hypothesis regarding etiology, psychopathology and treatment plan depending on the paradigm the authors would refer to. In this presentation, we will elicit why school refusal can be considered as a new idiom of distress for adolescents in western societies, and we will show how, in clinical practice, these situations can become a genuine Babel tower in which no one, among health-care professionals, teachers, parents and patients, are speaking the same language.

Keywords School refusal; School phobia; Truancy; Adolescents; Idiom of distress

Psychological responses to traumas of children younger than 6 years old diagnosed with posttraumatic stress disorder

M. Stankovic^{1,*}, G. Grbesa², M. Simonovic², J. Kostic¹, N. Ilic¹

¹ Clinic for Mental Health Protection, Child Psychiatry, Nis, Serbia

² Medical Faculty- University of Nis-Serbia, Psychiatry, Nis, Serbia

* Corresponding author.

Introduction Criterion A2 causes many controversies in the diagnostic process of posttraumatic stress disorder (PTSD) among young children. Depending on the manner in which the trauma is indirectly experienced, clinical picture of disorder could be formed by different groups of symptoms. Profiles of symptoms groups are dependent of children ability to speak, describe or of play observation by expert.

Methods The study included 8 children younger than 6 with PTSD diagnosis. Children were observed in a routine clinical practice.

Results Examinees under the age of six, whose can describe traumatic event, produce symptoms that represent compaction of a traumatic event, associated with fantasies and meanings related to previous traumatic experiences. Reexperiencing symptoms associated with A2 criterion (intrusive thoughts, images, scenes of the traumatic event, recurring nightmares with onerous sequences of the accident) were rare. Avoidance and inhibited reactions were attributable.

Discussion Manners in which children younger than 6 experienced the trauma shows a large range from florid symptoms stated by the existing accepted classification. The results point out possible multifactorial cause of PTSD etiology.

Side effects of a psychiatry drug: Effect of phenytoin and aging on regulation of 3 enzymes of gingival fibroblasts in pediatrics and adults

V. Surena

Tehran, Iran

Introduction Epidemiologic data has shown that gingival overgrowth as a side effect of phenytoin, one of the major drugs against Epilepsy is more common in pediatrics than in adults. The alteration of cytokine balance is suggested to exert greater influence on gingival overgrowth compared to the direct effect of drug on the regulation of extracellular matrix metabolism or proliferation of gingival over growth.

Purpose Current study was performed to evaluate the phenytoin effect on the regulation of collagen, lysyl oxidase and elastin in the gingival fibroblasts in pediatrics and adults.

Methods and materials Normal human gingival fibroblasts (HGFs) were obtained from 4 healthy children and 4 adults. Samples were cultured with phenytoin. MTT test was used to evaluate the proliferation and ELISA was performed to determine the level of IL1 β and PGE2 production by HGFs. Total RNA of gingival fibroblasts was extracted and RT-PCR was performed on samples. The analysis of proliferation was assessed by independent ANOVA; Kruskal-Wallis was used to assess the production of mediators with an alpha error level less than 0.05.

Results There was significant difference in the expression of elastin between the controls and treated samples in both adult and pediatric groups and also in the lysyl-oxidase expression of adult controls and treated adult. No significant difference was found between the collagen expressions in adults.

Conclusion The only significant difference was in the elastin and lysyl oxidase expression between adult and pediatric samples indicating the significant effect of age in their production of both control and experimental groups.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Department of Mental Health, Psychiatry, Los Angeles-California, USA

³ Pitzer College, Psychology, Claremont–California, USA

⁴ Department of Mental Health, Juvenile Court Mental Health Service, Monterey Park–California, USA

* Corresponding author.

Introduction Telepsychiatry is increasingly utilized to evaluate and treat diagnostically and geographically diverse youth. (Szeftel et al., 2012; Hilty et al., 2013). Important public health implications arise for US psychiatrically ill youth, most of whom receive no treatment, others depend on pediatricians without input from a child psychiatrist (Goldstein and Myers, 2014). Potential advantages of telepsychiatry include increased access to care from child psychiatrists directly, and through collaborations with pediatricians, and uniquely positive response in patients more communicative in this setting (Pakyrek et al., 2010).

Objectives – To present the effectiveness of Telepsychiatry in psychiatrically ill youth, and specific subgroups who especially benefit.

– To show increased access to psychiatric care occurs through collaborations between child psychiatrists and pediatricians.

Aims To present the advantages of telepsychiatry for child and adolescent mental health and clinicians.

Methods Review of selected published Telepsychiatric evidence-based research and best practice recommendations.

Results – Psychiatrically ill youth are effectively evaluated and treated using Telepsychiatry (Myers et al. (2011), Hilty et al., 2013). – Very young children and youth with Autism Spectrum Disorders, or anxiety disorders respond particularly positively to Telepsychiatry (Szeftel et al., 2012; Pakyuerek et al., 2010; Myers et al., 2010). – Telepsychiatry provides increased access to care through collaborations between child psychiatrists and pediatricians (Goldstein and Myers, 2014; Myers et al., 2011).

Conclusion Telepsychiatry is a promising advantageous modality for youth based on effectiveness, broad administration and unique benefit for very young and socially impaired youth.

Management of psychiatric symptoms in pediatric anti-NMDA receptor encephalitis: Case report and systematic review

S. Tang*, O. Alpert

Children's Hospital of Philadelphia, Child and Adolescent Psychiatry, Philadelphia, USA

* Corresponding author.

Introduction Anti-N-methyl-D-aspartate (NMDA) receptor encephalitis is an autoimmune condition that causes serious psychiatric symptoms. Nearly 40% of affected patients are pediatric in age. Few publications detail management of psychiatric symptoms.

Objective To guide clinical decision-making for psychiatrists managing pediatric patients with anti-NMDA receptor encephalitis.

Aims We present a systematic review of literature and an illustrative case report of a 17-year-old girl who presented with psychosis, agitation, and insomnia, and underwent treatment with olanzapine, clonazepam, and clonidine.

Methods PUBMED was searched for publications in English describing anti-NMDA encephalitis (2007–November 2015). Publications were included if they met all of the following:

- novel data;
- reported treatment of psychiatric phenomena for patients aged ≤18 years
- full text available. Thirty-four publications detailing 38 unique cases were included.

Results Psychiatric symptoms are summarized in Table 1; common treatment modalities are presented in Table 2. The most frequently used antipsychotics were risperidone ($n = 16$, 57%), haloperidol ($n = 10$, 36%), and olanzapine ($n = 10$, 36%). Significant adverse effects occurred, with neuroleptic malignant syndrome diagnosed with high probability in 4 cases (13%), and suspected in 5 cases (16%). Dystonia, rigidity, tremors, and bradykinesia were also linked to medication side effects. All reported adverse events coincided with antipsychotic administration.

Conclusions Psychiatric symptoms in pediatric cases of anti-NMDA receptor encephalitis were frequently managed with antipsychotics and benzodiazepines. Though antipsychotics may be necessary, serious side effects are concerning. Unlike in delirium resulting from other causes, benzodiazepines do not seem to be contraindicated. ECT may also be of utility and was well-tolerated in reported cases.

Table 1 Summary of psychiatric symptoms.

	All Cases	Ages 3 - 12 years	Ages 13 - 18 years
n	38	10	28
Females	25 (66%)	5 (50%)	20 (71%)
Agitation	32 (84%)	8 (80%)	24 (86%)
Psychosis	27 (71%)	5 (50%)	22 (79%)
Sleep Disturbance	18 (47%)	5 (50%)	13 (46%)
Catatonia	17 (45%)	2 (20%)	15 (54%)
Mood Disturbance	15 (39%)	3 (30%)	12 (43%)
Anxiety	7 (18%)	4 (40%)	3 (11%)

Table 2 Management of psychiatric symptoms.

	All Cases	Ages 3 - 12 years	Ages 13 - 18 years
n	38	10	28
Antipsychotics	32 (84%)	9 (90%)	23 (82%)
First Generation Only	6 (16%)	4 (40%)	2 (7%)
Second Generation Only	15 (39%)	4 (40%)	11 (39%)
Both First and Second	7 (18%)	0 (0%)	7 (25%)
Unspecified	4 (11%)	1 (10%)	3 (11%)
Benzodiazepines	24 (63%)	8 (80%)	16 (57%)
Non-Pharmacologic	11 (29%)	4 (40%)	7 (25%)
Electroconvulsive Therapy	5 (13%)	1 (10%)	4 (14%)
Melatonin	5 (13%)	3 (30%)	2 (7%)

Feasibility of the stress and anger management program on children with high functioning autism spectrum disorder in a sample population from Karachi

B. Tauseef*, Z. Zadeh, B. Fatima

Bahria University, Institute of professional Psychology, Karachi, Pakistan

* Corresponding author.

Introduction Research shows that individuals with Autism Spectrum Disorder, struggle with emotional competence as compared to their typically developing counterparts. This leads to internalizing (stress) and externalizing (anger management) problems in the affected population. The stress and anger management program (STAMP) designed by Scarpa et al. is a manualized treatment protocol with good clinical efficacy.

Objective The objective of the present study is to test the feasibility and suitability of STAMP as a systematized treatment protocol

in Karachi and to enable the sample population, to become emotionally competent.

Aim The aim is to evaluate the effectiveness of STAMP on the reduction of symptoms in the sample population.

Method Ten children with high functioning autism spectrum disorder will be selected from various institutes in Karachi, and randomized to experimental and waitlist control group after pre-intervention assessment. Upon completion of the intervention with the experimental group, the waitlist control group will be offered the intervention. Both the groups will be assessed, immediately after the intervention, followed by a one-month follow up assessment.

Results It is expected that STAMP will significantly reduce the incidence of problem behaviours as measured by the standardized assessment questionnaires from the manual; as well as significantly reduce the severity of scores on the internalizing and externalizing components of the strength and difficulties questionnaire, in the experimental group as compared to the control group.

Conclusion It is expected that the results of the present study could be utilized to train mental health professionals in Karachi for systematized treatment of ASD and related problems.

Temperament and resilience of children of alcohol dependent individuals

C. Thanikachalam^{1,*}, A. Dhandapani², S. Choudhury¹, A. Sankaran¹, E. Subramaniam¹

¹ Mahatma Gandhi Medical College and Research Institute, Psychiatry, Pondicherry, India

² National Institute of Mental Health and Neurosciences, Psychiatry, Bangalore, India

* Corresponding author.

Introduction Children of alcohol dependent individuals are affected by disturbed parent-child relationship and exhibit externalizing symptoms, arrhythmicity, negative mood and low persistence.

Objectives To assess the temperament and resilience of children of alcohol dependent individuals and to study their relationship with the father's severity and problems of alcohol intake.

Aims To assess the psychological profile of children of alcohol dependent individuals.

Methods Cross-sectional study conducted in a tertiary care centre from January to August 2015. Severity of alcohol dependence in father and problems related to it was assessed using 'short alcohol dependence data' and 'alcohol problems questionnaire'; the temperament and resilience of their children ($n = 31$) was assessed using 'temperament measurement schedule' and 'strengths and difficulties questionnaire' respectively.

Results The sample comprised of 48% boys and 52% girls with mean age (SD) of 9.32 (3.02) years. Eighty-one percent belonged to lower socioeconomic status. Their fathers' mean age (SD) was 37.13(4.9) years and duration of alcohol dependence being 16.32 (5.7) years, average use/day being 19.19 (14.9) units with moderate (45.2%) to high (41.9%) dependence. Significant association was observed between severity of alcohol dependence and temperamental domain-threshold of responsiveness ($\chi^2 = 17.272$, P value = 0.002) (Table 1). The average units of alcohol consumed/day were a significant predictor for the presence of emotional problems in the child (OR = 30.12; 95%CI 1.33–677.86).

Conclusion There's a significant association between father's alcohol use and child's psychopathology which indicates the need for preventive and curative mental health measures.

Table 1 Significant correlation between alcohol problems in father and child's temperament and resilience (* $P < 0.05$).

Alcohol problem	Temperament&Resilience	Pearson's correlation (r)	p value
Duration of alcohol intake	1.Externalising symptom	0.428	0.016*
	2.Approach- withdrawal	-0.445	0.012*
Average use of alcohol	'Emotionality' factor	0.360	0.046*
Marital problems due to alcohol use	Peer relationship problems	0.487	0.005*

Managing an effective treatment for catatonia and Cotard syndrome in an adolescent with comorbidities and CYP2D6 polymorphism

S. Turan*, B. Ay, B. Güller, B. Serim, S. Miral, Ö. Gencer Kidak Dokuz Eylül Medicine Faculty, Child and Adolescent Psychiatry, Izmir, Turkey

* Corresponding author.

We describe a patient with catatonia and symptoms of psychosis who developed neuroleptic malignant syndrome after using risperidone, olanzapin and clozapin, thus requiring life support equipment and Dantrolene, Bromocriptin, later recovering after five days. From a psychiatric and neurological point of view, however, the persistence of catatonic syndrome and Cotard syndrome delusions was observed, based on assertions such as 'I don't have an arm' (ideas of defalcation), 'They killed me', 'My body's getting melt' and statements about the patient being responsible for the 'death of the whole family' (ideas of guilty). Brain MRI shows that a venous angioma has been in right frontal lobe. Also echocardiographic findings were associated with history of myocarditis. Both venous angioma and myocarditis sequel seemed to be relative contraindication for electroconvulsive therapy according to literature. In addition; genotyping revealed that he was heterozygosis for a CYP2D6*4 wild type allele. The patient responded well to ECT after 13 sessions and with ketiapin 1200 mg/day medication. The case highlights the importance of therapeutic drug monitoring in identification and differentiation of drug induced effects in psychiatric disorder to NMS recurrence and also managing an effective treatment for catatonia and Cotard syndrome.

Potential neurobiological ADHD biomarkers

M. Uzbekov*, E. Misionzhnik Moscow Research Institute of Psychiatry, Brain Pathology, Moscow, Russia

* Corresponding author.

Objectives Pathogenetic mechanisms of hyperkinetic syndrome (HKS) or attention deficit hyperactivity disorder (ADHD) are not clear.

Aim To elucidate some aspects of monoamine involvement in pathogenesis of disorder and response of monoaminergic systems to psychostimulant medication.

Methods Levels of different monoamines, their metabolites and N-methylnicotinamide (end product of kynurenine pathway) were measured in daily samples of urine from children (7–11 years old) with mild and severe HKS using fluorimetric and chromatographic methods as well as platelet monoamine oxidase (MAO) activity. Thirty children with mild HKS received psychostimulant Sydnocarb 5–15 mg daily for 1–1.5 months (for ethical reasons children with severe HKS were not included in study).

Results HKS was accompanied by activation of dopaminergic and inhibition of noradrenergic systems. There were found metabolic differences between two forms of HKS. Compared with mild HKS, severe HKS was characterized by significant 2-fold increase of MAO activity and L-dopa, dopamine and adrenaline excretion. After sydnocarb treatment children's clinical status improved along with decrease of excretion of homovanillic, vanillylmandelic and 5-hydroxyindoleacetic acids and increase of N-methylnicotinamide.

Conclusions Results indicate that dopaminergic and noradrenergic systems play important role in pathogenesis of HKS. Clinical improvement of HKS children was accompanied by significant increase of N-methylnicotinamide excretion. It is proposed that increased urine excretion of kynurenine metabolite–N-methylnicotinamide and N-methylnicotinamide/5-hydroxyindoleacetic acid ratio can serve as potential biomarkers for evaluation of efficacy of psychostimulant medication. We hypothesize that kynurenine system plays significant role in pathogenesis of HKS/ADHD.

EV309

Neuroanatomical basis of emotional dysregulation in children and adults with ADHD

R. Vela

Massachusetts General Hospital, Psychiatry, Chelsea MA, USA

Introduction Since the advent of DSM III, emotional dysregulation has been relegated to “associated features” of ADHD. However, research has shown that 25% to 40% of children and 30% to 70% of adults with ADHD have emotional dysregulation. Deficient emotional dysregulation is an important cause of disability, and poor clinical course.

Objectives At the end of this presentation, the participants will be able to:

- discuss the prevalence, disability and clinical/behavioral manifestations of emotional dysregulation in ADHD as a dimensional trait;
- discuss the major brain functions of the hypothalamus, amygdala, ventral striatum, cingulate gyrus, anterior insula and orbitofrontal cortex, and how these may explain emotional dysregulation in ADHD.

Aims The aim of this presentation is to elucidate the relationship between clinical manifestations of deficient emotional self-regulation in ADHD and the neuroanatomical structures and neurocircuitry involved in emotional regulation.

Methods This presentation will selectively review specific research findings of functional imaging ADHD studies and analyze them in the context of emotional regulation exerted by the interrelationships between the amygdala, ventral striatum, medial prefrontal cortex, orbitofrontal cortex and anterior insula.

Results Bottom-up neuroanatomical mechanisms involve the detection of hypothalamic and amygdalar firing, signaling higher cortical structures that control is needed. Top-down regulatory processes in ADHD subjects fail in the allocation of attention to emotional stimuli and reward valuation necessary to maintain focus on a goal.

Conclusions Further research is needed to continue elucidating the anatomical structures and functional connectivity underlying deficient emotional self-regulation in ADHD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Understanding of self-harm behaviour in adolescents

L. Santric¹, A. Razić Pavlic², A. Vuk^{3,*}, A. Tomac¹

¹ Clinic for Psychological Medicine-University Hospital Center Zagreb, Child and adolescent psychiatry, Zagreb, Croatia

² Clinic for Psychological Medicine-University Hospital Center Zagreb, Adult psychiatry, Zagreb, Croatia

³ Psychiatric Hospital 'Sveti Ivan', Adult psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction The incidence and prevalence of self-harm behaviour, with or without suicidal intent, is on the rise, both in other countries as well as in Croatia. Understanding the nature of patients who show self-harm behaviour can help us to better understand the components that contribute to their morbidity and mortality.

Objectives To expand the understanding of self-harm behaviour in adolescents as a contribution to the planning and implementation of preventive and curative programs.

Aims To explore the psychopathological characteristics of adolescents with and without self-harm behaviour who seek psychiatric help for their mental health problems.

Methods In this study participated 150 adolescents, aged 14–18 years, of which 52% showed some form of self-harm behaviour. During the initial examination of child and adolescent psychiatrist, participants completed self-reported questionnaires: functional assessment of self-mutilation (FASM, 1997) and the youth self report (YSR, 2001).

Results Statistically significant difference between groups of female adolescents with and without self-harm behaviour was observed in all of eight problem scales, while in male adolescents it was observed in five of them. This indicates considerably higher level of psychopathological features in the group of patients with self-harm behaviour.

Conclusions It is necessary to intensify monitoring of adolescents who show self-harm behaviour because of the overall level of psychopathological symptoms and the comorbidity which significantly complicates the therapeutic process. It is particularly important to continuously assess the suicide risk.

EV311

Resilience in children of depressed parents – a systematic review of protective factors

O. Włodarczyk*, A. Schramm, F. Metzner, S. Pawils

University Medical Center Hamburg-Eppendorf, Department of Medical Psychology, Hamburg, Germany

* Corresponding author.

Introduction Children of depressed parents have an increased risk of developing mental disorders. While there are various studies concerning a pathogenetic perspective, fewer studies examined factors that protect mental health of these children. Knowledge about protective factors is necessary to establish prevention projects.

Objectives This systematic review gives an overview of protective factors for mental health of children of depressed parents.

Methods Databases PsycINFO, Embase, Medline, PSYINDEX, PubMed, ISI Web of Science, and CINAHL were searched for relevant studies in German or English published until August 2014. Targets were epidemiological studies concerning protective factors for children up to the age of 21 years who have at least one depressed parent. Selection process and assessment of methodological quality of the studies were conducted by two reviewers using a checklist.

Results Out of 3526 screened studies, finally thirteen studies were included. Efficient stress management strategies – in particular primary and secondary control coping – were identified as protective factors for mental health of affected children. Children's social competences as well as parental positive parenting skills also seem to have a protective impact. Restrictions to specific search terms, databases, and languages could have caused missing relevant studies with other characteristics. Limitations could also result from possible publication bias as well as methodological and qualitative differences regarding included studies.

Conclusions In the context of prevention projects, children of depressed parents should be supported in adequately and efficiently coping with stress. Moreover, practitioners should aim at the promotion of social competences and the involvement of parents within prevention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosocial profile of encopretic children and their caregivers in relation to parenting style

E. Zaky^{1,*}, M. Rashad¹, H. Elsafoury², E. Ismail¹

¹ Ain Shams University, Pediatrics, Cairo, Egypt

² Ain Shams University, Pediatric Surgery, Cairo, Egypt

* Corresponding author.

Background The role of psychological factors in the development and maintenance of encopresis is controversial.

Objectives Assessment of the psychosocial profile of encopretic children and their caregivers in relation to parenting style compared to controls.

Methodology The current cross sectional study comprised 90 Egyptian children classified into three groups: group I (encopresis without constipation and overflow incontinence), group II (encopresis with constipation and overflow incontinence), and group III (clinically healthy controls); each group included 30 children. Thorough clinical evaluation and psychometric assessment were carried out for all enrolled children while caregivers were evaluated for their parenting styles, anxiety, depression, and introversion scores. **Results** Hardness, undue blaming, and indecisive parenting styles were significantly more prevalent among caregivers of group I. Encopretic children of group I & II had poorer self-esteem and higher prevalence of clinically manifest depression compared to healthy controls. Furthermore, there was a higher prevalence of clinically manifest paternal anxiety, depression, and introversion and maternal depression among caregivers of group II and higher prevalence of clinically manifest paternal anxiety and depression among fathers of group I.

Conclusion The approach of toilet training, not the time of its initiation, seems to be the factor that really matters in predisposing to and perpetuating encopresis. Further exploration is needed to determine if the documented association of psychological disorders of enrolled encopretic children and their caregivers was causal or being just the impact of the child's encopresis.

¹ Centro Hospitalar Psiquiátrico de Lisboa, Ward 1 - First Psychotic Episode Unit, Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Ward 6 - Schizophrenia and Schizoaffective Disorders Unit, Lisboa, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Ward 2 - Neuropsychiatry and Dementia Unit, Lisboa, Portugal

* Corresponding author.

Introduction Clinical concepts regarding atypical psychosis such as the French bouffé délirante, the German cycloid psychosis, and the Scandinavian reactive and schizophreniform psychoses are now under the category of F23 'Acute and transient psychotic disorders' (ATPD) of the tenth revision of the International Classification of Mental and Behavioural Disorders (ICD-10).

Aims The authors' aim is to highlight the clinical and scientific relevance of atypical psychosis from the historical concepts to the current perspective.

Methods A PubMed database search using as keywords "atypical psychosis", "acute and transient psychotic disorders", and "brief psychotic disorder" and retrieved papers were selected according to their relevance.

Results Different psychiatric schools, often of a regional or national character, have provided concepts for transient psychotic states. The acute and transient psychotic disorders of ICD-10 and the brief psychotic disorder of Diagnostic and Statistical Manual of Mental Disorders (DSM-5) reflect the diversity of the history of such concepts. The available evidence suggests that case identification and follow-up is difficult in ATPD due to the heterogeneous and infrequent nature of this clinical phenomenon. Furthermore ATPD has a low diagnostic stability and there are few studies focused on brief psychotic disorders.

Conclusions The present definition of acute and transient psychotic disorders and brief psychotic disorder, while taking into account the history of the concepts involved, leave many questions open to further studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Anxiety and undiagnosed pheochromocytoma

C. Cocho Santalla^{1,*}, C. Sanahuja²

¹ Hospital Universitario Infanta Cristina, Unidad de Psiquiatría, Madrid, Spain

² Hospital Universitario Fuenlabrada, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction Pheochromocytomas are rare catecholamine-secreting tumours from the adrenal medulla. The clinical presentations may mimic other disorders due to nonspecific symptoms produced by catecholamines in blood.

Objectives We report a case of undiagnosed pheochromocytoma in a 29-year-old woman with a two year history of anxiety. We undertook a literature review.

Methods PubMed search using “pheochromocytoma”, “anxiety” as key words. Follow by a manual review of identified publication. We report a case of a 29-year-old with a two-year history of anxiety pharmacologically treated without success. She presents episodes of acute anxiety accompanied, sometimes, by nausea or headache, without high blood pressure. She presented a previous medical history of thyroid carcinoma. The patient was referred to the endocrinology service for thyroid review, postulated as potential source for drug resistance. High catecholamine levels were found and pheochromocytoma diagnosis was confirmed histopathologically.

Results The releasing catecholamine in blood can lead to a number of symptoms that can include paroxysmal hypertension, headache, palpitations, anxiety, chest/abdominal pain, nausea. Hypertension may not be the main symptom. These symptoms can be misinterpreted as psychiatric disorders, in particularly anxiety disorders. Elevated urinary catecholamine suggested the diagnosis of pheochromocytoma.

Conclusions Pheochromocytoma should be included in the differential diagnosis of anxiety disorders, especially if pharmacological treatment is not effective. The suspected cases should be investigated, even in the absence of hypertension, due to the potential morbidity of untreated pheochromocytoma.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Ganser syndrome: Review and case report

R. Faria*, D. Brandão, T. Novo, L. Quintela, A. Fonte
Unidade Local de Saúde do Alto Minho, Departamento de Psiquiatria e Saúde Mental, Viana do Castelo, Portugal

* Corresponding author.

Introduction First described by Sigbert Ganser in 1887, Ganser syndrome consists in a rare condition, characterized by the following four clinical features: approximate answers, dulling of consciousness, conversion symptoms and hallucinations.

Objectives To present a case suggestive of Ganser Syndrome and to review the literature with particular regard to the aetiology of this condition.

Methods Literature review, using computerized databases (MEDLINE®, Medscape®). Articles were selected based on the content of their abstract and their relevance.

Results A 58-year-old woman was admitted to a Psychiatric Unit of a General Hospital for presenting behavioural abnormalities of acute onset. During hospitalization, the patient displayed indifference, incoherent speech with approximate answers, motor abnormalities and auditory pseudohallucinations. The patient was evaluated by a neurologist and various exams were performed (blood tests, CT, MRI, EEG) that showed no significant abnormalities. Pharmacological treatment consisted of antidepressant and antipsychotic medications. During the follow-up, there was a slow but gradual improvement of symptoms. Six months after hospitalization the patient decided to end up the follow-up.

Conclusions Little is still known about Ganser Syndrome. The four aetiological perspectives consider: hysterical origin, malingering or factitious disorder, psychotic origin and organic origin. The lack of reports and information about Ganser syndrome made it worthwhile reporting this case.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evolution of diagnostic frequency in schizophrenia spectrum disorders in Acute Psychiatric Unit in Barcelona

M. Grifell^{1,*}, L. Galindo¹, M. Campillo¹, L. Gonzalez¹, A. Palomo¹, C. Diez-aja¹, A. Grau¹, L. San-Emeterio¹, M. Ibarra¹, R. Sanchez¹, L.M. Martín¹, L. García¹, O. Orejas¹, T. Salvador¹, H. Manteca¹, V. Pérez^{1,2}

¹ Parc de salut mar, Institut de neuropsiquiatria i addiccions, Barcelona, Spain

² Centro de investigación Biomédica en Red de Salud Mental CIBERSAM G21, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Several studies have suggested variations in the prevalence of schizophrenia spectrum disorders diagnosis across time. This could be due to a change in diagnostic practice motivated either for changes in DSM criteria as for local culture factors. The aim of this study is to explore the evolution of the schizophrenia spectrum disorders. We hypothesize that we would observe a transference from the schizophrenia diagnosis to psychosis not otherwise specified.

Methods A retrospective review of all psychiatric discharges in acute unit in the INAD of Parc de Salut Mar of Barcelona, between 2002 and 2014 was performed, relating each discharge to its axis I psychiatric diagnostic. An ANOVA analysis was used to calculate the differences between the months and the frequency of the diagnosis.

Conclusion We have not been able to observe any transference between diagnoses across years. We observe a decrease of the proportion of schizophrenic spectrum disorders in its prevalence at discharge from 2012 to 2014. The proportion of not otherwise specified psychosis remains quite constant as a third of the schizophrenia diagnoses.

Disclosure of interest The authors report no conflict of interest in this study. LG is funded by the Instituto.de.Salud.Carlos.III (CM14/00111).

Disruptive mood dysregulation disorder in adults: A case report

O. Kilic^{1,*}, E. Demirbas Cakir², A.E. Tufan²

¹ Beykent University, Psychology, Istanbul, Turkey

² Abant İzzet Baysal University İzzet Baysal Mental Health Research and Training Hospital, Child and Adolescent Psychiatry, Bolu, Turkey

* Corresponding author.

Introduction Disruptive mood dysregulation disorder (DMDD) defined by DSM-V is characterized by severe and recurrent temper outbursts and persistently irritable or angry mood.

Objectives Our aim is to attract attention to an adult case with DMDD since the literature is lacking adult manifestations.

Case report A 18-year-old boy have been on follow-up in our outpatient clinic since he was 12 with complaints of being increasingly irritable and angry during most of the day. He had temper tantrums six or seven times per week involving verbal rages, physical aggression and throwing things to friends and family members. There had never been a distinct period lasting more than one day

during which the full symptom criteria, for a manic, hypomanic or a depressive episode had been met. He was also reported to be hyperactive, impulsive, and had difficulty concentrating and focusing since he was seven. Laboratory evaluations were within normal limits. Results of screening forms provided by parents and teachers supported the presence of attention deficit and hyperactivity disorder (ADHD). ASRS, YMRS, STAXI, SCID-I, Diagnostic Interview for Adult ADHD (DIVA) were the psychometric evaluations carried out in order better to characterize the clinical situation.

Results He was considered as fulfilling DSM-5 criteria for ADHD and DMDD, and started on sertraline 50 mg/day and OROS methylphenidate 36 mg/day. At the following visits, temper tantrums were much reduced and there were moderate improvement in ADHD symptoms.

Conclusions By defining the adult manifestations of DMDD accurately, clinicians will be able to improve diagnosis and care.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical manifestations in patients with acute and transient psychosis

Á. López Díaz^{1,*}, A. Soler Iborte², S. Galiano Rus¹, J.L. Fernández González¹, J.I. Aznarte López²

¹ Hospital San Juan de la Cruz, Mental Health Services, Úbeda, Spain

² Hospital San Agustín, Mental Health Services, Linares, Spain

* Corresponding author.

Introduction The term, acute and transient psychosis, is comprehended as a heterogeneous group of disorders, which share, as a common feature, the abrupt and brief deployment of typical psychotic behaviour, either polymorph, delusional, or schizophreniform. This diversity of symptoms may also be present in other psychotic disorders, for which, some authors question its reliability.

Objective To analyse the clinical manifestations present in acute and transient psychotic disorders (ATPD), and determine the differences between its different subcategories.

Method Retrospective chart review study of adult patients admitted in our psychiatric unit between 2011 and 2015, with a mean diagnosis of ATPD at hospital discharge. Diagnostic criteria was according to the International Classification of Diseases (ICD-10). Symptoms were divided under operative procedures, as set out in psychopathologic descriptions. For methodological reasons, statistical analysis was conducted between polymorphic features group (PM) and nonpolymorphic group (NPM). Chi-squared test and Fisher's exact test (as appropriate) were performed, using MedCalc software.

Results Thirty-nine patients met the inclusion criteria. Acute polymorphic psychotic disorder with and without symptoms of schizophrenia (39%), acute schizophrenia-like psychotic disorder (20%), acute predominantly delusional psychotic disorder (23%), other and NOS (18%). There were statistically significant differences between PM and NPM groups in emotional turmoil (>PM, $P=0.0006$), grossly disorganized or abnormal motor behaviour (>PM, $P=0.0038$), and type of onset (sudden >PM, $P=0.0145$).

Conclusion Currently, the same concept encompasses two categories (PM and NPM) to be differentiated. The ATPD construct is under review, due its long-term instability.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gender differences in acute and transient psychotic disorder

Á. López Díaz^{1,*}, S. Galiano Rus¹, A. Soler Iborte²,

J.L. Fernández González¹, J.I. Aznarte López²

¹ Hospital San Juan de la Cruz, Mental Health Services, Úbeda, Spain

² Hospital San Agustín, Mental Health Services, Linares, Spain

* Corresponding author.

Introduction In the recent decades, there is a growing interest in gender differences in psychotic disorders. Also, in the field of acute and transient psychosis, according to various studies, women seem to have higher prevalence and long-term diagnostic stability.

Objectives To determine whether there are gender differences in clinical features of acute and transient psychotic disorders (ATPD).

Methods Descriptive cross-sectional study in the adult patients with ATPD were admitted between 2011 and 2015 in our acute psychiatric ward. Diagnostic criteria was according to the International Classification of Diseases (ICD-10). Descriptive and inferential statistical procedures for clinical symptoms and diagnostic subcategories were performed, using the MedCalc software, version 15.8.

Results Thirty-nine patients met the inclusion criteria. Males were (MG) 41%, females (FG) 59%. There were some statistically significant differences between gender in the polymorphic features group (>FG, $P=0.048$), and in the presence of acute stress (>FG, $P=0.0277$). Length of stay was also different, but without statistical significance (>MG, $P=0.0607$). In contrast, symptomatic sets, family history of psychosis, and type of onset (sudden or acute) were similar for both groups.

Conclusions The gender differences seem to be in favour of a higher prevalence of polymorphic psychotic symptoms, in relation to stressful events in women. Somehow, these factors could be a condition, which would determine a greater diagnostic stability in female patients, even in cases of recurrences.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical and functional impact of differences between the diagnostic criteria of DSM IV-TR and DSM V for mental retardation: A case report

B. Navarro^{1,*}, M. Torres²

¹ Red de Salud Mental de Bizkaia, Barakaldo CSM, Bilbao, Spain

² Red de Salud Mental de Bizkaia, Zaldibar Psychiatry Hospital, Bilbao, Spain

* Corresponding author.

Introduction The new edition of the DSM has introduced some changes involving differences, sometimes significant, in the conceptualization and classification of mental pathology. One of the most important has been the case of mental retardation.

Objectives and aims Discuss, with a clinical and pragmatic perspective, the relevance of those changes in the diagnosis and classification of mental retardation in DSM.

Methods A 45-year-old woman diagnosed with mental retardation is admitted in a psychiatric rehabilitation unit for behavioral disorders and psychotic symptoms. Once controlled the symptoms and studied the patient, a disability not corresponding with the diagnosis presented (mild mental retardation according to DSM IV) is shown. Clinicians start a reevaluation of the diagnosis.

Results A comprehensive rehabilitation program according to the pathology and deterioration of the patient is designed. With the diagnosis review is possible to find new resources and community programs, better fit for the patient needs.

Conclusions DSM V changes in mental retardation diagnosis and classification allows a better perspective of the disease and its impact of functionality.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A case of acute and transient psychosis—What to expect?

M. Oliveira*, J. Rebelo, A.S. Costa, C. Santos

Centro Hospitalar São João, EPE, Psychiatry and Mental Health Clinic, Porto, Portugal

* Corresponding author.

Introduction The Tenth Revision of the International Classification of Diseases (ICD-10) introduced the category of Acute and transient psychotic disorders (ATPD), that assimilate clinical concepts such as the French Bouffée Délirante, Kleist and Leonhard's cycloid psychosis, and the Scandinavian reactive psychosis.

Methods and aims The authors present a clinical case of ATPD and a literature review based on PubMed/MEDLINE, using the keywords: "acute and transient psychotic disorder", "prognosis" and "diagnostic stability", aiming to discuss the main challenges regarding the diagnosis, treatment and prognosis.

Results The patient is a male with 37 years old with two previous psychotic episodes (with 2.5 years of interval), both with an acute onset (of 7 and 3 days respectively), and a fast response to antipsychotic treatment, with periods of complete symptom's remission. He maintains treatment with 6 mg of paliperidone. In the literature, we found scarce information on ATPD. Though several variables have been described as having influence on the prognosis (gender, pre-morbid functioning, acute onset and presence of affective symptoms), this topic remains controversial. Another difficult aspect about ATPD seems to be its low diagnostic stability, with diagnosis changing mostly to Schizophrenia, Schizoaffective disorder and Bipolar disorder. Duration of treatment after complete remission of symptoms is another controversial aspect of this disease.

Conclusions ATPD seems to have low diagnostic stability and poor research investment, and so it represents a challenge for psychiatrists on managing these patients in terms of treatment and follow-up plan. Further studies should be held regarding prognosis and treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The first reference to the shared delusions emerged in France in the nineteenth century. Shared delusions can be classified in three frames with different nosological value: simultaneous *folie à deux*, imposed *folie à deux* and communicated *folie à deux*.

Objectives A review of the structures of presentation of this psychiatric disorder through a case report and checking the categorization of the classic *folie à deux* in the current diagnostic manuals.

Methods Discussion through a case report of delusional disorder among twins. After several interviews with the patients we found that both have a complex delusional system, structured and bizarre at the same time. There was a clearly paranoid tinge in the narration which main theme is religion.

Results Delusional clinical appears identically and simultaneously in both subjects with equal readiness and doesn't give up after the admission of the patients in two different psychiatric hospitalization units.

Conclusions In the ICD-10 and DSM-5, diagnostics would be different depending on the kind of *folie à deux*. In simultaneous *folie à deux* and communicated *folie à deux* the dominant partner would receive a diagnosis of delusional disorder with ICD-10 and DSM-5. The acceptor partner would receive a diagnosis of delusional disorder induced with the ICD-10 and a diagnosis of unspecified schizophrenia spectrum and other psychotic disorder with the DSM-5. In a simultaneous *folie à deux*, both subjects would have a diagnosis of delusional disorder in both manuals. We think that this is the right choice.

Presentation of the Comprehensive and Brief International Classification of Functioning, Disability and Health Core Sets (ICF-CS) for schizophrenia

O. Pino^{1,*}, G. Guilera², E. Rojo³, J. Gómez-Benito²

¹ Hospital Benito Menni CASM, University of Barcelona, Psychiatry, Barcelona, Spain

² University of Barcelona, Methodology and Behavioural Sciences, Barcelona, Spain

³ Hospital Benito Menni CASM, University International of Catalonia, Psychiatry, Barcelona, Spain

* Corresponding author.

Objective The aim this presentation is present the results of the preparatory studies were presented at an international consensus conference, a multi-stage, iterative, decision-making and consensus process that took place 12–14 May 2015 in Barcelona, Spain. At this consensus conference, schizophrenia experts from different countries worldwide and working in a broad range of professions decided which ICF categories should be included in the first version of the ICF Core Sets for schizophrenia.

Method Four preliminary studies intend to capture the researcher's perspective, the patient's perspective, the expert's perspective and the clinician's perspective, respectively, on the most relevant aspects of functioning of persons living with schizophrenia. The final definition of ICF Core Sets for schizophrenia have been determined by integrating the results of preliminary studies in a consensus conference with international expert.

Result The experts included 97 categories in the Comprehensive ICF Core Set and 25 categories in the Brief ICF-CS. The specific categories of each ICF-CS are shown in this presentation. The Comprehensive ICF-CS can guide multidisciplinary assessments of functioning in persons with schizophrenia, and the brief version is ideal for use in both clinical and epidemiological research, since it includes a small and practical number of categories, but sufficiently wide for finding utility in clinical assessments.

Conclusion ICF-CS are being designed with the goal of providing useful standards for research, clinical practice and teaching, and it will stimulate research and will improve understanding of functioning, health and environmental factors in schizophrenia.

Personality Behavior Inventory (PBI): An introduction, factors, psychometric properties, comparison with MMPI and PAI

L. Rollè^{1,*}, D.G. Lyrakos², E. Gerino¹, A.M. Calderara¹, P. Brustia¹

¹ University of Torino, Psychology, Torino, Italy

² Filistos Psychosocial Testing and Consulting, Psychology, Athens, Greece

* Corresponding author.

The Personality Behavior Inventory (PBI) is a multidimensional tool for evaluating psychopathology, physical problems, behavioral characteristics and typical features of a personality. It is the shortest in the field with 197 questions and language level of the language level of the third grade of elementary school. That is for the Greek as well as the English version. The PBI provides clinical diagnoses, screening, and treatment planning for psychopathology, it also covers all the constructs most relevant to a broad-based assessment of mental disorders. The validity of the PBI is established on the basis of results from data from three samples; a normative census-matched sample from 1478 community based adults who were matched on the basis of race, gender, and age; a sample consisting of 1472 psychiatric and psychological patients (inpatients and outpatients), a sample from 982 forensic participants, who have been accused and convicted for a variety of crimes and finally a sample of 121 correctional and public safety employees. According to the reliability scores, the PBI scales reflect a greater level of internal consistency. At the present study, we will present the characteristics of the PBI, its usages on the clinical, occupational and forensic setting as a description of its psychometric properties and its advantages over the other MMPI-II and PAI.

Olfactory reference syndrome

C. Sanahuja^{1,*}, A. Espinosa²

¹ Hospital Universitario de Fuenlabrada, Mental Health, Fuenlabrada, Spain

² Instituto Psiquiatrico Jose Germain, Mental health, Leganés, Spain

* Corresponding author.

Introduction The term “olfactory reference syndrome” (ORS), introduced by Pryse-Phillips in 1971, is a persistent false belief and preoccupation with body odor accompanied by significant distress and functional impairment. Nowadays, it is not a distinct syndrome and it is currently classified as a delusional or obsessive-compulsive disorder.

Objectives and aims Review the history of ORSs classification and discuss why it should be considered as a separate diagnostic in the current health care classification systems.

Methods Description of a clinical case of a 36-year-old man and review the published articles on ORS by using PubMed database with the keywords: “olfactory reference syndrome”, “chronic olfactory paranoid syndrome”, “hallucinations of smell”, “chronic olfactory paranoid syndrome”, “delusions of bromosis” and “taijin kyofusho”.

Results The published literature on ORS spans more than a century and provides consistent descriptions of its clinical features but nowadays is not explicitly mentioned in current classification systems as Diagnostic and Statistical Manual of Mental Disorders (DSM) or International Statistical Classification of Diseases and Related Health Problems (ICD). ORS is overlap with different diagnostics such as delusional disorder, body dysmorphic disorder, obsessive-compulsive disorder, and hypochondriasis.

Conclusions Right now, it is not clear how the ORSs should best be classified so we consider interesting to include it as a separate diagnosis in our set classifications, since we understand that an adjusted diagnosis is important in order to help patients and therapists to work on a treatment and to establish a more accurate prognosis.

Psychotic and affective disorders diagnosis stability in a Portuguese psychiatry inpatient unit – A retrospective evaluation

M. Santos*, D. Mota, J. Perestrelo, N. Trovão, N. Couto, S. André,

A. Venâncio, L. Monteiro, G. Lapa

CHVNG/E, Psychiatry, Gaia, Portugal

* Corresponding author.

Introduction Psychiatric diagnosis is based on clinical manifestations; those are the consequences of patient’s inner state, their life situation, the evolution of the disease but also the response to our clinical actions. To this day, there are few objective clinical data to help establish a diagnosis, therefore, psychiatry diagnosis is mainly based on diagnostic criteria like DSM and ICD-10. The DSM frames entities by their diagnostic stability, however there are several causes for variability categorized by Spritzer et al. (1987): subject variance (changing in patients), occasions variance (different episodes), information variance (new information) and observation variance (different interpretations).

Objectives The main objective is to determine the long term diagnosis stability of patients with psychotic or affective disorders among readmitted patients at our Psychiatric Unit.

Aims To understand to what extent do our patients diagnosis evolve and in what way.

Methods Retrospective analysis of the diagnosis of patients with affective or psychotic disorders who have readmissions to our unit. We have a study sample of 210 patients that meet our criteria in a 30-month frame.

Results Although data are still being analyzed, we are now aware that our Inpatient Unit has a high rate of readmission of patients with these diagnoses. It is clear that for many of these patients, diagnosis must be seen as a guidance rather than a label.

Conclusions Knowing our own data can make us aware that a transversal look at patients can be insufficient and only time can determine a closed diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cycloid psychosis: From Kleist until our days

A. Sousa^{1,*}, C. Solana², J. Gomes³, P. Barata⁴, R. Serrano⁴,

M. Lages⁴, C. Oliveira⁴, J. Chainho³

¹ Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

³ Centro Hospitalar Barreiro-Montijo, E.P.E, Psychiatry, Barreiro, Portugal

⁴ Hospital Prof. Doutor Fernando Fonseca, Psychiatry, Amadora, Portugal

* Corresponding author.

Introduction After Emil Kraepelin’s division of psychoses into a group of dementia praecox and manic-depressive insanity, the classification of psychoses with atypical symptoms, which could not

be assigned in this dichotomy created a debate, that lasts until our days. These “atypical psychoses” had been described under many terms and concepts in different countries.

In 1926, Kleist coined the term “cycloid psychosis” to describe cases which did not meet the typical presentation shown in Kraepelin’s dichotomy. Three decades later, Karl Leonhard established the concept of cycloid psychosis as a nosologically independent group of endogenous psychosis.

Objectives/Aims Make an historical review of the concept of cycloid psychosis. Discuss the clinical features and debate the classification of this clinical entity.

Methods A bibliographical review is made of the cycloid psychosis, based on the data published in Pubmed.

Results According to Leonhard, cycloid psychosis generally present with bipolar, polymorphous clinical symptomatology, and run a phasic course with complete remissions after each episode. Furthermore, Leonhard delineated three subtypes: anxiety-happiness psychosis, confusion psychosis and motility psychosis presenting with different symptoms. In 1981, Perris and Brockington formulated the first set of operational criteria for cycloid psychoses. In recent years, new data about this entity have been acknowledged due to information displayed by different clinical studies and imaging techniques.

Conclusion The phenomenology and classification of cycloid psychosis still needs more evidence for a greater use in clinical practice. However, this clinical entity can solve the void for the diagnosis of many of the so-called “atypical psychoses”.

Are neurocognition and facial emotion recognition related in schizophrenia?

A. Arous*, J. Mrizak, R. Trabelsi, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Departement Psychiatry F, Tunis, Tunisia

* Corresponding author.

Introduction Patients with schizophrenia (SCZ) show impairments in many social cognition domains including facial emotion recognition (FER). The existence of a relationship association between FER and neurocognitive functioning (NF) remains uncertain.

Objectives To investigate the association between ToM functioning and neurocognitive functioning in SCZ.

Methods FER was evaluated in 58 patients with stable schizophrenia with a newly validated FER task constructed from photographs of the face of a famous Tunisian actress representing the Ekman’s six basic emotions. They also completed a neurocognitive battery comprising the following tests: the Hopkins Verbal Learning Test–Revised (HVLT–R), the Letter Digit Substitution Test (LDST), the Stroop Test (ST), the “Double Barrage” of Zazzo (DBZ), the Modified Card Sorting Test (MCST), Verbal Fluency (VF), the Trail Making Test–Part A (TMT–A) and the Digit Span (DS).

Results Patients who performed better in the FER task had better performance in the VF task ($P=0.001$) and in the immediate recall of the HVLT–R ($P=0.021$). No correlations were found with the other neurocognitive tests.

Conclusions Our results suggest that FER represents an autonomous cognitive function which does not necessarily require good NF.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Neuropsychological characteristics of individuals with mild cognitive impairment

Q. Wang*, Y. Sheng

Peking Union Medical College, School of Nursing, Beijing, China

* Corresponding author.

Introduction As the population ages, cognitive impairment is prevalent among older adults and this may cause a huge burden to society. In order to take precautions effectively, we need to understand the characteristics of cognitive function of older adults, especially the individuals with mild cognitive impairment (MCI).

Objectives To explore the characteristics of cognitive function changes in individuals with mild cognitive impairment.

Methods A total of 108 individuals with MCI as MCI group and 108 volunteers as control group were recruited in the study. The age, gender and years of schooling were matched between the two groups. The cognitive function was evaluated with the Montreal Cognitive Assessment (MoCA).

Results Individuals of MCI group performed poorer than those of control group on executive function, attention, calculation, language and delayed memory. The difference between the two groups was statistically significant ($P<0.05$). The cognitive impairment in participants with MCI were delayed memory (100%), language (75%), executive function (66.7%), attention (44%) and calculation (20.4%).

Conclusions The impairment of memory, language and executive function is the primary characteristics in individuals with MCI. Individuals with MCI have similar characteristics with early stage Alzheimer’s disease (AD). We should take preventive measures to improve or delay AD.

Frontotemporal dementia and psychosis: Literature review

D. Brandão^{1,*}, J. Massano²

¹ ULSAM, Psiquiatria, Tunis, Portugal

² Hospital Pedro Hispano, Neurologia, Porto, Portugal

* Corresponding author.

Introduction Frontotemporal dementia (FTD) is a progressive neurodegenerative disease especially sporadic. About 30–40% have positive family history, with an identifiable genetic mutation in a percentage of cases increasing. Although the FTD psychosis has been recognized for many years, it is not included in the clinical criteria.

Objectives To assess the prevalence and characteristics of psychotic symptoms in FTD, compare the presence of psychosis in FTD C9+ versus C9– and analyze the occurrence of wrong diagnoses in FTD with psychosis.

Methods Literature review, using computerized databases (Pubmed®). Articles were selected based on the content of their abstract and their relevance.

Results It is frequently the presence of psychotic symptoms in FTD associated with C9+ versus C9–. These may arise as initial symptom often leading to a psychiatric diagnosis years

before obtaining diagnosis of FTD. There is no conclusive evidence about the anatomical correlation of psychotic features in the FTD, although there is the possible association with the right brain degeneration.

Conclusions The existence of psychotic symptoms do not argue against the diagnosis of FTD verifying a high frequency of psychosis in FTD – C9⁺. As can be the first symptom in FTD is critical to differentiate psychiatric disorders. Further studies are needed in order to obtain a better characterization of psychotic symptoms in FTD – C9⁺.

Relationship between emotional intelligence and neurocognition in severe mental disorders

E. Chapela^{1,*}, I. Morales², J. Quintero^{1,2}, M. Félix-Alcántara¹, J. Correas³, J. Gómez-Arnau³

¹ Hospital Universitario Infanta Leonor, Psychiatry, Madrid, Spain

² Psikids, Psychiatry, Madrid, Spain

³ Hospital del Henares, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction The severe mental disorders are the subject of growing research in the area of emotional intelligence because of his relationship with psychosocial functionality loss. Despite treatment advances, patients continue to experience high levels of social, professional and personal disabilities, related to the presence of deficits in cognition. These changes are manifested in two areas: the neurocognitive and social cognition.

Objectives To better understand the relationship between neuro- and sociocognition in schizophrenia and bipolar disorder.

Aims The aim of this research is to study the factors related to emotional intelligence, with particular interest in neurocognitive deficits.

Methods A total of 75 adult patients with schizophrenia and bipolar disorder type I were evaluated. The assessment protocol consisted of a questionnaire on socio-demographic and clinical-care data, and a battery of clinical and cognitive scales, including MSCEIT, WAIS-IV, TMT and Rey Figure.

Results MSCEIT was negatively correlated with age, the severity of the clinical symptoms (BPRS, CGI-S), the TMT-A and the Test of Complex Figure, and positively with the intelligence quotient.

Conclusions The deficits in emotional intelligence are part of a set of cognitive, social and non-social skills, which are altered in these severe mental disorders. Emotional intelligence worsens with the deterioration of cognitive functioning, executive dysfunction and severity of psychiatric disorder.

Are we able to influence cognitive dysfunction in multiple sclerosis?

E.I. Davidescu^{1,*}, S.A. Nicolae¹, I. Buraga¹, C. Tudose², N. Popa³

¹ University of Medicine and Pharmacy “Carol Davila”, Colentina Clinical Hospital, Neurology, Bucharest, Romania

² University of Medicine and Pharmacy “Carol Davila”, Alexandru Obregia Clinical Hospital of Psychiatry, Psychiatry, Bucharest, Romania

³ Alexandru Obregia Clinical Hospital of Psychiatry, Psychiatry, Bucharest, Romania

* Corresponding author.

Introduction Multiple sclerosis (MS) is the most common chronic neurologic disease affecting young people. Cognitive dysfunction is an important part of disability, interfering with quality of life (QoL). Disease modifying therapies (DMT) are gold standard of long-term treatment in MS.

Objectives Assessment of DMT impact on evolution of cognitive dysfunction.

Aims To analyze the cognitive status in a lot of 74 patients with MS, with a mean age of 40.4 years, treated with different DMT in the National Health Program.

Methods Testing patients during 2014–2015 for cognitive dysfunction, by applying MMSE, Sunderland Clock Test, Beck Depression Inventory, Fatigue Impact Scale and QoL Short form-36 scores every 6 months; analyzing demographic, clinical and magnetic resonance imagery (MRI) data.

Results Thirty-six percent of lot showed memory and concentration changes (12 patients with secondary progressive MS, 15 with relapsing-remitting MS); mean age of these patients was 46.29 years, with a mean period of evolution of the disease of 9.8 years before starting DMT; cortical atrophy was present on MRI in 37% of these patients. Mean age of those who didn't present cognitive disturbances was 37.01 years, with a mean period of evolution of 6.2 years before starting DMT. Disturbances appeared independently of the presence of cortical atrophy, as this marker appeared in 5% of patients with no cognitive dysfunction.

Conclusions When starting DMT, age and time of evolution of the disease are essential for further developing of cognitive dysfunction. Mood and anxiety disturbances can be a prodromal marker of neurocognitive troubles. DMT have neuroprotective outcome in MS.

The effect of interpersonal multisensory stimulation on the self-face recognition in adults with autistic syndrome disorder

N. Deltort^{1,2,*}, J.R. Cazalets², A. Amestoy^{1,2}, M. Bouvard^{1,2}

¹ Centre hospitalier Charles-Perrens, centre ressource autisme, Bordeaux, France

² CNRS, INCIA, UMR 5287, Bordeaux, France

* Corresponding author.

Studies on individuals without developmental disorder show that mental representation of self-face is subject to a multimodal process in the same way that the representation of the self-body is. People with autistic spectrum disorder (ASD) have a particular pattern of face processing and a multimodal integration deficit.

The objectives of our study were to evaluate the self-face recognition and the effect of interpersonal multisensory stimulation (IMS) in individuals with ASD. We aimed to show a self-face recognition deficit and a lack of multimodal integration among this population. IMS consisted of the presentation of a movie displaying an unfamiliar face being touched intermittently, while the examiner applied the same stimulation synchronously or asynchronously on the participant. The effect resulting from IMS was measured on two groups with or without ASD by a self-face recognition task on morphing movies made from self-face and unfamiliar-face pictures.

There was a significant difference between groups on self-recognition before stimulation. This result shows a self-face recognition deficit in individuals with ASD. Results for the control group showed a significant effect of IMS on self-face recognition in synchronous condition. This suggests the existence of an update of self-face mental representation by multimodal process. In contrast, there was no significant effect of IMS demonstrated in ASD group,

suggesting a multimodal integration deficit for the constitution of self-representation in this population.

Our results show the existence of a self-face recognition deficit in individuals with ASD, which may be linked to a lack of multimodal integration in the development of the self-face representation.

Sex differences in the neural basis of theory of mind during development

C. Frank

Fielding Graduate University, School of Psychology, Santa Barbara, USA

Introduction Theory of mind (ToM) is the ability to predict behaviors of others in terms of their underlying mental states. It is carried out in order to make sense of and predict behavior. Impairments in ToM have been found in many psychiatric/neurological disorders including schizophrenia and autism spectrum disorders. Previous research has indicated sex difference in ToM development. Previous research has also found some differences in the neural basis of ToM.

Objectives/aims An objective/aim of the present study was to examine possible sex differences in the neural mechanism associated with ToM development. Another objective was to examine the neural basis of ToM that is shared by both sexes throughout development.

Methods Thirty-two adults (16 women) and 24 children (12 girls) were assessed with fMRI while performing a false belief (FB) task.

Results During the ToM relative to non-ToM condition, adults and children of both sexes showed increased activity in the medial prefrontal cortex (mPFC) and the temporo-parietal junction (TPJ). Both boys and girls recruited more brain regions than adults. Moreover, children employed structures involved in the human mirror neuron system (hMNS) more than adults. More specifically, boys recruited the inferior frontal gyrus (IFG) more than men, while girls recruited the precentral gyrus more than women.

Conclusions These results suggest that boys/men and girls/women employ different brain regions for ToM during development.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ Wroclaw, Poland

² Wroclaw University of Technology, Faculty of Computer Science and Management, Wroclaw, Poland

³ Wroclaw Medical University, Department of Genetics, Wroclaw, Poland

* Corresponding author.

Introduction Humans learn how to behave both through rules and instructions (explicit learning) as well as through environmental experiences (implicit learning). It has been shown that instructions can powerfully control people's choices, often leading to a confirmation bias.

Aim To explore confirmation bias with respect to cognitive functioning in healthy adult participants.

Methods We recruited 25 healthy adult control subjects (9 males, 16 females, age 31.40 ± 6.08 years). Participants completed Repeatable Battery of Neuropsychological Status (RBANSS) as well as Instructed Version of Probabilistic Selection Task (IPST) (Doll et al., 2009).

Results Based on the performance on IPST into two groups: a group with higher and lower susceptibility to confirmation bias. We found no difference between these groups with respect to any of the cognitive domains measured with RBANSS (immediate memory, visuospatial abilities, language, attention and delayed memory) (U Mann-Whitney test, $P > 0.05$).

Conclusion In healthy adults, susceptibility to confirmation bias is independent of cognitive functioning (immediate and delayed memory, visuospatial abilities, language and attention).

⁴ Hospital Ramón y Cajal, Enfermedades Infecciosas, Madrid, Spain

* Corresponding author.

Introduction HIV-related damage of the central nervous system is manifested in varying severity of neurocognitive disturbances. Research on measures of executive functioning has confirmed that HIV infection is associated with progressive difficulties in these abilities. Moreover, several studies in recent years have shown that an impaired cognitive function confers a higher risk of poor adherence to antiretroviral therapy.

Objectives/Aims The aim of this study is to analyze the relationship between executive functions and ART compliance.

Methods We designed a cross-sectional case-control survey. Cases were defined as HIV-infected patients who missing at least 10% intakes in the last year (reported by hospital pharmacy) and self-reported non-adherence by Simplified Medication Adherence Questionnaire (SMAQ). Controls were defined as HIV-infected patients who accomplishing at least last 95% intakes in the last year (reported by hospital pharmacy), and self-reported adherence by SMAQ. Patients with adherences between 90–95% were not included. Executive functions were evaluated with Wisconsin Sorting Card Test. Linear regression was employed as statistical analysis. Results were adjusted for follow-up years. Wisconsin score was already adjusted for gender, age and education level when data were corrected.

Results Our sample was compound by 63 patients: 37 controls and 26 cases. A statistical signification ($P < 0.05$) was found for total correct, total errors, perseverative responses, perseverative errors, conceptual level responses and trials to complete first category score between adherence and non-adherence treatment patients.

Conclusions In our sample worse executive function score, measured by Wisconsin Card Sorting Test, was linked to poor adherence to antiretroviral treatment in HIV patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The prevalence of personality disorders presented an exponential increase in recent decades. However, the increase is due to the advance of psychopathological clinical criteria as well as progress by neuroscientists began to reveal certain aspects and symptom dimensions. To these are added advances in psychopharmacological and psychotherapeutic techniques that have allowed outlining treatment strategies based on evidence reported. From clinical care practice, the various actors within the Mental Health experience a change in demand and the interrelationships of these pictures with psychopathological constructs defined by psychiatry, which put on view updating and sharpness of the professionals in the detection and management of these patients. We cannot ignore the decisive influence of cultural aspects in both the detection and diagnosis and course of these attentive to a dynamic society disorders. These entities have psychodynamic psychopathology and neurobiological bases in constant revision. We propose in this paper an update on the current clinical approach and treatment modalities of personality disorders and psychopathy, focusing on the biopsychosocial rehabilitation of patients and their psychopathology association with criminal behavior, as well as an updating etiology, clinical and therapeutic foundations of personality disorders and psychopathy in view of a changing culture.

Verbal and visual-spatial working memory performance in Arabic monolingual and English/Arabic bilingual Kuwaiti children

F. Khashawi

Kuwait University, Psychology, Kuwait, Kuwait

Introduction Research in psycholinguistics focusing on cognitive processing in bilinguals and the role played by working memory about cognitive processing indicated that Working Memory (WM) was instrumental in cognitive processing in bilinguals, but that its role was different and generally more complex than it was in monolinguals. However, the specific manner in which the use of WM differed between monolinguals and bilinguals was not always clear.

Objectives This research explored the verbal and visual-spatial WM performance in an Arabic monolingual group and a bilingual English/Arabic group.

Methods The participants were 396 Kuwaiti (198 monolingual aged 7.99 ± 1.97 years and 198 bilingual aged 8.03 ± 1.92) with no significant age differences ($t = 0.23$, $P > 0.05$). The two groups were compared on how they performed in the Automated Working Memory Assessment (AWMA), to measure a verbal and visual-spatial WM tasks. The tasks were Listening Recall, Counting Recall, Mr. X, Backward Digit Recall, Odd-one-out and Spatial Span. All tasks were internally consistent (Alpha = 0.91, 0.93, 0.87, 0.88, 0.87, and 0.91 respectively). The data was analyzed using Independent Sample *t* Test.

Results The findings showed that there was significant group difference as the monolingual Arabic group (L1) performed better than bilingual English/Arabic group (L2) on both of verbal WM ($t = 3.25$, $P < 0.002$) and visuospatial WM ($t = 3.04$, $P < 0.002$).

Conclusion The monolingual children obtained higher scores on both verbal and visuospatial WM. These findings were explained in terms of the complexity of the Arabic language and cultural context in which the second language is being practiced. This warrants further investigation.

Cognitive impairment in patients with epilepsy and effectiveness of overcoming stress behavior

V. Korostiy*, B. Gerasimov

Kharkiv national medical university, Psyhyatry, narcology and medical psychology, Kharkov, Ukraine

* Corresponding author.

Introduction Today cognitive impairment study epilepsy in children and in people taking anticonvulsants. Unfortunately, we do not know enough about neuropsychological features of mild cognitive impairment in epilepsy, clinical and pathogenetic patterns of their development, role in the development of social exclusion.

Aim To study the mild cognitive impairment and their relationship with clinical features of epileptic disease forms, socio-psychological characteristics of patients.

Methods Clinical-psychopathological, psychodiagnostic.

Results We first used Addenbrooke's cognitive examination (ACE-R) in patients with epilepsy to quantify cognitive disorders in this group. The specified scale detects violations of cognitive function to mild dementia and allows us to differentiate the prevalence of certain disorders of mental processes. We revealed that the reducing the effectiveness of stress overcoming behavior through cognitive disorders in thinking and attention are one of the pathogenomic psychogenic mechanisms of affective disorders in patients with epilepsy. The complex of individual therapeutic measures for patients with epilepsy and MCI is based on the study features of cognitive disorders results. Psychotherapy and psychological correction measures for patients with epilepsy and MCI have to improve the social functioning and quality of life. We also created recommendations for the prevention of cognitive disorders in patients with epilepsy.

Conclusions The features of cognitive disorders in patients with epilepsy, depending on the clinical form of epilepsy (symptomatic, idiopathic, cryptogenic). It should be used as additional differential diagnostic criteria forms of epilepsy (symptomatic, idiopathic, cryptogenic).

Disclosure of interest The authors have not supplied their declaration of competing interest.

The syndromic approach to the rehabilitation of the higher mental functions (HMF) of patients with progressive cognitive disorders in L.S. Vygotsky–A.R. Luria School

M. Kovyazina^{1,*}, Y. Zinchenko², N. Varako²

¹ Moscow original, Mytishchi, Moscow, Russia

² Moscow State University, Psychological, Moscow, Russia

* Corresponding author.

Background The method of “rehabilitation training”, developed in the Soviet psychology, based on the idea that the human HMF are realized in complex functional systems, developed during cultural- and ontogenesis.

Aims To show the importance of the development of approaches to the rehabilitation of HMF in Luria’s neuropsychology.

Methods The disturbances in brain activity leads to the neuropsychological syndrome appearance that could be called self-developing system. According to the systemic principles, each neuropsychological syndrome HMF disorders in accordance with brain injury localisation has the common “cause” – destroyed neuropsychological factor. In the case of patients with dementia several neuropsychological factors are usually included. So the rehabilitation processes should be aimed at the maximum preserved and strengthened stereotypes and behavior strategies in past experiences.

Results The binary syndrome structure (set of symptoms of destroyed neuropsychological HMF and abnormal neuropsychological factor itself) allows us to define two strategies of neuropsychological rehabilitation programs. The first strategy involves choice as a “target” of the most destroyed mental function. The second strategy could be directed to the rehabilitation of abnormal neuropsychological factor that should be accompanied by the rehabilitation of several systemic interrelated mental functions. Recourse to past knowledge, interests and emotionally important topics is assisting and supporting the rehabilitation processes.

Conclusions Use of both strategies ensures targeted restoration of cognitive functions within Vygotsky-Luria approach.

* Corresponding author.

Introduction Comprehensive language testing shows a strong relationship between overall severity of cognitive decline and language deficit. Moreover, the language performance can be affected also by neuropsychiatric symptoms of dementia.

Aim To detect the language deficits in sentence comprehension in patients with MCI and dementia and to determine the relationship between them, the severity and the structure of cognitive impairment and independently between them and BPSD.

Method In the sample of 46 cognitively declined patients (MCI and dementia, majority of them with Alzheimer’s disease), we evaluated the severity and the structure of cognitive impairment by means of MoCA instrument, language deficits by our own sentence comprehension test and BPSD by means of NPI-Q.

Results The average performance in the sentence comprehension test was about 90% of normal in the group of MCI patients, about 75% in mild, about 60% in moderate and only about 20% in the group of severe dementias. According to individual cognitive domains, their impact on language performance was different. We found a strong correlation between the overall severity of BPSD and the language performance, too.

Conclusion At earlier stages of cognitive disorders/dementias, the language specific test should be used to discover comprehension deficits, because at the simple level of word the language skills are preserved. BPSD are also associated with language deficits even when the severity of dementia is controlled for. Identification of these communication disturbances can help to detect cognitive decline earlier and to start preserving treatment in time.

Dementia due to HIV infection: Case report

R. Almeida Leite*, C. Gama Pereira, E. Conde, T. Queirós Santos, M. Almeida, T. Azevedo Santos, A. Mesquita Figueiredo
Baixo Vouga Hospital Centre, Psychiatry and Mental Health Department, Aveiro, Portugal

* Corresponding author.

Introduction The majority of HIV infected patients exhibit central nervous system disorders. The most severe is dementia, which is the most common cause of non-traumatic dementia in young patients. It may affect the progression of the disease, compromising the adherence of treatment and increasing the mortality rate.

Objectives Report of a clinical case of dementia due to HIV infection in a 33-year-old male patient, admitted in the Acute Inpatient Unit of the Psychiatry and Mental Health Department in Baixo Vouga Hospital Centre.

Methods The results were gathered based on the clinical history of the patient, his objective exam, diagnostic exams and family information and from medical research included on PubMed and Google Scholar platforms.

Results The patient presented evident cognitive deterioration with memory loss, attention and concentration deficits, apathy, indifference, psychomotor retardation and behavioral changes in the past few weeks, with a significant impact in his life. The patient did supplementary diagnostic tests, which showed progressive multifocal leukoencephalopathy and global and diffuse cortical atrophy involving the fronto-temporal regions and a neuropsychological assessment whose results confirmed a moderate cognitive deficit. During the hospitalization there was a positive stabilization of behavior with antiretroviral therapy and antipsychotics.

Conclusion The lack of knowledge about the factors that predispose dementia in HIV patients is a relevant limitation nowadays. The clinical effectiveness of antiretroviral therapy has improved in recent years with a reduction in the prevalence of HIV dementia, which now is estimated at 10%.

³ Interdisciplinary Center IDC, Sagol Center for Brain and Mind- Baruch Ivcher School of Psychology, Herzliya, Israel

* Corresponding author.

Emotions of others can be highly contagious, affecting one’s own emotional and neural responses. Yet, the neural mechanisms

underlying interpersonal emotional transmissions have been mainly studied using static images in non-social setups. Here, we investigated how the human brain responds to dynamic emotional input, coming from another, co-present individual.

Using an innovative approach developed in our lab, we provided participants with continuous emotional feedback from another participant while they watched emotional movie in the fMRI scanner. To disentangle between the socially-driven and stimulus-driven effects, we introduced a control group, in which participants received identical stimulus, but thought that the feedback is generated by a computer algorithm.

We mapped the brain regions, which exhibited reliable activity in the experimental and control groups. In addition, we assessed neural response synchronization with the time-course of the social-emotional feedback and compared it across groups.

Comparing the experimental and the control groups, we found that response time-courses in the bilateral insula, amygdala, thalamus and dorsal MPFC exhibited moment-by-moment alignment with the feedback time-line. In addition, right lateral prefrontal regions were reliably recruited in the experimental (social) but not in the control (non-social) groups. Finally, synchronization with the feedback in the right amygdala and in the MPFC was strongly associated with the emotional effects of the feedback, reported after the experiment.

Taken together, our results suggested that continuous processing of emotional input from others shape one's own responses by evoking response synchronization in the core emotion brain regions and recruitment of prefrontal emotion regulation mechanisms.

* Corresponding author.

Introduction Alexithymia is a multifactorial personality trait observed in several mental disorders, especially those with poor social functioning. Although it has been proposed that difficulties in interpersonal interactions in highly alexithymic individuals may stem from their reduced ability to express and recognize facial expressions, this still remains controversial.

Aim In everyday life, faces displaying emotions are dynamic, although most studies have relied on static stimuli. The aim of this study was to investigate whether individuals with high levels of alexithymia differed from a control group in the categorization of emotional faces presented in a dynamic way. Given the highly dynamic nature of facial displays in real life, we used morphed videos depicting faces varying 1% from neutral to angry, disgust or happy faces, with a video presentation of 35 seconds.

Method Sixty participants (27 males and 33 females) were divided into high (HA) and low levels of alexithymia (LA) by using the Toronto Alexithymia Scale (TAS-20). Participants were instructed to watch the face change from neutral to an emotion and to press a keyboard as soon as they could categorize an emotion expressed in the face.

Results The results revealed an interaction between alexithymia and emotion showing that HA, compared to LA, were more inaccurate at categorizing angry faces.

Neuro-Behçet's psychiatric symptoms

F. Maduro^{1,*}, S. Neiva², C. Pissarra¹, F. Duarte¹, L. Marques¹

¹ Centro Hospitalar Universitário de Coimbra, Serviço de Psiquiatria, Coimbra, Portugal

² Centro Hospitalar Universitário de Coimbra, Serviço de Pedopsiquiatria, Coimbra, Portugal

* Corresponding author.

Neuro-Behçet (NB) results from inflammatory peri-vasculitis affecting the central nervous system. Non-specific neurological and psychiatric symptoms are rarely the first presentation and may difficult or delay diagnosis and treatment.

We review, based on a case study and published literature, the psychiatric symptoms of NB when no clear evidence of neurologic disease activity is present.

We present the case of a female patient, who was diagnosed NB at age 23 for recurrent meningo-encephalitis, that showed progressive behavioral changes, with increased impulsivity, disinhibition, hostility and self-neglect.

Raised in a dysfunctional family, she ran away from home at 16, abandoned her studies, started abusing cannabinoids and showed an erratic life course.

In 2015, because of increasing psychiatric symptoms, she was admitted to hospital and a complete neuropsychological evaluation showed that she had a significant decline from an above average premorbid cognitive function, specifically related to memory deficits. CT and MRI didn't show typical signs of active disease. However, a SPECT scan showed hypo-perfusion of the frontal cortex compatible with the patient's symptoms.

It is difficult to assess NB's activity as brain inflammation is only observed after structural changes are present. In this case the SPECT correlated well with psychiatric symptoms. The differential diagnosis includes organic pathology with psychiatric symptoms, psychiatric disease, personality disorders and substance abuse.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Transcatheter laser treatment of Binswanger's disease

I. Maksimovich

Clinic of Cardiovascular Diseases named after Most Holy John Tobolsky, interventional neuroangiology, Moscow, Russia

Introduction Due to increasing lifespan, the number of patients with Binswanger's disease is growing. The study of the effectiveness of brain transluminal laser revascularization in the treatment of Binswanger's disease.

Methods Fourteen patients, 9 male (64.29%) and 5 female (35.71%), aged 58–81 (average age 77) with Binswanger's disease were examined. Each patient underwent CDR, CT, MRI, SG, REG, cerebral multi-gated angiography (MUGA).

Single postischemic microcysts (3–4 mm) of brain's white matter were detected in 1 case; multiple microcysts including the merged ones – in 13 cases. All the patients had leucoarosis, involutive changes of the cerebral cortex, unocclusive hydrocephalus. Intracranial atherosclerotic lesion type was detected in all cases. Multiple arteriovenous shunts of brain's white matter were detected in all cases. All the patients underwent transcatheter laser

revascularization. Low-energy laser systems were used for revascularization of distal intra cerebral branches. Postoperatively, the patients underwent desagrigatory, anticoagulatory and vasodilator therapy following advanced interventional radiology schemes. Clinical evaluation of postoperative results was carried out using the CDR.

Results Good immediate angiographic outcome manifested in the restoration of lumen and patency of the affected vessels as well as in collateral revascularization was obtained in all cases:

– good clinical outcome (no dementia) was obtained in 6 (42.86%) cases;

– satisfactory clinical outcome (dementia reduction) – in 8 (57.14%) cases;

– no negative effect was observed after the interventions.

Conclusions The method of brain transcatheter laser revascularization is an effective one in the treatment of atherosclerotic lesions of brain's white matter accompanied by the development of Binswanger disease.

Inconsistent decline of executive functions in patients with early and late Huntington's disease

S. Mörtl*, C. Blesl, A. Tmava, W. Wurm, A. Holl, A. Painold
Medical University of Graz, Psychiatry, Graz, Austria

* Corresponding author.

Background Huntington's disease (HD) is characterized by executive dysfunctions like problems with planning, accuracy, inhibition and impulsivity. During the course of the disease executive function worsens with ongoing pathological changes in the basal ganglia. However, it is not clear whether cognitive dysfunction develops gradually or not during the course of the disease.

Methods We assessed the development of executive dysfunction in 23 patients with early HD and 29 patients with late HD on the Tower of London (ToL) for the number of solved problems, planning time and number of breaks.

Results HD patients showed a linear decrease of accuracy (as assessed by number of solved problems) during the course of the disease. Controls scored significantly higher than early stage HD patients and early stage HD patients scored significantly higher than late stage HD patients. In planning time and number of breaks a non-linear decrease was found.

Conclusion Executive dysfunctions in HD are not alone connected to degenerative changes in the striatum as they do not develop gradually and linear during the course of the disease. Obviously, executive function could not be seen as a single component, but as a combination of different abilities, which show a non-linear and non-parallel decline.

Neuropsychiatric manifestations of vitamin B12 and folate deficiencies: Data from an inpatient psychiatric department

A. Mota^{1,*}, M. Lázaro¹, R. Alves¹, A. Moreira², M. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

² Hospital de Dona Estefânia, Pedopsychiatry, Lisboa, Portugal

* Corresponding author.

Introduction The prevalence of vitamin B12 and folate deficiency is significant in the psychiatric population. These deficiencies may be associated with varied neuropsychiatric signs and symptoms, caused by different pathophysiological mechanisms.

Objectives Characterize the main neuropsychiatric signs and symptoms associated with vitamin B12 and folate deficiencies. Evaluate the prevalence of these vitamins deficiencies in an acute inpatient psychiatric department, dedicated to Affective Disorders.

Aims To review the clinical significance of vitamin B12 and folate deficiencies in psychiatric disorders and reflect on the importance of routine screening in mental health care.

Material and methods Observational, retrospective and descriptive study, with analysis of clinical and blood tests data concerning the total number of inpatient episodes in 2015. Non-systematic review of the scientific literature.

Results A small case series of the patients that had folate or B12 deficiency detected is presented. The prevalence of vitamin B12 and folate deficiencies found in our study is in accordance with the data found in the literature.

Conclusions Vitamin B12 and folate deficiencies should be considered in the approach to the psychiatric patient as its neuropsychiatric manifestations are varied, can be severe, and may constitute a potentially treatable cause of mental disorder. Our data shows that folate and B12 deficiencies are significant in inpatients and we believe it justifies routine screening at admission.

The association between childhood trauma and facial emotion recognition in patients with stable schizophrenia

J. Mrizak*, A. Arous, R. Trabelsi, A. Aissa, H. Ben Ammar, Z. El Hechmi

Razi Hospital, Psychiatry F, Mannouba, Tunisia

* Corresponding author.

Introduction The impairment of facial emotion recognition (FER) among patients with schizophrenia (SCZ) is a significant feature of the illness. Childhood trauma (CT) is reported with a high prevalence in SCZ and is considered one of its risk factors.

Objectives To investigate the relationship between FER and CT in SCZ.

Methods Fifty-eight outpatients with stable SCZ completed the Childhood Trauma Questionnaire retrospectively assessing five types of childhood trauma (emotional, physical and sexual abuse, and emotional and physical neglect). They also completed a newly developed and validated FER task constructed from photographs of the face of a famous Tunisian actress and evaluating the ability to correctly identify Ekman's six basic facial emotions (happiness, sadness, anger, disgust, fear and surprise).

Results Patients with higher scores of CT performed significantly worse in FER task. Our results suggest that the presence of sexual abuse is specifically correlated to a poor identification of anger ($P=0.02$) and disgust ($P=0.03$) while the presence of emotional abuse and physical neglect are correlated to a poor identification of happiness and sadness.

Conclusions CT may represent one of the causes of the FER deficits in schizophrenia. Further studies are necessary to confirm the link between specific kinds of childhood trauma and deficits in the recognition of discrete emotions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

From clinical cases to clinical research: Neurocognition and social cognition in schizophrenia

I. Gurovich, O. Papsuev*, A. Shmukler, L. Movina, Y. Storozhakova

Moscow Research Institute of Psychiatry, Outpatient Psychiatry and Organization of Psychiatric Care, Moscow, Russia

* Corresponding author.

Introduction Neurocognition and social cognition are the core deficits influencing social outcomes in patients with schizophrenia. These deficits are present in prodromal phase and throughout the illness, in first-degree relatives and are considered in the framework of neurodevelopmental or neurodegenerative models.

Method Four clinical cases with patients reflecting different cognitive profiles were chosen to demonstrate heterogeneity of cognitive biases and their influence on the social function *en vivo*. The patients have undergone a number of neurocognitive and social cognitive measures.

Results In these four patients, we would like to highlight the dissociation of neurocognitive deficits, clinical manifestations and social functioning. Social cognitive measures revealed heterogeneity of biases in different domains. As a result of our observation, we can hypothesize that better social functioning was achieved by patients with better abilities to discriminate negative emotions and states of mind in others.

Conclusion Despite certain limitations of case-report studies, it is hard not to point out heterogeneity and incoherence of social and neurocognition. We assume that intact domains of Processing of Emotions and Theory of Mind predispose to better social functioning, while it's hard to trace this connection to neurocognition. This result needs to be challenged on large samples in future research, concerning emotionality in Theory of Mind and capacity for empathy and its' role in social functioning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ VUmc, Department of Psychiatry and Neuroscience, Amsterdam, Netherlands

⁴ Antwerp University Hospital, University Department of Psychiatry, Antwerp, Belgium

⁵ VUmc, EMGO Institute of Health and Care Research, Amsterdam, Netherlands

* Corresponding author.

Introduction The literature on the neurobiology of emotional processing in panic disorder (PD) remains inconsistent. Clinical heterogeneity could be causing this.

Objective To investigate differences in brain activity between PD and healthy controls using the emotional faces fMRI paradigm.

Aims To elucidate neurobiological mechanisms underlying emotional processing in PD and previously identified subtypes (Pattyn et al., 2015).

Methods The main analysis compared the neural processing of different emotional facial expressions from a large group of PD

patients ($n = 73$) versus healthy controls ($n = 58$) originating from the Netherlands Study of Depression and Anxiety (NESDA). A second analysis divided the PD group into the three previously identified subgroups: a cognitive-autonomic ($n = 22$), an autonomic ($n = 16$) and an aspecific subgroup ($n = 35$). The fusiform gyrus, the anterior cingulate cortex and the insula were used in a ROI approach.

Results Comparing PD patients with healthy controls, a decreased activity on angry faces was observed in the left fusiform gyrus. The subgroup analysis showed more activity in the anterior cingulate cortex on neutral faces in the cognitive-autonomic subgroup versus the autonomic subgroup and a decreased activity in the left fusiform gyrus on angry faces compared to the aspecific subgroup. Less activity was observed in the right insula on neutral faces in the autonomic subgroup versus the aspecific subgroup.

Conclusion Reduced activity in the left fusiform gyrus was differentiating panic disorder patients from healthy controls. In accordance with clinical subtyping, between-subtype differences are an indication that a phenomenological approach could provide more insight in underlying neurobiological mechanisms in emotional processing in PD.

The advantage of fear stimuli in accessing visual awareness

N. Gomes¹, S. Silva², C. Silva³, J. Azevedo^{4,*}, S. Soares^{3,5}

¹ Portuguese Catholic University, Institute of Health Sciences, Lisboa, Portugal

² University of Aveiro, DETI/IEETA, Aveiro, Portugal

³ Center for Health Technology and Services Research, University of Aveiro CINTESIS-UA, Department of Education, Aveiro, Portugal

⁴ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

⁵ Karolinska Institutet, Department of Clinical Neuroscience, Division for Psychology, Sweden, Sweden

* Corresponding author.

Introduction Several studies have shown that evolutionary relevant fear stimuli hold a privileged access to the fear module, an independent behavioral, psychophysiological and neural system that is automatically and selectively activated, and is relatively encapsulated from more advanced human cognition. However, to the best of our knowledge no study has yet directly assessed whether such stimuli are granted a facilitated access to visual awareness, compared to stimuli without such evolutionary relevance.

Objective In the present study we used an interocular suppression technique, the Continuous Flash Suppression, known to reduce the activity along the geniculostriate pathway and to strongly suppress processing in the visual cortex.

Aim Our goal was to investigate whether ecologically relevant fear stimuli (snakes and spiders) overcame suppression and accessed awareness to a larger extent than non-evolutionary relevant animal stimuli (birds).

Method Thirty university students volunteered to participate. Participants were asked to identify the screen quadrant in which the stimulus was presented in order to ensure that there was indeed a conscious processing.

Results The results confirmed our hypothesis by showing an advantage of fear stimuli (snakes and spiders) over the control stimulus (birds) in emerging from suppression into awareness, which was evidenced by significantly shorter response times.

Conclusions Our findings support the notion that evolutionary relevant stimuli hold a privileged access into awareness, most likely involving a direct brainstem-thalamic route to the amygdala.

Importantly, they contribute to elucidate the functions and mechanisms of the fear system and may have important implications for understanding emotional disorders, since many of these involve the fear system.

Alterations in retinal processing in regular cannabis users

R. Schwan^{1,*}, T. Schwitzer^{1,2}, A. Giersch², V. Laprevote¹

¹ CPN Laxou, Psychiatry, Nancy, France

² Inserm U1114, Psychiatry, Strasbourg, France

* Corresponding author.

Introduction Cannabis is one of the most prevalent drugs used worldwide. However, the neural consequences of cannabis remain poorly understood. There is a need for a rapid improvement of the scientific knowledge on the cerebral impact of cannabis use. Since the retina is an easy-to-access part of the central nervous system, it can reflect the neurochemistry of the brain.

Objectives Considering the anatomical and functional distribution of the cannabinoid system in the retinal ganglion cells, the objective of this study was to assess whether the regular use of cannabis could affect the ganglion cells functioning.

Aims Assessment of the ganglion cells function in regular cannabis users compared to healthy controls.

Methods Recordings of pattern electroretinogram (PERG) were performed in regular cannabis users and healthy controls using standard of the International Society for Clinical Electrophysiology of Vision (ISCEV). The amplitude and implicit time of the PERG N95 were assessed.

Results The N95 implicit time of PERG was significantly decreased in regular cannabis users compared to healthy controls.

Conclusions We found alterations in the ganglion cells function in regular cannabis users, as showed by the increase in N95 implicit time. The ganglion cells represent the ultimate retinal relay before the visual information is relayed to the brain and, according to these results, we suppose that the signal elicited by these cells and transferred through the visual pathways is altered in cannabis users. A direct action of exogenous cannabinoids in the retinal glutamatergic transmission is discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Cognitive dysfunction in patients with systemic lupus erythematosus affects 10–36% of them.

Objective To determine a profile of selected cognitive functions in systemic lupus erythematosus.

The aim To investigate and characterize selected cognitive parameters in patients with systemic lupus erythematosus (SLE) using a standardized, comparable and reproducible computer-based method.

Material and methods The study included 25 patients with SLE. For neuropsychological assessment, the Cambridge Neuropsychological Test Automated Battery was used. Following parameters were investigated: mean latency and mean error in motor screening (MOTML, MOTME), big little circle (BLC), paired associated learning (PAL), problems solved in minimum moves in stockings of Cambridge (SOC PSMM) and graded naming test (GNT). Results were referred automatically to determined ranges of norms matched according to age and gender.

Results In patients with SLE results displayed by median and upper and lower quartiles were as follows: MOTML = 1.1 (0.9–1.34), MOTME = 0.41 (0.31–0.52), BLC = 0.16 (0.16–0.18), PAL = –0.43 (–1.28; –0.18), SOCPSMM = –0.62 (–1.19–0.04), and GNT = –0.8 (–1.6; –0.32).

MOTML correlated negatively with MOTME ($r = -0.51$), MOTME correlated with SOCPSMM ($r = 0.41$), and PAL correlated with GNT ($r = 0.48$) ($P < 0.05$).

Conclusions In our study, predominant abnormalities were those related to lexical and semantic memory, revealed by the GNT, spatial planning and spatial working memory, assessed by the SOC, together with visual memory and new learning, assessed with the PAL.

Laser test for identification of latent tremor at alcohol and drug addiction

I. Sosin*, Y. Chuev, O. Goncharova

Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

* Corresponding author.

Introduction Distinctness of tremor in abstinent disorders at alcohol and drug addiction are polymorphous in expressiveness degree, localization, typical dynamics of growing from latent, subclinical to big swing tremor of fingers.

Aims and objectives To elaborate the differentiated diagnosis method for tremor in drug addicts to solve examination and medical problems in clinical narcology.

Method The new method of expert diagnosis of latent tremor in narcology with complex examination of the respondent's capacity to complete test tasks for the precisement of purposeful sensorimotor movements and operations coordination with laser test was introduced. Laser beam pointer visual manual guidance at 2–3 meter distance standard target and the beam fixation at the centre ("top ten") reveals the patient's capacity within 5–10 seconds. Laser light spot trembling appearance out of "top ten" circle while twice-thrice completing the test is considered the positive result and tremor severity is evaluated depending on the beam vibration amplitude.

Results Twenty-five alcohol and 25 drug addicts were examined. Visually, tremor presence and severity coincided with testing results entirely. Ability to keep beam in "top ten" area demonstrated tremor absence; laser spot vibration over "top ten"—the latent tremor; laser spot trembling within circles 9–10 – the moderate tremor; within the 6th–4th circles – medium severity; from 3rd–1st and 0th circle – the severe tremor is identified.

Conclusions The method allows to increase the diagnosis efficiency and tremor identification at narcological diseases that gives

opportunity to solve definite differential diagnostic problems in the expert centers for intoxication states examination.

Problems of activation of attention psychophysiological functions and peripheral visual perception of traffic lights color analogues

I. Sosin*, Y. Chuev, O. Goncharova

Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

* Corresponding author.

Introduction Statistical data prove that the most traffic accidents happen at the traffic lights controlled crossings predominantly due to decreased attention at permanently changing traffic lights triad and narrowing traffic parameters panoramic view.

Aims and objectives To develop method optimizing human psychophysiological functions (perception, attention, peripheral vision, operative memory) as integral base for most intellectual functions.

Method The new approach for psychophysiological functions activation consists of addition of the traffic lights complete color gamut to the famous Schulte test (1–25 numbers depicted in black at consequently changing red, yellow and green background in cells).

Results Two groups each of 25 respondents were examined. New technology on modified Schulte table (once–twice a day 25–30 min exercise repetition for 7–10 days) was used in the main group. Traditional (black-and-white) Schulte tables were applied in control group. Training efficiency in the main group 2.1 times exceeded this in control group. Thus, the main group respondent's ability for high operation speed in attention (average evaluation) was reached after the 3-day training while in the control group—by 6th day. Considerably quicker the main group could demonstrate the ability for panoramic perception of traffic lights color analogues and identification of ordinal numbers in modified Schulte table. It has been established that modification of Schulte tables improves intensity, volume, concentration, stability, distractibility of attention and mobilization of memory.

Conclusions The elaborated method allows to concentrate at information aspects of traffic, isolate the external stimuli, control the own activity in anti-accident paradigm and traffic safety.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Impairment in cognitive performance is an important characteristic in many psychiatric illnesses, such as Bipolar Disorder and Major Depressive Disorder. Initially, cognitive dysfunctions were considered to be present only in acute depressive episodes and to improve after symptoms recovered. Reports

have described persistent cognitive deficits even after significant improvement of depressive symptoms.

Aims/Objectives We wanted to understand the dimension of cognitive impairment in unipolar and bipolar depression and also to underline the differences between cognitive profiles of patients diagnosed within the two mentioned disorders.

Method This review examined recent literature about unipolar and bipolar depression.

Results Both depressed patients presented cognitive deficits in several cognitive domains. Different aspects of attention were altered in both patients but impairment in shifting attention appeared specific to unipolar disorder while impaired sustained attention was particular for bipolar disorder. Both types of patients showed memory deficits that were associated with poor global functioning. Two recent studies described that bipolar depressed subjects were more impaired across all cognitive domains than unipolar depressed subjects on tests assessing verbal memory, verbal fluency, attention and executive functions. The most consistently deficits were displayed on measures of executive functioning – such as tasks requiring problem solving, planning, decision making – suggesting that this cognitive domain is a trait-marker for depression.

Conclusions Cognitive deficits are present in both disorders during a depressive episode but they display slightly different patterns of impairment.

Clinical neuroscience and psychosocial rehabilitation

A.G. Vaccaro*, F. Manfrin, C. Zoppellaro, A. Catania
Comunità TESEO, Crest, Milan, Italy

* Corresponding author.

There is a physical world and a world of meanings, symbols and social relationships. Neuroscience considers brain as a biological machine. Social science studies the human relationships.

Nowadays we know cerebral processes underlying several aspects of social behavior.

Cerebral damages or dysfunctions can influence the social behavior, as well as the social experiences can shape the development, structuring and functioning of the brain and, consequently, condition the further responses of the individuals to the social events. Humans are embodied subject. In an objective sense we are bodies with a brain, in a subjective sense we are individuals in a social world. This is a relevant matter for all the medical sciences, not only for psychiatry.

The real-life functioning of individuals with schizophrenia shows deficits in several daily-life abilities, in social relationships and in the work activities. According to literature and clinical practice, basic criterions are: bio-psycho-social vulnerability, stressful life events, coping strategies as well as social and relational competence.

Neurocognitive activity shows a straight correlation, albeit indirect, with the real-life functioning. Positive symptoms, negative symptoms and disorganized behavior can considerably influence the real-life functioning. While social and relational competence, the general functioning and resilience are protective factors that can positively condition real-life functioning. Moreover, welfare services (i.e. assisted job placement; disability subsidies; etc.) and a good family and social network can considerably influence the results.

According to the results above, we can affirm the importance to adopt integrated and personalized therapeutic-rehabilitative program for the treatment of schizophrenia and other serious mental disorders.

Neuropsychological rehabilitation training in residential mental health services

A. Vaccaro*, A.S. Cusmai, A. Catania, C. Zoppellaro, F. Manfrin
Comunità TESEO, Crest, Milan, Italy

* Corresponding author.

The neuropsychological rehabilitation in our mental health service is a central pillar of psychosocial rehabilitation. These interventions are integrated into a more complex program of psychosocial rehabilitation based on cognitive behavioral method.

We devote particular attention to the empowerment of the cognitive functions: attention, memory, language, logical and abstract reasoning.

The aim of this research is to evaluate efficacy of neuropsychological rehabilitation training in cognitive rehabilitation of psychotic patients.

The subjects that took part to the training were psychotics patient, residents in a mental health Community. Patients were both females and males, aged between 18 and 55 years. They were divided in two experimental groups and a control group. The instrument used was a battery of neuropsychological standardized tests. Tests were managed by an eye-tracker specialist.

Preliminary results seem to confirm a certain degree of improvement due to the training. Eye tracking integration during assessment appears to be a powerful tool as well, in order to define more patient-tailored strategies.

The training based on the empowerment of cognitive functions (attention, memory, language, logical and abstract reasoning) seems to change significantly the cognitive functions of the psychotic patients.

The role of mirror neurons in autism impairment

M.D.L. Guedes Neta¹, C. Varanda^{2,*}

¹ Paulista University, Human Sciences, Santos, Brazil

² University of São Paulo, Department of Physical Therapy, Speech-Language Pathology and Audiology, and Occupational Therapy, São Paulo, Brazil

* Corresponding author.

Introduction The discovery of mirror neurons, considered to be responsible for empathy, intrigued researchers all over the world. Many studies have been developed associating mirror neurons to the incidence of Autism Spectrum Disorder (ASD).

Objective Identifying a possible influence of mirror neuron in autism.

Aims Reviewing the recent trajectory of neuroscience in relation to the connection of impaired mirror neurons in autism.

Method Bibliographical review of studies in English, published in SciELO and LILACS databases, between 2008 and 2013. The keywords used were: autism, brain, cortex and mirror neuron.

Results Different subjects explored the influence of mirror neurons in autism as shown below (Fig. 1). Among 17 studies, 12 were bibliographical reviews and 5 involved experiments. Seventy-six percent of the studies were favorable to the influence of these neurons, while 24% were not.

Conclusion There was a balance in the distribution of themes explored in the articles and few studies exploring the role of mirror neurons in autism. Even though the current research may not be conclusive, it can be said that currently neuroscientists tend to agree that mirror neurons significantly influence ASD. Recent studies suggest that, if properly stimulated, ASD individuals can develop their social skill and, consequently, be socially inserted. According to most author studied, technological development is needed in order to enable scientific advances involving mirror-neurons and ASD.

Fig. 1 Percentage of themes explored in the studies.

Psychodynamic intervention in brief psychotherapy

M. Viederman^{1,2}

¹ Weill Cornell Medical College, Emeritus Professor of Psychiatry, New York City, USA

² Training and Supervising Psychoanalyst, Columbia Psychoanalytic Center for Training and Research, Columbia University, Columbia, USA

This paper will describe a framework for an intensive psychotherapeutic intervention useful in consultation and its extension in brief psychotherapy. The approach is designed to address symptomatic expressions of distress that arise as the expression of unconscious conflict provoked by situations of crisis. It may also be a model for selected patients in longer therapies that address ongoing problems. This therapeutic approach has elements familiar to any experienced therapist, but is specific in its conceptualization. What distinguishes this therapy from others is the induction and utilization of a special positive quality in the therapeutic relationship as a therapeutic aim and “curative factor” in its own right beyond its role as the substrate for a trusting relationship that underlies all successful psychotherapeutic elements. This involves a specific strategy and technique designed to develop a “benevolent transference” to effect change, sometimes to achieve symptom relief, sometimes as a precursor to meaningful insight. In this respect the relationship, considered to be a central feature of the therapy, compliments

understanding as a vehicle for change. A variety of interventions are described to facilitate this process and are illustrated in case presentations.

This presentation is a synthesis of a number of papers on active engagement of the patient in psychodynamic psychotherapy. Two DVDs that illustrate this approach in consultations with patients are available for presentation. One is a three-session psychotherapy with an eight-month follow-up. The patient interviews are edited and may be the focus of separate sessions.

Tardive dyskinesia: When one should suspect of another diagnosis?

R. Almendra^{1,*}, A.R. Figueiredo², V. Espirito Santo¹, A. Almeida¹, P. Guimarães¹, A.G. Velon¹

¹ Centro Hospitalar Trás-os-Montes e Alto Douro, Neurology, Vila Real, Portugal

² Centro Hospitalar Trás-os-Montes e Alto Douro, Psychiatry, Vila Real, Portugal

* Corresponding author.

Introduction Tardive dyskinesia is a collection of symptoms related to the side effects of neuroleptic medications that can mimic other types of disorders. Accurate diagnosis can be challenging, as there is no single test for tardive dyskinesia.

Case report Female patient, 64 years old, with personal history of Chronic Myeloid Leukaemia and psychosis since forth decade, currently medicated with quetiapine 350 mg/day, risperidone IM 50 mg 15/15 days and trazodone 150 mg/day (previously medicated with haloperidol, amisulpride and olanzapine). She started with involuntary movements interpreted as tardive dyskinesia after 2 years on neuroleptic treatment. The difficult control of involuntary movements motivated the reference to ambulatory Neurology department. The review of personal history suggested a family history of involuntary movements and psychiatric illness. Physical examination showed generalized choreic movements. The analytical and imagiologic study was unremarkable. The presence of family history and involuntary movements atypical to be classified as tardive dyskinesia supported a genetic test for Huntington's disease who detected a CAG expansion with 43 repetitions in *HTT* gene. Despite treatment with amantadine and riluzole she maintains disease progression and evident cognitive deterioration.

Conclusion The diagnostic process of involuntary movements may involve more than one physician and requires the review of a detailed medical history, a physical examination and a neuropsychological evaluation in order to determine whether one is indeed suffering from tardive dyskinesia or a different neurological disorder.

Toxic consumption among patients suffering delusional disorder

C.M. Carrillo de Albornoz Calahorra*, A. Porras, M. Guerrero, J. Cervilla Ballesteros

Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

* Corresponding author.

Introduction Several epidemiological studies describe the association between substance abuse and appearance of psychotic symptoms. There is a higher prevalence of psychotic symptoms among cannabis and cocaine consumers compared to the general population.

The cannabinoid receptors regulate the release of dopamine and cocaine has a strong inhibitory action on reuptake of the same. This may explain the greater proportion of subjects moderately or heavily dependent on cocaine or cannabis experience symptoms of psychotic sphere.

Objectives/Aims Describing the profile of drug consumption among a group of patients diagnosed with delusional disorder.

Methods Our data come from a case register study of delusional disorder in Andalucía (Spanish largest region). By accessing digital health data, we selected 1927 cases who meet criteria DSM 5 for delusional disorder collecting different toxic consumption habits.

Results It was found that 1070 (93.4%) of patients diagnosed as delusional disorder according DSM 5 did not consume cannabis, compared to 75 (6.6%) who do so. Among patients diagnosed as "other psychoses", 243 (85%) did not use drugs and 43 (15%) consume other drugs of different types of cannabis.

Conclusion In our sample, we found that the use of drugs such as cannabis and cocaine is less common among patients diagnosed with delusional disorder compared with other individuals diagnosed as "other psychosis".

Psychosis, cause or consequence of substance use disorder

M.C. Cancino Botello*, M.D.L.A. Canseco Navarro,

A. Peña Serrano, F. Molina López, J.M. Hernández Sánchez

Consorcio Hospital General Universitario, Psychiatry, Valencia, Spain

* Corresponding author.

Introduction The use of psychostimulants, such as amphetamines and cocaine in psychotic patients is 4 times more frequent than non-psychotic ones. It is believed that people with psychosis may use substances as a self-treatment for negative symptoms. However, early onset of substance use disorder can develop psychotic and/or negative symptoms, leading to confusion between primary or secondary psychosis.

Method Systematic review of the literature in English (PubMed) and patient's clinical record. Keywords: "Substance use disorder"; "psychosis".

Objectives to highlight the importance of an adequate characterization of psychotic symptoms in patients with substance use disorder.

Case A 29-year-old man, with psychostimulants and cannabis abuse since adolescence and very short abstinence episodes. Later on, he developed paranoia symptoms that slightly improved once he decreased drugs dosage, but they were still present even on complete abstinence. Over the last year he has showed negative and psychotic symptoms that have been worsening with aggressive behavior during the last months, so he had to be hospitalized. During this period, he has been treated successfully with aripiprazole depot once monthly. His evolution has been positive, it has

disappeared psychotic symptoms and paranoia, and after discharge he has managed to remain abstinent to psychostimulants.

Conclusions Adequate characterization of patients with psychotic symptoms and substance abuse is essential to determine whether the psychotic disorder is associated with primary or induced TUS. Therefore, it is essential a thorough clinical evaluation to make an accurate diagnosis and to draw an individualized treatment plan.

Psychiatric disorders among asthmatic patients: Literature review

C.A. Moreira*, A.M. Marinho, L.C. Gil, M. Bairrão, L. Queiroz
Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal
* Corresponding author.

Introduction Asthma is a major public health problem and its prevalence has increased in both developed and developing countries during the last few years. Once it is a chronic illness, it has also revealed psychological consequences. Moreover, recent studies have suggested an association between asthma (especially of severe grade) and mental disorders.

Objectives The authors pretend to make a brief review concerning psychiatric disorders among asthmatic patients.

Aims To understand and to be able to deal with the psychiatric disorders among chronic asthmatic patients.

Methods The review was based on scientific documentation published in PubMed database, using the following terms as keywords: “asthma”, “depression”, “anxiety” and “panic disorder”.

Results Compared to the general population, both anxiety and mood disorders rates are at least two times those observed in asthmatic patients. Moreover, certain psychiatric disorders rates, including panic disorder (PD) and major depressive disorder, are as much as six times more prevalent among asthmatics when compared to the general population. The association between psychiatric disorders and poor asthma control and asthma-related quality of life could occur through several pathways, such as behavioural pathways; cognitive or perceptual pathways; or through the direct physiological effects of depression and anxiety on the autonomic nervous system (ANS) and immune systems which increase asthma symptomatology.

Discussions/Conclusions There is a close correlation between anxiety, PD and depression, and a poor controlled asthma. A better understanding of this association may have major clinical implications, mainly in patients with poor controlled asthma in whom the presence of anxiety and depression should be investigated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Opioids consumption and delusional symptomatology

A. Duque Domínguez^{1,*}, R. Duque Domínguez², L. Martín Díaz¹, C. García Montero¹, M. Palomo Monge³, M.D.M. Lázaro Redondo¹, F. de la Torre Brasas¹, N. Echeverría Hernández¹

¹ Complejo Asistencial de Ávila, Servicio de Psiquiatría, Ávila, Spain

² Hospital Universitario de Fuenlabrada, Servicio de Psiquiatría, Madrid, Spain

³ Complejo Asistencial de Talavera de la Reina, Servicio de Psiquiatría, Talavera de la Reina Toledo, Spain

* Corresponding author.

Introduction Opioids are the most powerful drugs commercialised for acute and chronic pain relief. The main emerging problem in our midst is the abuse and addiction to synthetic opioids iatrogenically established in general population.

Objectives We report the case of a female patient aged 48 admitted to the Acute Psychiatric Unit after a suicide attempt. She refers she finds herself more irritable and depressed since she began a treatment with oxycodone after she was diagnosed with fibromyalgia. She has lost a lot of weight, is not able to get to sleep and has become socially isolated.

Methodology During the first few days, the patient is uncooperative and shows a marked self-referentiality and verbalises delusional ideation related to her immediate surroundings. Once the treatment with opioids was withdrawn and we had prescribed paliperidone ER, she seemed more cooperative and calmed. She was discharged from the Psychiatric Day Hospital showing a good evolution.

Results Paranoid personality disorder (F60); mental and behavioural disorders due to use of opioids (F11); recurrent depressive disorder, current episode moderate (F33.1); fibromyalgia (M79.7).

Conclusions The use of synthetic opioids (tramadol, fentanyl, oxycodone) in easy-to-use formats (patches, pills, dispersible tablets, lollipops) and their dissemination in pain treatment, is leading to an increase of problems related to it, both their side effects (psychotic symptoms) and the generation of misuse and addiction. We should pay greater attention to the prescription of opioids to patients with dysfunctional personality traits.

The effect of alcohol administration on social behavior of rats with experimental schizophrenia

A. Egorov*, E. Kutcher, N. Chernikova, M. Dorofeikova
I.M. Sechenov Institute of Evolutionary Physiology and Biochemistry, Behavior Neurophysiology and Pathology, St-Petersburg, Russia
* Corresponding author.

Experimental animal modeling of schizophrenia and alcoholism allows understanding the mechanisms of comorbid pathology formation. The aim was to investigate the effect of ethanol administration on social relations in rats with experimental schizophrenia. The study was carried out on 30 Wistar adult male rats aged. After 2 weeks isolation rat social ranks were determined. Alcohol preference was evaluated in the two-bottle test. Schizophrenia was modeled by administering to rats ($n = 15$) dopamine precursor levodopa-carbidopa (LC) during 5 days each month in four months experiment. The control animals ($n = 15$) received water. All animals were subjected to intermittent alcoholization throughout the experiment after the introduction of the LC. The behavioral parameters evaluated in the “open field” and “despair” tests.

It was found out that the experimental rats who received alcohol did not differ in the number of interactions compared to the rats who received only alcohol. In the rats with experimental schizophrenia a significantly higher social interactions were observed compared to the control group. This is consistent with the results of the clinical studies, which have shown that patients often drink alcohol to relieve anxiety and tension. The two-bottle test has shown the difference between the experimental and control groups only in the first week of the experiment. Apparently, this can be explained by the prolonged isolation. In the despair test, before the alcoholization, the rats with experimental schizophrenia were completely immobilized, compared to the controls. After alcoholization the differences in the despair test were not observed.

² Hédi Chaker University Hospital, pulmonary department, Sfax, Tunisia

* Corresponding author.

Introduction Quality of life (QoL) is a complex concept that depends on many factors such as life style, past experiences, expectations, future plans and ambitions. It may be altered in patients suffering from chronic disease.

Objectives Assess QoL in patients with asthma as well as associated factors.

Methods We conducted a cross-sectional, descriptive and analytic study, including 30 patients followed for asthma at pulmonary outpatient department, Hedi Chaker Hospital, Sfax, Tunisia. Asthma control level was evaluated by the Asthma Control Test (ACT). QoL was assessed using the 36-item Short Form Health Survey (SF-36), that contains 36 questions grouped into 8 domains (D1: Physical Functioning, D2: Role limitations due to physical problems, D3: Bodily Pain, D4: General Health, D5: Vitality, D6: Social Functioning, D7: Role limitations due to emotional problems and D8: Mental Health).

Results The mean age was 51 ans. The mean duration of disease was 11 years. The average ACT score was 16.8 points. Asthma was uncontrolled in 1/3 of patients. The mean of average overall scores SF-36 was 46.22. QoL was altered in 83.3% of patients. The most altered domains were D8 followed by D7 then D4 and D2. The average overall score SF-36 was correlated to ACT score ($P < 0.001$), early age of onset of the disease ($P = 0.049$) and poor asthma control ($P < 0.001$). Altered QoL was associated to advanced age ($P = 0.016$), long duration of disease ($P < 0.001$) and low ACT score ($P = 0.034$).

Conclusion Optimum asthma and associated comorbidities support would improve control and therefore the patient's quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Alcohol consumption associated with other psychiatric disorders in outpatient psychiatric comorbidity is a common, yet often underdiagnosed and undertreated, resulting in a worse prognosis of both diseases.

Objective To evaluate the prevalence of alcohol consumption in psychiatric outpatient consultations and compared to drug addiction consultations.

Methods A total of 25 outpatient psychiatrists of Extremadura and 10 doctors of substance abuse centers of Extremadura (CEDEX) participated in the study. They were included in the study a total of 373 patients, 244 who were in treatment at mental health center and 129 as a center of drugs.

Results The mean age of patients in psychiatric consultations was 50.05 years and 42.60 years of CEDEX. The percentage of women was 54% of cases in psychiatric consultations and 18.6% in the CEDEX. Diagnoses included in psychiatric consultations were: anxiety disorders (17.2%), depressive disorders (46.3%); personality disorders (7.8%); mild mental retardation (2.5%); psychotic disorders (12.3%); dementia (2.5%); bipolar disorder (6.1%); and ADHD (1.2%). In the consultations of drugs they were: 45.4% alcohol dependent; 15.7% to cannabis; 13.3% cocaine; 10.9% heroin; 8.1% more heroin to cocaine; and 6.6% to other addictions. A total of 18.9% of patients in psychiatric consultations had a score of 2 or more in the CAGE and 62.8% of the CEDEX.

Conclusions We found nearly a fifth of the patients attending psychiatric outpatient clinics which have a hazardous drinking, harmful or alcohol dependence, for almost two thirds of drug queries.

Prevalence of problematic alcohol consumption in patients with anxiety of depressive disorders

M.D.C. García Mahía^{*}, Á. Fernández Quintana
CHU A CORUÑA, Psychiatry, A Coruña, Spain

* Corresponding author.

Introduction Depression and alcohol problems are common in psychiatric outpatients, but there are few studies including patients with anxiety disorders.

Aims To study the prevalence of problematic alcohol consumption in a sample of patients diagnosed of anxiety or depressive disorder and treated in a mental health clinic and to analyze clinical and sociodemographic variables associated to alcohol consumption.

Methods The sample studied included 194 outpatients (31.9% men and 68.1% women) treated in an outpatient clinic and diagnosed of any anxiety or depressive disorder included in DSM-IVTR as main diagnose. Instruments used were Beck Depression Inventory (BDI), and the Alcohol Use Identification Test (AUDIT). Other variables studied included age, civil status, level of studies, and specific psychiatric diagnoses.

Results A total of 64.9% were diagnosed of anxiety disorder and 35.1% were diagnosed of depressive disorder. The prevalence of problematic alcohol consumption was 7.8%, being more frequent in men, especially in men and in middle ages. Problematic alcohol consumption was found with more frequency in patients with generalized anxiety disorder and major depression, in this order. Patients with other comorbidity disorders in Axis II presented the highest prevalences of problematic alcohol consumption.

Conclusions Problematic alcohol consumption presents high prevalence in patients with anxiety or depressive disorders and dual diagnose usually is associated with poor prognosis. It is necessary to make efforts to detect alcohol problematic consumption in psychiatric patients and develop specific treatment programs directed to this group of patients in both primary and specialized care units.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Study of sleep disturbances in patients with alcohol abuse or dependence

M.D.C. García Mahía*, Á. Fernández Quintana
CHU A CORUÑA, Psychiatry, A Coruña, Spain

* Corresponding author.

Introduction Previous studies inform that psychiatric patients often report problems with their sleep and alcohol increase sleep disturbances.

Aims To analyze the prevalence of sleep disturbances in patients diagnosed of Alcohol Abuse or Dependence and to study clinical and sociodemographic variables associated with sleep disorders.

Methods The sample is composed of a randomized sample of patients diagnosed of Alcohol Abuse or Dependence following DSM-IV-TR criteria and treated in a Mental Health Clinic in a period of 3 years. Medical records were reviewed. Quality and patterns of sleep were evaluated using the Pittsburg Sleep Quality Index (PSQI) with a cut-off point 5-6.

Results A total of 102 patients were included in the study, 69% were male and 31% were female. Mean age 39.4 years (SD 9.26). Sleep disorders were found in 91.6% of patients. The most altered subscales in the overall sample were the Use of Sleeping Medication and Sleep Disturbances. Women presented worse sleep quality compared to men ($P < 0.01$) with higher number of altered subscales. The most altered subscales in women were Subjective Sleep Quality ($P < 0.005$) and Sleep Disturbances ($P < 0.02$).

Comorbidity with other psychiatric disorders and other clinical and sociodemographic variables are analyzed.

Conclusions Sleep disorders have high prevalence in patients with alcohol abuse of dependence, especially in women and patients with other psychiatric comorbidity. Poor quality sleep may have a powerful impact on the global functioning and prognosis of these groups of psychiatric patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

O.B. Martínez García¹

¹ Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain

² Hospital Santa Ana Motril, Psicología, Motril, Granada, Spain

* Corresponding author.

Introduction The existence of independent services and facilities for mental health and for addictions in Andalusia stand in the way of addressing dual pathology. The strong comorbidity between substance use and early psychosis has been deeply studied in recent literature. The aim of this paper is to analyse a group of consumers in the First Episode Psychosis Program (FEP) to address the lack of the actual interventions performed.

Methods Descriptive statistical analysis of demographic and clinical variables of a group with drug consumption ($n = 17$) is compared to a non-consumer group ($n = 7$).

Results Our sample of patients included, consumers who represent 71% of the sample. All consumers were users of cannabis or derivatives and 35% of consumers were diagnosed at some point of Toxic psychosis. Only 23% received care in drug addiction centers. They have less education. The duration of untreated psychosis (DUP) is greater than in non-users and only 35% of the cases were detected in Primary Care. PANSS with higher scores. Greater differences in general psychopathology. The Social Functioning Scale (SFS) were worse in the Isolation scale. The Family Questionnaire (FQ) showed more difficulties in the family setting. Finally the

Global Assessment of Functioning (GAF) gives an average of 8 points lower (severe symptoms).

Discussion We would like to point out the low percentage of users who receive specialized care for their addiction. Better collaboration with Primary Care is required to improve the capacity of detection to reduce the time slot of untreated symptoms.

Psychiatric manifestations in porphyria: A case report of psychosis

S. González-Parra*, T. Aparicio Reinoso, M. Leonor,
J.D.D. Molina, I. Hernan, F. Ricote

Hospital Dr Rodríguez Lafora, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Porphyrias are rare inherited disorders due to specific enzyme abnormalities of heme biosynthesis. Among the hepatic forms, three of them are clinically characterized by acute abdominal pain and neuropathy, sometimes associated with psychiatric disorders like mood changes, organic brain syndrome and psychosis.

Case report Here, we present a 38-year-old male patient with intermittent porphyria and chronic psychosis who was hospitalized. He had been treated by benzodiazepines and neuroleptic medication for several years. Exposure to certain drugs, dieting, starvation and infection may precipitate AIP attacks.

Discussion Underlying organic causes of psychiatric disorders such as psychosis should be considered among patients with atypical symptoms and/or resistance to standard therapy.

Conclusion It is important to increase awareness amongst psychiatric and neurological professionals with regard to certain inborn errors of metabolism. Early detection of porphyria may diminish morbidity and mortality rates, and perhaps heal some chronic atypical psychiatric illnesses.

Cannabis psychosis, gender matters

I. Hamilton*, P. Galdas, H. Essex

University of York, Health Sciences, York, United Kingdom

* Corresponding author.

Introduction Despite recent findings pointing toward cannabis psychosis as one area where gender differences may exist, there has been a widespread lack of attention paid to gender as a determinant of health in both psychiatric services and within the field of addiction.

Objectives To explore gender differences in treatment presentations for people with cannabis psychosis.

Aims To use national data sets to investigate gender differences.
Methods Analysis of British Crime Survey data and a Hospital Episode Statistics data set were used in combination with data from previously published epidemiological studies to compare gender differences.

Results Male cannabis users outnumber female users by 2:1, a similar gender ratio is found for those admitted to hospital with a diagnosis of schizophrenia or psychosis. However this ratio increases significantly for those admitted to hospital with a diagnosis of cannabis psychosis, with males outnumbering females by 4:1.

Conclusions This research brings into focus the marked gender differences in cannabis psychosis. Attending to gender is important

for research and treatment with the aim of improving understanding and providing gender sensitive services.

Parkinsonism and mental health disorders among Latino migrants

L. Herrera Duran^{1,*}, N. Mejia², Y. Wang¹, M. Alegria¹

¹ Massachusetts General Hospital, Disparities Research Unit, Boston, USA

² Massachusetts General Hospital, Department of Neurology, Boston, USA

* Corresponding author.

Introduction Mental health disorders and parkinsonism (mobility slowness, rigidity, rest tremor, gait instability) often co-exist. Approximately 40% of the 7-10 million people living with Parkinson's disease globally experience co-existent depression and/or anxiety. Furthermore, people treated with dopamine-blocking medications (antipsychotics, antiemetics) or those who suffer vascular, infectious, toxic, or structural brain insults may have symptoms of "secondary" parkinsonism.

Objectives To describe the existence of parkinsonism among Latino immigrants with behavioral health and substance abuse problems.

Methods Data from the International Latino Partnership (ILRP) gathered at primary care clinics in Boston, Madrid, and Barcelona included 4 parkinsonism screening questions.

Results A total of 151 participants out of 567 (26.6%) screened positive for at least one parkinsonism question and 15 (2.6%) screened positive for all 4 questions. A small group of participants who screened positive for parkinsonism had co-existent schizophrenia, schizoaffective disorder, bipolar disorder, and/or exposure to lithium or valproic acid. We found that age 50+, depression, and anxiety were more often associated with people having parkinsonism ($P < 0.1$). Gender, race, language, and educational level were not significant predictors of parkinsonism.

Conclusions Parkinsonism and behavioral health disorders co-exist among Latino immigrants in the United States and Spain. This may be related in part to exposure to dopamine-blocking medications. Future studies should focus on early detection of mental health co-morbidities among Parkinson's disease patients as well as on prevention of "secondary" parkinsonism among people living with mental health disorders.

Most frequent clinic comorbidities in hospitalized patients in a psychiatric clinic

J. Jaber*, J. Veríssimo (Jr), T.T. Raposo, B. Reys

Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction Being hospitalized in a psychiatric clinic, patients present, in addition to the diseases that determine the hospitalization, clinic comorbidities, generally decompensated.

Objectives To present the most frequent clinic pathologies in a population of hospitalized patients having diverse mental disorders and establish a protocol for investigation and their early treatment.

Aims To know the most frequent pathologies in a population of hospitalized psychiatric patients and establish a protocol for their assessment, in a way that contributes to the global improvement of the patient health condition.

Methods For its mission realization, the clinic counts on a multi-disciplinary team. The participants were 762 patients, seen in the referred clinic, which presented a minimum period of hospitalization of 10 days and that were submitted to thorough clinic exam and complementary routine exams. The time frame referred to the period of March of 2012 to February of 2014, totalizing 24 months.

Results In the patients that had medical release after periods of hospitalization of, 90-day average, were obtained, in the totality of the cases, excellent evolution, evidenced by the improvement of the laboratory parameters.

Conclusions The results were achieved in the hospitalization system with careful medicament administration, differentiated diets established in agreement with the patients, supervised physical activities and psychological and psychiatric support.

* Corresponding author.

The metabolic syndrome (MetS) beside in peri- and postmenopausal women vastly reduces their quality of life. One of forming estimations quality of life is a change on the part of the psycho-emotional status of the women.

The purpose of the study Determination of the influence menopausal MetS beside peri- and postmenopausal women on psycho-emotional sphere to their life. The organized study 581 peri- and postmenopausal women (45-55 years). Depending on presence or absences component MetS, all women were divided into 2 groups - with presence of the criterion MetS (1 group, $n = 470$) and without MetS (2 groups, $n = 111$). Stating the diagnosis, MetS were a criteria IDF (2005). The estimation of presence and degree anxiety and depression conducted on the grounds of Hospital Anxiety and Depression scale. The estimation of the psychic status conducted by means of Mini Mental State Examination. The 1-group women practically in 1,5 once was more often revealed subclinical expressed anxiety (30%) and depression (21,9%), than beside 2 groups (21,6 and 17,2%). Cognitive frustration - beside 5,1% and 2,7%. Either as at recommendations of the interpreting the test MMSE, after undertaking the treatment anxiety and depression beside women with component MetS, us again marked women of the 1 group. It is revealed that in spite of reduction sign anxiety and depression in 2 times practically, accordingly on group, improvement cognitive status was flat. Reasonable alongside with psycho-corrective therapy to conduct the preventive maintenance and treatment menopausal MetS for the reason improvements quality of life getting old women.

Temporal epilepsy and psychosis - Comorbidities

V. Klaric^{1,*}, D. Klaric²¹ Zadar general hospital, department of psychiatry, Zadar, Croatia² Zadar general hospital, department of internal medicine, Zadar, Croatia

* Corresponding author.

Introduction The simultaneous presence of temporal epilepsy and psychosis includes a careful approach to diagnosis and titration of medication.

Aim To achieve remission of comorbid diseases resistant to therapy.

Methods Psychotherapy interview and support, laboratory measurements, EEG, cerebral CT and MRI scan, psychological testing.

Results The patient was a girl 16 years of age. In 2011, she started experiencing auditory hallucinations of disturbing content, ideas of persecution, and she feared that people were going to kill her, all of which were bothering her deeply. In the family anamnesis, her grandmother and aunt both suffer from schizophrenia. In the first neurological assessment, there were no aberrations. The patient was treated with high doses of various antipsychotics, but the hallucinations became unbearable to the extent that she was about to commit suicide. Anticonvulsive therapy was planned, and in the meantime, a second neurological assessment was performed, which confirmed the coexistence of temporal epilepsy. Combined therapy consisting of anticonvulsive and antipsychotic medication markedly abated the hallucinations. However, the patient began to feel cramping of the right arm, as well as experiencing the negative symptoms of psychosis. She wasn't functioning normally anymore, she was distinctly adynamic, depressive, with a lack of initiative, and poor memory and concentration. Psychological testing confirmed significant cognitive, emotional and personality disorders (of organic source).

Conclusion Treatment of the overlapping symptoms of temporal epilepsy and psychosis is complex, along with the presence of intellectual deterioration.

Schizophrenia or attention deficit hyperactivity disorder: drug abuse as a cause of wrong diagnosis

Y. Lazaro^{1,*}, M.P. Ibañez², A. Muro²¹ Hospital Clínico San Carlos, Psychiatry, Madrid, Spain² Parc Sanitari Sant Joan de Déu, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction It is common to find patients with overlapping attention deficit hyperactivity disorder (ADHD) and substance abuse disorder, specially alcohol, cannabis and cocaine. The anxiety, impulsivity and even psychosis derived from consumption often induce wrong diagnosis of patients, due to the camouflage of the basic psychopathology of ADHD.

Objectives Analyze a clinical case in order to point out the difficulty of diagnosis existent in ADHD patients with substance abuse disorder comorbidity.

Aims To gain insight in the psychopathology of ADHD patients, to make the right discernment and to improve the quality of their lives.

Methods Thirty-four-year-old man, ex-drug user of cannabis and cocaine, diagnosed with paranoid schizophrenia several years ago on an outpatient basis. Currently in prison, with regular follow-up by psychiatry in the last year. The toxic withdrawal, the collection of medical history and the successive consultations finally

orientated the diagnosis to ADHD-combined subtype, receiving treatment with atomoxetine instead of antipsychotics. After few months of observation, we confirmed an excellent general clinical response and a better adaptation to the prison environment.

Results Psychoticism disappeared with drug abstinence. Antipsychotics were interrupted due to the absence of psychopathology of schizophrenia. Free of psychotropic drugs, ADHD symptoms became apparent.

Conclusions Due to ADHD comorbidity, it is important to pay attention to the profile to make the right discrimination between different entities for therapeutic and prognosis implications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical aspects of depression in Parkinson's disease

F. Leite^{1,*}, H. Salgado², O. Campos², P. Carvalho²,M. Pinto da Costa², P. Queirós², C. Cochat²¹ Matosinhos, Portugal² Hospital de Magalhães Lemos, Psychiatry, Porto, Portugal

* Corresponding author.

Introduction Parkinson's disease is the most common neurodegenerative movement disorder in the elderly population. The disease is clinically characterized by major motor symptoms that include bradykinesia, rigidity, tremor and postural instability. In addition to the motor symptoms, Parkinson's disease is characterized by emotional and cognitive deficits, which reduce quality of life independently from motor manifestations.

Objectives/Aims To discuss the clinical manifestations of depression in Parkinson's disease according to the most recent scientific literature.

Methods Online search/review of the literature has been carried out, using Medline/Pubmed, concerning, "Parkinson's disease" and "depression".

Results Depression is the most frequent psychiatric disorder in Parkinson's disease. In up to 30% of the cases, the depressive symptoms precede the development of motor symptoms. Independently of the age of appearance, duration and severity of the motor symptoms, depression is generally an integral part of the disease. Depression in Parkinson's disease is generally mild or moderate, with premature loss of self-esteem and volition. Although the high rates of suicidal ideation, suicide is rare. There is also a high prevalence of panic attacks and anxiety.

Conclusions It is difficult to correctly identify depression in Parkinson's disease as some symptoms assigned to Parkinson's disease itself can in fact be the clinical manifestation of a depressive disorder. On the other hand, depressive symptoms may not be recognized as such, but considered manifestations of Parkinson's disease.

Huntington's Korea or Huntington's disease is a pathology of the nervous central system that provokes involuntary movements those who are named Korea or San Vito's evil, changes of conduct, psychiatric alterations and dementia. It thinks that it is a slightly frequent disease among the caucasian ones (1 every 100,000 or 200,000 persons), except in Venezuela that has the highest rate of the world (1 every 10,000). It is named badly of San Vito because he was the saint, the one that was evoked to treat this type of disease. It is a neurodegenerative disease and is accompanied of atrophy of the fluted body and loss of neurons on decrease of neurotransmitters. Members' spasmodic movements and facial muscles as dance, uncoordination motorboat. These movements woke fear and superstition up in an epoch. Alterations motorboats attitude, march and abnormal movements. Loss of weight for faults in swallowing besides the loss of calories (approximately 4000 daily ones for the constant movement). Not only it is a disease motorboat, the patient loses aptitude to communicate and dies in 10-15 years. There are psychiatric symptoms as the depression, changes of personality, decrease of intellectual capacity and suicide. Let's sense beforehand a clinical case of a 69-year-old patient with psychiatric depressive precedents of years of evolution with treatment psychopharmacology and worsening in last 2 years. Treatment is prescribed with antipsychotic and before a not well-taken quake, is studied by neurology who diagnoses Huntington's disease.

Peculiarities of comorbid addictions in neurotic disorders

N.O. Maruta*, S.P. Kolyadko, M.M. Denysenko, G.Y. Kalenska, V.Y. Fedchenko

Institute of neurology - psychiatry - and narcology of the NAMS of Ukraine, department of neuroses and borderline conditions, Kharkov, Ukraine

* Corresponding author.

Introduction Under contemporary social circumstances, there is a tendency to increasing of amount of persons disposed to addictive behavior (AB) as a mean to remove psychoemotional tension and to solve their significant problems. This tendency raises in patients with neurotic disorders (ND) that influences on clinical manifestations of the pathology and impedes diagnosis and timely care for this category of patients.

Aim To investigate AB in the structure of neurotic disorders (F44.7, F40.8, F48.0).

Methods Assessment of personal addictive status with AUDIT-like tests to detect disorders related to substance and non-substance abuse; 109 patients with ND (main group) and 52 persons without ND (control group) were examined.

Results It was revealed that patients with ND had significantly higher risk of AB formation (59.73% compared with 21.15% in healthy persons; $P < 0.0001$). According to the group comparison, in patients with ND levels of AB expression on parameters of "Job" (12.06 points), "Food" (11.98 points), "Internet" (11.10 points),

"TV" (8.82 points), "Shopping" (6.59 points) were significantly higher than in healthy persons (9.73; 9.23; 9.00; 7.38; 4.25 points, respectively; $P < 0.05$). However, levels of keenness on computer were significantly higher in healthy persons (3.48 points) than in patients with ND (2.34 points; $P < 0.05$). AB connected with substance abuse was not registered in the groups.

Conclusions The results suggest that the patients use AB in forms of food, Internet, job, TV, shopping dependencies as a subconscious mechanism substituting unsatisfied needs and decreasing motivation-emotional tension under conditions of a frustration conflict.

Introduction Anxious-depressive disorder is a serious medical and social problem, significantly affecting the quality of life of patients with somatic profile. In this paper, we analyzed the incidence and severity of comorbid psychiatric disorders in patients with hypertension and heart failure, a comparative assessment of anxiety and depression, according to the sex and age of the patient, reflected the impact of mood disorders on the quality of life of patients with cardiovascular disease.

Objectives 1. To investigate the anxious-depressive disorder in patients with hypertension and the syndrome of heart failure. 2. Rate the quality of life of patients with hypertension and heart failure with affective comorbid disorders of depressive spectrum. 3. To assess the anxiety and depression, according to the sex and age of the investigative patients.

Aim The aim of this study was to establish the influence of the level of anxiety and depression on quality of life and clinical manifestations of heart failure and hypertension based on gender.

Methods We used the following methods: Zung Scale of depression self-assessment, Hamilton Anxiety Rating Scale (HAM-A), a technique of assessing the quality of life of the EuroQoL-5D method.

Results Undoubtedly available anxious-depressive disorders are the basis for accession to the classical scheme of treatment of CHD or GB psychotherapeutic correction and psychotropic drug therapy.

Conclusions There is reason to assume that the connection of antidepressants may contribute to the reduction of risk of cardiovascular events and to facilitate the flow of cardiovascular diseases, to improve quality of life of patients.

Is social attachment an addictive disorder? Role of the latest findings in the opioid system

G. Montero González^{1,*}, M.S. Mondragón Egaña²

¹ Hospital of Zamudio. Red de Salud Mental de Bizkaia- Osakidetza, Psychiatry, Zamudio, Spain

² Hospital of Galdakao- Osakidetza, Psychiatry- Unidad de Desintoxicación, Galdakao, Spain

* Corresponding author.

Introduction The endogenous opiate system (EOS) has been linked to social attachment in classical animal experiments, to addictive disorders (AD) and, more recently, to specific traits of personality through research in genetic polymorphisms and neuroimaging techniques.

Objectives To expose the relation between social bonding and AD, via the latest neurobiological findings in the EOS. To propose a theoretical framework which may allow a clinical approach based upon respect and no stigmatization.

Methods Literature review in MEDLINE database with the keywords “opioid”, “polymorphism”, “object attachment”, “addictive behavior”, “personality”.

Results Polymorphisms in the mu-opioid receptor gene lead to different attachment behaviors in primates. The EOS in humans has been related to pain and placebo effect and recently, to social rejection and acceptance. Thus, some authors talk about “social pain”. Interestingly, the EOS has a role in harm avoidance and in the reward system. These traits of personality (harm avoidance and reward dependence) predispose to AD, and likely, pathological models of social bonding may drive to a need of palliating excessive discomfort originated by an altered opioid function through addictive behaviors. The origin of AD must be focused on the individual vulnerability rather than in the addictive substance/behavior.

Conclusions The latest findings in the EOS yield concrete evidences that support the classical hypothesis of an opioid nexus between social attachment and AD, and shift the spotlight from the addictive object to the vulnerable subject. This theoretical framework may ease a clinical approach based upon respect and no stigmatization.

Mental disturbances in patients with acute medical condition

B. Fedak

Kharkov medical academy of postgraduate education - Kharkov, psychotherapy, Kharkov, Ukraine

Contemporary remains understudied health issue - the psychological aspect of the acute therapeutic diseases problem. Among the most common diseases - coronary heart disease (CHD), myocardial infarction (MI), crisis states in patients with arterial hypertension (AH), transient ischemic attack (TIA) and acute stroke (AS), gastric ulcer and duodenal ulcer (GU&DU). Clinical features of the structure, dynamics, current and immediate link with the medical conditions is not fully understood. The basis of our research, the purpose of which, was to identify mental disturbances in patients with acute therapeutic diseases. One hundred and eighty-seven patients were examined, 34 CHD patients, 37-MI, 38 - TIA, 39-AH, 39 - GU&DU, 65% male and 35% female aged 20 to 60 years. The main research method was clinical and psychopathological. A high-level affective and neurotic disorders in these patients was observed. Structured analysis allowed identifying four main options disturbances: nosogenic neurotic reaction-68 patients; somatogenic asthenic syndrome-46 patients; reaction psychological maladjustment-34 patients; acute stress reactions-39 patients. Stratification of structure psychopathological syndroms allowed systematizing them in 4 different groups: asthenic-24%; anxiety - 46%; subdepressive - 11%; somatoform - 19%. That was the basis for the determination early psychotherapeutic correction program, formed by integrative model. The high efficacy was shown in 74% patients, middle range-in 15%, low-in 11% patients.

The prevalence of drug use in patients suffering ADHD is very high. The main purpose of this paper is to make a review of the recent literatura in this field.

We make a review in PUB Med using “ADH” and “drug abuse”, selecting papers not older than 5 years.

The conclusions are that adult patients suffering ADHD presents higher prevalence of drug use and/or dependence, showing that ADH is a risk factor for this comorbidity.

This conclusion implies the necessity of strat the treatment in young people, treating to avoid drug use and/or dangerous behaviors in this group of patients.

ADH is one of mental disease with a higher prevalence of alcohol and drug abuse. ADH is a risk factor for drug use, and that's true in the reverse sense. The mutual influence in both disorders is clear and the presence of both disorders together could be a real challenge for a clinical professional.

The main objective of the study is to evaluate the influence of the psychopharmacological treatment in the longterm outcome of this sample, using a measurement drug use, adherence to the treatment and impulsivity.

We make a study that includes a group of patients with both disorders. We select a sample from the Centro de Día Zuría. The patients complete a battery of scales (SCL-90, Barratt, SF-36) before and after the beginning of psychopharmacological treatment.

Our results shows a better prognosis in the patients with a good adherence to treatment, with a decrease in frequency and levels of drug use and a decrease in impulsivity, with a low level of behavioral disorders and violence.

The aim of this case report is to present importance of psychotherapy in treatment of schizoaffective disorder. Method used in psychotherapy setting is Open dialogue, approached and used in school of cybernetics and system therapy. As significant and clinical operable comorbidity to schizoaffective disorder, appears one non-specific phobia that never before got respectable therapeutical attention. Phobia got more serious patognomonic importance during last psychotic deterioration while inpatient had suffocated by solid food and ended up in intensive care unit. After her vital psychophysical condition was stabilized, hospital psychiatric treatment was suggested as next step. That included combined psychopharmacotherapy, occupational therapy and two times a week individual psychotherapy. In clinical interview was noticed a solid food phobia - rare and non-specific phobia. So, initial psychology testing has been made. Next 8 weeks, client had passed two times a week in 45 minutes duration individual psychotherapy setting based on open dialogue. Eight weeks after client talked about fears and gave them personal interpretation which created a non-psychotic sense and new therapy meaning, almost analog to heteroanamnestic data. Another psychology testing has been repeated. Results have shown that nature of swallowing perturbances has strictly psychological background.

Between Scylla and Charybdis: Where does the treatment of Addison's disease in late-life depression go first?

S. Petrykiv^{1,*}, M. Arts², L. de Jonge³

¹ GGZ Friesland, Emergency Psychiatry, Leeuwarden, Netherlands

² UMC Groningen, Old Age Psychiatry, Groningen, Netherlands

³ UMC Groningen, Epidemiology, Groningen, Netherlands

* Corresponding author.

Introduction Older adults with adrenocortical insufficiency, including Addison's disease (AD), are at an increased risk for developing late-life depression. Treatment of AD with glucocorticoid replacement therapy may exacerbate depressive symptoms and may complicate treatment of late-life depression. Objectives To present a case with algorithm of decision-making in a particular case of glucocorticoid induced depression in patient with syndrome of Addison. Aims To report a case-study, describing treatment of Addison's disease in LLD. Methods A case report is presented and discussed, followed by a literature review. Results A 77-year-old female, diagnosed with Addison's disease, was referred with persistent fatigue, weakness, weight loss,

sleep disturbances, and depressive symptoms over the previous 6 months. She was taken losartan 100 mg/day, zolpidem 10 mg/day, fludrocortisone 100 μg/day, and hydrocortisone 35 mg/day. There was no personal or family history of psychiatric problems. Clinical examination was normal aside from skin hyperpigmentation. After initial minimal dose reduction of glucocorticoids, Addison's disease remained under control. One week later, her depressive symptoms disappeared without administration of antidepressants. Conclusion The association between glucocorticoid replacement therapy and late-life depression is not well understood. The current case shows that treatment of glucocorticoid-induced depression in subjects with Addison's disease is achievable by minimal adjustments in glucocorticoid regimen. However, collaboration with endocrinology is of vital importance to prevent an Addison's crisis. Pharmacokinetic dose-finding studies are required to find optimal glucocorticoid adjustment strategy. Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The links between ADHD and SUD are demonstrated in the scientific literature. The existence of dual diagnosis affects both prognosis and clinical-therapeutic assessment. Objective and aims Describe the general characteristics of a sample of patients with SUD (n = 162) who seek treatment for their addiction, based on the presence of symptomatic contamination by ADHD, compared to a sample of adults (n = 246) without addictive pathology (parents of children with different risk for ADHD). Methods We assessed using different scales the properties of the sample (visual analogical [general state of health, sadness, anxiety, irritability, suspiciousness], WURS, BDI and Exploratory List of ADHD symptoms). Results The average age in the group of parents was 40.59 versus 35.88 on the SUD group, with 42% and 87% males respectively. SUD group presented worse general state, with higher average of sadness, anxiety, irritability and suspiciousness, as well as WURS and exploratory symptoms of ADHD, as shown in Tables 1 and 2. Conclusions The SUD group had higher ADHD symptomatic contamination respect to Parents group. These results are preliminary and are pending more thorough analysis as part of a more extensive and complex study, requiring further confirmation in future studies.

ADHD “Symptomatic contamination” in dual pathology (II): Specific analysis of the “Sym.Con” sample

F.J. Pino Calderon ^{1,*}, J.M. Zoido Ramos ², J.R. Gutierrez Casares ³

¹ Servicio Extremeño de Salud, ESM Montijo-Puebla, Montijo, Spain

² Servicio Extremeño de Salud, CEDEX “Los Pinos”, Badajoz, Spain

³ Servicio Extremeño de Salud, Hospital Perpetuo Socorro, Psicología, Badajoz, Spain

* Corresponding author.

Introduction The general data of this sample were presented in “ADHD symptomatic contamination in a Dual Pathology (I): General Analysis of the Sym.Con Sample”. We evaluated the presence of symptomatic contamination by ADHD in a SUD group compared with a group of non-consumers adults (parents of children treated in a CAP unit).

Objective and aims Describe more specifically the peculiarities of the sample Sym.Con according to the type of substance consumption (Alcohol [*n* = 65], Cocaine [*n* = 48], Cannabis [*n* = 49] assessing the presence of ADHD symptomatic contamination.

Methods We use different Visual Analogical Scales plus the WURS, BDI, and Exploratory Lists of symptoms of ADHD.

Results As can be seen in **Tables 1 and 2**, the subgroup of Alcohol has a poorer “scalar” status with worse general state, more sadness and anxiety, being the subgroup of cocaine the most “suspicious”. The presence of ADHD-symptomatic contamination is more noticeable in the Cannabis subgroup.

Conclusions ADHD symptomatic contamination in our Sym.Con sample is frequent, being the cannabis subgroup the more

contaminated one. More studies that corroborate the results obtained in this sample are required.

Comorbidity between delusional disorder and depression. Results from the DelirAnda case register

A. Porras Segovia ^{1,*}, C. Carrillo de Albornoz Calahorra ², M. Guerrero Jiménez ², J. Cervilla Ballesteros ^{1,3}

¹ University hospital San Cecilio, mental health services, Granada, Spain

² Santa Ana hospital, mental health services, Motril, Spain

³ University of Granada, psychiatry department, Granada, Spain

* Corresponding author.

Introduction Comorbidity between two or more mental disorders is highly frequent. Depression is one of the diseases that more often accompanies other conditions.

Objectives The objective of this study is to establish the prevalence of depression in patients with delusional disorder and describe the treatment used in these cases.

Aims The aim is to provide useful information regarding this frequent, often disregarded, comorbidity.

Methods Our results proceed from the Andalusian delusional disorder case register. We reviewed 1927 clinical histories of patients diagnosed of delusional disorder. Upon having verified the diagnosis, following DSM-V criteria, we recollect several data, including

sociodemographic factors, depression comorbidity and antidepressive treatment.

Results One thousand four hundred and fifty-two patients matched DSM-V delusional disorder criteria. 49,8% of our sample were women. Average following period was 9 years and 1 month, with an average of 0,84 hospitalizations. The prevalence of depression in patients with delusional disorders was 31,9%. 67,5% of them received some kind of antidepressive treatment. The antidepressive drugs most frequently used were selective serotonin reuptake inhibitors.

Conclusions Depression is a highly prevalent condition among patients with delusional disorder. Most of them are on antidepressive treatment, the most employed of which is based on selective serotonin reuptake inhibitors. Comorbid depression can have an important impact on the course of delusional disorder. A correct diagnosis and treatment should be made to help improve the prognosis and life quality of these patients.

Introduction Patients with anxiety disorders are more vulnerable to develop other comorbid conditions. In particular, large epidemiological studies show a strong association between different anxiety disorders and substance use disorders.

Objectives To show the prevalence of major anxiety disorders and the consumption of different substances. As well as the particular characteristics of this dual diagnosis and treatments that have proven more effective.

Methods Exhaustive review of all the material published on this topic in the recent years.

Conclusions Nearly 24% of patients with anxiety disorder suffer from a comorbid substance disorder use in their lifetime (17.9% diagnosis of alcohol abuse or dependence diagnosis and 11.9% of abuse or dependence on other drugs). Dual patients show a number of distinctive features, such as more frequency in males, family history of alcohol or other substances abuse and behavioral problems, early parental loss among others.

Introduction Dual diagnosis is a growing problem in Western society, despite which there are no large studies examining this issue, nor specific protocols to address them.

Objectives To raise awareness of the importance of dual diagnosis both its prevalence and special features that presents need a different performance plan from them separately.

Methods Comprehensive literature review of all published in the last 2 years, as well as the specific features.

Conclusion Dual diagnosis has very specific characteristics that we must know in order to develop therapeutic strategies adapted to the present conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Psoriasis is a multisystem inflammatory disease associated to several comorbidities with a significant impact on interpersonal and social life. Depression, anxiety symptoms and suicidal ideation—due to psychological distress—are frequently reported. The aim of the study was to assess whether psychological factors—psychopathology, perceived health status and coping strategies—together with clinical and sociodemographic factors, were independent predictors of Quality of Life (QoL) in adult psoriatic patients on topical and/or systemic pharmacological therapy. A cohort of 87 patients (53 M and 34 F), whose mean age was 46 ± 22 years, was analyzed. Coping responses were assessed by COPE and general psychopathology by Self-Reported-Symptom Inventory Revised (SCL-90), while HAM-D and HAM-A evaluated depressive and anxiety symptoms. In addition, perceived health status and QoL were analyzed by Short-Form-36 (SF-36) while the disease's burden assessed by PSODISK. Univariate analyses were performed for each variable to explore the relationship with QoL. Preliminary results indicated that, although not severe, anxiety and depressive symptoms were the most reported among patients along with somatization and obsessive-compulsivity. Female patients used more frequently mental disengagement, focus on and venting of emotions, use of instrumental social support and religious coping. Physical pain and mental health, instead, greatly affected QoL of subjects in a negative manner. PSODISK data analysis showed that general health, itching, serenity, shame and degree of extension of the disease on the skin were the most compromised areas. Moreover, correlation analysis indicated that a worse perception of patients' health status was associated to poor QoL.

Epilepsy and self-esteem

M. Turki^{1,*}, I. Bouchhima¹, N. Halouani², E. Turki¹, M. Bouzidi¹, M. Dammak¹, O. Amami², C. Mhiri¹

¹ Habib Bourguiba university hospital, neurology department, Sfax, Tunisia

² Hedi Chaker university hospital, psychiatry department, Sfax, Tunisia

* Corresponding author.

Introduction Epilepsy is a public health problem that often affects personal and social patients' life. Self-esteem, an important factor contributing to psychosocial well-being, is generally disrupted in epilepsy.

Objective The aim of our study was to assess self-esteem and factors associated in patients suffering from epilepsy.

Methods We conducted a cross-sectional, descriptive and analytic study, including 20 patients followed for epilepsy at neurology outpatient department, Habib Bourguiba hospital, Sfax, Tunisia. We collected socio-demographic and clinical characteristics, and used the Rosenberg Self-Esteem Scale (RSES).

Results The mean age was 35.9 ans. Sex-ratio (M/F) was 3. Hobby practice was noted in 45% of cases. The disease evolves since 19.9 years on average. A worsening of health in the last year was felt in 30% of cases. The stigma was reported in 30% of patients. Self-esteem was: very low 5%, low 40%, average 40%, and high 15%. It was better among married patients, living in family and those with disease evolving since more than 10 years, but without a significant correlation. The factors correlated with good self-esteem were: practicing a hobby ($P=0.006$) and absence of stigma ($P=0.001$). Poor self-esteem was significantly correlated with perceived health worsened during the last 12 months ($P=0.02$). It was poor in unstable patients professionally, but without significant correlation.

Conclusion Our study confirms the decline of self-esteem in patients with epilepsy. A better education of these patients to accept their illness, as well as raising public awareness on this affection could facilitate social insertion and improve self-esteem.

EV397

Interest of admission clinical and paraclinical examinations for the detection of organic comorbidities in psychiatry

M. Turki*, N. Halouani, N. Hamza, R. Naoui, I. Gassara, J. Aloulou, O. Amami

Hedi Chaker university hospital, psychiatry department, Sfax, Tunisia

* Corresponding author.

Introduction Somatic comorbidities in patients with mental disorders have become an important issue. They complicate therapeutic management and aggravate the prognosis.

Objectives Outline the nature of somatic disorders observed in psychiatry and assess the different interactions between psychiatric pathologies and organic diseases.

Methods We conducted a descriptive retrospective study including 60 patients hospitalized in a psychiatry department during 2 years (2013 and 2014). We included patients having presented a somatic disorder at their admission. Data collection was based on psychiatric and clinical observations.

Results At the admission, somatic examination was abnormal in 53.3% of cases: skin abnormalities 28.3%; blood pressure abnormalities 8.3%. An abnormality of the initial biological tests has been reported in 51.7% of patients: leukocytosis 18.3%; liver test abnormalities 13.3%; hematologic abnormalities 8.3%. The electrocardiograph was pathologic in 35% of cases. These anomalies have required advices from medical and surgical services: cardiology 33.3%; endocrinology 10%, orthopedics 10%. The relationship between somatic and psychiatric pathology was: a comorbidity: 55%; a side effect of psychotropic drug: 5%; an organic origin of the psychiatric disorder: 6.6% and a somatic disorder secondary to the psychiatric pathology: 10%. In the course of this investigation, 6.6% of patients were transferred urgently to a specialist department, the psychotropic treatment was stopped in 10% of cases, and a therapeutic adjustment was necessary in 6.6% of cases.

Conclusion Our study confirms the importance of somatic assessment of patients with mental illnesses. This must be a systematic practice in order to detect in time patients at risk of somatic complications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV398

Assessment of eating disorders in patients diagnosed with major depressive disorder

D. Vasile*, O. Vasiliu, D.G. Vasiliu, F. Vasile

Central University and emergency military hospital "Dr. Carol Davila", psychiatry, Bucharest, Romania

* Corresponding author.

Introduction Evaluation of eating disorders in patients with major depression is an important part of the case management and a comprehensive approach to both psychopathological dimensions could lead to full remission of symptoms and a lower rate of relapse.

Objectives To assess the incidence of eating disorders in patients diagnosed with major depressive disorder (MDD).

Methods A group of 40 patients (female $n=28$, male $n=12$) diagnosed with MDD according to DSM 5 criteria, consecutively admitted in our department, were screened for eating disorders through a structured interview.

Results A number of 12 patients (30%) reported a type of eating disorder: binge eating disorder ($n=6$) of mild ($n=4$), moderate ($n=1$) or severe ($n=1$) intensity; night eating syndrome ($n=2$); purging disorder ($n=2$); bulimia nervosa ($n=2$) of mild ($n=1$) and moderate ($n=1$) severity. Obesity was recorded in a number of 10 patients (25%). Also, a number of 7 patients (17.5%) had several criteria for eating disorder (anorexia nervosa, bulimia nervosa or binge eating disorder), but insufficient to formulate a DSM 5 based diagnosis. A higher incidence of all the eating disorders and obesity was observed in women comparative to men (35.7% vs. 25%).

Conclusions A structured assessment of eating disorders in patients diagnosed with major depressive disorder could bring to the clinician' attention underlying symptoms that may be neglected during a usual psychiatric interview, also these symptoms have a high impact over the case prognosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction According to the World Health Organization (WHO), in 2015, 300 million people will suffer from obesity. Obesity leads to further health problems, which in return increase the prevalence and resistance to treatment.

Objectives The goals of this study are to determine the proportion of obese patients and overweight patients treated at the Psychiatric Hospital "Sveti Ivan" as well as determine whether there is a difference in the frequency of comorbidity with somatic diseases, suicidality and intensity of symptoms amongst the three tested groups (obese, overweight and average body weight).

Methods The sample covers a cross-sectional study including 15 female patients and 59 male patients under treatment in the Emergency Department at the Psychiatric Hospital “Sveti Ivan” in September 2015. The patients were divided into three groups, according to their BMI. All patients fulfilled the DASS 21 (Depression, Anxiety and Stress Scale by Fernando Gomez) and Suicide Severity Rating Scale (Columbia–Suicide Severity Rating Scale [Center for Suicide Risk Assessment] questionnaires).

Results In male patients, 30.91% were found to be obese and 36.4% overweight. In total, seven patients had from comorbidity, of which five were obese. In female patients, 33.3% were overweight whereas only six patients were obese. Of those six obese women, all had from comorbidity.

Conclusions The results identify that a significant part of individuals with psychological disorders are either obese or overweight, resulting in repercussions in the course of disease and treatment.

Casting wider diagnostic nets for anxiety and depression: Disability-driven cross-diagnostic subtypes in a large population study

R. Wanders^{1,*}, H.M. van Loo¹, K.J. Wardenaar¹, J.K. Vermunt², R.R. Meijer³, P. De Jonge¹

¹ University Medical Center Groningen, Department of Psychiatry, Groningen, Netherlands

² Tilburg University, Department of Methodology and Statistics, Tilburg, Netherlands

³ University of Groningen, Department of Psychometrics and Statistics, Groningen, Netherlands

* Corresponding author.

Introduction Data-driven techniques are frequently applied to identify subtypes of depression and anxiety. Although they are highly comorbid and often grouped under a single internalizing banner, most subtyping studies have focused on either depression or anxiety. Furthermore, most previous subtyping studies have not taken into account experienced disability.

Objectives To incorporate disability into a data-driven cross-diagnostic subtyping model.

Aims To capture heterogeneity of depression and anxiety symptomatology and investigate the importance of domain-specific disability-levels to distinguish between homogeneous subtypes.

Methods Sixteen symptoms were assessed without skips using the MINI-interview in a population sample (LifeLines; $n = 73403$). Disability was measured with the RAND-36. To identify the best-fitting subtyping model, different nested latent variable models (latent class analysis, factor analysis and mixed-measurement item response theory [MM-IRT]) with and without disability covariates were compared. External variables were compared between the best model's classes.

Results A five-class MM-IRT model incorporating disability showed the best fit (Fig. 1). Accounting for disability improved the differentiation between classes reporting isolated non-specific symptoms (“Somatic” [13.0%], and “Worried” [14.0%]) and those reporting more psychopathological symptoms (“Subclinical” [8.8%], and “Clinical” [3.3%]). A “Subclinical” class reported symptomatology at subthreshold levels. No pure depression or anxiety, but only mixed classes were observed.

Conclusions An overarching subtyping model incorporating both symptoms and disability identified distinct cross-diagnostic subtypes. Diagnostic nets should be cast wider than current phenomenology-based categorical systems.

* Corresponding author.

Background Pediatric bronchial asthma as a chronic airway inflammatory disorder has a significant impact on asthmatic children both biologically and psychologically. On the other hand, parental stress and depression has been linked to pediatric asthma and claimed to play an important role in its morbidity.

Objectives Assessment of pediatric asthma biomarkers as parameters of disease severity in relation to mental disorders of an Egyptian sample of asthmatic children and their caregivers.

Methodology The current cross-sectional study comprised 60 Egyptian asthmatic children as Group I and 35 clinically healthy children of comparable age and sex as Group II. Thorough clinical evaluation and psychometric assessment were carried out for all enrolled children and their caregivers. In addition, pulmonary function testing and measurement of eosinophilic count, IL-5, and total IgE were carried out for children of both studied groups.

Results Enrolled asthmatics had significant elevation of all studied asthma biomarkers with significant reduction of measured pulmonary functions compared to controls. Furthermore, asthmatics had significantly more encountered poor self-esteem, clinically manifest anxiety, and psychosocial impairment compared to controls. Meanwhile, parents of studied asthmatics had higher frequency of severer grades of clinically manifest isolation, anxiety, depression, and stress. Strikingly, the severer the asthma, the more the elevation of studied asthma biomarkers, the severer the asthmatic child's and caregivers' anxiety and depression, and the more the caregivers' isolation and stress.

Conclusion Pediatric asthma biomarkers as parameters of disease severity has been proven to be linked to mental health impairment of asthmatic children and their caregivers.

Paliperidone palmitate could reduce the consumption of drugs of abuse in psychotic patients?

A. Zangrando^{1,*}, F. Babici², E. Pascolo-Fabrici¹, A. Riolo³

¹ UCO Clinica Psichiatrica, department of mental health, Trieste, Italy

² CSM Domio Trieste, department of mental health, Trieste, Italy

Introduction It's not easy to choose between different antipsychotics in the treatment of patients with schizophrenia that use drugs of abuse both legal (alcohol, benzodiazepine, anticholinergics) and illicit (heroin, cannabis, cocaine). The use of substances is a powerful risk factor for poor outcome. From CATIE study, we know that the discontinuity is lower with Olanzapine but psychotic patients continue to take drugs of abuse despite medication.

Probably, an important aspect is the anhedonia secondarily produced by neuroleptics.

Objective We want to evaluate if Paliperidone Palmitate reduces addictive behaviors in a small group of psychotic patient who have agreed to recived injection after the switch from other antipsychotics.

Method We have identified four individual with chronic use of drugs of abuse in a Mental Health Center. These subjects were abusing alcohol, cannabis, spice and benzodiazepine. We administered before new treatment and after 2 months the Snaith-Hamilton Pleasure Scale of Snaith et al. (1995) and the Leeds Dependence Questionnaire of Raistrick et al. (1994).

Results The hedonic tone tends to improve and the addictive behavior decreased.

Conclusion The therapy with Paliperidone Palmitato is associated with a reduction of the addictive behaviors but we need studies with a larger number of patients.

* Corresponding author.

Introduction Only few international studies have focused on mental diseases among the hearing-impaired population. However, Fellinger et al. (2012) underline the high discrepancy between the current and future demand of mental treatment and the simultaneous impeded access to health care.

Aims The aim of this multicenter project is to conduct the first analysis of mental diseases among the hearing-impaired population in Germany in order to quantify and qualify the specific demands of treatment.

Objectives In order to achieve this aim, we compiled an extensive questionnaire battery.

Methods This questionnaire battery measured sociodemographic data, non-verbal intelligence, quality of life, perception and suffering from stress, psychosomatic symptoms as well as personality traits.

Results Our three samples consisted of 21 hearing-impaired patients with a history of mental diseases (EG-HI), 21 hearing-impaired subjects without mental diseases (CG-HI) and 21 hearing participants without any psychological disease (CG-H). Compared to the two control groups, the EG-HI shows significantly higher rates in different fields, i.e. participants perceive a lower quality of life, suffer from more psychosomatic symptoms and show more pronounced personality traits. The two control groups did not differ significantly from each other.

Conclusions Certain psychological characteristics among hearing-impaired patients can be detected which need to be accounted for in treatment. Furthermore, a hearing impairment is

not inevitably linked to a reduced quality of life or even mental disorders. Therefore, future research should focus on risk factors and protective factors which could prevent mental diseases among the hearing-impaired population.

Psychogenic stuttering: A case and review

A. Almada^{1,*}, R. Simões², M. Constante¹, P. Casquinha¹, M.J. Heitor¹

¹ Hospital Beatriz Ângelo, Psychiatry, Loures, Portugal

² Hospital Beatriz Ângelo, Neurology, Loures, Portugal

* Corresponding author.

Introduction Stuttering is a speech disorder characterized by involuntary repetition, prolongation or cessation of a sound. This dysfluency may be developmental or acquired. Acquired dysfluency can be classified as neurogenic or psychogenic.

Objectives This case report aims to describe and discuss a case of psychogenic stuttering, providing an updated review on this disorder.

Methods In and outpatient interviews were performed by Neurology and Psychiatry. Investigation to exclude organic causes included lab exams, electrocardiogram, electroencephalography, computed tomography scan and magnetic resonance imaging. A literature review in Science Direct database, with the keywords “psychogenic stuttering”, was also conducted.

Results A 63-year-old man was admitted to the Beatriz Ângelo Hospital with an acute stuttering. Speech was characterized by the repetition of initial or stressed syllables, little affected by reading out loud or singing. Comprehension, syntaxes and semantic were not compromised, as weren't sensory and motor abilities. During admission, stuttering characteristics changed. Multiple somatic complaints and stress prior to the onset and bizarre secondary behaviors were also detected. Work-up didn't show an organic etiology for that sudden change. An iatrogenic etiology was considered, as sertraline and topiramate were started for depression 1 month before. However, the stuttering pattern, the negative results, the psychological and the social life events suggested a psychogenic etiology.

Conclusions Psychogenic stuttering finds its origin in psychological or emotional problems. It is best classified as a conversion reaction. The differential diagnosis between psychogenic and neurological stuttering can be challenging.

Illness or simulation

A.M. Alvarez Montoya^{1,*}, C. Diago Labrador², T. Ruano Hernandez³

¹ Algeciras, Spain

² Clinica Privada, Psiquiatria, Algeciras, Spain

³ Clinica Privada, Psicologia Clinica, Malaga, Spain

* Corresponding author.

Objectives The revision of the differential diagnosis of simulation cases versus real psychopathological cases. Analysis of a case of the Ganser syndrome by revising the diagnosis criterions and their historical characteristics.

Method We analyze the case of a 38-year-old male who came to the community mental health team and reference hospital. Following symptoms were observed: involuntary movements of the upper extremities associated with delirium coinciding with the

premature birth of a child. This refers also to a compatible episode of a dissociative fugue.

Results To establish the diagnosis, we differentiate against disorders such as Simulation, factitious disorders with psychological symptoms or Factitious Disorders with somatic symptoms (Münchhausen syndrome). In order to support our diagnosis, we base on the CIE-10 and the DSM-IVTR classification.

Conclusions We don't diagnose the clinical pictures in which we don't think. The Syndrome of Ganser could be positioned between neurosis and psychosis and between illness and simulation. The recommended treatment includes hospitalization in order to insure the diagnosis. While some authors recommend neuroleptics and others - anxiolytics, the psychotherapy is obligatory. The goal is to help the patient restore function and adapt to his environment again.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Impact of a type-D personality on clinical and psychometric properties of patients with a first myocardial infarction in a Turkish sample

B. Annagür^{1,*}, K. Demir², A. Avci², Ö. Uygur¹

¹ Selcuk university- faculty of medicine, psychiatry, Konya, Turkey

² Selcuk university- faculty of medicine, cardiology, Konya, Turkey

* Corresponding author.

Objective Recent studies have shown that a Type D personality is associated with an increased risk of cardiac mortality. This study aimed to examine impact of a Type D personality on clinical and psychometric properties of patients with a first myocardial infarction (MI) in a Turkish sample.

Method The study included 131 patients who were admitted to the coronary care unit of a hospital with a first MI. All the patients underwent a psychiatric assessment within 2–6 months post-MI. Psychiatric interviews were conducted with the Structured Clinical Interview for DSM-IV (SCID-I).

Results The first study group (Type D personality) included 50 patients, and the second study group (non-Type D personality) included 81 patients. There was a 38.2% prevalence of the Type D personality in the patients with a first MI. Those with this type of personality had a significantly higher frequency of hypertension and stressful life events. The Type D patients also had more psychiatric disorders, depressive disorders, and anxiety disorders than the non-Type D patients.

Conclusions Our findings suggest that Type D personality traits may increase the risk of hypertension and the risk of psychiatric morbidity in patients with a first MI. Considering that a Type D personality is a stable trait; we suggest that this type of personality is a facilitator of clinical depression and anxiety disorders. These findings emphasize the importance of screening for a Type D personality as a cardiovascular risk marker and a psychiatric risk marker in MI patients.

Misdiagnosis of anterior cutaneous nerve entrapment syndrome as a somatization disorder

M. Arts^{1,*}, J. Buis², L. de Jonge¹

¹ UMCG, Old Age Psychiatry, Groningen, Netherlands

² GGZ Friesland, Psychiatry, Leeuwarden, Netherlands

* Corresponding author.

Introduction Anterior cutaneous nerve entrapment syndrome (ACNES) is a frequently overlooked disease, causing chronic abdominal wall pain due to entrapment of an anterior cutaneous branch of one or more thoracic intercostal nerves. It is often misdiagnosed as a psychiatric condition, particularly under the heading of a somatization disorder.

Objectives We describe the case of a patient who developed depressive symptoms after months of suffering from chronic abdominal wall pain.

Aims To report a case-study, describing ACNES as a cause of persistent depressive symptoms.

Methods A case-study is presented and discussed, followed by a literature review.

Results A 35-year-female was referred to a psychiatrist for her depressive symptoms and persistent cutaneous abdominal pain for months. There she was diagnosed with a depression and possible somatization disorder and she received psychotherapy. Through Internet search, the patient found ACNES as a possible cause for her persistent abdominal pain. Since administration of anesthetic agents only shortly relieved her symptoms, a surgeon decided to remove the nerve end twigs. After surgery, her somatic problems and depressive mood disappeared.

Conclusion The awareness of ACNES is still very limited in medicine. This may lead to incorrect diagnoses, including psychiatric disorders such as somatization disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Admitting biases before admitting patients: Mental health simulation training for clinical decision-making

C. Attoe*, Z. Jabur

South London & Maudsley NHS Foundation Trust, Maudsley

Simulation, London, United Kingdom

* Corresponding author.

Introduction With the number of people presenting to services, being diagnosed with, and requiring support for mental health problems continuing to increase, more and more decisions are being made by more and more mental health clinicians about the treatment and futures of their patients. This is in the context of reductions to inpatient psychiatric beds, and increasing numbers of people attending Emergency Departments with mental health concerns. However, decision-making can be an ambiguous process, with clinicians having varied opinions, and guidelines not always being clear.

Aims To outline briefly the design of a simulation course for decision-making in mental health, before presenting the findings of a mixed methods evaluation.

Method Simulation training used 6 scenarios involving every participant and trained actors, followed by a structured and reflective debrief on the decisions made in assessment and treatment. Pre- and post-questionnaires ($n=82$) were employed to collect quantitative and qualitative data regarding participants' skills and knowledge of decision-making, which was further bolstered by qualitative follow-up surveys.

Results Analyses found statistically significant increases in participants' knowledge and awareness of the decision-making process and personal biases, while qualitative responses showed significant changes pre- and post-course. Themes from qualitative feedback also identified self-reported changes to the clinical practice of participants, from awareness of biases, to reflecting on decisions.

Conclusion Decision-making processes require explicit acknowledgement and exploration in psychiatry, with such training have a potential impact on the care and decision delivered

by participants, a significant step in patient experience and outcomes.

Occult abdominal infection and psychiatric symptoms: A case report

M. Bairrão^{1,*}, G. Pereira¹, J.M. Jara², M.H. Esteves¹

¹ Lisbon Psychiatric Hospital Center, Psychiatry, Lisbon, Portugal

² Lisbon Central Hospital Center, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction The clinical presentation of numerous infectious processes can include diverse psychiatric symptoms. Subtle cognitive dysfunction or mood change (e.g., irritability), depression, psychosis and delirium are the most likely symptoms to occur and may result from a small focus of chronic infection.

Aims Disclose an unusual clinical case with psychiatric symptoms as the first presentation of an occult infection.

Methods The review was based on scientific documentation published in PubMed database, journals and reference textbooks. We used the following terms as keywords

“infection”, “occult infection” and “psychiatric symptoms”.

Results We present the case of a 48-year-old woman without psychiatric history until January 2015, time when she had insidiously developed personality changes with emotional instability. Five months later, during her stay in urgency department after her second suicide attempt, her dysphoric mood, defiant behaviour and persistent suicidal ideation were interpreted as a personality disorder that has led to a compulsory admission. Forty-eight hours after the admission, she became febrile with fluctuation of consciousness and ended up being transferred with sepsis to an intensive care unit. The carried out investigation has shown an occult abdominal infection, i.e. peritoneal abscesses without isolated infectious agent. With the resolution of the infectious process, the psychiatric symptoms subsided and she returned to her premorbid personality level.

Conclusions Infectious diseases can firstly present with psychiatric symptoms. Timely investigation of the underlying etiology for psychiatric symptoms that persist after conventional psychiatric treatments is crucial for appropriate intervention and full recovery of the patient.

Speechless soma: The trauma's language in the psychosomatic

J. Becker^{1,*}, G.A. Da Silva², A. Dal Sasso³

¹ Universidade de Coimbra, Master's Degree in social and cultural psychiatry, Coimbra, Portugal

² Fundação Universitária Mário Martins, psychology, Porto Alegre, Brazil

³ Fundação Universitária Mário Martins, Student of psychotherapy, Porto Alegre, Brazil

* Corresponding author.

The study begins by approaching the psychological traumatism concept, recognizing it as an important precipitating of psychosomatic disorders. Based on studies of anthropologists, psychiatrists and psychoanalysts, we present trauma as a consequence of an unexpected event from where is originated intense fear, an abruption, which disorganizes and incapacitates the victim. The Institut Psychosomatique de Paris (IPSO) works with the theory that trauma is an excessive disorganization in the mental apparatus and the

psychosomatic disease is the alternative that the body finds to discharge excitation, is an attempt to resolve a conflict. The psychosomatic patient is characterized by difficulty to qualify his affections, it is observed in his super adapted speech and his linear thought, which, together, differ him from neurotic and psychotic patients. Considerations about the child development and the affects qualification are made to introduce the importance of this primitive period, but we pretend to demonstrate that they are not determinants to produce psychosomatic symptoms. When the psychological pain is intense and constant, it provokes a split between mind (psyche) and body (soma) and, in the place of the elaboration and representation about the experience, explodes psychosomatic disorders.

General hospital inpatients with delirium: A cross-sectional pilot study of patients referred to a consultation liaison psychiatry service

P. Buvanaswari

Changi general hospital, psychological medicine, Singapore, Singapore

Introduction A significant number of referrals to consultation-liaison psychiatry are for delirium, which is often mistaken for a primary psychiatric illness. Delirium is associated with poor outcomes, particularly when it is not recognised.

Aims To identify the rate of missed delirium and the factors associated with it, so as to inform interventions aimed at reducing the proportion of patients whose delirium is missed.

Objectives To perform a cross-sectional survey of inpatients referred to a consultation-liaison psychiatry service in a general hospital who have an eventual diagnosis of delirium, in order to determine the proportion of patients with missed delirium and characteristics of such patients.

Methods Data was collected retrospectively for a sample of 30 inpatients with delirium who had been referred to a consultation liaison psychiatry service, and analysed for associations with missed delirium.

Results Only a third of patients with delirium were accurately diagnosed before referral, and there was a mean delay of about 4 days between delirium onset and psychiatry consultation. Misdiagnosed patients were most commonly thought to have either dementia or a mood disorder. The factors most closely associated with missed delirium were: being of Chinese ethnicity, not having any history of psychiatric problems, not having fluctuations in the mental state, not having agitated behaviour, and being of younger age. None of these associations were statistically significant.

Conclusion Two-thirds of patients with delirium in this sample were misdiagnosed before referral. Further study is needed to identify factors which may contribute to missed delirium.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Ng Teng Fong general hospital, nursing, Singapore, Singapore

⁵ Ng Teng Fong general hospital, psychiatry, Singapore, Singapore

⁶ Ng Teng Fong general hospital, renal medicine, Singapore, Singapore

* Corresponding author.

Introduction Anxiety and depression are distinct clinical entities associated with mortality in haemodialysis (HD) patients.

Aims This study aims to identify the prevalence of anxiety and depression in HD patients and uncover the association of anxiety and depression in relation to the dialysis adequacy and nutritional status.

Objective This would help reinforce early detection and treatment to improve quality of life and patient's outcome in HD treatment.

Method Forty HD patients were assessed for anxiety and depression with the Generalised Anxiety Disorder Assessment (GAD-7 and Patient Health Questionnaire [PHQ-9]). The scores of GAD-7 and PHQ-9 were correlated with the demographic, clinical and laboratory variables and nutritional status assessed by a dietitian through the Subjective Global Assessment (SGA).

Results Out of the 40 HD patients, 7 (17.5%) were anxious and 15 (37.5%) were depressed. Patients were more anxious and less depressed with better nutrition. They were less anxious and depressed with increasing albumin levels, Charlston comorbidity index based on combined condition and age-related score and Kt/V. The univariate logistic regression analysis showed only a significant inverse correlation between depression and albumin level ($P=0.041$, OR=0.88 [95% CI=0.78 to 0.99]) and Kt/V ($P=0.054$, OR=0.03 [95% CI=0.01 to 1.07]).

Conclusion Depression is more prevalent than anxiety in HD patients. The risk of depression also increases with poorer dialysis adequacy and nutritional status. Thus, by improving dialysis adequacy and nutritional status, we can reduce the incidence of depression. However, a significant correlation cannot be drawn for anxiety.

A study to assess the prevalence of depression and impact on social functioning in patients post stroke

C. Daly*, H. Parvathaiah, S. Macsuibhne

Department of psychiatry- St. Lukes hospital, psychiatry, Kilkenny, Ireland

* Corresponding author.

Introduction Depression is a common and serious complication following stroke which is largely underdiagnosed by non psychiatric physicians in 50-80% of cases. Untreated depression may affect functional recovery, quality of life and lead to poorer rehabilitative outcomes. Although depression is common in patients following stroke, it is not routinely assessed for in a hospital setting. To date, few studies have been carried out in an Irish context. The aim of this study was to assess the prevalence of depression and impact on social functioning in post stroke patients in a local setting.

Methods Post stroke patients ($n=18$) were screened for the presence of depression greater than 6 weeks post stroke using the Montgomery Asberg Depression Rating Scale (MADRS) at the stroke clinic in a local hospital. The inclusion criteria were those >6 weeks post stroke, >18 years, those without cognitive impairment, without a prior history of depression or substance misuse. A 5-item work and social functioning questionnaire was also administered to assess the impact on the patients social functioning.

Results Of the 18 participants, 7 scored within the normal range, 6 had evidence of mild depression, 3 showed moderate depression and 2 were in the severe depression range. Nine of 18 (50%) of participants believed their occupational functioning to be affected.

Conclusion Sixty-one percent of participants showed evidence of depression, and their ability to work following their stroke was either markedly or very severely affected. Screening for depression should occur in order to ensure early identification.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Liasion psychiatry–1 year review in psychiatry department of centro hospitalar Trás-os-Montes e Alto Douro, Portugal

A.R. Figueiredo*, M. Silva, A. Fornelos, P. Macedo, S. Nunes, M. Viseu

Centro hospitalar Trás-os-Montes e Alto Douro, psychiatry and mental health department, Vila Real, Portugal

* Corresponding author.

Introduction Liasion psychiatry is a clinical area of psychiatry that includes psychiatric assistant activities in other medical and surgical areas of a general hospital. In Portugal, it has developed as a result of psychiatry integration in general hospitals. Historically, it started at the beginning of 1930s in USA. In Portugal, the law 413 of 1971 defined the articulation of mental health services with other health services–liasion psychiatry.

Objective We aim to define patients evaluated in the context of liasion psychiatry, as well as other medical and surgical areas needs of psychiatry collaboration.

Methods Retrospective analyses of collaboration requests realized to psychiatry department of centro hospitalar Trás-os-Montes e Alto Douro–Vila Real, between October 2014 and October 2015.

Discussion Most of collaboration requests came from Internal Medicine Service. Authors systematize the reasons for the requests, the time of response to those, the existence of psychiatric history, the type of intervention, the number of observations in the same patient, the most frequent diagnosis and treatment. This psychiatric service consists of four specialists and activity evaluated in this article is one of the clinical areas where these professionals intervene. Depending on the results, it is interesting then to assess needs and optimize available resources.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The prevalence of substance abuse in hospitalized medically ill patients in Rasoul-Akram hospital

A. Ghanbari Jolfaei^{1,*}, N. Norouzi²

¹ Hazrat-Rasool Hospital, Psychiatry, Tehran, Iran

² Mental Health Research Center, Psychiatry, Tehran, Iran

* Corresponding author.

Introduction Substance abuse can lead to increased risk of accidents leading to serious physical damage and can also cause medical diseases. On the other hand, patients with medical diseases may self-medicate with substances to improve some of their medical symptoms such as pain. Therefore, the risk of hospitalization of patients with substance abuse can be higher. Substance abuse can affect the course and prognosis of medical diseases.

Aims The aim of this study was to investigate the frequency of substance abuse in medically ill patients in Rasoul-Akram hospital.

Methods This study was a cross-sectional study. The sampling method was convenient. Demographic data and the data about substance use disorders were gathered through a clinical interview by a psychiatrist. Inclusion criteria included informed consent to participate in the study, an appropriate level of consciousness and the ability to talk in Persian.

Results From 423 patients participating in the study, 205 were female (48.5%). The average age of the patients was 18.4 ± 48.4 years. The prevalence of substance abuse was 39.7%, of which 60% were consuming daily. The prevalence of substance abuse between male and female was not significantly different. Marital status and low education and older age had significant association with substance abuse. Smoking and opioids followed by alcohol, cannabis and benzodiazepines were the most substances used by patients.

Conclusion The prevalence of substance use disorders in hospitalized patients in General hospital is high and it is crucial to assess substance use disorders in these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depression, somatic complaints and medical help-seeking in a Romanian sample

C. Giurgi-Oncu^{1,*}, C. Bredicean¹, F. Giurgi-Oncu², R. Romosan¹, M. Ienciu¹

¹ "Victor Babes" university of medicine and pharmacy of Timisoara, Timisoara, Romania

² Timișoara County emergency clinical hospital, psychiatry, Romania

* Corresponding author.

Introduction Depression as a disorder, with all its intensities and clinical forms, requires to be projected on the backdrop of human suffering. In evaluating a depressive episode of a somatically ill person, it is important to assess personality and social context as a whole.

Objectives To establish the degree of somatic comorbidity/somatization in depressive patients and the correlation with their social support network.

Aims To recommend cost-effective psycho-social interventions to offer relief and support.

Method We evaluated 60 patients with depression of various etiologies (Recurrent depressive disorder, Paranoid-depressive disorder, Anxious-depressive disorder). Self-report and observer rating scales were used (SCL-90, Beck, Hamilton) along with a supplementary consult (where required) by different specialists. Direct observations were made regarding the social support network, in terms of evaluating their scale and efficiency.

Results The majority of patients included showed an obvious inconsistency in terms of objective and subjective symptoms, correlated with the lack of an adequate social support network. This resulted in more medical help-seeking, a polymorphic array of somatic symptoms, oscillations of somatic complaints, some showing lack of adherence and only mild improvement with psychotropic therapy. Most of the somatized complaints were gastrointestinal, respiratory, pain-related and pseudo-neurological, with an increased overall evidence-based cardio-vascular comorbidity.

Conclusions We suggest that in order to help support patients and ensure fluidization of medical services, mental health care could also be delivered effectively in primary care settings, through community-based programmes and task shifting approaches that engage and support skilled non-specialist health professionals, lay workers, affected individuals, and caregivers (Kakuma, 2011).

Disclosure of interest The authors have not supplied their declaration of competing interest.

Burnout in pediatric oncology healthcare providers: Protection and vulnerability

C. Araújo¹, R. Gonçalves^{1,*}, J.M.V.D. Ferreira¹, S. Pedrosa¹, C. Pinho¹, S. Silva², M.J. Brito²

¹ Hospital Pediátrico - Centro Hospitalar e Universitário de Coimbra, child and adolescent psychiatry, Coimbra, Portugal

² Hospital Pediátrico - Centro Hospitalar e Universitário de Coimbra, pediatric oncology unit, Coimbra, Portugal

* Corresponding author.

Introduction Burnout is a condition characterized by emotional exhaustion, depersonalization and reduced personal accomplishment, resulting from the inability to cope with chronic job stress. Healthcare providers at pediatric oncology units, who care for children with life-threatening illnesses, are exposure to high levels of stress, which increases the risk for developing burnout, with consequences in their personal health and quality of patient care.

Objective To assess the prevalence and sources of burnout on a multidisciplinary team of a pediatric oncology unit.

Methods Participants were a convenience sample of 16 pediatric oncology professionals, including medical, nursing, and related health staff from a Portuguese pediatric oncology center. Participants completed the Portuguese version of the Copenhagen Burnout Inventory.

Results All three subscales that compose this Inventory were found to have burnout below normal levels (cut-off ≥ 50 points). However, personal and work-related subscales showed mean values in the superior limit of normality (48 ± 14 , 18 points and 49, 48 ± 12 , 23 points, respectively). Nevertheless, when analyzed the patient-related subscale, we found low levels of burnout in the majority of responders. These findings are similar to the existing literature, which suggests that patient care and interactions with children are the least stressful aspect of working in this specialty.

Conclusion Despite the high levels of stress exposure in pediatric oncology units, results suggest that the majority of professionals are not actually in burnout. However, the obtained values advice for the need of prevention and workplace approaches to staff's well-being and stress reduction, in order to avoid burnout development.

We report here three clinical cases as examples of our rich and frequent collaboration between the department of psychiatry and the department of medicine, nephrology and hemodialysis. This work can serve as a basis for further reflection in order to improve mutual demands. We based our description on three patients chosen for their homogeneity in demand, rapidity of evaluation, the same clinician who evaluated the demand. Either case: a 42-year-old woman, who was admitted for alteration of general state, severe headaches and chronic addiction to alcohol, 71-year-old woman suffering from recurrent unipolar depression who came for somatic exploration and severe weight loss or 55-year-old man who was transferred from cardio-pulmonary intensive care unit after a voluntary ingestion of neuroleptic- were reevaluated by

the psychiatrist and the special follow-up was indicated as the patient was discharged from internal medicine department. We were interested in studying how important to the patient this indication turned to be on time.

Introduction Obesity is a major public health problem in the world and getting obesity under control is one of the most important goals of the World Health Organization. Cognitive behavioral therapy techniques are helpful for adjusting lifestyle to stay at a healthy weight range. Success of web-based programs which designed with evidence-based behavioral strategies has been proven with different studies. However, a web-based program suitable for Turkish culture and eating habits is still missing.

Objectives Primary objective of this project is to develop and test a web-based obesity behavioral treatment program in collaboration with experienced academicians from different disciplines.

Aims The aim of this project is to develop a program which will help Turkish primary care physicians in treating and tracking obesity patients.

Method The web-based program will include a 12-week-long core behavioral program. Participants will be asked to record their daily dietary intakes and automatic feedback will be given by the system. Weekly behavioral training videos will be available during the core program. As participants watch the videos and record their daily intakes, they will get instant awards such as virtual diet-coin which they will be able to spend for gifts such as low calorie recipes. One hundred obese patients (with body mass index greater than 30 kg/m²) will be recruited to evaluate the effectiveness of the program. The changes in their blood pressures, body weights and waist circumferences will be recorded.

⁵ Dow institute of health sciences, psychiatry, Karachi, Pakistan

* Corresponding author.

Introduction There is strong association between depression and mortality rates among patients with CHF. Despite the massive burden of cardiac disease as well as that of depression in Pakistan, there is limited data regarding the prevalence of depression in patients suffering from CHF. The aim of this study was to assess prevalence of depression in patients with CHF and to compare the health related quality of life of depressed and non-depressed patients with CHF.

Methods A total of 1009 patients diagnosed with CHF were recruited from different public hospitals in Karachi, Pakistan. Depression was assessed at baseline using the Beck Depression Inventory (BDI) and health related quality of life was assessed using Euro Qol (EQ-5D).

Results Of the 1009 participants recruited to the study, 66.4% (n = 670) met the threshold for depression using the BDI measure. Of the depressed patients, 66.7% (n = 447) were male. Preliminary results indicate that participants who were depressed at baseline had poorer health related quality of life on EQ-5D measures as compared to those who were non-depressed (mean EQ-5D descriptive score 10.45 in depressed patients vs 7.37 in non-depressed patients and mean EQ-5D visual scale score 35.09 in depressed patients vs 52.19 in non-depressed patients).

Conclusion Considering the high prevalence of depression and its serious negative impact on quality of life of patients suffering from chronic physical illness, it is important to design and test culturally adapted psychosocial interventions to reduce depression and improve quality of life for these patients.

² University psychiatric hospital Vrapce, department of forensic psychiatry, Zagreb, Croatia

³ University hospital Dubrava, department of internal medicine, Zagreb, Croatia

* Corresponding author.

Introduction Various risk factors for development of acute coronary syndrome (ACS) have been discovered. ACS has numerous consequences, including physical and mental health disturbances. **Aim** To distinguish mental health consequences and risk factors for ACS.

Objectives To explore the interdependence between poor life-style choices (physical inactivity, cigarette smoking, unhealthy diet, alcohol consumption) and development of anxiety or depressive disorders 1 month and 6 months after ACS.

Methods Follow-up study on 120 subjects with ACS, retested after 1 and 6 months. Existence of previous or actual mental disorders were excluded in the first phase.

Instruments Mini International Neuropsychiatric Interview, questionnaire of general sociodemographic data and life-style factors, Acute Stress Disorder Interview and Clinician-administered PTSD Scale. Lipid levels and BMI were tracked.

Results After 1 month 27.5% of the subjects had acute stress disorder (ASD) and 13.8% had major depressive disorder (MDD). After 6 months, 37.5% subjects had PTSD and 27.3% had MDD. Alcohol consumption showed to be predictive for development of MDD in the second phase (P = 0.002; OR = 2.48), and physical inactivity showed

to be predictive for development of comorbidity of MDD and ASD in the second phase ($P=0.036$; $OR=100.00$).

Conclusion Cardiovascular disorders can cause anxious & depressive disorders in frequent alcohol consumers and physically inactive subjects. Since depression, anxiety, physical inactivity, and alcohol consumption cannot only be considered as risk factors for cardiovascular disorders, but also be seen as a consequence of cardiovascular disorders, strategies for primary and secondary prevention of coronary events should include a greater concern for mental health as well.

Prevention of postoperative delirium - A prospective nurse-led intervention on surgical wards in a general hospital

T. Kratz, A. Diefenbacher*

Ev. Krankenhaus Königin Elisabeth Herzberge, department psychiatry psychotherapy psychosomatics, Berlin, Germany

* Corresponding author.

Objective Delirium is a frequent postoperative complication in older and cognitively impaired patients in general hospitals. Delirium is associated with prolonged hospital stay as well as with an increased risk of nursing home placement after discharge. We wanted to study whether the implementation of a specialized delirium nurse on a surgical ward leads to a reduction in the frequency of postoperative delirium.

Methods In an open-label study on two surgical wards of a general hospital, first the prevalence rate of postoperative delirium in patients older than 70 years was assessed (March to August 2011). During the following intervention phase (September 2011 to June 2012), a trained geriatric nurse implemented delirium-preventative measures in accordance with the Hospital Elder Life Program (HELP). The second surgical ward provided standard treatment as usual as an in-house control.

Results Overall 20.2%, 95% CI [14.6, 26.4] of patients on both wards without special intervention developed postoperative delirium. By implementing preoperative screening measures and specific interventions by a delirium nurse, the incidence of postoperative delirium was reduced to 4.9%, 95% CI [0.0, 11.5]. The interventions were validation, improving sleep quality, cognitive activation, early mobilisation, improving sensory perception and optimising food and fluid intake. Most important predictors of postoperative delirium were Mini Mental Status Exam results, age and preoperative infection.

Conclusion The establishment of a specialised delirium nurse as well as the implementation of simple preoperative care measures increased postoperative attention, cognitive activation and is associated significantly with reducing risk of postoperative delirium in older and cognitively impaired inpatients.

Prevention, early detection and effective treatment of the psychological disorders in asthma and chronic obstructive lung disease

K. Zawada¹, A. Koźmin-Burzyńska², K. Krzysztof^{2,*}

¹ Medical university of Silesia, department of pneumonology, Katowice, Poland

² Medical university of Silesia, department of psychiatry and psychotherapy, Katowice, Poland

* Corresponding author.

Background Chronic respiratory diseases which embrace asthma and chronic obstructive pulmonary disease (COPD) are common conditions in the population. In a large number of cases, they are diagnosed very late. Statistics of deaths, especially in the case of COPD, are underestimated because morbidity and mortality can be affected by other comorbid conditions, for example cardiovascular disease.

Objective The objective of this analysis was to find out the correlation between the psychological distress and social factors in patients with asthma and chronic obstructive lung disease.

Methods A literature analysis on this topic was performed. Asthma and COPD impair not only physical functioning of patients but also affect their psychological state. Mood disorders and cognitive function impairment are more often observed in this group than in the general population. It has been proven that the coexistence of psychological dysfunction significantly worsens the functioning of patients (affects, among others, their work, family and social lives) and has an impact on the course of the treatment of the somatic illness. First of all, patients with cognitive deficits have greater problems in applying treatment recommendations. Accordingly, it seems to be important to pay more attention to the problem of mental disorders in patients with obstructive lung diseases.

Conclusions There is a clear need for a multidisciplinary approach that will enable prevention, early detection and effective treatment of the psychological disorders in that group of patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background Mindfulness based art therapy induces emotional relaxation in cancer patients and is a treatment known to improve psychological stability. The objective of this research was to evaluate the treatment effects of MBAT for breast cancer patients.

Methods Twenty-four breast cancer patients were selected as subjects of the study. Two groups, the MBAT group and control group with 12 patients each, were randomly assigned. The patients in the MBAT group were given 12 sessions of treatments. To measure depression and anxiety, low scales of the Personality Assessment Inventory (PAI) was used. Health-related quality of life was evaluated using the European organization for research and treatment of cancer quality of life questionnaire (EORTC-QLQ-C30). The treatment results were analyzed using Ancova and two-way repeated measures Anova.

Results The results showed that depression and anxiety decreased significantly and health-related quality of life improved significantly in the MBAT group. In the control group, however, there was no significant change.

Conclusions MBAT can be seen as an effective treatment method that improves breast cancer patients' psychological stability and quality of life. Evaluation of treatment effects using program development and large-scale research for future clinical application is needed.

⁷ Department of speech, language and hearing science, Ghent, Belgium

* Corresponding author.

Background To date, psychosocial outcomes after facial transplantation are promising although long-term consequences, outcome of blind patients and the impact on family members are less well investigated. The aim of this study was to examine the long-term psychosocial of a blind patient and his partner 2 and 3 years after facial transplantation.

Methods Depressive and anxiety symptoms, hopelessness, coping, resilience, illness cognitions, marital support, dyadic adjustment, family functioning and quality of life of the patient and the partner were assessed before and 2 and 3 years after transplantation. Reliable change index (RCI) was further calculated to evaluate the magnitude of change.

Results Most psychological, marital and family scores of both the patient and the partner remained within a normative and healthy range at follow-up. Resilience (RCI: 2.5 & 3.4 respectively), affective responsiveness (RCI: -4.1 & -3.2 respectively), physical quality of life (RCI: 8.7 & 7.2 respectively) and helplessness (RCI: -2.2 & -2.9 respectively) of the patient improved at 2 and 3 years follow-up. Further, dyadic cohesion (RCI: 2.4) of the patient improved at 2 years whereas marital depth (RCI: -2.0) of the partner decreased at 3 years.

Conclusions The results of this study point to positive long-term psychosocial outcomes of a blind patient and his partner after facial transplantation. Further, they may underscore the importance of patient selection, social support and involvement of family members in treatment.

Alternative treatment options for lithium-induced nephrogenic diabetes insipidus

S. López-Romeo*, G. Ledesma-Iparraguirre
Parc Sanitari Sant Joan de Déu, psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Lithium is currently a drug of choice for treating persons with bipolar disorder and is widely used in this population. Approximately, 30% of patients taking lithium experience at least one episode of lithium toxicity. Treatment of acute toxicity involves correction of electrolyte abnormalities, volume repletion followed by forced diuresis, and dialysis in severe cases. A case report is described and it is reviewed some alternative treatment options before considering withdrawal of lithium treatment in lithium-induced nephrogenic diabetes insipidus.

Case report A 58-year-old woman diagnosed of hypertension and bipolar disorder for 20 years. At first, she was controlled with valproic acid until she suffered a manic episode which required a mood stabilizer switch. She started a treatment with lithium 1200 mg/day and olanzapine to 10 mg/day and was completely recovered. After a year of stabilization, olanzapine was retired and she maintained stabilized with lithium 1000 mg/day during last 17 years. During last 8 months, she suffered polydipsia and polyuria (4 L/day). She was diagnosed of nephrogenic diabetes insipidus. Some measures like liquid restriction, lithium monodose and low sodium diet were carried out, obtaining a partial response. Taking into account, she was stabilised with lithium for many years, it was decided to introduce hydrochlorothiazide 25 mg/day, clinical and analytical resolution of nephrogenic diabetes insipidus was obtained. A year later, she maintains psychopathological stabilization, without any lithium secondary effects.

Conclusion Some treatment options for lithium-induced nephrogenic diabetes insipidus could be introducing thiazides, amiloride, indomethacin, desmopressin or carbamazepine, instead of withdrawal lithium.

New interferon-free therapies on HCV+ chronic hepatitis: Overcoming psychiatric side effects in a real world setting

M. Moneglia^{1,*}, A. Santangelo¹, A. Ballerini¹, V. Ricca¹, A.L. Zignego²

¹ Azienda Ospedaliero-Universitaria Careggi, department of neuroscience- psychology- drug research and child health, Florence, Italy

² Azienda Ospedaliero-Universitaria Careggi, center for systemic manifestations of hepatitis viruses MASVE- department of experimental and clinical medicine, Florence, Italy

* Corresponding author.

Introduction Interferon-alpha (IFN α) was the backbone therapy for HCV+ related chronic hepatitis (CH-C). However, it was associated with significant neuropsychiatric side effects and impaired health-related quality of life. Second Generation IFN α -free direct-acting antiviral agents (DAAs) seem to be associated with fewer side effects, better tolerability, high efficacy rates and better patient reported outcomes (PROs) [Younoussi, 2014].

Aims To describe the neuropsychiatric symptoms and PROs during Second Generation DAAs plus ribavirin oral treatment in a group of CH-C real world patients.

Methods Nineteen CH-C outpatients, scheduled for IFN α -free treatment, were assessed at enrolment (T0), at 4 (T1) and at 12 (T2) weeks, the end of treatment, by means of MDRS, HAM-D, HAM-A, MRS, Y-BOCS and SF-36. A pharmacological therapy, based on clinical evidence, was provided at psychiatric symptoms onset.

Results During the treatment, we didn't report any worsening in the administered psychometric scales. Furthermore, we observed a general improvement at week 12 (T2), statistically significant only for MRS ($P < 0.05$). Any statistically significant difference was found for SF-36 mean scores comparing T0, T1 and T2. However, SF-36

cluster analysis showed between T0 and T2 a meaningful and significant rise of global health clusters “General health perceptions” ($P < 0.05$), “Change in overall health status” ($P < 0.001$) and a significant impairment in cluster “Emotional role functioning” ($P < 0.05$).

Conclusions Our real world data are consistent with trial setting results [Younoussi, 2014]. Contrary to previous IFN α -based therapy, new regimens don't seem to be associated with psychiatric side effects and suggest an immediate gain in general health PROs over the treatment period.

Incapacity to decide in liaison psychiatry: Analysis of sample of patients admitted in somatic departments of a general hospital

M. Nascimento^{1,*}, F. Vicente², C. Oliveira², N. Silva³, C. Vieira¹, A. Luís¹, T. Maia¹

¹ Hospital Professor Dr. Fernando Fonseca- EPE, psychiatry, Amadora, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, psychiatry, Lisbon, Portugal

³ Centro Hospitalar de Vila Nova de Gaia/Espinho, psychiatry, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Decision capacity (DC) is a complex construct, whose assessment poses huge challenges to Liaison Psychiatrist (LP).

Objectives/aims Assess factors related to DC in patients with somatic disorders admitted in medical and surgical departments of a general hospital.

Methods Clinical records of patients who were submitted to a DC assessment at Hospital Fernando Fonseca (Portugal), from 1st January 2012 to 31st December 2014 were retrospectively analysed. Collected data were statistically analysed with SPSS[®]. Univariable analysis was performed, in order to determine factors related to DC.

Results Data from 35 patients subject to DC evaluation were considered, of whom 42.4% were considered unable to give consent to medical and/or surgical procedures. Most of these assessments were related to patients who refused treatment. Patients unable to decide were predominantly male and mainly affected by organic mental or neurocognitive disorders ($P < 0.05$). There were no statistical significant differences in the age of those considered able or unable to decide. After PL intervention, 40% of those considered unable to decide changed their decision. However, it was not significantly related to the ability to give consent.

Conclusions Neurocognitive disorders are common diagnosis found in patients admitted in somatic departments with no DC. Frequent change in decision after LP intervention may reflect not only cognitive fluctuations, but also a possible influence of LP intervention on patients' choices. Appropriate standardized measures are useful tools in assessing patients with cognitive impairment, reducing evaluation differences between professionals, and in order to increase LP decisions credibility.

Acute hypomania in systemic lupus erythematosus, differential diagnosis.

A case report

D.K. Ochoa García*, G.M. Chauca Chauca, L. Carrión Expósito
Hospital Infanta Margarita, Unidad de Salud Mental Comunitaria
Cabra, Cabra-Córdoba, Spain

* Corresponding author.

Introduction It is well known that seizures and psychosis are diagnostic criteria for systemic lupus erythematosus (SLE), however, there could be many other neuropsychiatric symptoms. The American College of Rheumatology Nomenclature provides case definitions for 19 neuropsychiatric syndromes seen in SLE (NPSLE), including cognitive impairment, psychosis, mood and anxiety disorders. Lack of specific manifestations difficult diagnosis and treatment.

Objectives To address the diagnostic difficulties that involve the appearance of hypomanic symptoms in the course of SLE treated with high doses of corticoids in a patient with a depressive episode history.

Method Description of case report and literature revision. We report the case of a 22-year-old woman who presented irritable mood, sexual disinhibition, insomnia and inflated self-esteem. The patient was recently diagnosed with SLE and was on treatment with 50 mg/d prednisone. She had familiar history for bipolar disorder and was taking 20 mg/d paroxetine since the last 6 months after being diagnosed with major depressive episode.

Results We proposed differential diagnosis between psychiatric symptoms secondary to central nervous system SLE involvement, a comorbid bipolar disorder or prednisone-induced mood symptoms. Fluctuation of hypomanic symptoms during hospitalization, poor relationship with variation in corticosteroid doses, findings on brain MRI compatible with vasculitis and positive antibodies, oriented this case to a neuropsychiatric manifestation of LES.

Conclusions We should keep in mind that symptoms of neuropsychiatric SLE may vary from more established manifestations of NPSLE to mild diffuses ones. More studies are needed to expand knowledge in the relationship between mood disorders and neuropsychiatric SLE.

Risk factors for a new cardiac event after a first acute coronary syndrome

P. Ossola^{1,*}, F. Scagnelli¹, A. Longhi¹, C. De Panfilis¹, M. Tonna², C. Marchesi¹

¹ University of Parma, Psychiatry Unit-Department of Neuroscience, Parma, Italy

² AUSL of Parma, Mental Health Department, Parma, Italy

* Corresponding author.

Introduction Depression is an established risk factor for acute coronary syndrome (ACS), nonetheless the mechanisms underlying this association are still unclear and literature disagrees on the role played by anxiety. Moreover, most of the studies included subjects with a long lasting history of heart disease or recurrent depressive episodes that could bias the results.

Objectives We performed serial assessments of anxiety, depression and new cardiac events in a cohort of never-depressed patients in the two years after their first ACS.

Aims Clarify the role of anxiety and depression in predicting new cardiac events.

Methods Two hundred and fifty-one consecutive patients completed the two-years follow-up. The presence of depression was evaluated with the Primary Care Evaluation of Mental Disorders (PRIME-MD) and its severity with the Hospital Anxiety and Depression Scale (HADS). Evaluations were collected at baseline, when GRACE-score was calculated, and at 1, 2, 4, 6, 9, 12 and 24-months follow-ups.

Results Forty-two patients (16.7%) developed a second cardiac event and, of these, eighteen (42.9%) had a previous depressive episode. At Cox Regression, controlling for confounding clinical variables (e.g. GRACE-score), developing a first-ever depressive episode was a significant risk factor (OR=2.38; 95%CI=1.11–5.14; $P=0.027$) whereas baseline anxiety was protective (OR=0.56; 95%CI=0.38–0.81; $P=0.002$). The latter, moreover, moderated the effect of incident depression on new cardiac events.

Conclusion Our results confirm the well-established detrimental effect of depression on cardiac prognosis and suggest clinicians to keep in mind anxious symptoms when facing a patient at his/her first ACS.

Affective disorders in multiple sclerosis

M. Said¹, S. Ouane^{2,*}, R. Nefzi¹, A. Aissa¹, H. Maatallah¹, H. Ben Ammar¹, Z. El-Hechmi¹

¹ Razi Hospital, Psychiatry F, Mannouba, Tunisia

² Razi Hospital, Mannouba, Tunisia

* Corresponding author.

Background Psychiatric disorders have a remarkable frequency in multiple sclerosis. The leading group of these disorders consists of affective disorders. These psychiatric conditions can worsen the outcome of multiple sclerosis, thus contributing to increase the burden of the disease to both patients and relatives. Managing such a complicated situation needs a focus on the underlying links between affective disorders and multiple sclerosis.

Objective To examine the hypotheses proposed to explain the high prevalence of affective disorders in patients with multiple sclerosis.

Methods Literature was reviewed using the Medline database and the following keywords “bipolar disorder” “affective disorder”, “mania” and “multiple sclerosis”.

Results PubMed research returned 13 results. After manual inspection, 10 articles were retained and examined. The cause of the high comorbidity between multiple sclerosis and mood disorders is regarded as being multifactorial: the medication used in multiple sclerosis possibly inducing/exacerbating mood disturbances, the demyelinating brain lesions which could bring about depression or mania, genetic overlapping with affective disorders and last the psychological reactions and adjustment difficulties to the neurological handicap.

Conclusion Despite the fact that the higher prevalence of affective disorders in multiple sclerosis is well established, these disorders still remain underdiagnosed and undertreated. A shift towards a better assessment of the psychiatric comorbidity in multiple sclerosis patients and the optimal treatment of those disorders is fundamental.

* Corresponding author.

Introduction Analyze the number of interdepartmental consultations carried out at Department of Psychiatry, Hospital Nuestra Señora del Prado from other areas of hospitalization during 2014.

Objectives The goal is to evaluate the prevalence of psychiatric disorders in patients who are hospitalized for other reasons, and which services are needed the most.

Methods Retrospective cross-sectional descriptive study. A record of consultations carried out by the psychiatry service in 2014 was collected. The data were analyzed according to the origin of the consultation service, the month when it was performed and the sex of the patient. The monthly percentage of interconsultations and the percentage represented by each interconsultation service were calculated. They classified according to sex.

Results In 2014, 211 interconsultations were carried out, 104 men and 86 women. Surgery 16, 11%, pneumology 13, 74%, internal medicine 12, 32%, traumatology 8, 06%, digestive 7, 11%), I.C.U. 6, 64%, cardiology 6, 16%, hematology 5, 69%, oncology 5, 21%, pediatrics 4, 27%, gynecology 2, 84%, emergency 1, 90%, palliative 1, 90%, endocrinology 1, 42%, urology 1, 42, nephrology 0, 95%, E.N.T. 0, 95%, obstetrics 0, 47%, dermatology 0%, ophthalmology 0%, rheumatology 0%. January 12, 8%, February 13%, March 9, 5%, April 6, 2%, May 5, 7%, June 8, 1%, July 6, 2%, August 4, 3%, September 8, 1%, October 12%, November 7, 6%, December 6, 2%.

Conclusions Most of the interconsultations were carried out in January, February and October. However, August was the least busy month. The busiest service was the Surgery service, followed by the Pneumology and Internal Medicine one. There were no interconsultations of the Ophthalmology, Rheumatology and Dermatology services. The consults were in demand mainly by men rather than women.

Psychological syndrome analysis (Vygotsky – Luria School) in psychosomatics: Clinical and psychological study of patients with mitral valve prolapse

E. Pervichko^{1,*}, Y. Zinchenko¹, A. Martynov²

¹ Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

² Moscow State University of Medicine and Dentistry, Faculty of General Medicine, Moscow, Russia

* Corresponding author.

Introduction One of the dominant methodological principles of Russian clinical psychology (the Vygotsky-Luria School) is the principle of Psychological syndrome analysis (PSA). It can also be heuristically applied to psychosomatics.

Objective To identify a psychosomatic syndrome in patients with mitral valve prolapse (MVP).

Materials and methods We applied various techniques for a qualitative and statistical data analysis of clinical and psychological study. We explored our patients' individual personality profiles, anxiety level (Spielberger et al., 1983), features of achievement motivation (Heckhausen, 1963), emotion regulation strategies (ERS) (Zinchenko, Pervichko, 2014; Pervichko, 2015), dynamics of the patient's emotional state in stress conditions, and degrees of manifestation of MVP clinical symptoms. The study comprised 134 MVP patients, mean age was 24.8 ± 1.2 years, and 73 healthy subjects, mean age was 27.5 ± 1.3 years.

Results MVP patients proved to be more prone to emotional stress; they were also inclined to choose less effective ERS as compared to healthy subjects. ANOVA data revealed dependence of intensity of such clinical symptoms as cardialgia, tension headaches and psychogenic dyspnea on the degree of anxiety level and the presence of dysfunctional ERS in MVP patients. The interpretation of the study results with PSA method suggested that the patients' psychological and clinical characteristics form into a psychosomatic syndrome. The first syndrome-generating factor is the presence of the approach – avoidance motivational conflict in achievement settings. Dysfunctions of emotion regulation appear as a second syndrome-generating factor in psychosomatic syndrome in MVP patients.

Conclusions PSA (the Vygotsky-Luria School) can be used as a means to approach diagnostic and prognostic tasks in Clinical psychology and Psychosomatic medicine.

Low-FODMAP-diet in irritable bowel syndrome offers benefits not only in terms of gastrointestinal symptoms, but also in terms of psychopathology in the medium- and long-term

D. Piacentino^{1,*}, S. Rossi², L. Piretta¹, D. Badiali², N. Pallotta², E.S. Corazziari²

¹ Sapienza-University of Rome, NESMOS Neuroscience-Mental Health-and Sensory Organs Department, Rome, Italy

² Sapienza-University of Rome, Department of Internal Medicine and Medical Specialties, Rome, Italy

* Corresponding author.

Introduction Low-FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diets are strongly recommended to improve irritable bowel syndrome (IBS) symptoms. They are also hypothesized to improve the psychopathological status that often accompanies the syndrome. A study (Ledochowski et al., 2000) suggested that the ingestion of FODMAPs affected negatively the mood and that the elimination of dietary FODMAPs improved depressive symptoms.

Objectives/aims We aimed to assess the levels of psychopathology pre- and post-diet in IBS patients free of any severe psychiatric disease (e.g., bipolar disorder, major depressive disorder, schizophrenia) or alcohol/substance abuse.

Methods We consecutively recruited 75 IBS outpatients (68% females; age range = 21–68 years) at the Gastrointestinal Outpatient Center of our University Hospital. They filled out the Symptom Checklist-90-Revised (SCL-90-R), a visual analogue scale (VAS) to rate the intensity of abdominal bloating/pain, and a 2-week diary card registering the frequency of bloating/pain. Then, they were blindly assigned to a low-FODMAP diet, a low-FODMAP gluten-free diet and a control diet for 4 weeks. During the last 2 weeks they filled out a 2nd diary card and re-rated the intensity of bloating/pain. Patients were reassessed after a 16-month follow-up. Independent

t-test, χ^2 test, and one-way ANOVA with Tukey post-hoc test were used.

Results Baseline characteristics did not differ between the three groups. Post-diet and at follow-up, the two low-FODMAP diets, vs. the test diet, improved not only the intensity and frequency of bloating/pain, but also the SCL-90-R GSI, anxiety, and phobic anxiety scores (*P*-values < 0.05).

Conclusions The low-FODMAP diet may improve psychopathology in IBS patients.

EV435 Life satisfaction and enjoyment in medication-overuse headache patients: The role of depression and insomnia

M. Pompili^{1,*}, G. Paolo², P. Martelletti³

¹ Rome, Italy

² Sapienza, Department Nesmos, Roma, Italy

³ Sapienza, Department of Clinical and Molecular Medicine- Sapienza University of Rome and Regional Referral Headache Centre-Sant'Andrea Hospital-Rome-Italy, Roma, Italy

* Corresponding author.

Introduction Epidemiological research has documented a strong association between medication-overuse headache (MOH) and psychiatric disorders, emotional disturbances, and disordered personality traits, which are associated with worse outcomes, poorer quality of life, and higher costs to the health care system.

Objectives Identifying risk factors for progression of headache into MOH represents one of the most relevant public health priorities and psychiatric comorbidity has been identified as a potential factor related to chronic phases.

Aims The aim of the present study was to determine whether depression and insomnia complaints were associated with satisfaction and enjoyment with one's own life in Medication-overuse headache (MOH) patients, and whether insomnia complaints were able to explain part of the variance of QoL explained by depression.

Methods Participants were 187 consecutive adult outpatients admitted to the outpatient headache clinic. Patients were administered the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q), the Beck Depression Inventory-II (BDI-II), and the Athens Insomnia Scale (AIS).

Results The BDI was associated with all the dimensions of the Q-LES-Q, with more severe depression being associated independently with lower satisfaction and enjoyment with one's own life. The AIS was independently and significantly associated only with physical health, such that patients with more insomnia complaints were 3.1 times (*P* < 0.001) more likely to report lower physical health satisfaction.

Conclusions Our findings confirmed that MOH has a negative impact on quality of life, and suggested that depression and insomnia were independently associated with satisfaction and enjoyment of life in MOH patients.

* Corresponding author.

Introduction Psoriasis has a significant impact on the mental and emotional functioning.

Objective It has been reported that the risk of psychiatric comorbidity increases with the severity of the disorder, and the most frequent associations appear to be those with depression and anxiety.

Aims To analyze the association between psoriasis, mental disorders and suicidal ideation in a sample of patients affected by psoriasis. To investigate the differences between psoriasis patients and patients with other dermatologic diseases.

Methods Participants were 242 consecutive patients (142 women and 100 men), 112 patients with psoriasis (46.3%), 77 with melanoma (31.8%) and 53 with allergy (21.0%). All patients were administered a structured sociodemographic interview and the following measures: the Hamilton Rating Scale for Depression (HAM-D) and the Hamilton Rating Scale for Anxiety (HAM-A). We also assessed current and previous suicidal ideation and previous suicide attempts.

Results Patients with psoriasis (compared to other groups of patients) more frequently had a comorbid mood disorder (16.1% vs 3.9% and 0.0%, respectively for patients with melanoma and patients with allergy; $\chi^2_2 = 14.98$; $P < 0.001$), past suicidal ideation (33.9% vs 15.6% and 18.9%, respectively for patients with melanoma and patients with allergy; $\chi^2_2 = 2.05$; $P < 0.01$) and attempts (6.3% vs 0.0% and 0.0%, for the other groups of patients; $\chi^2_2 = 8.37$; $P < 0.05$). Patients with psoriasis reported higher HAM-D scores than melanoma patients.

Conclusions The clinical evaluation of patients with psoriasis should include the assessment of psychiatric comorbidities and the routinely assessment of suicide risk.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Apathy and impulse control disorders association: A study in a sample of Parkinson's disease patients

N. Sáez-Francàs^{1,*}, N. Ramirez¹, J. Alegre-Martin², O. De Fabregues³, J. Alvarez-Sabin³, J. Hernandez-Vara³

¹ Hospital Saint Rafael, Department of Psychiatry, Barcelona, Spain

² Hospital Universitari Vall D'hebron, Vall D'hebron Institut de Recerca, Internal Medicine, Barcelona, Spain

³ Hospital Universitari Vall D'hebron, Vall D'hebron Institut de Recerca, Neurology, Barcelona, Spain

* Corresponding author.

Introduction Parkinson's disease (PD) is a neurodegenerative disorder that is associated with a wide range of motor symptoms, cognitive deficits and behavioral disorders. Apathy and impulse control disorders (ICDs) are common in these patients and have been considered opposite ends of a reward and motivation disorders continuum.

Aim To evaluate the association and impact of ICDs presence on apathy symptoms in PDs patients, considering the influence of other psychopathological symptoms on this association.

Methods This is a cross-sectional, observational study in which 115 consecutive medicated PD patients without dementia (mean age 61.22 ± 13.5 years; 63.5% men) were recruited. All the patients underwent a psychiatric and neurologic evaluation. Motor

dysfunction was assessed with the Unified Parkinson's disease Rating Scale (UPDRS), ICDs were evaluated with the Minnesota Impulse Control Disorders Inventory (MIDI) and apathy with the Lille Apathy Scale (LARS). The Hamilton Depression scale (HAM-D). The State-Trait Anxiety Inventory (STAI-S) and Barrat Impulsivity Scale (BIS) were also administrated.

Results Twenty-seven (23.5%) patients showed an ICD. Patients with an ICD scored higher in apathy ($P = 0.012$), trait anxiety ($P = 0.003$) and impulsivity ($P = 0.008$). There were no differences in depressive symptoms. In the linear regression analysis, TCI was associated with more severe apathy ($b = 4.20$, $t = 2.15$, $P = 0.034$).

Conclusions ICDs and apathy are frequent in PD. Although ICDs have been related with a hyperdopaminergic state and apathy with low dopamine levels, the observed frequent association suggests common etiopathological mechanisms.

Seizure as a conversion symptom, a case report

N. Salgado^{1,*}, S. Benavente², B. Macias¹, J.M. Coll³

¹ Hospital Dr. Rodriguez Lafora, Psiquiatria, Madrid, Spain

² Hospital Universitario 12 de Octubre, Psiquiatria, Madrid, Spain

³ Hospital Unversitario la Paz, psiquiatria, Madrid, Spain

* Corresponding author.

Introduction Patients with conversive disorder could show atypical clinical presentations with neurological symptoms that are not frequently seen currently.

Case Report A 21-year-old female who was diagnosed of conversive disorder was admitted into a short-stay psychiatric unit for two weeks to introduce treatment and receiving a diagnosis. She presented few seconds long seizures in members without biting her tongue and keeping control of sphincters, always surrounded by relatives. A neurological study was made with CT scan and electroencephalography and no evidences of neurological abnormalities were found. Various treatments were used but seizures went worse. Venlafaxine (150 mg/day) was prescribed after hipothymc reactive symptoms were observed, which together with pshycotherapy achieved clinical improvement in the two months follow-up.

Discussion Patients with conversive disorder don't respond appropriately to pharmacologic treatment. In order for patients to understand the situation it is important to keep them updated in an empathic manner. It is important to exclude other causes.

Conclusions A detailed psychopathological exploration should be made in all conversive patients, to explore symptoms and comorbidities that could reveal new therapeutic treatment.

⁴ Complejo Asistencial de Zamora, Gerencia de Atención Primaria, Zamora, Spain

* Corresponding author.

Introduction Diabetes mellitus (DM) has been associated with major depressive disorder, schizophrenia, Alzheimer's, Parkinson's and mild cognitive impairment. To determine the psychiatric and somatic comorbidity in diabetic patients treated by our Liaison Psychiatry Unit.

Methods Sociodemographic variables (age, sex, marital status, place of residence) and clinical (somatic disease that motivates the admission, comorbid somatic pathology, number of concomitant somatic diseases, drug consumption and its type, psychiatric history, previous psychiatric diagnosis, number of concomitant psychiatric disorders).

Study Design Epidemiological study of 172 diabetic patients, from the total of 906 consulted from 1 January 2012 until 31 December 2014.

Bioethical considerations The study complies with the principles of justice, non-maleficence, autonomy and beneficence.

Results The average age is 72 years, 50% are women, 49.4% are married, and 54.1% live in rural areas. Somatic diseases that most frequently motivate admission at the hospital are the endocrine-metabolic (14%), gastrointestinal (12%) and cardiovascular (12.2%). A total of 32.5% of the sample have six comorbid somatic diseases and 55.2% five. A percentage of 14.5 of patients recognize consumption of toxic (cigarettes–12.2%–7.6% Alcohol). One hundred and eight patients have a history of psychiatric disorders (62.8%), especially anxiety disorders (28.4%), depression (14.5%) and organic mental disorders (11.1%).

Conclusions There is a high psychiatric and somatic comorbidity in diabetic patients, therefore it would be desirable early diagnosis and treatment to provide symptomatic control of both types of pathologies.

Use of atypical antipsychotics in delirium

F. Sanchez*, M. Gutierrez Rodríguez, C. Moreno Menguiano, S.M. Bañon Gonzalez, P. Muñoz-Calero Franco

Hospital Universitario de Mostoles, Psychiatry, Mostoles, Spain

* Corresponding author.

Introduction Delirium is a generally abrupt clinical onset in which an impairment of attention and other brain functions occurs. May occur in up to 40% of patients admitted to intensive care unit. Clinical manifestations fluctuate throughout the day. Very different symptoms such as disorientation, agitation, drowsiness, hallucinations may occur. It is particularly common in hospitals and the elderly or patients with pre-existing disease. It should first rule out systemic causes: infectious, metabolic, toxic and drug.

Methods The literature sources were obtained through electronic search of articles in PubMed database of the last five years.

Discussion It was found atypical antipsychotic that are effective and safe in treating. Haloperidol compared showed similar efficacy. On the effectiveness of preventive treatment of this condition in patients with risk factors the results are inconclusive.

Keywords Atypical antipsychotic; Delirium; Efficacy

⁴ Uskudar University, psychiatry, Istanbul, Turkey

* Corresponding author.

Aim In this study we aimed to identify the perceptions and thoughts and their association with state/trait anxiety, depression that may lead to resistance to insulin treatment in patients with previously diagnosed type 2 diabetes mellitus (DM) patients in order to facilitate their compliance with insulin treatment.

Method In this study, 120 patients were recruited with a previous type 2 DM diagnosis from the diabetes outpatient clinic. Patients were evaluated with sociodemographic data, State-Trait Anxiety Inventory, Problem Areas in Diabetes Scale, Insulin Treatment Appraisal Scale, Beck Depression Inventory.

Results A majority of the patients were found to have resistance for starting insulin treatment. Most of the patients who were on other treatment alternatives reported that they wouldn't use insulin even if they were prescribed insulin. A significant number of patients reported negative perceptions and thoughts about insulin treatment such as "insulin is a punishment", "it is a shame to use insulin where other people can see". In women injection phobia was significantly higher. Injection avoidance was significantly high and was more related to feeling insufficient about administration instead of worries about pain. Psychological resistance to insulin was significantly related to depression but not associated with state or trait anxiety levels. Lack of education and knowledge was found to be another important contributor to this resistance.

Results Type 2 DM patients show psychological resistance to insulin treatment due to negative perceptions and thoughts about the treatment. Cognitive interventions targeting these factors may be useful to overcome psychological insulin resistance and facilitate glysemic control.

Alexithymia and the incidence of post-stroke depression

J.A. Su

Chang Gung Memorial Hospital - Chiayi, Department of Psychiatry, Chiayi, Taiwan

Backgrounds Post-stroke depression (PSD) is the most frequent neuropsychiatric consequence of stroke and often leads to poor recovery and higher mortality. Identification of patients at high risk of PSD and providing early interventions is important to alleviate negative outcomes. Alexithymia is a construct characterized by the inability to identify and describe emotions, and is also considered as a deficit in emotional processing. Alexithymia has a close relationship to depression. Our study aimed to determine whether alexithymia is a risk factor for the development of PSD.

Methods Patients with ischemic stroke admitted to a general teaching hospital were enrolled in this six-month study. Demo-

graphic data were collected, and the patients were evaluated with the Toronto Alexithymia Scale-20 (TAS-20), NIHSS, BAI and MMSE at baseline, and then followed up each month for detection of PSD using the Center for Epidemiologic Studies of Depression (CES-D) scale.

Results In all, 285 patients with ischemic stroke were enrolled, and 93.3% completed the 6-month study. The overall incidence of PSD within six months was 16.5%. In multivariate regression analyses, the incidence of PSD was significantly associated with higher BAI, higher NIHSS and higher TAS-20 scores.

Conclusions Higher levels of alexithymia, anxiety and stroke severity were identified as risk factors for PSD. This is the first study to address the significant relationship between alexithymia and PSD. Clinical professionals should pay more attention to stroke patients with alexithymic features and other risk factors, so as to be able to intervene and possibly prevent the occurrence of PSD.

The resource utilisation associated with medically unexplained physical symptoms

F. Sundram^{1,*}, K. Lee², M. Johnson¹

¹ University of Auckland, Psychological Medicine, Auckland, New Zealand

² University of Otago, Medicine, Dunedin, New Zealand

* Corresponding author.

Introduction Patients with medically unexplained physical symptoms (MUPS) may present frequently to hospital settings and receive potentially unnecessary investigations and treatments.

Objective A sample of 49 patients was drawn and their hand-written and electronic clinical records were examined in detail to extricate all MUPS-related secondary care activity within six months of the MUPS presentation (emergency department, inpatient stays, outpatient appointments, and all associated investigations, procedures and medications).

Aims We aimed to assess the frequency and type of MUPS presentations to clinical services and estimate the associated direct healthcare costs.

Method This study was undertaken at Waitemata District Health Board (WDHB), the largest DHB in New Zealand. All patients with a diagnosed presentation of MUPS in 2013 were identified using the WDHB clinical coding system. Their clinical records were screened to select all patients who matched the study inclusion and exclusion criteria. Standardised national costing methodology was used to calculate the associated healthcare costs.

Results Forty-five percent of patients presented to hospital settings at least twice over the one-year timeframe. The most common diagnoses were non-epileptic seizures (31%) and hyperventilation syndrome (30%). The total cost for the sample was NZ\$179, 271 (mean NZ\$3659). Costs were most significant in the areas of inpatient admissions and emergency care.

Conclusion MUPS can result in frequent presentations to hospital settings. The costs incurred are substantial and comparable to the costs of chronic medical conditions with identifiable pathology. Improving the recognition and management of MUPS has the potential to offer more appropriate and cost-effective healthcare nationally and internationally.

³ Hospital 12 de Octubre, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Interconsultations services are a fundamental part of the psychiatry departments as they constitute the junction point with other medical and surgical specialties.

Objectives Descriptive study of the psychiatric assessments and interventions in the consultation liaison unit of a general hospital over a period of one year (2014).

Aims Establish whether there is some degree of stability in the type of requested psychiatric assessment.

Methods Creation of a database from the information of the medical record of the units of psychiatrics' interconsultation with the subsequent statistical processing.

Results Regarding the results obtained during the year 2014 and compared it with the ones of 2013, it shows that despite the number of inquiries has increased almost twice (397 to 764) it has remained relatively stable the hierarchy order of requests but with a slight increase of adaptive depressive disorders (Fig. 1).

Conclusions Given our results, despite the limitations of this type of study (cross-sectional study), we consider that there is some stability in the type of psychiatric assessment requested. We believe it is essential to make this type of assessment as they allow the development of strategies in order to improve the psychiatric care.

A cognitive behavioral model for panic attack treatment in comorbid heart diseases (PATCHD): A pilot study from the real-world

P. Tully

University of Adelaide, Medicine, Adelaide, Australia

Background Treating panic disorder comorbid with heart disease is challenging due to:

- diagnostic overlap;
- the risk associated with ignoring chest pain and delaying seeking medical attention;
- that cognitive-behavioral therapy based on “catastrophic misinterpretation of bodily symptoms” requires adaption to incorporate the element of risk;
- that some interoceptive symptom inductions may be harmful.

Objective To describe a cognitive-behavioral therapy model of panic attack treatment in comorbid heart diseases (PATCHD).

Methods We developed a modified CBT model that is based on enhancing coping skills, performing safe interoceptive exposures, supervised exercise, and countering avoidance. Eighteen persons referred to PATCHD had a dominant clinical picture of panic attack/panic disorder after their heart failure (HF) diagnosis. We quantified the total number of admissions and the length of hospital stay (LOS) for CVD (ICD Codes I00–99) and psychiatric causes (F00–99). Hospital data was collated blinded to original diagnosis.

Results Using paired t-tests bootstrapped 1000 times we found evidence that there was a significant reduction in CVD admissions and hospital LOS in the 6 months after participation in PATCHD. There was however no significant change in psychiatric admissions or psychiatric LOS. Pre- and post-treatment data from 14 HF participants suggested a reduction in GAD-7 anxiety symptoms, total PHQ-9 depression, cognitive-affective depression symptoms, but not somatic depression symptoms.

Conclusions Pilot data suggested that PATCHD was associated with a reduction in cardiovascular hospital admission and LOS, general anxiety and depression, however the findings were based on non-randomized and paired-sample data.

psychological experiences reported in regarding hepatitis C and use of interferon: A clinical-qualitative study in a Brazilian university outpatient service considering its possible side effects

I.D. Fahl, F.D. Costa, R.S.B. Stucchi, E.R. Turato*

University of Campinas, Laboratory of Clinical-Qualitative Research, Campinas SP, Brazil

* Corresponding author.

Relevant emotional and behavioural reactions are associated with diagnosis and treatment of hepatitis C that can impair adherence to medical management. Hepatitis C accounts for significant number of both – liver transplants and deaths. Treatment has as major component the interferon alpha, and many of patients can experience side effects that often lead to non-adherence to drug treatment and dose modification.

Objective To discuss psychological meanings attributed to IFN alpha treatment's side effects and its symbolic relation with adherence or not to treatment, on viewpoint of interviewed outpatients at a Hepatitis Service.

Method Data collection was conducted using the Clinical-Qualitative Method, utilizing semi-directed interviews with open-ended questions in depth, fully transcribed. Qualitative Content Analysis employed for processing data, emerging meaning cores, with categorization into discussion topics. Sample closed by information saturation.

Results Nine interviews. The analysis revealed:

- coping attitude - handling the disease to have willpower; a moral feeling regarding the need to overcome the disease and treatment side effects to demonstrate “strength”, as well as to deny psychologically the occurrence of side effects;
- disruptive attitude: reports of anxiety regarding to patients presenting neuropsychiatric symptoms by medication;
- realistic attitude: speeches show perception of natural evolution and treatment real function.

Conclusion Guilt feelings emerged regarding to difficulties of being loyal to treatment, a strongly valorative speech on being ill what must lead to “overcome the evils of life”. Health teams must understand these meanings to talk openly about human feelings on illness and treatment, promoting an adequate adherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Stress factors and mental disorders in systemic sclerosis

D. Veltishchev^{1,*}, O.B. Kovalevskaya¹, O.F. Seravina¹, M.N. Starovoitova², T.A. Lisitsyna²¹ Moscow Research Institute of Psychiatry, Stress Related Disorders, Moscow, Russia² Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases, Moscow, Russia

* Corresponding author.

Introduction Systemic sclerosis (SSc) is a chronic, multisystem disease of unknown etiology characterized by autoimmune inflammation, abnormalities in small blood vessels, and progressive fibrosis of the skin and visceral organs. Mental disorders (MD), especially depression, occur quite often with SSc. The influence of childhood experience, relations' traumatic events with SSc and MD, and MD's clinical specific have not investigated carefully still. The investigation has been realized in accordance with the interdisciplinary program “stress factors and mental disorders in auto-immune inflammatory rheumatic diseases”.

Methods Sixty SSc patients (4 male and 56 female mean age 49.9 ± 13.5) were included. ICD-10 criteria were used for MD semi-structured interview. The stress factors were analyzed with the specially elaborated scale. The cognitive disorders and their severity were diagnosed by neuropsychology tests.

Results Early traumatic childhood experiences (parental deprivation mainly) observed in 90% cases. The significant stress factors were preceded SSc symptoms in 80% and MD in 70% cases. Most patients self-reported connection between stressful life events and exacerbation of SSc. MD preceded SSc in 76.6% cases. MD were diagnosed in 48 (80%) SSc patients: depressive episode (mild, moderate) – 26.6%, recurrent depressive disorder – 16.6%, dysthymia – 23.3%, adjustment disorder – 6.6% and schizotypal disorder – 40%. The mild or moderate cognitive impairments were diagnosed in all MD cases.

Conclusion Individual history of stressful life events is important factor for the predisposition and provocation of the rheumatic disease and MD in SSc patients. Depressive, schizotypal and cognitive disorders are the common MD in SSc patients.

Mental health of traumatized refugees and asylum seekers: Experiences of a centre of transcultural psychiatry in Hannover, Germany

U. Altunoz*, S. Castro Nunez, I.T. Graef Calliess
Klinikum Wahrendorff Psychiatry Hospital, Transcultural Psychiatry,
Hannover, Germany

* Corresponding author.

Introduction Germany has always been an important host country for traumatized refugees and asylum seekers. Although, recently an increasing number of investigations about mental health of individual migrant groups have been published in Germany, there is a paucity of research concerning mental health of asylum seekers and refugees.

Aims-objectives To investigate socio-demographic and clinical characteristics of traumatized refugees-asylum seekers who were applied to an outpatient psychiatry clinic in Germany.

Method A standardized data collection form (socio-demographics, diagnosis, suicidality, etc.) was filled by therapists for each traumatized refugee-asylum seeker who was applied to outpatient clinic of Klinikum Wahrendorff-Centre of Transcultural Psychiatry between April 2013 and October 2015.

Results Fifty-eight traumatized refugees-asylum seekers (F/M=27/31, age: 34.7 ± 1.4) were assessed. 53 (91.4%) of them were assessed via interpreters. Thirty (51.7%) of them were staying in refugee-dormitories, 25 (43.1%) of them were living alone. They've been living in Germany for 19.9 ± 16 months (min: 1–max: 82). Psychiatric symptoms appeared before 29.9 ± 19 months. Time to reach to psychiatric care in Germany was 14.2 ± 11 months. Psychiatric diagnoses were posttraumatic stress disorder (PTSD): 12 (21%), depression + PTSD: 44 (76%), depression: 2 (3%). Fifty-three (91.4%) of them had suicidal ideation and 16 (27.6%) of them had at least one suicide attempt before.

Conclusions Traumatized refugees in this study have high rates of suicidal ideation and suicide attempts and it takes months to years for them to reach a psychiatric care. Therefore, strategies should be developed for early detection of PTSD symptoms in traumatized refugees and access barriers to reach a psychiatric care should be overcome.

⁵ Centro Hospitalar V.N. Gaia/Espinho, Department of Psychiatry and Mental Health, V.N. Gaia, Portugal

* Corresponding author.

Introduction Sleep paralysis (SP) is relatively frequent condition, occurring either at sleep onset or sleep offset. It occurs at least once

in a lifetime in 40–50% of normal subjects. During SP, the patient experiences gross motor paralysis, while the sensory system is clear. Hypnagogic and hypnopompic hallucinations are common. This experience might be interpreted as a spiritual phenomenon in several cultures, each one with different interpretations and attributions.

Objective The authors revisit the clinical presentation of sleep paralysis and how this sleep disorder is seen from a cultural perspective.

Aims To describe several cultural interpretations of SP.

Methods A literature review of the theme is shortly surveyed.

Results It is very common during an episode of SP sensing the presence of menacing intruders in one's bedroom. Supernatural accounts of this hallucinated intruder are common across cultures. It has been traditionally labeled “ghost oppression” among the Chinese. In the Abruzzo region (Italy), the supernatural interpretation of the phenomena is called the Pandafecche attack. One study found that nearly half (48%) of the participants from the general Egyptian population believed their SP to be caused by the Jinn, a spirit-like creature. In Southwest Nigeria, Ogun Oru is a traditional explanation for nocturnal neuropsychiatric disturbances. The characteristics of the ‘a dead body climbed on top of me’ phenomenon suggest that is identical to sleep paralysis and a frequent experience among Mexican adolescents.

Conclusions Depending on the etiological interpretations of SP, which is largely culturally determined, patients react to the event in specific ways.

Does depression conciliate in marital adjustment?

A. Channa

Liaquat National Hospital, Psychiatry, Karachi, Pakistan

Marriage is one of the principal facets when it comes to interpersonal context of depression. There is evidence supporting bidirectional casual effect between depression and marital satisfaction. However the phenomenon of marital adjustment and its related variable has not been given much attention in the Pakistan.

Objective To determine the frequency of marital adjustment in patients with depression.

Method Depressed patients, who were aged between 15–65 were included. Patients who had documented co morbid of substance use or any unstable serious general medical condition were excluded. The severity of depression was evaluated by using Urdu validated Hamilton Depression Rating Scale. Marital adjustment is determined by using Urdu validated version of Kansas Marital Satisfaction Scale.

Result Only 8.6% were well adjusted in their marital life, and all were females. The association of marital adjustment and severity of depression and difference in both genders on KANSAS was insignificant. The longer duration of illness was positively interrelated to the marital adjustment with odd ratio of 7.6. Being employed and above 30 years of age were inversely related to marital satisfaction with odd ratio of 6.1 and 5.4 respectively. However, the correlation between other independent variables and marital adjustment were insignificant in both genders.

Conclusion This study confirms the presence of high frequency i.e. 91.4% of marital dissatisfaction in depression in both male and females, irrespective of their severity of depression.

The impact of traditional healers on the treatment of psychotic patients in Alexandria, Egypt

S. Darwish

Mamoura Mental State Hospital, Adult Psychiatry and Addiction, Alexandria, Egypt

Introduction Psychotic symptoms in the Egyptian community have always been mixed up with supernatural phenomena. This makes patients and their families seek help from traditional healers who can abuse them physically, financially and sexually.

Aim The aim of the study was to assess the impact of the traditional healers on the psychotic patients in the Egyptian community.

Objectives To measure the percentage of patients going to traditional healers and how much they pay and for how long.

Methods The study was conducted on a total of 555 psychotic patients. Four hundred and fifty-five psychotic patients from the Mamoura Mental state Hospital and 100 psychotic patients from a private hospital in Alexandria in duration of three months in 2006. A special questionnaire was designed and was run for all patients and their families.

Results A total of 67.4% of male patients consulted healers while 88.4% of the females consulted healers. Only 9.4% of the females who went to the healers were highly educated compared to 19.7% of the male patients. The majority of the patients who improved were illiterate or can only read and write. Lower socioeconomic groups tend to have a higher percentage in consulting healers and a longer duration of staying in treatment with them. Although therapy at the first session tended to be for free, from the second session forward patients pay more than they would pay seeing a psychiatrist.

Conclusions Traditional healers have a negative impact on the psychiatry practice and are sources of patient's abuse in Egypt.

Stress management versus cognitive restructuring: A randomized clinical study on traumatized refugeesM. Ekstrøm^{1,*}, J. Carlsson¹, C. Sonne¹, E.L. Mortensen²¹ *Mental Health Centre Ballerup, Competence Centre for Transcultural Psychiatry, Ballerup, Denmark*² *University of Copenhagen, Department of Public Health, Copenhagen, Denmark** *Corresponding author.*

Background and aim There is a lack of evidence regarding which kind of psychotherapy that is the most effective when treating traumatized refugees. Studies on the effect of psychotherapy among other patient groups with PTSD suggest a good effect using cognitive behavioural therapy (CBT). The competence center for transcultural psychiatry (CTP) has specialized in the treatment of traumatized refugees. The objectives were to study the effect of CBT with a focus on either stress management or cognitive restructuring in a clinical sample of traumatized refugees with PTSD and to identify predictors for the treatment effect.

Methods All patients ($n=143$) referred to CTP from June 2011–March 2012 and fulfilling the inclusion criteria were offered to participate in the study. Participants were offered combined treatment with a psychiatrist (psycho-education and psychopharmacological treatment when needed) and a psychologist (CBT). The duration of the treatment was 6–7 months. The participants were randomized to either CBT with a focus on stress management or cbt with focus on cognitive restructuring. The primary outcome was PTSD measured by the Harvard Trauma Questionnaire.

Results The results are presently being analyzed and will be presented at the congress.

Conclusions Both research results and the clinical experience at CTP suggest, that cognitive restructuring is not always a useful tool and that stress reducing techniques could be more useful. This hypothesis was tested in the present study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV453

The treatment of traumatised refugees with sertraline versus venlafaxine in combination with psychotherapy – a randomised clinical studyM. Ekstrøm^{1,*}, C. Sonne¹, J. Carlsson¹, P. Bech², A. Elklit³¹ *Mental Health Centre Ballerup, Competence Centre for Transcultural Psychiatry, Ballerup, Denmark*² *University of Copenhagen, Psychiatric Center North Zealand, Hillerod, Denmark*³ *University of Southern Denmark, National Center of Psychotraumatology, Odense, Denmark** *Corresponding author.*

Background and aim Today we lack sufficient evidence to conclude which type of treatment approach that is most efficient when it comes to trauma-affected refugees. That is a problem for both patients and doctors as well as for society. Also there is a lack of studies, which examine the relation between psychosocial resources and treatment efficiency, in order to find reliable predictors of treatment outcome. This study therefore aims to produce new evidence within this field in order to optimise treatment for trauma-affected refugees with complex PTSD.

Methods The study included 207 patients referred to Competence Centre for Transcultural Psychiatry between April 2012 and September 2013. Patients were randomised into one of the two treatment groups: a sertraline group ($n=109$) or a venlafaxine group ($n=98$). Patients in both groups received the same manual based cognitive behavioural therapy, specially adapted to this group of patients. The trial endpoints were PTSD-and depression symptoms and social functioning, all measured on validated ratings scales. Furthermore the study examined the relation between expected outcome of treatment from a range of predictors and the relation to the treatment results for the individual patient.

Results Data are presently being analysed and results will be ready for the conference.

Conclusion The study is among the largest randomised studies ever conducted on pharmacological treatment among traumatised refugees. It is expected to bring forward new knowledge about clinical evaluation and medical treatment of traumatised refugees.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Stigma towards psychiatric disorders in a sample of depressed females in two different communitiesM. Elsheikh^{1,*}, H. Haltenhof², M.H. Bahary³¹ *Rhein-Jura-Klinik, Psychiatry and Psychotherapy, Bad Säckingen, Germany*² *HBK-Zwickau-Teaching Hospital- Leipzig University, Psychiatry and Psychotherapy, Zwickau, Germany*

³ Alhussien University Hospital-Azhar University, Psychiatry, Cairo, Egypt

* Corresponding author.

Introduction Stigma and discrimination experienced by persons suffering from mental illness, unlike other medical conditions, recognized as a barrier in countries rich and poor, and in countries with well-developed mental health services and those with limited services. It was hypothesized that depression may affect patients' attitude towards mental illness "public stigma" as well as self-stigmatization and that there will be a difference between Egyptians and Germans.

Aims This study sets out to identify and compare public- and self-stigma among depressed women in two different communities.

Objectives To test findings from transcultural comparative study of two patient groups of depressed women from two different communities. Participants were 50 adult females diagnosed with depression from Egypt and Germany.

Method Participants completed after clinical interviewing and diagnosis with depression two questionnaires: the inventory of attitude towards mental illness (Shokeer, 2002) and the explanatory model interview catalogue EMIC (Weis et al., 2001).

Results Analysis indicates that positive attitudes towards mental illness were more for the German respondents than for the Egyptians. There were significant differences between the two groups in the causal attributions of mental illness. Psychotherapy was widely accepted in the two groups as a helpful method for treatment of mental illness.

Conclusion It was concluded that the traditional beliefs affect the understanding of illness causality and that the subjective experience of depression may affect attitude towards mental illness and mentally ill people. The effect of the social desirability is discussed.

The old concept of psychogenic psychosis revisited from a transcultural approach: A case series

J. Gómez-Arnau*, R. Puente-García, S. García-Jorge, M. Benítez-Alonso, H. Dolengevich-Segal, J. Correas-Lauffer
Hospital Universitario del Henares, Psychiatry, Coslada Madrid, Spain

* Corresponding author.

Introduction The concept of psychogenic psychosis was introduced by Wimmer in 1916 and subsequently extended by Strömberg in the mid twentieth century. It typically describes a polymorphic psychotic episode of abrupt onset and which follows a trauma or stressful life situation. The duration of the episode is usually brief and remission occurs ad integrum. In recent decades, the notion has fallen into disuse in clinical psychiatry and international classifications. This could be due to a general improvement in living conditions, with less exposure to traumatic situations.

Objective We intend to study the characteristics of psychogenic psychosis in immigrants. We believe that the condition could be observed better in this population, given their greater vulnerability to trauma. For this purpose, we chose a sample of Romanian patients, who nevertheless have considerable cultural affinity with the Spanish population.

Methods We collected the clinical and biographical data of four cases of psychogenic psychosis admitted to our clinic between 2012 and 2015.

Results Four Romanian women aged 25 to 42 were diagnosed with psychogenic psychosis in this period. Mean length of hospitalization was 5, 0 days. All patients reported familiar or occupational stress prior to the onset of symptoms. Psychotic symptoms remitted quickly with low doses of medication, despite being initially intense.

Conclusions Reported cases fit remarkably well with the original description of Wimmer. The concept of psychogenic psychosis, along with similar brief psychotic entities, could be useful in describing the psychopathology derived from new social models and crises.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Perceptual symptoms in the latino psychiatric patients attending inner city outpatient clinic

L. Gonzalez*, A. Khadivi, W. Gu, P. Korenis
Bronx Lebanon Hospital Center, Psychiatry, Bronx, USA

* Corresponding author.

Introduction Psychotic symptoms occur in a variety of psychiatric disorders and medical conditions. In addition, a significant proportion of the general population reports history of psychotic symptoms in the apparent absence of a psychiatric disorder. Reviewed literature suggests that Latino patients report certain forms of visual and auditory hallucinations without other indications of psychotic illness. In addition, it is common that some individuals with diverse religious or cultural backgrounds may present with psychotic transient experiences, which can be culturally normative.

Objective To determine the prevalence of hallucinations and describe the nature of hallucinatory experiences in relation to cultural belief in Latino and non-Latino psychiatric outpatients.

Methods We conducted a retrospective case control study of 146 patients who were admitted to the outpatient psychiatric clinic for a period of ten months. We assessed clinical characteristics of these patients and reviewed the extended mental status examination, which contained questions about various form of hallucinations and spiritual experiences. This poster will explore the prevalence of hallucinations in the Latino population and determine the percentage of patients with a diagnosis of psychotic illness. A discussion of the phenomenological hallucinatory experiences and its relationship to cultural beliefs in the Latino psychiatric patients will also be presented.

Conclusions Psychotic symptoms present differently across cultures. The Latino population is most likely to have psychotic like symptoms related to their cultural beliefs. Clinicians must understand the diverse cultural experiences and beliefs of the patients they work with to prevent misdiagnosis of culturally normative experiences.

Community psychiatry in Mozambique – a transcultural journey

A. Guerra*, M. Croca
Hospital de Santa Maria–Centro Hospitalar Lisboa Norte, Psychiatry and Mental Health Department, Lisbon, Portugal

* Corresponding author.

Historically the psychiatric clinical practice in Mozambique evolved from an eminently reclusive care setting (colonial period) to a phase where the patients were rapidly deinstitutionalized into their communities (post-independence years). In 1990, in order to restructure the mental health care network, the National Mental Health Plan was approved. Its main goal was to promote a semi-open treatment setting, activating the community role in the

rehabilitation and social reintegration of the psychiatric patient. To cope with the scarcity of human resources, a three-year technical degree was created, training medical technicians in psychiatry. Presently, there are two specialized psychiatric hospitals, one in Maputo and another in Nampula. Through the description of our 3-month community psychiatry internship in Mozambique, we intend to depict the country's mental health care reality. Our internship took place in São João de Deus Mental Health Centre, the psychiatric hospital located in Nampula, which is responsible for the country's northern region. Besides offering in-patient and ambulatory treatment, it also aims to intervene at a community level. We will address the hospital's community intervention project, the developed activities, the most commonly observed pathologies, the cross-cultural relevant aspects, as well as the challenges we had to face in a harsh environment. As one would expect, the social and medical realities we encountered were quite different from the ones we are used to, forcing us to adapt constantly in order to surpass challenges of a multiple nature. Nonetheless, these were also the circumstances that turned this experience into something unique, extremely enriching and certainly unrepeatably.

Phenomenology and cultural aspects of panic attacks and panic disorder among patients attending a psychiatric clinic in Northern India: An exploratory study

A. Gupta^{1,*}, P. Sharan¹, R. Sagar¹, S. Kant²

¹ All India Institute of Medical Sciences, Department of Psychiatry, New Delhi, India

² All India Institute of Medical Sciences, Centre for Community Medicine, New Delhi, India

* Corresponding author.

Introduction The clinical presentation of panic attacks and panic disorder in any culture is influenced by its concepts of physiology and ensuing catastrophic beliefs. Western diagnostic paradigms may be inconsistent with the concept of illness in the eastern world. However, the role of culture in defining expression of panic symptoms in native Asian populations is rarely studied.

Objective The study was aimed at exploring the phenomenology of panic attacks and panic disorder in Northern India to understand the culturally relevant qualitative characteristics and contextual features.

Methodology Six focus group discussions and five key informant interviews involving various stakeholders were conducted to elicit local concepts and descriptions of the phenomena. Patients' focus groups consisted of 30 participants (age range 23–45 years) presenting with 'panic attack-like episodes'. They were recruited through purposive sampling from the rural and urban psychiatric clinics of a tertiary care institution. Healthcare professionals' views were explored through focus groups comprising of 12 psychiatrists and 5 key interviews with other medical specialists. The sessions were tape-recorded and transcripts analyzed qualitatively using grounded theory technique.

Results Four major themes emerged from the analysis:

- differential panic symptom endorsement and culture-specific symptoms;
- idioms of distress with underlying unique ethnophysiological concepts;
- possible existence of cultural variants of panic attacks not confirming to ICD-10 or DSM-5 classical descriptions;
- causal attribution of illness and help seeking.

Conclusion This is the first ethnographic study on panic disorder from India. It provides preliminary insights into the issues of diagnostic universality and cultural specificity, which require further systematic investigation.

EV459 Aboriginal and Torres Strait Islander. Not just a matter of cultural diversity

M. Hernandez Garcia^{1,*}, L. Rodriguez¹, T. Ballesta¹, G. Bellido², C. Medrano³, I. Sevillano¹, S. Cepedello¹, S. Sanchez¹, R. Hernandez¹, C. Noval¹, H. De La Red¹, A. Alonso¹, A. Alvarez¹, L. Gallardo¹

¹ Hospital Clínico Universitario de Valladolid, Psiquiatría, Valladolid, Spain

² Hospital Universitario Virgen del Rocío, Salud Mental, Sevilla, Spain

³ Hospital Universitario Reina Sofía, SaludMental, Córdoba, Spain

* Corresponding author.

Aboriginal and Torres Strait Islander culture is the oldest living culture in the world, dating over 60,000 years. An understanding of the complexity and richness of Aboriginal and Torres Strait Islander cultures, including the relationship between land and health, is still yet to be fully realised and as a result this people suffer ongoing social and health inequalities. These inequalities contribute to higher rates of ill health and a 17-year life expectancy gap between Aboriginal and Torres Strait Islander and non-Aboriginal and Torres Strait Islander Australians. Aboriginal and Torres Strait Islander Australians report higher levels of psychological distress compared with other Australians, with 77 percent reporting experiencing at least one major stressor in the past 12 months, the most common stressor being the death of a family member or close friend (42%). Particularly in rural and remote Australia, have higher rates of depression, substance abuse, co-morbidity and post-traumatic stress disorder. However, Aboriginal and Torres Strait Islander Australians do not access community and outpatient mental health services at a level that is commensurate with their need. In contrast, hospitalisation rates for mental health-related causes involving specialised psychiatric care are almost twice the rate, and for mental health-related causes without specialised psychiatric care are around three times higher, compared with non-Aboriginal and Torres Strait Islander Australians and death rates from 'mental and behavioural disorders' are much higher for Aboriginal and Torres Strait Islander Australians than for non-Aboriginal and Torres Strait Islander people.

Cultural factors, depression, and somatic symptoms among Chinese Americans and European Americans

Z. Kalibatseva^{1,*}, F. Leong²

¹ Stockton University, Psychology, Galloway, USA

² Michigan State University, Psychology, East Lansing, USA

* Corresponding author.

Introduction Previous research suggests that people of Chinese descent may somatize psychological distress and depression. Cultural variations in depression among Chinese may be associated with differences in culturally relevant factors, such as self-construal, loss of face, emotion regulation, and acculturation.

Objective The study examined how cultural factors associate with the report of depressive and somatic symptoms among Chinese American and European American college students.

Methods Data were collected from 205 Chinese American and 316 European American college students using online questionnaires.

Results Independent *t*-tests revealed no ethnic differences in depression scores between Chinese and European Americans. However, European Americans surprisingly reported more somatic symptoms than Chinese Americans. Post-hoc analyses revealed that this difference was largely due to the high report of somatic symptoms among European American females. When somatic symptoms and gender were controlled for, an ethnic difference in depression emerged with Chinese Americans reporting higher scores than European Americans. As hypothesized, this ethnic difference was not longer significant when the culturally relevant psychological variables were included in the regression.

Conclusions This study did not find evidence for somatization among Chinese Americans and suggested that depression differences could be explained by examining culturally salient constructs. Clinical implications include the reduction of health disparities in accessing and receiving quality depression treatment and provision of culturally sensitive treatments for depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Perceptions of health professionals treating psychosis in South Asians to develop the culturally adapted relatives education and coping toolkit (CA-REACT)

A. Karbhari^{1,*}, R. Lutaaya², A. Syed³, A. Bikha⁴, S. Patel³, D. Edge², F. Lobban², N. Husain⁵, A. Karbhari⁶

¹ Blackburn, United Kingdom

² University of Manchester, Institute of Brain Behaviour and Mental Health, Manchester, United Kingdom

³ Lancashire Care NHS Foundation trust, Research and Development, Preston, United Kingdom

⁴ Harvey House Social Enterprise, Research, Bury, United Kingdom

⁵ University of Manchester, Institute of Brain Behaviour and mental health, Manchester, United Kingdom

⁶ LCFT, Research and Innovation, Preston, United Kingdom

* Corresponding author.

Background Reports indicate the incidence and prevalence of psychotic disorders, suicide, and self-harm are on the rise among South Asians. NICE guidelines for schizophrenia recommend that each service user should be offered cognitive behavior therapy and family intervention. Despite knowledge about the high incidence and prevalence of psychosis among British South Asian in the UK, no psychological intervention to our knowledge has been developed for this population segment.

Objective To conduct individual interviews with the health professionals to do explore views on the CA-REACT.

Aim To identify barriers that health care professionals encounter in their bid to provide care to South Asian families who are caring for individuals suffering from psychosis.

Method In-depth interviews were conducted with 10 experienced health professionals. Interview transcripts were then analysed using thematic analysis.

Results The results of the study suggest that health professionals generally acknowledge that there is a deficit in appropriate services for supporting and engaging carers of South Asian patients

suffering from psychosis. They recognise the need to adapt services in order to offer more effective and culturally-sensitive services. Results indicated that adaptation of the current family interventions is likely to meet the needs of families of South Asian service users.

Conclusion The results indicate a need for culturally sensitive family intervention (FI) services as well as more education on psychosis for British South Asian families. There is a need for training professionals in working across cultures, as well as addressing language barriers and social stigmas.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Unemployment is common in persons with severe mental illness (SMI) and more in Latino population. Department of Mental Health and Addiction Services (DMHAS) of Connecticut offers a supported employment (SE) Program to help clients get competitive work in integrated settings with nondisabled workers in the community.

Objective Capture perspectives of key informant groups to describe barriers for linking Latinos with SMI to employment and adapt SE Services for subpopulations.

Method Four focus groups were conducted (employment specialists, case managers and peer support counselors/employers/two with clients-one in Spanish and other in English). They were conducted during January-February 2015, 70-90 minutes each one. A question guide was developed for each group. Participants per focus group ranged from 3-10, voluntarily. Two new questionnaires to the baseline pack were developed: challenges to Employment Assessment-provider and client version.

Results Thirty individuals participated. Several barriers to employment were reported. Clients and staff reported criminal record, lack of employment history and lack of motivation. Staff described client hygiene, mental status, physical health, substance abuse and discrimination. Clients, staff and employers reported language barrier for Latinos who don't speak English. Non-adherence to medication was reported by clients and employers. About Spanish-Speaking Latinos with mental illness, medication, discrimination, previous abuse by employers, inappropriate employment, difficulties of the job interview and computer skills appeared as challenges. English-Speaking Latinos with mental illness identified transport, stability, support, keeping apartment and financial needs.

Conclusions Focus groups can help in knowledge about the diversity of Latino communities to improve SE Services and outcomes for Latinos.

Religion, spirituality, culture, and mental health: Is it a 'taboo' or 'to be' in modern-age psychiatry

M.F. Moosa*, T. Sandhu

Birmingham Children's Hospital, Forward Thinking Birmingham, Birmingham, United Kingdom

* Corresponding author.

Introduction Religion, Spirituality and Culture are considered to play a significant and influential part in people's lives, and are deemed to be both risk and protective factors in the context of mental health. Given the diversity that exists within communities, worldwide, exploring and unpicking these issues will help Psychiatrists, with equally diverse backgrounds, share and learn from each other, the focus being on improving the outcomes for patients and carers in need of help and support.

Aim/s To raise awareness and understanding of the concepts of religion, spirituality, culture, custom and practice, and their influence in the context of mental health in multi-ethnic and multi-cultural communities, so as to better inform mental health practitioners.

Objective To define the terms religion, spirituality and culture. To critically appraise the influence of religion, spirituality and culture on mental health. To incorporate faith-based beliefs and practices, spirituality, culture and customs into the therapeutic environment and relationship, ensuring positive outcomes for all concerned—patient and therapist. To develop ourselves as reflective practitioners.

The challenges of post conflict reintegration in Africa

S. Okpaku

Nashville, USA

Introduction In the past 50 years, the continent of Africa has witnessed major conflicts ranging from civil wars and liberation wars to chaos from failed States. Increasingly in these political upheavals, kidnapping and abductions of women and young persons have become more prominent.

Aims/objectives/methods In this paper the consequences of political upheavals will be discussed. For the community there are economic, political and social disruptions. For the individuals there are family disruptions and improvements. For the abducted and kidnapped individuals there are physical, psychological and cognitive impairments, as well as consequences of sexual injuries.

Findings There is controversy as to prevention, reduction, and management of young victims of war and conflicts. Some workers have suggested that:

- the imposition of peace agreements by foreign powers may not be strictly relevant to the parties engaged in the conflicts;
- culturally appropriate rituals have efficiency in the readjustment of boy soldiers and abducted girls. Nevertheless the guidelines suggested in international disagreements provide a basis for there adjustment of young war conflict victims.

Conclusion –Traditional healing rituals have a place in the healing and reintegration in person's abduction in post conflict situations. – Community approaches are superior to individual approaches.

Introduction Due to constant flow of people in and out of Europe several drugs are now days appearing in European markets that were previously unknown. There is a need to gain awareness and knowledge about these new substances and to recognize their use and learn about their effects and management.

Aims/objectives Ayahuasca commonly called yagé is a traditional spiritual medicine in ceremonies among the Indigenous peoples of Amazonian Peru. It is undetected in urine or blood and therefore it is important to understand and ask about its usage during clinical assessment.

Methods/results Thirty-six years old woman immigrant from South America came to us with auditory hallucinations. About three years ago she was introduced who introduced her to a community of Euto people that performed daily rituals of spiritual awareness involving the use of Ayahuasca. She became a part of it and started consuming Ayahuasca daily. She started becoming socially isolated accompanied by delusional and mystical religious ideations. She later began having persecutory delusions and auditory hallucinations that Archangels speak to her about how to create music. Patient was involuntary admitted in a mental health unit and started on risperidone. Gradually her condition improved and she stopped having auditory hallucinations. After being discharged from the hospital, patient was followed on an outpatient basis with injectable risperidone.

Conclusions Due to the blend of different cultures in Europe, it is necessary to have a better understanding about the cultures, rituals and the substances that are relatively new and are currently been used.

EV466 Characterization of the refugee population in a psychiatry clinic in Lisbon

H. Prata-Ribeiro^{1,*}, A. Bento¹, A. Ponte¹, B. Costa Neves², L. Gil³

¹ Centro Hospitalar Psiquiátrico de Lisboa, General and Transcultural Clinic, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Serviço de Tratamento e Estabilização de Agudos, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Serviço de Esquizofrenia, Lisbon, Portugal

* Corresponding author.

Abstract The refugee population has been a growing concern to the developed countries in general and to Europe in particular. The recent mass migrations are changing the population that is getting to the psychiatric hospitals, not only culturally but also pathologically. The aim of this study is to characterize the refugee population that contacts with the clinic of transcultural psychiatry

in Centro Hospitalar Psiquiátrico de Lisboa, understanding the most frequent pathologies and nationalities. The methods used consisted in analyzing the refugee population that attended a psychotherapeutic group and consultation in the Transcultural clinic of Centro Hospitalar Psiquiátrico de Lisboa during the past year. Analyzing the population, 66 refugees were in contact with the transcultural clinic, 44 of which were men, being the other 22 women, representing a total of 23 countries. The more frequent nationality was Iranian (20) and the most frequent diagnosis was “adjustment disorder and anxiety” (38). We can reach the conclusion that more refugee men contact with our psychiatric hospital than women, accounting for 66, 6% of the total; 30, 3% of the refugees were from Iran, followed by Pakistan with 10, 6%. The fact that the most frequent diagnosis is adjustment disorder and anxiety, accounting for 57, 6% of the sample, seems to point out the extreme stress refugees undergo.

The sense of community in times of secularization and modernism

D. Rosa

Universidade de Coimbra, Master's Roads to Democracies, Coimbra, Portugal

Based on theoretical studies we approach the secularization process and the introduction of the Modern ideas effects over the community sense. The object's removal from the religious institutions' domain or its signification from the sacred and the exaltation of the rational and the urbanization unveil how both phenomena affect social relations regarding its interference over social symbols, meanings and, therefore, over the identity that underlies the community sense. What is shown are the deep social transformations that inflict over the still recent structures of urbanization, not enough assimilated or well understood in concerning of the forces that act over the relationships and daily life of whom integrates them. Religion is conceived as a human projection and, therefore, as a result of a necessary unconscious signification process that occurs through a mechanism of self-defense for inner conflict, with the intention of externalize it. Thereby, the Modern ideas can't provide a tolerable interpretation of reality to fulfill the emotional void resulted from secularization. In this context, the solidarity, responsible for the community identity, decline while happened the decrease of common representations. Nonetheless, the necessity of signification doesn't decrease. Thus, against modernist predictions, community's members tend to redirect its projections, qualifying new symbols. What is noticed is that no process can remove representation's meaning without offer a substitute or witness the redirection of it to other object. Nonetheless, it is possible to provide tools that will help community to detach of projections when the necessity of them be surpassed conceiving the reality.

Dreaming the memories of our parents: Understanding neurobiology of transgenerational trauma and the capacities for its healing

I. Rozentsvit

Object Relations Institute for Psychotherapy and Psychoanalysis, Parent-Child Development Program, Fresh Meadows, USA

Selma Freiberg once said that “trauma demands repetition”. What if actual trauma did not happen in real life of one particular person, but he/she feels that it was real, as it is repeated every night – in every dream? Do children and grandchildren of survivors of holocaust and of the pogroms dream the memories of their parents and grandparents? Does their imagination “make them up” or do they have a transgenerational connection to the traumatic past of their parents and grandparents, even if they were protected from knowing and hearing the horrors of what actually happened to their loved ones sometime one or two generations apart? Are these people born with some specific biological markers (e.g., lower cortisol levels)? Can fear be passed along from parents to children by smell? All these questions can be answered positively (see work of Jacek Debiec, Dias and Ressler, and many others), and can be explained on the level of neurobiology and epigenetics (thanks to contributions of Moshe Szyf and Michael Meaney from McGill University, and others). This presentation will offer some neuro-psychoeducational reflections on the topic of transgenerational trauma, its epigenetic transmission and its neuro-psycho-biological constructs, as well as a very personal touch, a personal story of growing up in a very nurturing and cultured, but very small family, and not knowing of the circumstances of “why small?”

Mental health treatment and media preferences for persons of Latino Heritage

T. Sorrell

University of Colorado-Denver, College of Nursing, Aurora, USA

Studies show the benefits of culturally sensitive methods of care and treatment for minorities needing mental health services. Determining culturally based methods of care to align with patient values and preferences has remained a focal point in mental health services provision; although few studies have focused on the mental health treatment preferences for persons of Latino heritage. Treatment preferences could reflect personal characteristics, acculturation perspectives about mental health issues and illness and treatment experience, along with media influences in English and Spanish. Achieving patient-centered care in mental health services begins with understanding patient values and preferences and adapting services to meet needs, as well as aligning services with values and preferences. Twenty-one participants were interviewed individually and their responses analyzed using Atlas-ti qualitative analysis software. The participants reported twenty-five mental health treatment preferences, which will be reviewed and discussed based on participant demographics. Media preferences and media influences on mental health information were also assessed and will be discussed as to the cultural relevance of findings. Mental health services for persons of Latino heritage should include varying holistic and traditional mental health treatment practices to increase Latino utilization, participation, and satisfaction in mental health treatment services. Media provision of mental health information for Latinos should recognize the need for utilization of varied media modes, including in-person and mobile service utilization, and for the presentation of mental health information by multi-lingual, engaging methods for dissemination of information and for overall improvement in mental health service utilization.

Attitude of attendants for E.C.T. to be given in patients of psychiatric disorders

S. Srivastava
Lucknow, India

Introduction Utilization of E.C.T. has diminished since the middle of 20th century but, in spite of widespread use of pharmacological agents for treatment of major psychiatric disorders, E.C.T. is still treatment of choice for patients with severe suicidal symptoms, catatonia and diseases resistant to various pharmacological agents. But in spite of its excellent effect in various psychiatric disorders, acceptance of E.C.T. is very poor in society.

Objective Objective of this study was to know the attitude of attendants for E.C.T. and acceptance after detailed description of procedure and discussing merits and demerits of E.C.T.

Aims As still it is the best treatment for certain psychiatric disorders, so to increase the awareness about its benefits and try to remove the negativity regarding E.C.T. in society.

Method In this study, 61 patients were randomly selected who had indication for E.C.T. without any discrimination of male and female. Their attendants were categorized by their socioeconomic status. All the attendants were asked open questions regarding their opinion for E.C.T. before taking consent.

Result Sixty patients were selected who had indication for E.C.T. and their attendants were asked to give their opinion for E.C.T. Amongst them 9.84% were from upper socioeconomic status, 68.86% were from middle socioeconomic status and 21.31% were from lower socioeconomic status. Only 11.48% had a positive attitude, 75.40% had a negative attitude and 16.39% had no comments.

Conclusion After developing good rapport and confidence with attendants and detailed explanation of E.C.T. procedure, its merits and demerits 75.40% had given a positive attitude, 22.95% had given negative attitude and still 1.64% had no comments.

Impact of language fluency level on patients' pathway and clinical outcome of the Japanese psychiatric service

A. Yuasa^{1,*}, S. Nagasawa², A. Yu¹

¹ Meijigakuin University, Clinical Psychology/Psychology, Tokyo, Japan

² Yotsuya Yui Clinic, Clinical Psychologist, Tokyo, Japan

* Corresponding author.

Language fluency often impacts on patients' behaviors. It might affect their pathways, how they find an available psychiatric clinic, and the clinical outcomes, if they continue their treatments. Multicultural services deficiency is serious concern in Japanese psychiatric fields. According to the Ministry of Health, Labor and Welfare in 2014, more than two million of foreign visitors live in Japan, however, the psychiatric institutions providing multilingual services are rare and inadequate comparing the situation in Europe. The research sets the objective of analyzing the status quo in a multi-language providing psychiatric clinic, how the pathways and outcomes of language diffident patients differ from these of the local patients. It further aims to find the significance of foreign

patients, and strives the improvement of language services for non-native patients in Japanese mental health cares. The research utilized and quantitatively analyzed the retrospective research data among 900 Japanese patients and 902 non-Japanese patients, who have visited a psychiatric clinic located in Tokyo. The analysis revealed that the significant proportion of foreign patients relied on their acquaintances as their pathways, and that the lower their language levels were, the higher proportion they had this path. For the outcomes, the lower their language levels were, the higher continuity status they had. Our research suggested that two of the common ways to find a psychiatric service when local patients suffer from psychopathological maladjustments are researching Homepages and neighboring clinics, however, the foreigners with limited language abilities tended to follow the different pathways and outcome patterns.

The characteristic of auditory hallucinations in patients with schizophrenia, schizoaffective and bipolar disorder with psychotic features in Iran

S.M. Zamir*, S.A. Haji Seyed Javadi, M. Majidi
Qazvin university of medical sciences, Psychiatry, Qazvin, Iran
* Corresponding author.

Introduction Auditory hallucinations are perceptual experiences that occur in schizophrenia, schizoaffective disorder and bipolar disorder with psychotic features. Characteristic of these hallucinations may have relation with cultural factors.

Aim We have done this study to understand more about content and characteristic of auditory hallucinations in Schizophrenia, schizoaffective and bipolar disorder with psychotic features in Qazvin, a state in north-center of Iran.

Methods We used the questionnaire that prof. Romme and Escher developed in 1987 for research purposes. Sixty patients diagnosed with schizophrenia, schizoaffective and bipolar disorder with psychotic features that admitted or attended at clinic of Qazvin medical science university hospital, psychiatry ward, were interviewed.

Results The 45 men and 15 women in three groups were interviewed. The most were men, single, and in fourth decade of their life. Most patients mentioned that they heard one voice. Mean age of appearing voices in patients were 19 to 29 years old. Most patients in the schizoaffective and bipolar group heard male voices and in schizophrenia were both sexes. Eighty-five percent of bipolar patients, 65% of patients with schizoaffective disorder heard friendly voices. It was 30% in patients with schizophrenia. Fifteen percent of bipolar patients, 75% of schizophrenia and 45% of schizoaffective stated that voice was hostile.

Conclusion Our study has revealed that culture affected content and characteristic of auditory hallucinations. We suggested that some complementary studies will be done in future from different Iranian cultures not just people of Qazvin.

Keywords Auditory hallucination; Schizophrenia; Schizophrenia; Bipolar disorder; Cultural factors

EV473

A study of mood status in children with type I diabetes mellitus: Relationship with parental stress and metabolic control

M. Abdelhameed^{1,*}, B. Ali²¹ Minia university, Psychiatry and Neurology, Minia, Egypt² Minia university, Pediatrics, Minia, Egypt

* Corresponding author.

Introduction It has been widely recognized that DM can result in psychological, social and physical problems. Parents of children with DM are likely to be highly distressed.

Objective The study of the relationship between mood status of children with type I DM and some factors that might be implicated in its determination.

Aims To evaluate the presence and degree of depression in a sample of children with type I diabetes and how much it might be affected by their metabolic control and the level of their parents' stress.

Methods Ninety-three children were diagnosed with DM type I. They were clinically interviewed and examined. They went through Childhood Depression Rating Scale (CDI), Family Attitudes Questionnaire and HbA1c% assessment. An age and sex matched control group was taken.

Results The age range of diabetic children was 7–18 and two thirds of them were females. Thirty-five patients (37.6%) were depressed according to CDI results. Diabetic children had significantly higher CDI total score and total parenting stress index (PSI) compared to the control group. CDI total score was positively and significantly correlated with indicators of poor diabetes control (frequency of DKA and HbA1C%) and with duration of diabetic illness. CDI total score was also positively and significantly correlated with PSI score.

Conclusions Depression was highly present in this sample of diabetic children. The degree of their mood impairment was positively correlated with duration of diabetic illness, indicators of poor metabolic control of DM and to the level of their parents' stress.

Recent and childhood adversities in patients with depressive disorders

M. Abdelhameed*, A. Kamal, N. Abdelfadeel, S. Morsy

Minia university, Psychiatry and Neurology, Minia, Egypt

* Corresponding author.

Introduction A strong association is believed to exist between stressful life events and the development of depressive disorders. Childhood adverse experiences contribute to person's vulnerability to such disorders.

Objective The study of the complex interplay between child abuse, stressful life events and the development of depression.

Aims To study the effect of type and severity of child abuse and magnitude of pre-onset stress on the severity and duration of adulthood depression.

Methods Seventy-five patients with depressive disorders not having a comorbid mental illness were studied using Social Readjustment Rating scale (SRRS) and Childhood Trauma Questionnaire (CTQ).

Results The mean age of the patients was 34.96 ± 12.32 years, 69.3% of patients were females, duration of the illness ranged from

2–288 weeks with a mean of 30.94 ± 54.61 and 36% of the sample had severe depression. There was a statistically significant relationship between urban residence and magnitude of stress ($P=0.049$), married patients suffered less severe depression than unmarried ones ($P=0.02$) and a positive and significant correlation was found between magnitude of stress and severity of depression ($P \leq 0.001$). Duration of depressive illness was positively and significantly correlated to the raw score of SRRS and to the severity of emotional neglect as measured by CTQ ($P=0.02$ and 0.04 respectively).

Conclusions The development of depression in adulthood is significantly associated with past exposure to child abuse and stressful life events. Childhood history of emotional neglect and magnitude of pre-onset stress may be contributing factors to duration of depressive illness.

EV475

Gender and cultural differences in depression among undergraduates from Arabian Gulf countries

H. Abdullatif

Kuwait University, Faculty of Social Sciences, Psychology, Kaifan, Kuwait

Introduction Assessing depression within gender and cross-cultural context using a valid and reliable framework would therefore provide significant benefit when selecting and predicting college students.

Objective The aim of the current investigation was to explore cultural and gender related differences in depression using undergraduates recruited from 16 Middle Eastern countries.

Method Standard Arabic Version of the Beck Depression Inventory-II (BDI-II), was administered to Arabic undergraduates, recruited from the following countries: Emirates, Iraq, Kuwait, Oman, Bahrain, Qatar, Saudi Arabia, and Yemen ($n=4462$). Reliabilities ranged from 0.84 to 0.91 with a mean.87 (alpha) denoting good internal consistency. The convergent correlations in eight samples between BDI-II and Kuwait University Anxiety Scale KUAS (mean $r=0.66$) for validity coefficients.

Results It was found that females had significantly higher mean depression scores than their male counterparts in five countries: Iraq, Kuwait, Oman, Qatar, and Saudi Arabia. However, no significant gender differences were found in three countries: United Arab Emirates, Yemen, and Bahrain. Overall gender differences ($f=9.52$, $P<.002$), cultural differences ($f=10.79$, $P<.001$) and the interaction between both culture & gender ($f=8.56$, $P<.001$).

Conclusion Therefore, it is safe to conclude that gender differences overshadow similarities. Female preponderance of depression has been a consistent finding within literature. Furthermore, the results revealed a cultural difference in depression where Iraq, United Arab Emirates, Oman and Saudi Arabia had the highest means.

⁶ Ain Shams university, faculty of medicine, department of psychiatry, Cairo, Egypt

⁷ Zagazig university, faculty of medicine, psychiatry department, Zagazig, Egypt

* Corresponding author.

Objective to examine the longitudinal effect of depression on glycemic control in a sample of patients with type 2 diabetes.

Methods the patients were recruited from diabetes clinic in Saudi airlines medical center, in Jeddah, the base line study community consisted from 172 patients with type 2 diabetes. They were assessed for depression using BDI II, and diagnostic interview, and for diabetic control using HbA1c. We created a person-period data set for each patient to cover 6 months intervals up to 3 years. We used generalized estimation equation (GEE) for analysis of longitudinal data. HbA1C was the response variable while depression and time were the main covariates. Variables were included in GEE models based on clinical importance and preliminary analysis. Other variables included as covariates were gender, education, duration of diabetes, co-morbidity and LDL. All statistical analysis used $\alpha = 0.05$ level of significance and were performed using SPSS software version 21.

Results Unadjusted HbA1c means were significantly higher in depressed vs. non-depressed subjects at all time points. The adjusted HbA1c means in final GEE model were significantly higher in depressed vs. non-depressed subjects. In all adjusted models depression was a predictor of glycemic control weather it was BDI score (estimate = .049, $P = .002$), diagnoses of MDD (estimate = 2.038, $P = .000$), or other depressive diagnosis (estimate = 1.245, $P = .000$).

Conclusion This study on clinical sample of type 2 diabetic patients demonstrates that there is a significant longitudinal relationship between depression and glycemic control and that depression is associated with persistently higher HbA1c over time.

³ Boylam Psychiatry Institute, Psychiatry, Ankara, Turkey

* Corresponding author.

Objective This study aims to demonstrate the reliability and validity of Turkish version of DSM-5 level 2 depression adult Scale which was developed to measure the severity of depression.

Material-methods The study group included 51 patients who met the criteria for major depressive disorder according to DSM-5. Sixty-five volunteers without any mental or physical disease were also recruited as a control group. Beck Depression Inventory (BDI), which is the most widely used self-report scale, was used for

concurrent validity. Internal consistency coefficient and item-total correlation analysis were performed for reliability. Exploratory factor analysis was used for validity as BDI was used for concurrent validity.

Results Mean age was 40.5 ± 11.4 in the patient group and 21.8 ± 4.9 years in the control group, respectively. A total of 62.1% of the sample group ($n = 72$) were female. A total of 59.5% of the group were college graduates, 16.4% were primary school graduates and 14.7% were high school graduates. Disease duration for major depressive disorder was 13.5 ± 10.5 years for the patient group. The internal consistency of the Level 2 Depression Adult was 0.96. Item-total correlation coefficients were between 0.71–0.90 ($P < 0.0001$). For the exploratory factor analysis of sample adequacy of DSM-5 Level 2 Depression Adult Scale, Kaiser-Meier-Olkin (KMO) coefficient and Bartlett coefficient was calculated as 0.91 and 1026, 62 ($P < 0.0000$), respectively. Single-factor solution was obtained with an eigen value of 6.27, representing 78.3% of the variance. Factor loadings of the items were between 0.77–0.92. Correlation coefficient of Level 2 Depression Adult Scale with BDI was found as $r = 0.76$ ($P < 0.0000$).

Conclusion The Turkish version of DSM-5 Level 2 Depression Adult Scale is reliable and valid.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Agomelatine vs fluoxetine: Efficacy and improvement of cognitive functions in patients with MDD

E. Aydın^{1,*}, M. Güleç², E. Oral², A.G. Daloğlu³

¹ Atatürk University School of Medicine, Psychiatry, Erzurum, Turkey

² İzmir Katip Çelebi University School of Medicine, Psychiatry, İzmir, Turkey

³ Mersin State Hospital, Psychiatry, Mersin, Turkey

* Corresponding author.

Introduction In major depressive disorder (MDD) neurocognitive functions are impaired. In addition to melatonergic properties of agomelatine, via 5-HT_{2C} antagonism it increases extracellular noradrenaline and dopamine in frontal cortex and may improve the neurocognitive functions of patients with MDD.

Aims and objectives To investigate the extent of neurocognitive improvement and efficacy of agomelatine and fluoxetine in patients with MDD.

Material and method Agomelatine 25 mg/day ($n = 24$) and fluoxetine 20 mg/day ($n = 24$) were administered to drug-naive unipolar, non-psychotic, non-suicidal MDD patients according to DSM-IV. Evaluations were performed just before the treatment and at the sixth week of treatment via administering Hamilton Depression Rating Scale, Rey Auditory Verbal Learning Test, Controlled Oral Word Association Test (COWAT), Digit Span Test (DST), Trail Making Test (TMT-A/B), Stroop Test and Wisconsin Card Sorting Test.

Results Both agomelatine and fluoxetine was found to be efficacious for the treatment of MDD ($P < 0.05$ for both). Further there was no difference between the antidepressant efficacy of two drugs. Both of the drugs improved measured neurocognitive functions ($P < 0.05$), except scores of DST ($P > 0.05$) and only fluoxetine improved significantly scores of COWAT ($P < 0.05$). Only in terms of TMT-B there was significant difference between groups and agomelatine was superior to fluoxetine ($P < 0.05$).

Conclusion Agomelatine and fluoxetine were efficacious in treatment of MDD. Furthermore both of the drugs improved cognitive functions in patients with MDD. Superiority of agomelatine in improvement of executive functioning (TMT-B) is important and therefore it could be an appropriate choice for MDD patients who have pronounced executive disturbances.

Depressive episode among young Moroccan students

I. Jaouahir^{1,*}, F.Z. Azzaoui², A. Ahami¹, M. Faid³

¹ Faculty of Science, Department of Biology, Kenitra, Morocco

² Faculty of Science Ben M'sik, Department of Biology, Casablanca, Morocco

³ Agronomic and Veterinary Hassan II Institute, IAV, Rabat, Morocco

* Corresponding author.

Introduction In Morocco, 48.9% of the population surveyed in 2003, had at least one mental health disorder [1,2]. Mood disorder was the most prevalent psychopathology found among children of 15 years (26.5%) [2].

Objective To study the prevalence of depressive episode (DE) of young Moroccan students.

Subjects and methods The present study is a cross-sectional study conducted among 942 students, aged 18 to 25 and studying in a vocational training institute in Mohammedia (North West of Morocco). DE is evaluated by the Mini International Neuropsychiatric Interview.

Results The results showed that 86% of trainees present a DE. The distribution of DE percentages varies according to its different degrees; 50% of studied students suffer from a severe DE, 62% suffer from a moderate DE, 24% had a mild DE and 14% had no DE.

Conclusion The rate of depression is very high among these students. Deeper investigations are needed to determine all factors involved in this psychopathology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction This study assessed the levels of immune factors, demographic and clinical characteristics, and pharmacological

treatments of patients with depressive disorders and compared them between patients with mild-to-moderate and moderate/severe-to-severe anxiety.

Methods This study included 177 patients diagnosed with a depressive disorder who were hospitalized between March 2012 and April 2015. The patients were categorized into mild-to-moderate anxious distress and moderate/severe-to-severe anxious distress groups, based on the criteria of the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) based on the “with anxious distress” specifier. The current severity of symptoms was determined using the Hamilton Depression Rating Scale (HAM-D) scores on the Agitation and Anxiety-Psychic subscales. The charts of the patients were reviewed to evaluate immune factors, including C-reactive protein (CRP) and white blood cell (WBC) levels, confounding factors, such as smoking, other general medical disorders, and body mass index (BMI), and demographic and clinical characteristics.

Results The moderate-severe to severe anxious distress group tended to have higher CRP and monocyte levels compared with the mild to moderate anxious distress group. However, after adjusting for the total HAM-D scores, there was a significant difference only in monocyte levels. After this adjustment, patients with moderate-severe to severe anxious distress had a significantly greater trend toward significance for suicidality and a higher rate of antipsychotic use.

Conclusions High levels of anxiety symptoms may influence various underlying pathophysiological factors and modulate the inflammatory response and course of illness, affecting treatment planning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effectiveness of various potential predictors of response to treatment with SSRIs in patients with depressive disorder

M. Bares^{1,*}, T. Novak¹, M. Brunovsky²

¹ National Institute of Mental Health Czech Republic, 2nd Department, Klecany, Czech Republic

² National Institute of Mental Health Czech Republic, Department of Applied Electrophysiology of Brain, Klecany, Czech Republic

* Corresponding author.

Introduction The substantial non-response rate in depressive patients indicates a need to identify predictors of treatment outcome.

Objective and aims The aim of the open-label, 6-week study was: – to compare efficacy of a priori defined predictors: $\geq 20\%$ reduction in MADRS score at week 1, $\geq 20\%$ reduction in MADRS score at week 2 (RM $\geq 20\%$ W2), decrease of prefrontal theta cordance value (RC) and increase of serum/plasma brain-derived neurotrophic factor (BDNF) at week 1;

– to assess whether the combination of these factors yield more robust predictive power than when used singly.

Methods All patients ($n = 38$) were hospitalized and treated with various SSRIs. Areas under curve (AUC) as well as predictive values were calculated to compare predictive effect of single and combined predictor model.

Results Twenty-one patients (55%) achieved response. The RM $\geq 20\%$ W2 (AUC-0.83) showed better predictive efficacy compared to all other predictors with exception of RC. Other significant differences were not detected. The identified (logistic regression) combined predictive model (RM $\geq 20\%$ W2 + RC) predicted response with accuracy of 82% (AUC-0.92) and was significantly better than other predictors but not RM $\geq 20\%$ W2 and RC.

Conclusions Our findings indicate that the $RM \geq 20\%$ W2 alone and in combination with RC may be useful in the prediction of response to SSRIs. Serum/plasma BDNF did not show strong predictive potential.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Seasonal affective disorder associate with common chronic diseases and symptoms in a population-based study

S. Basnet^{1,*}, I. Merikanto², T. Lahti³, T. Partonen¹

¹ National Institute for Health and Welfare THL, Department of Health, Helsinki, Finland

² National Institute for Health and Welfare-Helsinki Finland, Department of Health, Helsinki, Finland

³ University of Health, Public health, Helsinki, Finland

* Corresponding author.

Background Seasonal affective disorder (SAD) is a recurrent mood disorder with 22%–42% of the patients experiencing symptoms even after 5–11 years after diagnosis, and 33%–44% developing non-seasonal symptoms. The purpose of this study was to assess how seasonality is associated with some of the most common non-communicable diseases in the general Finnish population.

Methods The global seasonality score (GSS) and the experiences of problems due to the seasonal variations from FINNRISK 2012 dataset were used to measure the seasonality in 4689 Finns aged 25–74 years living in five geographical regions in Finland, and assess their association with common non-communicable diseases (NCDs). The regression models and odds ratios were adopted to analyze the associations adjusted for covariates.

Results The prevalence of SAD in the Finnish general population is 21%. Seventy percent of the participants had seasonal variations in sleep duration, social activity, mood and energy level, while 40% had seasonal variations in weight and appetite. Angina pectoris and depression were significantly associated with seasonality, including seasonal variations in sleep duration, mood, weight, appetite, social activity and energy level. Depression was significantly associated with the increased odds for experiencing a problem due to the seasonal variations ($OR = 4.851, P < 0.0001$) and SAD symptoms ($OR = 4.075, P < 0.0001$), and with the GSS ($P < 0.0001$).

Conclusion Our data suggest that seasonality is associated with depression and angina pectoris. The co-occurrence of the seasonal variations in mood and behavior with common NCDs warrants the need for future research to have insights into the etiology and potentially shared pathways and mechanisms of action.

Introduction Chronic pain is a common experienced symptom among patients diagnosed with major depressive disorder (MDD). The intensity of depression and chronic pain inter-correlated, having negative impact on the daily functioning of the patients.

Objectives Our aim was to explore the presence of chronic pain in patients diagnosed with MDD (single episode or recurrent), correlation between intensity of depression and chronic pain, its interference on daily functioning, as well as sex differences regarding the explored variables.

Methods The study sample consisted of 51 (62.2%) female and 31 (37.8%) male patients diagnosed with MDD ($n = 82$), aged between 18 and 65 years old (mean age of 46.21). Assessment instruments included The Beck Depression Inventory-II (BDI-II), The Brief Pain Inventory-Short Form (BPI) (consisting of BPI-I factor of pain intensity, and BPI-II-factor of pain interference with daily functioning), and semistructured questionnaire for sociodemographic characteristics.

Results The presence of chronic pain was found in the 51 (62, 2%) of patients with MDD. The mean score on the BDI-II for the whole sample was 22.5 (SD 12.8). There was a positive correlation between intensity of depression (BDI-II) and intensity of chronic pain (BPI-1), and its interference on the level of daily functioning (BPI-2) ($P < 0.01$). Women diagnosed with MDD experienced chronic pain of higher intensity and with greater interference on daily functioning.

Conclusion Our research data show a high frequency of chronic pain among patients diagnosed with MDD and its positive inter-correlation which results in negative impact on daily functioning, especially in females.

Augmentation strategies in the treatment of major depressive disorder

S. Bise^{1,*}, B. Kurtovic¹, D. Begic², O. Cemalovic²

¹ Psychiatric Hospital, women, Sarajevo, Bosnia and Herzegovina

² Psychiatric Hospital, Intensive care, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

Augmentation strategies for the treatment of Major depressive disorder (MDD) are needed when patients with MDD have a partial, or not responded to antidepressant monotherapy. The focus of augmentation therapy has been combining an antidepressant (AD) medication with another AD. Atypical antipsychotics (AAP) are becoming commonly used to augment antidepressants. Beyond AD and AAP, alternative augmentation strategies include mood stabilizers (MS).

Aim To analyze the characteristics of therapy in patients with diagnosis of MDD and to investigate the frequency of augmentation therapy.

Method Study included 28 patients hospitalized during one year with MDD diagnosis. Statistical analysis was performed with χ^2 and t-test.

Result Among patients with MDD there were 18 (64.28%) women with an average age 57.5 and 10 (35.71%) men with an average age 53.5. Of the 28 patients with MDD, 25 (89.28%) were treated with a combination therapy, and monotherapy in the remaining 3 patients (10.71%). Of 25 patients with augmentation strategy treatment, 22 (88%) used two medications and the remaining 3 (12%) tree psychotropic medications (AAP, AD, MS). The most frequent combinations were a combination of AD and AAP (17 patients, 68%). Beyond that frequent combination were AD and MS (6 patients, 24%). Two patients used combination two AAP, and one patient with two AD and one patients used AAP and MS.

Conclusion Augmentation strategy is often used in patients with MDD. There is no significant difference in the use combination therapy based on gender and age.

The Mini-Spadin, an efficient alternate to Spadin in the depression treatment

M. Borsotto*, A. Djillani, C. Devader, C. Heurteaux, J. Mazella
IPMC, UMR7275, Valbonne, France

* Corresponding author.

Objectives We previously discovered spadin as a new antidepressant drug concept. Spadin exerts its antidepressant actions on the TREK-1 potassium channel, a new antidepressant (AD) target. We have shown that spadin acts more rapidly in comparison to other ADs. We have pointed out that spadin induced neurogenesis after only 4-day treatments. We have demonstrated that spadin did not display side effects at the cardiac level and on TREK-1 controlled functions such as stroke, epilepsy or pain.

Objectives With the final goal to make spadin a drug for human clinic, our objective was to find analogs of spadin demonstrating a better affinity or a better in vivo stability or both.

Methods Several analogs of spadin were synthesized. Their ability to block the TREK-1 channel activity were first tested by electrophysiology on HEK293 cells stably transfected with TREK-1 channels. AD effects were measured by using the forced swim test and the novelty suppressed feeding test. Neurogenesis was investigated by measuring the expression level of the synaptic protein PSD-95 in in vitro cultured neurons.

Results Our data allow us to identify a shortened spadin, called mini-spadin, that displayed the same AD properties as spadin and a 400 fold increase in the TREK-1 affinity. Mini-spadin increased the synaptogenesis marker PSD95 levels after only 24 hours of treatment, suggesting that like spadin, mini-spadin was able to induce neurogenesis and synaptogenesis.

Conclusions Even if further experiments are required, the mini-spadin appears to be more efficient than spadin offering a very promising alternate to spadin as human drug.

Short-term study in patients treated with desvenlafaxine

M.P. Calvo Rivera^{1,*}, L. Aguado Bailón¹, B. Girela Serrano²

¹ San Cecilio University Hospital, Psychiatry Service, Granada, Spain

² Santa Ana Hospital, Psychiatry Service, Motril-Granada, Spain

* Corresponding author.

Introduction Desvenlafaxine is an antidepressant inhibitor of the reuptake of norepinephrine and serotonin (SNRI). Several publications support its efficacy in reducing depressive symptoms in the short term.

Objectives The objective of this paper is to estimate the effect of short-term (12 weeks) of patients with depressive disorder treated with desvenlafaxine.

Methodology This is a prospective observational study tracking a cohort of outpatients with depressive disorder treated with Desvenlafaxine for three months. To accomplish our goal we used the Montgomery-Asberg scale performing three measurements (baseline, one month and two months after initiate the treatment). The size of our sample was 24 patients.

Results We found that in about 80% of patients the treatment was effective, no significant differences in relation to sex, age or

treatment dose were reported. Regarding the severity of the symptoms, in the initial assessment 16% of the patients had a mild depressive episode, 70% a moderate episode and about 12% had a severe episode; while in the last evaluation, almost 46% of patients were in recovery, nearly 42% had mild symptoms, 8% moderate symptoms and only 4% had mild symptoms.

Conclusion We can conclude that the treatment with Desvenlafaxine has been effective at improving in the short-term the depressive disorder, independently of gender, age and dose administered.

Depression and ischemic heart disease: The role of the endogenous stress response system

V. Caivano¹, F. Monteleone¹, R. Farina², D. Nunziata¹, G. Cascino^{1,*}, A. De Rosa¹, G. D'Agostino¹, L. Steardo³, F. Piscione¹, P. Monteleone¹

¹ University of Salerno, Department of Medicine and Surgery, Salerno, Italy

² AOU "San Giovanni di Dio e Ruggi D'Aragona", UTIC, Salerno, Italy

³ University of Naples SUN, Department of Psychiatry, Napoli, Italy

* Corresponding author.

Introduction Depression increases the risk of ischemic heart disease in healthy people and impairs the outcome of heart diseases. The endogenous stress response system, including the autonomous nervous system and the hypothalamus-pituitary-adrenal (HPA) axis, seems to play a primary role in the connection between depression and ischemic heart disease.

Objectives and aims We investigated concomitantly the HPA axis and the sympathetic nervous system (SNS) activities in patients with acute coronary syndrome (ACS), in relation to the presence of concomitant or ongoing depression.

Methods Fifty men and women consecutively admitted to the inpatient cardiology unit of the Department of Medicine of the University of Salerno with a diagnosis of ACS underwent saliva sample collection at awakening and 15, 30 and 60 min after awakening within the 7th day of their ACS attack. They were screened for comorbid depression at admission and after 1, 3 and 6 months after their ischemic event. Saliva cortisol and alpha-amylase levels were measured.

Results Major depression was diagnosed in 10% of the patients. As a group, they exhibited a cortisol awakening response (CAR) significantly enhanced as compared to subjects without depression. Alpha-amylase levels did not differ significantly between the two groups.

Discussion Present findings suggest that an increase of HPA axis activity, as measured by CAR, in the first days after an ischemic cardiac event is associated with the risk of major depression. The extent to which this may predict also the cardiac outcome is currently under evaluation.

Facing depression with botulinum toxin: Literature review

M. Cátia Alves*, G. Sobreira, M.A. Aleixo, J.M. Oliveira

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Affecting over 120 million people, major depressive disorder (MDD) is characterized by low mood, lack of interest and

a cluster of other vegetative and cognitive symptoms causing significant distress of functioning. It has a relapsing and recurring course and frequently becomes chronic. Thus, there is a need to further develop therapeutic techniques to improve the course and the prognosis of depressive disorders. Recent clinical trials suggest that botulinum toxin (BTX) treatment may also have an antidepressant effect.

Objective The authors aim to conduct a non-systematic review in order to understand the relationship between MDD and BTX treatment.

Aims To assess whether current evidence supports the BTX to treat major depressive patients.

Methods A non-systematic review of English scientific literature was conducted through research in the PubMed search engine, using the keywords “botulinum toxin” and “depression”.

Results There is a small but growing body of evidence suggesting that botulinum toxin may be useful for the treatment of depression. The main hypothesis for the proposed beneficial effects of botulinum toxin is through the facial feedback. Low mood and depression are often associated with a sad facial expression. Injecting botulinum toxin and improving facial expression would lead to the improvement of depression symptoms.

Conclusions Positive effects on mood have been observed in subjects who underwent treatment of glabellar frown lines with botulinum toxin. It supports the concept that the facial musculature not only expresses, but also regulates mood states.

Impact and importance of anhedonia as a mediating variable in amelioration of social functioning in depressed patients

D. Gourion^{1,*}, F. Vinckier², S. Mouchabac³

¹ Private practice, Paris, France

² Centre hospitalier Saint-Anne, Psychiatry, Paris, France

³ Centre hospitalier Saint-Antoine, Psychiatry, Paris, France

* Corresponding author.

Background Anhedonia is a core dimension of major depressive disorder (MDD). Paradoxically, the association between anhedonia and social impairment is poorly known.

Objective To determine the longitudinal relationships between depressive symptoms, anhedonia, and social functioning in depressed patients treated with agomelatine.

Material and method One thousand five hundred and seventy patients with MDD starting treatment with agomelatine prescribed by their GPs were included in a prospective study (follow-up: 10 to 14 weeks). Patients were assessed at baseline and at the end point of the study, using the MADRS to assess antidepressant efficacy, the SHAPS scale and an original visual analog scale exploring the subjective pleasure felt by patients in their main leisure activity to measure anhedonia, and the QFS to measure social functioning in its qualitative and quantitative dimensions. In addition to the univariate analyses, a mediation path analysis was performed using the Sobel test.

Results The results showed a robust and significant improvement in symptoms of depression, anhedonia, and social functioning. The correlations between the SHAPS and QFS scores were high and significant. Subsequent analyses showed that amelioration of anhedonia is a significant mediating variable between the progression of depressive symptoms and social functioning (Δ QFS $G = -14.3$, $P < 0.0001$) and explains around one third of the variance of the model (35.37%).

Conclusion Anhedonia, a major dimension of depression, provides specific insights into the understanding of the complex links

between residual symptoms of MDD and social functioning. In conclusion, improving the evaluation of anhedonia is a fundamental issue in primary care.

Acceptance and commitment therapy (ACT) predictive factors of return to work after depression

S. Darbada*, J.C. Seznec

Institut national de la santé et de la recherche médicale Inserm, UMR-1178 Mental Health and Public Health, Paris, France

* Corresponding author.

Introduction Prolonged sick leaves are a major risk to quit the world of work and depression is the leading cause of disability in France. New therapies from the third wave of CBT as the Commitment and Acceptance Therapy (ACT) may be interesting to promote the return to work (RTW).

Objectives To assess predictive factors of return to work after depression.

Methods This is a descriptive, prospective and multicentric study. The recruitment of investigating doctors was conducted by the publication of an advertisement in a French journal of occupational medicine. Each investigator recruited patients during reinstatement medical examination after a prolonged sick leave for depressive syndrome. Sociodemographic, occupational, medical and psychological factors (particularly in connection with the ACT) was assessed at baseline and 3 months later.

Results Thirty-one patients were initially included in the study, but 2 were lost to follow up at 3 months and 29 were analyzed. Twenty three patients RTW at 3 months. Those who RTW were less anxious ($P = 0.023$), less depressed ($P = 0.021$), had a better impression of improvement ($P = 0.0066$) and had a lower score of experiential avoidance ($P = 0.0025$).

Conclusions The ACT, through its action on the reduction of experiential avoidance, and the definitions of new life values could allow a faster RTW after a sick leave for depressive syndrome.

Childhood abuse in adult women with unipolar depression seeking treatment at a tertiary care centre in India, compared to healthy women

G. Devasthali^{1,*}, K. Jangam², T. Ka², A. Raj², M. Kesavan¹

¹ National Institute of Mental Health and Neurosciences, Dept of Psychiatry, Bangalore, India

² National Institute of Mental Health and Neurosciences, Dept of Psychiatry Social Work, Bangalore, India

* Corresponding author.

Introduction Childhood abuse has been reported as a precursor and maintaining factors for adult psychiatric disorders. Childhood physical abuse, neglect and sexual abuse have been independently reported in women with depression. There is a serious dearth of literature on the incidence of childhood abuse among women with depression from India.

Objectives & aims We investigated and compared the incidence of childhood abuse (overall) – physical, emotional and sexual (individual components) – among women seeking treatment for unipolar depression (UD) compared to healthy women (HW).

Methods We compared the data of women diagnosed with UD ($n = 134$) from a larger pool of women seeking treatment for psychiatric disorders from our hospital ($n = 609$) with HW ($n = 100$) for the purpose of this study. The participants were screened using the MINI International Neuropsychiatric Interview (MINI) and for childhood abuse using the ISPCAN Child Abuse Screening Tool - Retrospective (ICAST)-R. The incidence of childhood abuse between the two groups was compared using the Chi-squared test.

Results The UD women have significantly more childhood emotional abuse than HW (69.5% vs 30.5%; $\chi^2 = 4.819$, $P < 0.05$). There was no statistically significant difference between the two groups on overall abuse, physical or sexual abuse (all $P > 0.16$).

Conclusions Consistent with world literature, significantly more childhood emotional abuse was seen among Indian women with UD compared to HW. It is likely that that repeated emotional abuse in childhood leads to negative attributions among children, later getting generalised to life events resulting in depression in adulthood.

Anxiety and depression in patients with hepatic versus cardiac disease

A. Dolfi^{1,*}, A. Anton², V. Marinescu¹

¹ Alexandru Obregia Clinical Psychiatric Hospital, Psychiatry 7 Ward, Bucharest, Romania

² Carol Davila University of Medicine and Pharmacy, General Medicine, Bucharest, Romania

* Corresponding author.

Background In both hepatic and cardiac disease, a bidirectional relationship exists between somatic and psychiatric symptoms: is anxiety/depression caused by the somatic burden of the symptoms or the psychiatric symptoms and stress are an important pathophysiological factor for the somatic disease?

Objective The objectives of our observational study were to see if any differences exist regarding the anxiety level in patients with hepatic versus cardiac disease and if the depressive symptomatology differs between the two groups of patients.

Materials and methods : We conceived a 2X2 study model by including two independent variables (the somatic pathology, hepatic and cardiac) and two dependent variables (anxiety and depression) which included 66 patients (35 with hepatic and 31 with cardiac pathology) who completed both STAI X1 scale for anxiety and BECK scale for depression with good reliability for both scales (Cronbach's alpha value of 0.74 for STAI X1 and 0.76 for BECK), data analyzed with SPSS 17.

Results We obtained a low level for anxiety (mean = 17.76) and a medium level for depression (mean = 49), both anxiety and depression level being higher in the patients with hepatic disease versus cardiac patients ($P > 0.05$). The patients with hepatic failure had a higher medium anxiety score (54.66) vs cardiac failure patients (42.61). The depression score was 19.71 in patients with hepatic failure and 15.55 in patients with cardiac failure.

Conclusion Both anxiety and depression severity scores were increased in patients with hepatic disease vs patients with cardiac disease in the studied groups.

Keywords Anxiety; Depression; Cardiac failure; Hepatic failure

Clinical status after two-weeks of antidepressant treatment: A prognostic factor in unipolar major depression?

I. Domínguez^{1,*}, L. Nuño¹, G. Oriolo¹, R. Quintero¹, V. Navarro², C. Gastó²

¹ Hospital Clínic, Department of Psychiatry and Clinical Psychology, Barcelona, Spain

² Hospital Clínic-IDIBAPS-CIBERSAM-UB, Department of Psychiatry and Clinical Psychology, Barcelona, Spain

* Corresponding author.

Although most unipolar depression clinical guidelines advise against evaluating the efficacy of antidepressant pharmacological treatment until it has been administered in therapeutic doses for a minimum of 4–6 weeks, there is an increasing tendency to make therapeutic decisions after only 2 weeks of treatment. We present a study which aim is to determine whether the clinical course, following 2 weeks of antidepressant treatment, allows therapeutic decisions to be made for patients affected by a moderate/severe depressive episode. The study has an 8-week, prospective, observational design in which all consecutive in- and outpatients with moderate/severe unipolar major depression aged over 17 years received antidepressant treatment based on a standardized treatment protocol. Clinical status was assessed at baseline and at 2-, 4-, and 8-weeks. The final sample consisted of a total of 114 subjects. In our sample, the rate of remitters versus non-remitters was similar between the 2-week improvers and the 2-week non-improvers. It should also be emphasized that it was not possible to explain, based on the epidemiological and clinical characteristics assessed, which 2-week non-improvers would tend towards remission and which would show a partial or full response. Based on these results, for patients affected by a moderate/severe unipolar depressive episode, it would not be appropriate to make new therapeutic decisions following 2 weeks of anti-depressive pharmacological treatment depending on whether the patient has shown clinical improvement or not.

¹ Complejo Asistencial de Ávila, Servicio de Psiquiatría, Ávila, Spain

² Hospital Universitario de Fuenlabrada, Servicio de Psiquiatría, Madrid, Spain

³ Complejo Hospitalario de Talavera de la Reina, Servicio de Psiquiatría, Talavera de la Reina Toledo, Spain

* Corresponding author.

Introduction Dysthymia is defined as a chronic mood disorder that persists for at least two years in adults, and one year in adolescents and children. It is important to distinguish it from other types of depression, as early as possible. The therapeutic management of dysthymia is similar to the one used in major depressive disorder.

Objectives We report the case of a female patient aged 45, diagnosed with depressive disorder not otherwise specified since she

was 20. Her psychopathological progress has gradually become aggravated, having now longer periods of depressive mood and an important tendency towards isolation.

Methodology The patient is admitted to the Psychiatric Day Hospital presenting with important depressive symptoms. After various antidepressants were withdrawn, lithium salts were introduced. It is then that the patient starts improving her mood.

Results – Dysthymia (F34.1).

– Mixed and other personality disorders (F61.0).

Conclusions In spite of having an appropriate pharmacological, unfortunately, antidepressants improve dysthymia just in 50–70% of patients. Antidepressants resistant dysthymia cases have been studied. In those cases, it has been necessary to add lithium or thyroxine. This confirms that, when it comes to this disorder, there are many neurochemical mechanisms involved, given the positive response to the combination of drugs, notwithstanding the severity of the adverse effects.

⁵ ADI International Institute for Advancement of Drug Development GmbH, ADI International Institute for Advancement of Drug Development GmbH, Basel, Switzerland

* Corresponding author.

Background Serum BDNF levels are decreased in major depressive disorder (MDD) and tend to normalize under antidepressant treatment, serving as a treatment outcome predictor. BDNF is initially synthesized as precursor protein proBDNF and is cleaved to mature BDNF (mBDNF) while only the latter exerts neurotrophic activity.

Aim The aim was to explore if a specific enzyme-linked immunosorbent assay (ELISA) kit for mBDNF in serum would be superior to the unspecific assessment of total serum BDNF in predicting treatment response in MDD.

Methods Twenty-five patients with MDD underwent standardized treatment with duloxetine. Severity of depression was measured by Hamilton Depression Rating Scale (HDRS) at baseline (BL), after one (W1), two (W2) and six weeks (W6) of treatment. Treatment response was defined as a HDRS \geq 50% reduction of BL score at W6. mBDNF and total BDNF serum levels were determined at BL, W1 and W2.

Results A high and stable correlation was found between mBDNF and total BDNF serum levels over all measurements. The predictive value of mBDNF BL levels and mBDNF Δ W1 to response was similar to that of total BDNF BL and total BDNF Δ W1. The assessment of serum mBDNF was not superior to total BDNF in prediction of treatment outcome.

Conclusions Not only baseline total BDNF but also mBDNF is predictive to treatment outcome. The later might represent the main

player in this respect, which supports the idea of a functional link between neuroplasticity and MDD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Unipolar depression is a public health problem and is the most common psychiatric disorder among people with long-term sick leave in Denmark. Patients with unipolar depression are often associated with deficits in cognitive function long after the affective symptoms have disappeared. This could explain the long-term sick leave among patients suffering from unipolar depression. Computer-based cognitive training has been used to increase cognitive function in other patient groups.

Objectives It is unknown whether cognitive functions are improved in patients with depression by help of a cognitive computer program. Further we investigate whether this intervention shortens sick leave.

Aims To investigate whether a computer-based cognitive training group present a higher score in cognitive function after training and return to their employment earlier compared to the control group.

Methods The study includes patients who have been admitted because of depression, but are finished with their treatment. When the patients are discharged, they will be randomized into two groups and evaluated on their cognitive function. Only one of the two groups will receive computer-based cognitive training. After 12 week the two groups' cognitive function will be compared. Furthermore there is a six-month follow up, to show if or when the participants have returned to work.

Results The results will be presented at the EPA March 2016 in Madrid.

Conclusion Based on the results of study it is our intention to conclude whether or not to implement computer-based cognitive training in treatment of patients with depression.

* Corresponding author.

Introduction Comorbidity between alcoholism and depression has long been acknowledged, and the possibility that similar brain mechanisms, involving both serotonergic (5-HT) and noradrenergic systems (NE), underlie both pathologies has been suggested. Thus, inhibitors of NE and 5HT uptake have been proposed for the treatment of alcoholism, as they have shown to reduce alcohol intake in various animal models. However, most of the studies mentioned were carried out acutely and there is a lack of knowledge of the possible long-term effects. Clinical studies report an overall low efficacy of antidepressant treatment on alcohol consumption, or even a worsened prognosis. In addition, several cases of alcohol dependence following antidepressant treatment have been reported in the literature.

Objectives We aimed at comparing the acute and chronic effects of the treatment with the antidepressant drug reboxetine on alcohol consumption.

Methods We used a rat model of alcohol self-administration, and two different schedules of reboxetine administration (acute and chronic).

Results Our results confirm the acute suppressant effects of reboxetine on alcohol consumption but indicate that, when this drug is administered chronically in a period of abstinence from alcohol, it can significantly increase the rate of alcohol self-administration.

Conclusions These results are important for the understanding of the clinical reports describing cases of increased alcohol consumption after antidepressant treatment, and suggest that much more research is needed to fully understand the long term effects of antidepressants, which remain the most widely prescribed class of drugs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction This experimental trial aims to describe the experiences felt by a group of patients diagnosed with different psychotic disorders (schizophrenia, delusional chronic disorder, etc.) in which the use of Benzodiazepine derivatives were related to emergence of lucid dreaming and dissociative events (to see oneself out of your one body, etc.), and to a lesser extent had subsequent depressive symptoms. Fifty-six patients were monitored and linked to the emergence of depressive symptoms related to the use of Benzodiazepines or sedative-hypnotic. While on this treatment, they had vivid or lucid dreaming.

Aims-objectives To explore the relationship between occurrence of drug dreams (DDs) and daytime negative affect with lucid awakening during the course of a 9-week treatment.

Methods Using the dream journal methodology, 56 participants reported occurrence of dreams, dream content, and ratings of affect. The relationships between the experience of DD, dream content (“active” vs “passive”), and affect were analysed using mixed model methods.

Results The experience of DD was associated with higher levels of negative affect ($P < 0.001$). The occurrence of DD did not decrease significantly over the 9 weeks of the study. Benzodiazepine users reported a higher occurrence of Lucid Awakening ($P < 0.05$) than the other drug groups (zolpidem and clometiazol).

Conclusions These results are consistent with the hypothesis that DD can act as drug-conditioned stimuli to elevate negative affect. Although correlational, such findings support the implementation of psychological and pharmacological interventions aimed at minimizing the impact of DD on patients with lucid awakening and psychosis.

The sunshine induced placebo effect in major depressive disorder patients exhibits gender differences

J. Gailledreau^{1,*}, B. Gailledreau¹, P. Desbonnet², P. Khalifa Soussan³, N. Desbonnet², S. Becque¹

¹ Private CIC Ambroise-Paré, Psychiatry, Elancourt, France

² Résidence Saint-Michel, Psychiatry, Gailledreau, France

³ GICIPI, Psychiatry, Toulouse, France

* Corresponding author.

Rationale Sunshine increases placebo effect in major depressive disorder (MDD) patients (Gailledreau et al., 2015). Kokras et al.

(2014) showed that sunshine induces different responses in female than male mice in preclinical models of depression.

Objective To determine whether the sunshine induced placebo effect exhibits gender differences in human.

Material and methods Data from 9 double-blind, randomized, placebo-controlled studies of antidepressants conducted by the French GICIPI network were reviewed. MADRS (5) or HAM-D 17 (4) were used as the main efficacy tool. For each patient, variation of scores (Delta MADRS/Delta HAM-D) between two consecutive visits were correlated with the average sunshine index observed at noon between these visits. Sunshine indexes were provided by Météo-France. Correlations were computed with Microsoft Excel. **Results** Analysis of both genders ($n=52$) showed no statistically significant (NS) correlation ($r^2=0.0064$) between sunshine and score variations. Analysis of males ($n=8$) failed to demonstrate any significant correlation in cloudy (< 1000 Joules/cm²), variable (1000–2000 Joules/cm²) or sunny (> 2000 Joules/cm²) weather. Analysis of females ($n=44$) showed NS correlation as well for cloudy or variable weather ($r^2=0.0016$), but a strong correlation was observed for females exposed to sunny weather: $r^2=0.315$, $n=20$, $P<0.01$. This correlation was even stronger in the subpopulation of females aged less than 50 years: $r^2=0.6398$, $n=12$, $P<0.001$.

Discussion The hypothesis underlying this correlation between sunshine index and variations of MADRS/HAMD scales will be discussed.

Conclusion Sunshine increases placebo effect in female patients aged less than 50. This insufficiently known effect may be responsible for failure of a number of double-blind, randomized, studies of antidepressant compounds.

Depressive symptomatology and learning: Does intermediate testing or restudying the information determine long-term memory retrieval of novel symbols?

V. Giannouli

Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

Introduction There is a hypothesis in cognitive psychology that long-term memory retrieval is improved by intermediate testing than by restudying the information. The effect of testing has been investigated with the use of a variety of stimuli. However, almost all testing effect studies to date have used purely verbal materials such as word pairs, facts and prose passages.

Objective Here byzantine music symbol–word pairs were used as to-be-learned materials to demonstrate the generalisability of the testing effect to symbol learning in participants with and without depressive symptoms.

Method Fifty healthy (24 women, M age = 26.20, SD = 5.64) and forty volunteers with high depressive symptomatology (20 women, M age = 27.00, SD = 1.04) were examined. The participants did not have a music education. The examination material was completely new for them: 16 byzantine music notation stimuli, paired with a verbal label (the ancient Greek name of the symbol). Half of the participants underwent intermediate testing and the others restudied the information in a balanced design.

Results Results indicated that there were no statistically significant differences in final memory test performance after a retention interval of 5 minutes for both groups of participants with low and high level depressive symptomatology ($P>0.005$). After a retention

interval of a week, tested pairs were retained better than repeatedly studied pairs for high and low depressive symptomatology groups ($P<0.005$).

Conclusions This research suggests that the effect of testing time on later memory retrieval can also be obtained in byzantine symbol learning.

Anhedonia, anxiety, and depression components of Edinburgh postnatal depression scale in cesarean delivery

L. Giliberti*, F. Volpe, G. Soldera, G. Tesolat, R. Maione, G. Straface, V. Zanardo

Policlinico Abano Terme, Division of Perinatal Medicine, Abano Terme, Italy

* Corresponding author.

Introduction Previous studies have indicated that cesarean delivery might pose risk factors for post-partum depression (PPD). However, results are conflicting and have failed to clearly distinguish between elective (EICD) and emergency (EmCD) cesarean delivery.

Objective The rate of elective cesarean delivery is rapidly increasing all over the world and it is important to identify whether the mode of delivery has an influence on PPD. The Edinburgh Postnatal Depression Scale (EPDS) is a widely used instrument for PPD screening, also capable to detect in subscales anhedonia, anxiety, and depression factors.

Methods A cohort of 959 Italian mothers delivering a healthy baby at Policlinico Abano Terme, Italy, completed the EPDS 2 days after delivery.

Results EPDS scores were significantly higher in mothers with a cesarean delivery compared to mothers with a vaginal delivery (7.0 ± 4.8 vs 6.1 ± 4.2 , $P<0.01$), but only the women who elected to have a caesarean section had significantly higher scores (7.1 ± 3.9 vs. 6.8 ± 4.1 , $P<0.001$). Additionally, the factor analysis of EPDS indicated that anhedonia, anxiety, and depression were significantly higher in women who elected to have a caesarean section.

Conclusions The results of our study indicate that women who had an EICD have an increased risk of developing early symptoms of post-partum depression, anxiety, and anhedonia. In particular, this study shows that the use of EPDS subscales in the immediate post-partum is a good tool to better understanding the spectrum of maternal post-partum psychological problems related to delivery mode.

Chronotherapy for depression: A useful adjunctive therapy?

J. Gomes*, A. Sousa, H. Afonso, G. Lima

Centro Hospitalar Barreiro-Montijo, Psychiatry, Barreiro, Portugal

* Corresponding author.

Introduction Since ancient times the influence of chronobiological factors on the pathogenesis, course, and treatment of depression has been well known. Chronotherapy is the controlled exposure to environmental stimuli that act on biological rhythms in order to achieve therapeutic effects in the treatment of psychiatric conditions. It includes sleep deprivation, bright light therapy and sleep phase advance.

Objective To analyze the chronotherapeutic strategies in the management of depression, regarding indications, contraindications and efficacy.

Methods A literature review was made by searching for articles in PubMed. Additional articles were included through review of reference lists.

Results In recent years some techniques (mainly light therapy and sleep deprivation) have passed the experimental developmental phase and reached the status of powerful and affordable clinical interventions for the treatment of depressed patients. About sixty percent of all depressed patients improve after a single night of total or partial sleep deprivation. It has been shown that a combination of pharmacotherapy with antidepressants and sleep deprivation is superior to pharmacotherapy alone. Light therapy with bright artificial light is especially beneficial in patients with a fall/winter pattern of depressive symptomatology that has been termed seasonal affective disorder. Antidepressant chronotherapeutics target the broadly defined depressive syndrome, with response and relapse rates similar to those obtained with antidepressant drugs and good results are obtained even in difficult-to-treat conditions such as bipolar depression.

Conclusions Chronotherapeutics offer a benign alternative to more radical treatments of depression. Adding Chronotherapy to the treatment choices may overcome drug-resistant Depression and shorten treatment duration.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Antidepressant efficacy and tolerance of agomelatine in daily practice in Switzerland

B. Guido^{1,*}, H.T. Edith²

¹ HUG, Mental Health and Psychiatry, Geneva, Switzerland

² Center for Affective- Stress and Sleep Disorders ZASS, Psychiatric Clinics UPK of the University of Basel, Basel, Switzerland

* Corresponding author.

Introduction The antidepressant efficacy and tolerance of agomelatine, MT₁/MT₂ agonist and 5-HT_{2C} antagonist, has been proven in clinical trials. Non interventional studies give the opportunity to evaluate these properties in real life.

Objective To evaluate the efficacy and tolerance of agomelatine in depressed outpatients in Switzerland.

Methods Non-interventional study in 934 depressed (51.2% severely) patients given 25–50 mg agomelatine for 12 and 24 weeks. Main endpoints were change in MADRS score, and response ($\geq 50\%$ reduction in total score) and remission (MADRS ≤ 12) rates. CGI was also assessed. Reported adverse drug reactions, sexual dysfunction, and weight changes were recorded. Liver function tests were performed according to the summary of product characteristics.

Results MADRS total score decreased significantly ($P < 0.0001$) from baseline (29.5 ± 8.9) to weeks 12 (12.8 ± 9.6) and 24 (9.7 ± 8.6). Responder rate was 66.8% and 78.3% and remission rate 54.2% and 70.2% at weeks 12 and 24, respectively. Results corroborated by CGI scores, were similar for severely depressed patients. Early improvers (MADRS $\geq 20\%$ reduction after 2 weeks; 461 patients) had the highest responder and remission rates. Agomelatine was well tolerated and no relevant weight changes or deleterious sexual function was reported. Ten patients had ALT/AST > 3 ULN, thereof 2 without baseline and one with elevated baseline. Most physicians rated the efficacy and tolerance of agomelatine as “good or very good”.

Conclusion Long-term agomelatine treatment improved mood symptoms of depressed patients with high levels of response and remission and a favorable tolerance profile.

Relation between major depressive disorder as regards severity in a sample of Egyptian population and serum level of tumor necrosis factor alpha

S. Harby*, T. Molokhia, H. Aboelwafa, D. Elneely
Alexandria Faculty of Medicine, Neuropsychiatry, Alexandria, Egypt
* Corresponding author.

Introduction Depression is a life threatening psychiatric disorder. STAR-D study stated that remission rates decrease, and relapse rates increase. It produces chronic diseases and worsens mean health when co-morbid with these diseases. The depressive symptoms in humans are analogous to the ‘sickness behavior’ syndrome seen in animals when injected by pro-inflammatory cytokines.

Objective This study was done to clarify the relation between the severity of depression and serum level of tumor necrosis factor alpha (TNF), so improving the quality of pharmacological management.

Aim This study was done to prove that inflammatory process is involved in the pathogenesis of depression by assessing the serum level tumor necrosis factor alpha (TNF alpha)

Methods Our study is comparing between 60 patients with major depressive disorder and 30 healthy controls regarding the serum level of tumor necrosis factor alpha. Patients were diagnosed by a semi-structured interview using Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition. Patients were subdivided into mild, moderate and severe depression according to Hamilton Rating Scale for Depression (17 items). Assessment of serum level of tumor necrosis factor alpha was done using enzyme-linked immunoassay technique.

Results Serum level of TNF alpha was significantly higher among patients than among controls ($Z = 4.710^*$ $P \leq 0.001^*$) regardless the severity of depression.

Conclusions Serum TNF alpha can be used as a biomarker of depression but not for the disorder severity. However, further study is needed to detect if there is a relation between major depressive disorder and serum level of other inflammatory markers as C-reactive protein.

Prevalence of major depression among community pharmacists practicing in Iran: A cross sectional study

F. Hashemian*, E. Roohi

Faculty of Pharmacy- Islamic Azad University- Pharmaceutical Sciences Branch, Department of Clinical Pharmacy, Tehran, Iran

* Corresponding author.

Introduction Major depression is known to carry the heaviest burden of disability among mental and behavioral disorders. It may have negative impact on both personal and professional level. There have been several studies investigating prevalence of major depression among different population. However, its prevalence among a group of healthcare professionals, namely community pharmacists have not yet been studied.

Aims The aim of the present study was to investigate the prevalence of major depression across a sample of Iranian community pharmacists.

Methods One hundred and eighty surveys were distributed among community pharmacists attending different continuous medical education programs from all over the country during winter 2015. Beck Depression Inventory was used to measure characteristic attitudes and symptoms of depression. Descriptive statistics were utilized to find prevalence of mild, moderate or severe depression among the study sample. Independent sample *t*-tests were used to find possible differences between age and gender of the respondents and prevalence of depression.

Results Survey response rate was calculated to be 84.7%. According to the results, 72.7% of the respondents were categorized to be normal, whereas 12.8% were found to have mild, 11.7% moderate, and 2.8% severe depression. Moreover, no significant relationship was found between age of the respondent and prevalence of depression ($P > 0.05$). However, the prevalence was found to be higher among females ($P < 0.001$).

Conclusions Prevalence of depression among community pharmacists was reported to be low. However, it may affect healthcare services that they provide in the healthcare system. Further studies with larger sample size are suggested.

Depression and its correlation with the risk of cardiovascular mortality in primary care population in Latvia

R. Ivanovs^{1,*}, M. Trapencieris², J. Vrublevska³, R. Logins⁴, L. Berze⁴, E. Rancans³

¹ Riga, Latvia

² University of Latvia, Institute of Philosophy and Sociology, Riga, Latvia

³ Riga Stradins University, Department of Psychiatry and Narcology, Riga, Latvia

⁴ Riga Stradins University, Department of Continuing Education, Riga, Latvia

* Corresponding author.

Introduction Depression is one of several preventable causes of disability worldwide, with coronary heart disease (CHD) being the largest cause of disability. Depression has been confirmed as a risk factor for CHD.

Objectives Few studies tried to find an interrelation between depression and a risk of cardiovascular mortality according to systematic coronary risk evaluation (SCORE) chart.

Aims The aim of study was to examine the correlation of depression with the risk of cardiovascular mortality (SCORE).

Methods Study was conducted in 2015 within the framework of National Research Programme BIOMEDICINE. All patients aged 18 and older at 24 primary care facilities were interviewed with a sociodemographic questionnaire supplemented by measurements of blood pressure and total cholesterol. Within 2 weeks after the visit psychiatrist administered the Mini International Neuropsychiatric Interview (MINI) by telephone. SCORE was assessed using high risk chart.

Results Totally 920 patients age 40–69 were included in the data analysis. According to the MINI 9.3%(95%CI 7.5–11.5%) of 40–69 years old patients had current depression. Current depression was more common among women than men, 10.4% and 6.8%, respectively. The prevalence of current depression was highest among patients with SCORE 3–4%. Multivariate logistic regression did not suggest statistically significant odds ratio for having depression based on SCORE.

Conclusions Only one of the measurements used for SCORE (smoking status) was significant predictor for having current depression, while systolic blood pressure and total cholesterol were not significant predictors for depression. As pharmacotherapies for reducing blood pressure and cholesterol are widely used by patients further research should include use of these medicines as potential mediators.

Energy drinks changed the treatment of antidepressant drugs

Ç. Macit¹, B. Kadioğlu¹, G. Dalan², M. Maassarani², E. Yönel³, T. Çelik^{1,*}

¹ Yeditepe University, School of Pharmacy-Department of Pharmacology, Istanbul, Turkey

² Yeditepe University, School of Pharmacy, Istanbul, Turkey

³ Yeditepe University, School of Pharmacy- Department of Clinical Pharmacy, Istanbul, Turkey

* Corresponding author.

Introduction The increasing use of antidepressants (ADS) whether it is for the management of depression or off-label use is apparent and it is important to have a closer look on the possible effects that accompany the use of ADS with other neurotonic agents, such as the ones found in energy drinks(ED). ED pose a threat on public health since they can be consumed by everyone with no limitations.

Aims We investigated the unknown interaction that might occur when ADS are used in combination with ED.

Methods The effect of both low (4 mL/kg) and high (12 mL/kg) ED doses on mice treated with an ADS (citalopram 15 mg/kg, IP) and non-treated were investigated after acute exposure and 14 days of chronic exposure. The changes that resulted from performing the Locomotor Activity test (LMA) and the Porsolt's Forced Swim test (FST) were recorded.

Results The administration of both low and high energy drink dose resulted in significant impairments in LMA of mice. High dose ED showed a significant increase in the immobility time in FST. Mice treated with citalopram resulted in a decrease in the immobility time when compared to mice administered only saline and/or to mice exposed to ED. However, for the mice that were exposed to both low and high dose ED, citalopram administration did not significantly decrease their immobility time.

Conclusion High dose energy drink caused an increase in the immobility time in FST. Concomitant use of citalopram and ED decreased the antidepressant effect of citalopram. Thereby patients using ED with ADS may encounter insufficient drug therapy.

Introduction Even though the association between dermatological conditions in pregnancy with psychiatric findings is vital for patient management, studies on these issues are limited.

Objective To determine the frequency and nature of dermatological problems in pregnant women having primary psychiatric illness.

Aim To establish an association between cutaneous manifestations in pregnancy with the hypothesis that psychiatric illness also has a role in pregnancy.

Methods This was a case control study and non probability convenient sampling was used on 50 pregnant patients with cutaneous manifestations along with psychiatric illness and 50 age matched non pregnant patients free from dermatological conditions and psychiatric illness. The Diagnostic and Statistical Manual of Mental Disorders (DSM IV) Criteria was used to diagnose psychiatric illness and for skin manifestations patients underwent a physical examination of skin.

Results Pregnant patients with depressive disorders were associated with atopic eruption of pregnancy [odds ratio (OR) 1.19; 95% (CI): 1.13–1.49], pruritic urticarial papules [(OR) 2.89; 95% (CI): 2.55–2.97], plaques of pregnancy [(OR) 2.14; 95% (CI): 2.01–2.39], prurigo of pregnancy [(OR) 1.33; 95% (CI): 1.17–1.45], intrahepatic cholestasis of pregnancy [(OR) 2.45; 95% (CI): 2.29–2.67], pemphigoid gestationis [(OR) 1.57; 95% (CI): 1.50–1.68], impetigo herpetiformis [(OR) 1.83; 95% (CI): 1.65–2.24], and pruritic folliculitis of pregnancy [(OR) 2.34; 95% (CI): 2.20–3.62], psoriasis [(OR) 1.75; 95% (CI): 1.64–2.37], melasma [(OR) 1.88; 95% (CI): 1.63–2.49], intrahepatic cholestasis [(OR) 2.77; 95% (CI): 2.14–3.48].

Conclusion The results of the study support the hypothesis, that there is an association between psychiatric and skin diseases in pregnancy.

Introduction The global burden of depression is high for women in both high income and low-and-middle income countries WHO.

Depression is particularly common during pregnancy and in the postnatal period and phenomenology said to be the same as in non-child bearing age. Despite high prevalence of prenatal and postnatal depression in Pakistan, research on the effectiveness of psychological interventions is limited.

Aims This study aimed to assess the feasibility of group interpersonal psychotherapy (IPT) intervention for maternal depression in Karachi, Pakistan.

Methods A total of 50 mothers aged 18 years and above with children below 3 years of age, and experiencing mild to moderate depression were recruited. Assessments were done using Edinburgh Postnatal Depression Scale (EPDS) Rosenberg's Self-Esteem Scale and EuroQoL-5D at baseline, 3 months, and 6 months. Rosenberg's Self-Esteem Scale and EQ-5D were also used to measure self-esteem and health related quality of life. Participants were randomly assigned into IPT plus treatment as usual (TAU) and TAU groups. Ten sessions of group IPT were delivered to intervention group.

Results Results indicated significant difference between intervention and control group on EPDS. The mean score at baseline for the IPT group (mean = 14.76) reduced to (mean = 6.40) ($P < 0.000$) at 3-month and to (mean = 6.64) ($P < 0.001$) at 6-month intervals as compared to TAU (mean = 11.44) ($P < 0.000$) at 3-month and to (mean = 11.08) at 6-month ($P < 0.001$) after randomisation.

Conclusion IPT is a successful fit for women with maternal depression in low-income areas and IPT can be the appropriate treatment option as it is time limited, specific, and evidence based.

¹ University of Manchester, Psychiatry, Manchester, United Kingdom

² Pakistan Institute of Learning and Living, Research, Karachi, Pakistan

³ Glasgow Institute of Psychosocial Intervention, psychology, glasgow, United Kingdom

* Corresponding author.

Introduction Prevalence of Common Mental Disorders (CMD) is high in low and middle-income countries. The prevalence rate of postnatal depression in Pakistani women and its effect on the growth and development of young children and child mortality is very high. Despite availability of interventions to improve maternal health, the major issue in implementation of those interventions is because of limited availability of trained health professionals.

Aims The aim of this study is to deliver CBT based intervention called "change your life with 7 sheets of paper" to women with mild to moderate PND through trained Traditional Birth Attendants (TBAs).

Methods During first stage of this rather blind feasibility randomized control trial 5 TBAs were trained to deliver CBT. Total 36 participants with PND having child between the ages 0–12 months will be recruited from community. Participants will be assessed using Edinburgh Postnatal Depression Scale, Patient Health Questionnaire (PHQ-9) and World Health Organization Quality of Life scale at baseline and then at 3 months. Eight group sessions of CBT will be delivered by trained TBAs.

Results Outcome assessments will be done after completion of intervention of intervention i.e., 3 months after baseline. Preliminary findings will be presented in the conference.

Conclusion Findings from this trial will help us to understand how the involvement of TBAs can help in overcoming the challenge

of non-availability of trained health professionals and in attainment of millennium development goals of reducing mother and child mortality.

EV512

Pros and cons of prescribing potentially addictive medications for patients with refractory depression and anxiety

D. Kolar

Queen's University, Kingston, Canada

Treatment resistant depression and refractory anxiety disorders are major mental health problems associated with a poor quality of life and a risk of suicide. These conditions require intensive biological treatments combined with psychosocial interventions. There are new treatments that are effective, particularly in the short run, but they are associated with negative effects such as risk of addiction. Ketamine produces fast improvement in treatment resistant depression (TRD), but effects are short-lasting and there is no sustained benefit. Oral formulations of ketamine are associated with a risk of addiction. No one has idea how long time oral or intranasal ketamine should be used.

Stimulant augmentation may cause a significant reduction in some type of residual symptoms of depression but these improvements will disappear almost immediately after discontinuing stimulant medication. There is no consensus if a long-term use of stimulant medication, such as in ADHD, is acceptable in patients with treatment resistant depression. Treatment refractory anxiety disorders may not respond to SSRI/SNRIs as expected. Although a long-term use of benzodiazepines is not recommended, benzodiazepine augmentation is currently again supported. However, treatment effects usually disappear upon discontinuing BZDs. There is a common practice of using synthetic cannabinoid, nabilone for nightmares in PTSD. Long-term use of nabilone is unfortunately not uncommon. Some patients may even prefer a medical marijuana to get short improvements in their anxiety symptoms and depression. Physicians should be very cautious when prescribe medications with addictive potential particularly if there is no strong scientific evidence of their efficacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does the supplementation of vitamin D affect depressive symptoms?

P. Kolarov*, M. Stoimenova

Medical University – Pleven – Bulgaria, Department of Psychiatry and Medical Psychology, Pleven, Bulgaria

* Corresponding author.

Introduction Depression has been linked to decreased levels of vitamin D in adults and the altered dietary intake of calcium and vitamin D has been reported to have implications for the development of depressive symptoms. Although, the relation between vitamin D and depression has been established, it is not yet clear whether the supplementation of vitamin D could affect the clinical manifestation of depression. Therefore, the aim of this study was to determine whether the supplementation of vitamin D could affect the development/course of depression.

Material and methods A systematic literature search was performed for randomized control trials (RCTs) in which vitamin D was supplemented and depression was measured.

Results and discussion Six studies were identified as being eligible to be included in this review. The results regarding the supplementation of vitamin D and its effect on the course and manifestation of depression were conflicting. One study concluded that the supplementation of vitamin D3 had beneficial effect in depression and another study reported no improvement in the indices of mental well-being in the vitamin D supplemented group and rejected the hypothesis that an annual high dose of vitamin D3 could prevent depressive symptoms. The remainder four studies reported inconclusive results regarding vitamin D supplementation and the course of depression.

Conclusion As current literature displayed contradictory results and no sound conclusion could be drawn regarding the supplementation of vitamin D and its effect on depression, there is a need of RCTs to determine whether the supplementation of vitamin D levels could affect depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV514

The meaning of loss in the context of elderly homes

C. Laranjeira

Piaget Institute, Research in Education and Community Intervention RECI I&D, Viseu, Portugal

Introduction Family plays a pivotal function in life of all human being and their significance even increases with the age. However, living in a elderly home may result in a multitude of losses which must be addressed by individual through the process of grief.

Aim The purpose of this study was to explore situations of loss and grief among institutionalized elders.

Methods It is a qualitative, descriptive and exploratory research. Data was collected from two Portuguese elderly homes in the municipality of Viseu, Portugal. A purposeful sample of 7 elders was recruited, and audiotaped face-to-face semi-structured interviews were conducted.

Results Three dimensions of emotional loss were created: loss by death, loss by separation and other losses. Loss by separation was further divided into three subcategories: marriage separation, family separation and separation of peers living in the elderly home. The death of a loved one reminds the elderly individual of his/her own mortality, complicating the process of mourning. Separation, however is much more difficult to overcome because there is a loss among the living, with the possibility to lose the meaning of life with the other one.

Conclusions Understanding loss and grief among elderly people is fundamental for nursing care, in order to help them with the process of coping and to prevent institutionalization to become an unpleasant experience. This will also offer health care facilities suggested ways to reduce or combat loneliness and depression among the elderly people.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence and risk factors of peripartum depressive symptoms among South Korean women – Preliminary data of a large prospective study

S.Y. Lee^{1,*}, H.M. Ryu²

¹ Dankook University College of Medicine-Cheil General Hospital and Women's Health, Psychiatry, Seoul, Republic of Korea

² Dankook University College of Medicine–Cheil General Hospital and Women's Health, Obstetrics and Gynecology, Seoul, Republic of Korea

* Corresponding author.

Objective The aim of this study was to assess period prevalence and risk factors of peripartum depression in South Korean women.

Methods Two thousand four hundred and forty-nine women in their first trimester of pregnancy were recruited, 1355 women were followed to the end of the study (1 month after delivery), 423 women are before the 1 month after delivery, 671 were dropped out. There were four time points of assessment – 12, 24, 36 weeks of gestation and 1 month after delivery. Depressive symptoms were assessed using the validated Korean version of the Edinburgh Postnatal Depression Scale. Risk factors were assessed across the demographic features, past histories, obstetric histories, and psychosocial status.

Results The prevalence of peripartum depressive symptoms (above 10 points of K-EPDS) was found to be 18.8% at 1st trimester, 12.9% at 2nd trimester, 12.6% at 3rd trimester, and 15.7% at 1 month after delivery. Identified risk factors of depression at 1st trimester were unmarried status, employed status, low family income, familial history and past history of depression, multigravida, unplanned pregnancy, hyperemesis, and threatened abortion. In psychological aspects, higher distress, lower marriage satisfaction, and lower quality of life increased the risk of depression. The analyses to identify risk factors of postpartum depression will be performed after the deliveries of recruited mothers are complete.

Conclusion A substantial proportion of mothers suffered from peripartum depression from their early pregnancy in Seoul, Korea. Intervention based on identified risk factors would be recommended to help depressive pregnant mothers.

Mindfulness, self-compassion and spiritual well-being in chronic depression

E. Silva, S. Simões, H. Espírito-Santo, M. Marques, L. Lemos*
Miguel Torgal Institute, Psychology, Coimbra, Portugal

* Corresponding author.

Introduction Depression is one of the main causes of incapacity worldwide. Research has shown that mindfulness practice, self-compassion promotion, and spiritual well-being are beneficial for depressed individuals.

Objective Analyze the associations between compassion, mindfulness, and spiritual well-being, during and after a therapeutic intervention (concluded less than a year ago).

Aims To determine if mindfulness, self-compassion, and spiritual well-being are predictors of depression.

Method Patients diagnosed with chronic depression were treated in a residential therapeutic community for a period of six to eight months. The 63 participants (M = 32.84, SD = 10.24, range = 15–50 years old; 32 during treatment; 31 after treatment) were assessed with the Beck Depression Inventory, the Questionnaire of the Five Facets of Mindfulness, the Self-Compassion Scale, and the Spiritual Well-Being Questionnaire.

Results There were differences in mindfulness, self-compassion, spiritual well-being and depression by sex, existence of previous psychiatric treatment, moment of the study (during versus after intervention), and depression levels. After intervention the group had higher levels of mindfulness and self-compassion (common humanity) and lower levels of over-identification, compared with group during treatment. The predictors of depression were the self-judgment dimension of the self-compassion scale and, negatively, the mindfulness dimensions of non-reactivity and non-judging, and the spiritual well-being dimension of personal well-being.

Conclusion Results confirm the relationship between the study variables and depression. This reinforces the importance of intervention based on positive psychology enhancing positive areas of human experience, rather than focusing on psychological pain, weaknesses, and disabilities.

Characteristic distributions of CBF changes in remitted geriatric depression

W. Liao^{1,*}, Z. Wang², H. Shu¹, Z. Zhang¹

¹ Neuropsychiatric Institute and Medical School of Southeast University, Neurologic Department, Nanjing, China

² Hangzhou Normal University, center for cognition and brain disorders, Hangzhou, China

* Corresponding author.

Background The cerebral blood flow (CBF) is an absolute measure that superior to the relative measure of neural activity, blood oxygenation-level-dependent (BOLD). The previous studies have reported CBF abnormalities in the adult depressive patients. However, it is not clear whether the abnormal CBF could be improved in the remitted geriatric depression (RGD).

Methods We enrolled 82 RGD patients and 90 age and education matched healthy controls. All the subjects underwent 3-T MRI with pseudo arterial spin labeling (pASL), and the pASL data were analysis voxel-by-voxel with control the gray matter volume.

Results Compared with the healthy controls, the RGD patients demonstrated higher relative CBF value in left inferior temporal gyrus and left precuneus; while lower relative CBF value in right medial temporal and occipital cortex, right insula operculum (including parts of frontal, temporal and parietal cortex) and insula, right medial frontal cortex. When compared with the remitted early onset depression (EOD), the remitted late onset depression (LOD) showed lowed relative CBF value in right angular gyrus. While there was no significantly different relative CBF value between the RGD patients accompany with MCI and RGD patients with cognitive normal.

Conclusion The late life depression persists with CBF abnormalities in the remitted state. And it is implicit that hyperperfusion in the left brain cortex and hypoperfusion in the right brain cortex could be the specific form to RGD patients.

Civilization syndrome. New diagnosis and new therapeutic approach

B. Łoza*, M. Polikowska

Medical University of Warsaw, Psychiatry, Warsaw, Poland

* Corresponding author.

Introduction Although the relationship between the content of stress and serious diseases, such as depression is not so obvious, underlying mechanisms encouraging more and more authors to define a 'civilization syndrome' as a link between our modern lifestyle, the civilization we live and psychosocial health problems. With regard to the 'civilization syndrome', there are several new candidates that have been spotted as the challenges for psychiatric research, like burnout, infertility and solitude. All these phenomena seem to increase epidemically and require urgent conceptual and therapeutic studies.

Aim . The program was addressed to three groups of patients with burnout, infertility, and social relationship/loneliness crisis.

Method Using the new stress reduction program (SRP), engaging both pharmacological and psychotherapeutic approach, and also several lifestyle factors, like physiotherapy, nutrition aspects, coaching, social media contact and monitoring, most of patients improved in terms of emotional and behavioral markers, in short- and long-term (4–6 months) observations.

Material Patients and clients (N43) with F3.x-F4.x disorders according to ICD-10.

Results A variety of PRS scales were used to assess patients' improvement outcomes. Significant reductions (4–6 months) were observed at Maslach Burnout Inventory (-23.4% , $P=0.000$), Fertility Problem Inventory (-34.5% , $P=0.000$), UCLA Loneliness Scale, ver. 3 (-43.3% , $P=0.000$), and Perceived Stress Scale (44.0% , $P=0.000$).

Discussion This program interplays between stress and mental health problems and opens up new possibilities for diagnosis and therapy, focusing on the challenges of civilization, and especially opens up preventive options in stress-related problems and diseases, which represent a growing health burdens in modern society.

Metabolic dysregulation as predictor for the course of late-life depression

R. Marijnissen^{1,*}, N. Vogelzangs², M. Mulder³, R. van den Brink⁴, H. Comijs², R. Oude Voshaar⁴

¹ Wolfheze, Netherlands

² VU University Medical Center, Department of Psychiatry/GGZinGeest & Institute for Extramural Medical Research EMGO, Amsterdam, Netherlands

³ Arnhem, Netherlands

⁴ University Medical Center Groningen- University of Groningen, University Center of Psychiatry & Interdisciplinary Center for Psychopathology of Emotion Regulation, Groningen, Netherlands

* Corresponding author.

Introduction Depression is associated with the metabolic syndrome (MS). Recently, the concept of 'metabolic depression' has been proposed based on a protracted course of depressive symptoms over time.

Objective and aims Within the Netherlands study of depression in older persons, we examined whether metabolic dysregulation predicted the two-year course of depression.

Methods A cohort study ($n=285$) of depressed persons (≥ 60 years) with two-year follow up. Depression was classified according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV). Severity of depression was assessed with sum score as well as subscale scores of the Inventory of Depressive Symptomatology (IDS) at six-month intervals. The metabolic syndrome was defined according the National Cholesterol Education Program (NCEP-ATP III). We applied logistic regression and linear mixed models adjusted for a wide range of confounders and severity of depression at baseline.

Results The number of MS-components predicted non-remission at two-years (OR=1.28 [95% CI: 1.00–1.58], $P=0.047$), which was driven by waist-circumference, HDL-cholesterol and triglycerides. MS was only associated with the somatic symptom subscale score of the IDS over time, but not with its sum score (interaction time \times somatic subscale, $P=0.002$). This effect was driven by waist circumference, elevated fasting glucose level and hypertension.

Conclusion Metabolic dysregulation predicts the course of late-life depression. This effect seems to be driven by visceral obesity (as indicated by the waist circumference) and lipid dysregulations and with respect to the somatic symptoms of depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of self-compassion in lifetime history of depression: A study in Portuguese pregnant women

E. Bento¹, S. Xavier¹, J. Azevedo¹, M. Marques^{1,2}, M.J. Soares¹, M.J. Martins^{1,3,*}, P. Castilho³, N. Madeira², A. Macedo^{1,2}, A.T. Pereira¹

¹ Faculty of Medicine-University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre-Portugal, Psychiatry, Coimbra, Portugal

³ Faculty of Psychology and Educational Sciences - University of Coimbra, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Although self-compassion has been pointed as an effective strategy for coping with depression, there are not any studies investigating its association with lifetime history of depression (LTHD).

Objective To compare self-compassion levels in pregnant women with vs. without LTHD and to analyze if self-compassion dimensions are significant predictors of LTHD.

Methods Four hundred and twenty-seven pregnant women with a mean age of 33 years (± 4.785) in their second trimester of pregnancy completed the Self Compassion Scale validated for pregnancy (SCS; Bento et al., 2015) and a new self-report questionnaire to evaluate the presence of LTHD according to DSM-5 criteria for depression.

Results Ninety-seven (23.0%) women had LTHD. Bisserial Spearman correlations between LTHD and SCS total score were significant, negative and moderate ($r=-0.31$). SCS subscales, except Common Humanity, showed significant correlations: Self-Kindness/SK ($r=-0.130$), self-judgement (SJ) (0.313), isolation (0.357), mindfulness ($r=-0.102$), over-identification (OI) ($r=0.393$). Independent sample *t* tests revealed that women with vs. without LTHD had significantly lower levels of total SCS, SK and Mindfulness scores and higher levels of SJ, Isolation and OI. Logistic regression (assumptions were fulfilled, Tabachnick and Fidell, 2007) showed that the SCS explained 26.7%–43.6% of the LTHD variance and correctly classified 86.9%; the odds ratio (OR) was 865 (95% CI 0.834–0.898; $P<0.001$). The model composed by the correlated dimensions explained 15.9%–24.0% and correctly classified 80.6%. Odds ratios: SK=0.017; SJ=0.021; isolation = 16.027; mindfulness = 0.167 and OI = 20.178 (all $P<0.05$).

Conclusions Self-compassion, specifically the ability to treat oneself with care and understanding and to be aware and accepting one's present-moment experiences, decrease the probability of having LTHD.

Interictal depressive disorders in epilepsy patients

A. Matos Pires^{*}, Y. Martins, M. Suarez Gomez
Local Health Unit of Baixo Alentejo, Department of Psychiatry and Mental Health, Beja, Portugal

* Corresponding author.

Introduction Depression is recognized as more frequent psychiatric disorder in epilepsy patients with significant impact on their health-related quality of life.

Aims To analyze the occurrence and clinical particularities of different types of interictal depression in epilepsy patients.

Methods One hundred and fourteen epilepsy patients with interictal depression were assessed with a clinical interview and Hamilton depression and anxiety rating scales. Diagnostic criteria of ICD-10 and of the International League Against Epilepsy (ILAE) were used.

Results A total of 45.6% of patients met ILAE criteria of interictal dysphoric disorder (IDD) with predominance of depressive mood, irritability, fear and atypical pain. All patients had chronic epilepsy with specific epileptic personality changes. Comorbid adjustment disorders (depressive and anxious-depressive reactions) were diagnosed in 27.2% of patients. The most frequent trigger situations were: family problems, serious illness, unemployment, financial difficulties. In more than half of patients were registered specific personality changes whose severity was in inverse ratio with trauma severity. A total of 18.4% of patients met criteria of comorbid affective disorder (depressive and bipolar) with some specific clinical traits due to personality changes. In 8.8% of patients, anticonvulsant-induced depression was observed; it was clinically simple, resolved after offending medication withdrawal.

Conclusions Observed depressive disorders were heterogeneous: comorbid or attributed to epilepsy or its treatment. The most frequent condition was IDD. Specific personality changes may contribute to higher susceptibility and development of psychogenic depression. We emphasize the importance of treatment history (possibility of anticonvulsant-induced depression).

Regulation of serum spadin propeptide: An antidepressant response probe

J. Mazella*, C. Devader, M. Roulot, M. Borsotto, C. Heurteaux
Institut de pharmacologie moléculaire et cellulaire, CNRS–Life science, Valbonne, France

* Corresponding author.

Objectives We previously discovered that spadin, a short analogue of the propeptide (PE) released from the maturation of sortilin, displays potent antidepressant properties. Since the PE level can be measured in the blood, we aimed to investigate how the PE serum concentration is regulated in mice. We wondered whether the PE serum levels vary between healthy subjects and patients with major depressive disorder (MDD).

Methods We developed a dosing method based on the AlphaScreen™ technology (Perkin) which allow to selectively detect both PE, spadin and metabolic products from these peptides with a detection range of 1 ng/mL.

Results We found that insulin significantly up-regulated serum PE concentration from 26.15 ± 2.63 to 41.43 ± 6.27 nM ($P=0.0318$). Analysis during circadian cycle in mice revealed that the amount of PE and its derivatives significantly varied during the cycle being higher during the period of maximal activity (dark period). We also measured serum insulin concentration between 1 and 7 pm and observed a significant rise confirming the relationships between insulin and PE concentration. We showed that the serum level of PE is lower in depressive patients than in healthy non-psychiatric. We observed that the weaker level of PE in depressive patients can recover the level of healthy subjects after a chronic antidepressant treatment.

Conclusions Dosing the serum level of PE could be a promising approach for the diagnosis of depression and to determine the remission of the disease.

Treatment of mild to moderate major depressive disorder with agomelatine in patients with cardiovascular disorders (national observational multicenter study “pulse”)

V. Medvedev

Moscow, Russia

Introduction The urgency of depression treatment in patients with cardiovascular diseases (CVD) is determined by the increasing prevalence of affective disorders. For these patients, tolerance and safety of antidepressants are of great importance.

Objective To obtain additional data on therapeutic efficacy and tolerance of agomelatine in the treatment of mild to moderate depressive disorders in cardiologic practice in Russia.

Methods Eight hundred and ninety-six adult patients with CVD (86.5% arterial hypertension, 29.5% stable angina, 16% myocardial infarction, 23.6% conduction disturbances, 17.6% chronic heart-failure) were treated with agomelatine 25-50 mg for 12 weeks. Depression and anxiety symptoms were evaluated via Hospital Anxiety and Depression Scale (HADS), Clinical Global Impression (CGI-S and CGI-I), Visual Analog Scale (VAS), Spielberger Anxiety Scale (SAS), Whitely Hypochondria Index (WHI) and quality of life questionnaire (SF-36). Safety and tolerance were also monitored according to the summary of product characteristics recommendations.

Results HADS scores decreased throughout the study and severe anxiety rate decreased from 95.9% to 15%. After 12 weeks of treatment, remission (HADS < 7) rate was 84.6%. Subjective assessment of patient health significantly improved ($P < 0.00001$). WHI decreased significantly ($P < 0.00001$). Physical and mental health significantly improved ($P < 0.00001$). Heart rate and blood pressure decreased. Treatment acceptability was considered “excellent” by 82% of doctors and 75% of patients.

Conclusion Agomelatine significantly improved depressive symptoms, anxiety and hypochondria in depressed patients with CVD and demonstrated good tolerance. This suggests the possibility of wide and safe use of agomelatine for treatment of depression in patients with CVD.

³ Verve Rehabilitation, Oulu, Finland

* Corresponding author.

Introduction Personality traits have been associated with risk for depressive disorders. Studies with premorbid measures on personality are uncommon.

Objective Estimate effect of premorbid personality as a predictor for remission in depressive disorders.

Aim To study premorbid personality as a predictor for remission in depression in a population based sample.

Methods The sample is based on the large Northern Finland Birth Cohort 1966. Temperament traits were measured at age 31 years using the Temperament and Character Inventory. At the age of 46 years depressive symptoms were measured using the Beck Depression Inventory – II (BDI). The sample included those with self-reported life-time depression history at age 46 years but not yet at age 31 years ($n = 298$). Temperament at age 31 years was used to predict remission ($BDI \leq 13$) at age 46 years using logistic regression analysis, with gender and educational level as confounders. Cohen's d was used as effect size measure.

Results Two hundred and one (67.4%) of individuals with self-reported depression were on remission at the follow-up. Low harm avoidance (total scale, and subscales anticipatory worry, shyness, and fatigability), low impulsiveness and high exploratory excitability (subscales of novelty seeking), and low sentimentality (subscale of reward dependence) predicted significantly remission with effect sizes between 0.28 and 0.45, highest effect being in harm avoidance.

Conclusions Different temperament traits were able to predict remission status in depression. Effect sizes were between small and moderate. Temperament may associate with treatment response in depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The importance of art therapy in the integrative treatment of recurrent depressive disorder – case study

J. Pavlovic Stojkovic¹, M. Milosavljevic^{1,*}, M. Vukovic¹, L. Vidic¹, D. Lecic Tosevski^{1,2,3}

¹ Institute of Mental Health, Clinical Department for Crisis Situations and Affective Disorders, Belgrade, Serbia

² Serbian Academy of Sciences and Arts, Medicine, Belgrade, Serbia

³ University of Belgrade, Medical Faculty, Belgrade, Serbia

* Corresponding author.

An integrative treatment of patients with affective disorders during hospitalisation also includes art therapy. Art therapy, as a form of expressive therapy, uses the creative process to encourage communication, expression of feelings and offers the space for mutual mirroring. This paper presents a patient who has been treated for approximately five years under the diagnosis of a recurrent depressive disorder (F33) and mixed personality disorder (F61). The patient has been experiencing unrecognised and untreated problems of the depression spectrum since 1993, when he took part in the Yugoslav war. The main issue was the somatic symptoms (headaches, nausea etc). Another major problem during his psychiatric treatment and an additional cause of unsatisfactory therapeutic effect was his inability to verbalise his feelings. In the course of art therapy, when the patient was given a topic "How I see myself in five years", he drew a man who appeared to be sleeping and explained that he could not see himself in five years' time, since he would not be alive at the time and that he could not see a way out of the current situation. With the help of a supportive group, for the first time since the beginning of his treatment, he spoke about his thoughts and feelings of hopelessness, sorrow, alienation and loneliness. This enabled new insight into the patient's depression. This clinical example shows how art therapy and reaction of the group, which was supportive and highly associative, can turn the non-verbal into verbal and non-communication into communication.

Toward evidence-based medical statistics: Re-evaluate the efficacy of antidepressants by using Bayes factors

R. Monden^{1,*}, D.V. Stijn¹, W. Klaas¹, R. Annelieke¹, M. Richard², W. Eric-Jan³

¹ University Medical Center Groningen, Psychiatry, Groningen, Netherlands

² Cardiff University, School of Psychology, Cardiff, United Kingdom

³ University of Amsterdam, Psychology, Amsterdam, Netherlands

* Corresponding author.

Introduction Studies have been reported the similar efficacy of antidepressants (effect size around 0.3), and it is difficult for clinicians to select an antidepressant. This may partly due to the use of a $p < .05$ null-hypothesis significance testing (NHST) framework to evaluate "substantial evidence". This framework only allows dichotomous conclusions and does not quantify the strength of evidence supporting efficacy. In addition, meta-analyses based on publications may offer positively biased results due to selective publications.

Objectives Demonstrate that the Bayesian framework can provide valuable information on the strength of the evidence for drug efficacy.

Aims Re-evaluate the efficacy of FDA-approved antidepressants applied to anxiety disorders and depression by means of Bayes factors.

Methods To avoid selective publication, data of double-blind placebo-controlled trials for FDA-approved antidepressants for the treatment of anxiety disorders and depression were extracted from the FDA. Bayes factors (BFs) were calculated and compared with the results obtained under NHST framework.

Results A large variance of evidence for the efficacy of antidepressants was found for both depression and anxiety disorders. Among trials providing "substantial evidence" according to the FDA for anxiety disorders, only 27 out of 59 dose groups obtained strong support for efficacy according to the typically used cut-off of $BF \geq 20$. For depression, all FDA-approved antidepressants had $BF \geq 20$, except for bupropion. Moreover, it was shown that the tested antidepressants can be differentiated based on the strength of evidence and effect size.

Conclusions The BFs quantified the comparative evidence base for the efficacy of antidepressants.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background Depression and anxiety were common psychiatric morbidity among breast cancer patient. This study aims to study the level of depression, anxiety, QoL and PSS among Malaysian breast

cancer women over a period of 12 months and their associations at baseline, 6 and 12 months.

Methods It is a 12-months prospective cohort study. Two hundred and twenty one female patients were included into the study. They were assessed at the time of diagnosis, 6 months and 12 months using Hospital Anxiety and Depression Scale (HADS), Quality-of-Life Questionnaire (QLQ-C30), Version 3.0 and Multidimensional Scale of Perceived Social Support (MSPSS). Relevant socio-clinical characteristic information was collected.

Results The HADS anxiety and depression subscales scores of the subjects were relatively low. The level of anxiety reduced significantly at 6 and 12 months (baseline – 6 months, $P=0.002$; baseline – 12 months, $P<0.001$). There were no changes in the level of depression over the study period. The global status of QoL and MSPSS scores were relatively high. There was positive correlation between the global status of QoL and MSPSS for the study subjects (Spearman's $\rho=0.31-0.36$). Global status of QoL and MSPSS scores were negatively correlated with anxiety and depression.

Conclusion Malaysian breast cancer women had relatively better QoL with lower level of anxiety and depression. Perceived social support was important associated factor for better QoL with low level of psychological distress. It reflected the importance of enhancing and maintaining the social support system for breast cancer patients.

Introduction Major depressive disorder (MDD) is the second leading cause of disability in China.

Objective To analyze functioning during the course of treating MDD in China, Taiwan and Hong Kong.

Aims To study the influence of pain and clinical remission on functioning.

Methods This was a post-hoc analysis of a 6-month, prospective, observational study ($n=909$) with 422 patients enrolled from China ($n=205$; 48.6%), Taiwan ($n=199$; 47.2%) and Hong Kong ($n=18$; 4.2%). Functioning was measured with the Sheehan Disability Scale (SDS), pain with the Somatic Symptom Inventory, and severity of depression with the Quick Inventory of Depressive Symptomatology-Self Report 16 (QIDS). Patients were classified as having no pain, persistent pain (pain at any visit) or remitted pain (pain only at baseline). A mixed model with repeated measures was fitted to analyze the relationship between pain and functioning.

Results At baseline, 40% of the patients had painful physical symptoms. Patients with pain had a higher QIDS and lower SDS ($P<0.05$) at baseline. At 6 months, patients with persistent pain had lower functioning ($P<0.05$). The regression model confirmed that clinical remission was associated with higher functioning at endpoint and that patients with persistent pain had lower functioning at endpoint when compared with the no pain group.

Conclusions Patients presenting with pain symptoms had lower functioning at baseline. At 6 months, pain persistence was

associated with significantly lower functioning as measured by the SDS. Clinical remission was associated with better functional outcomes. The course of pain was related to the likelihood of achieving remission.

* Corresponding author.

Introduction Depression is a disabling disorder with a high socio-economic impact. It might require hospitalization for symptom control and/or harm prevention. Other depressive disorders might as well require hospitalization in benefit of the patient. Hospitalization may be involuntary. Hospitalization willingness in depressive patients has not been systematically studied in recent years.

Objective The aim of this study is to explore the necessity of involuntary hospitalization in patients presenting depressive symptoms at the emergency service that were later diagnosed with a depressive disorder.

Materials and methods From all patients visited in the psychiatric emergency service from 2012 to April 2015 those that were hospitalized in the acute mental health unit and diagnosed with a depressive disorder were studied. All those monopolar depression diagnoses were considered, excluding those within the bipolar spectrum. Diagnosis followed CIE-9 criteria. A descriptive cross-sectional study of the samples was then conducted. Statistical analysis was performed using SPSS software (SPSS Inc., Chicago, Ill.).

Results From all 385 depressive disorders, 169 were involuntary admissions (43.9%), 196 were voluntary (50.9%) and 20 were scheduled (5.2%), difference was statistically significant ($P<0.05$). Mean age, was 59.52 years for involuntary admissions, 61.7 for voluntary and 63.6 years for scheduled, with a statistically significant difference ($P<0.05$). Gender differences were not significant.

Conclusions Most depressive disorders were hospitalized voluntarily. However, a relevant percentage of patients required involuntary hospitalization. Younger patients presented a higher ratio of involuntary hospitalization. Reasons for involuntary hospitalization needs should be further studied.

Disclosure of interest The authors have not supplied their declaration of competing interest. Liliana Galindo is a Rio Hortega fellowship (ISC-III; CM14/00111).

This study explores the role of mood disorders' symptoms salience on different types of defense mechanisms (mature, neurotic, immature) predominance. Total of 255 both clinical and non-clinical participants in Mostar, Bosnia & Herzegovina, completed a Defense Style Questionnaire (DSQ-40; Andrews, Singh & Bond, 1993) and Beck Depression Inventory-II (BDI; Beck, Steer & Brown, 1996). The sample was additionally divided into four groups, given the level of symptoms experienced: 1. Minimal, 2. Mild, 3. Moderate, 4. Severe depression. Results show that participants with minimal depressive symptoms use mature defense mechanisms more often than other three groups. Immature mechanisms are most commonly used by the group with severe depression levels in comparison with other groups. These differences are discussed within the dynamic level of analysis to have a better understanding of the relationship between defense mechanisms' maturity and the degree of mood disorders' symptom severity. In addition, these results could serve as an implication for the future therapeutic treatment plans.

Introduction A considerable amount of studies support the association of depression with nutritional factors, especially fruit and vegetables. Little evidence exists concerning mood and nutritional habits of pregnant women in Greece.

Objective Our specific objective was to examine potential relationships between fruit and vegetable consumption and depression in pregnant women.

Aims The overall aim of this study was to investigate the nutritional habits and the depression level of healthy pregnant women in Greece.

Method Eighty-eight healthy pregnant women, aged 25–44 years (mean ± standard deviation: 32.41 ± 3.9), were studied with the aid of a questionnaire addressing eating habits and the Beck Depression Inventory (BDI).

Results Twenty-four women were found having mild to moderate depression (score 20–24, according to BDI) associated with lower consumption of salads ($P < 0.05$). No association was found between depression and consumption of fruit or fruit juices, or prescribed supplements (Ca, Fe, Mg, folic acid).

Conclusion Interestingly, in our sample an association of depression in pregnancy was found with the consumption of salads but not fruit or fruit juices. The presence of vitamin B in vegetables is one of the factors differentiating them from fruit. So it might be a crucial element for further research.

Mindfulness, self-compassion and depressive symptoms in pregnant women

A.T. Pereira^{1,*}, S. Xavier¹, E. Bento¹, J. Azevedo¹, M. Marques^{1,2}, M.J. Soares¹, V. Freitas¹, A.M. Pinto^{1,3}, C. Roque², A. Macedo^{1,2}

* Corresponding author.

Introduction Depressive symptoms in pregnancy are risk factors for postpartum depression and associated to adverse child outcomes (Glover, 2014). Depressive symptoms decreases after participation in mindfulness and self-compassion based interventions for pregnant women (e.g. Goodman et al., 2014). However, apart from intervention trials, there are not studies on the relationship between mindfulness, self-compassion and depressive symptoms in pregnancy (Zoeterman, 2014).

Objective To explore the association between mindfulness, self-compassion and depressive symptoms in pregnant women.

Methods Four hundred and twenty-seven pregnant women (mean age: 32.56 ± 4.785 years) in their second trimester of pregnancy completed a set of self-report questionnaires validated for pregnancy: Facets of Mindfulness Questionnaire-10 ([FMQ-10]; Azevedo et al., 2015; to evaluate Nonjudging of experience/NJ, acting with awareness (AA) and observing and describing (OD), Self-Compassion Scale ([SCS]; Bento et al., 2015; to evaluate self-kindness, self-judgment, common humanity [CH], isolation, mindfulness and over-identification [OD]) and Postpartum Depression Screening Scale-24 (PDSS-24; Pereira et al., 2013). Only variables significantly correlated with the outcomes were entered in the multiple regression models.

Results FMQ-10 and SCS Total scores were both significant predictors of PDSS-24 ($B = -0.294, -0.272$). Derealization and failure predictors were NJ and Isolation ($B = -0.234, 0.384$); Suicidal ideation predictor was NJ, OD and isolation ($B = -0.152; -0.115; 0.334$); concentration difficulties and anxiety predictors were isolation and CH ($B = 0.296; -0.201$); Sleep difficulties predictors were AA and isolation ($B = -0.199; 0.248$) (all $P < 0.05$).

Conclusions Mindfulness and self-compassion dimensions, particularly nonjudging of experience, acting with awareness, observing and describing are protective correlates of antenatal depressive symptoms. Isolation is a correlate of PD in pregnancy.

Somatic symptoms as measured by SSI-26 (Somatic Symptom Inventory) correlate with social and physical functioning (SF36) in depressed patients. The relative contribution of anhedonia

A.L. Pérez Morenilla^{1,*}, A. Salazar², I. Failde², J.A. Mico³

¹ University Hospital Puerta del Mar-Cádiz, Psychiatry, Cádiz, Spain

* Corresponding author.

According to the DSM5, Somatic Symptom Disorder (SSD) is characterized by somatic symptoms that are either very distressing or result in significant disruption of functioning. These criteria are significantly different compared with previous editions of DSM. For example, the DSM-IV diagnosis of somatization disorder required a specific number of complaints from among four symptom groups, however the SSD criteria no longer have such a requirement. Nevertheless somatic symptoms must be significantly distressing or disruptive to daily life. Very few studies have focussed on the influence of suffering anhedonia on the perception of somatic symptoms and how this impact on Health Related Quality of Life (HRQoL), particularly physical functioning. We studied the relative impact of somatic symptoms on the social and physical functioning in depressed patients. Moreover we have explored the influence of anhedonia as measured by the Snaith-Hamilton Anhedonia Pleasure Scale (SHAPS). We analysed the correlations between the scores of the 8 dimensions of the SF-36, the SSI-26 and the SHAPS questionnaires. The results show a significant correlation between SSI-26 score and physical functioning ($r = -0.565$; $P < 0.001$), role physical ($r = -0.551$; $P < 0.001$), bodily pain ($r = -0.659$; $P < 0.001$), general health ($r = -0.534$; $P < 0.001$), vitality ($r = -0.481$; $P = 0.001$), social functioning ($r = -0.302$; $P = 0.044$) and mental health ($r = -0.461$; $P = 0.001$). Additionally, SHAPS score correlates with vitality ($r = -0.371$; $P = 0.012$), social functioning ($r = -0.574$; $P < 0.001$) and mental health ($r = -0.445$; $P = 0.002$). The results demonstrated that both somatic symptoms and level of anhedonia negatively correlate with HRQoL, suggesting a potential relationship between level of anhedonia and some somatic symptoms. This could impact on the diagnosis and treatment of depressed patients with somatic symptoms and anhedonia.

* Corresponding author.

Minor depression is diagnosed when a patient suffers from two to four depressive symptoms for at least two weeks. Though minor depression is a widespread phenomenon, its pathophysiology has hardly been studied. To get a first insight into the pathophysiological mechanisms underlying this disorder we assessed serum levels of biomarkers for plasticity, glial and neuronal function: brain-derived neurotrophic factor (BDNF), S100B and neuron specific enolase (NSE). Twenty-seven subjects with minor depressive episode and 82 healthy subjects over 60 years of age were selected from the database of the Leipzig population-based study of civilization diseases (LIFE). Serum levels of BDNF,

S100B and NSE were compared between groups, and correlated with age, body-mass index, and degree of white matter hyperintensities (score on Fazekas scale). S100B was significantly increased in males with minor depression in comparison to healthy males, whereas other biomarkers did not differ between groups ($P = 0.10-0.66$). NSE correlated with Fazekas score in patients with minor depression ($r_s = 0.436$, $P = 0.048$) and in the whole sample ($r_s = 0.252$, $P = 0.019$). S100B correlated with body mass index ($r_s = 0.246$, $P = 0.031$) and with age in healthy subjects ($r_s = 0.345$, $P = 0.002$). Increased S100B in males with minor depression, without alterations in BDNF and NSE, supports the glial hypothesis of depression. Correlation between white matter hyperintensities and NSE underscores the vascular hypothesis of late life depression.

Introduction Depressive disorders are the most prevalent mental diseases and they cause a major impact in our society.

Objectives The objective of this study is to establish the prevalence of depressive disorders in Andalusia.

Aims The aim is to provide useful information regarding this prevalent and disabling condition, in order to contribute to its prevention and treatment.

Methods Our results proceed from the PISMA-ep study, undertook in Andalusia. In this cross-sectional community based study, 4507 participants between 18 and 75 years of age were interviewed by fully trained professionals. The main diagnostic tool was the Spanish version of the MINI Neuropsychiatric International Interview.

Results Our sample consists of 4507 participants. 50.9% of them were females. Mean age was 42.8 years. The estimated one-month prevalence of any mood disorder was 7.9% (7.1–8.6). The estimated one-month prevalence of major depression was 6, 4% (5.6–7.1). The prevalence of the other measured depressive disorders were as follows: Recurrent depressive episode: 3.7% (3.2–4.3), Melancholic depression: 3% (2.5–3.5), Severe depressive episode with psychotic symptoms: 1.4% (1.1–1.8).

Conclusions The PISMA-ep is the first large mental health epidemiological study ever developed in the largest region of Spain. The results obtained in this region show a higher prevalence of depressive disorders in Andalusia, when compared with prior studies that used a nationally representative sample (i.e. the ESEMeD study). The reasons for this higher prevalence are yet to be explored.

Introduction The quality of life in patients with depression may be a measure of the efficiency of its management. Although quality of life is a subjective concept, difficult to assess, it may be reflected by the degree of social adaptation and the individual’s level of functioning.

Objective The study evaluates the time evolution of depressive symptoms and of some parameters attesting the quality of life in patients diagnosed with depression who are on antidepressant treatment.

Aims Highlighting the evolution in time of depressive symptoms and patients’ perceptions on some aspects of quality of life.

Methods There were included 23 patients who met the criteria of depressive episode, single or within recurrent depressive disorder, according to the International Classification of Diseases (ICD-10-AM), requiring antidepressant treatment. Subjects were evaluated at baseline and after 12 weeks of treatment using the Hamilton Rating Scale for Depression (HAMD), Sheehan disability scale (SDS), Social Adjustment Scale – Self-report (SASS).

Results Statistically significant decrease in mean HAMD scores was observed in the second administration. There were registered statistically significant differences of scores obtained in the two administrations for the 17 items of the SASS scale. Correlations with statistical significance between HAMD scores and some of the SDS areas were observed.

Conclusions Results showed a favorable course of depressive symptoms while under treatment and differences in time of subjects’ perception on several aspects evaluated on SASS for the group studied. Correlations with statistical significance between HAMD scores and some SDS areas were observed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Depression leads to substantial suffering for the patients, their families and becomes an economic burden for system [1,2]. Patients and clinicians tend to rate the remission differently [3].

Objectives and methods We investigate if clinicians and patients rate different the treatment response. This study assessed the evolution of major depressive episode (MDE) in patients treated with Agomelatine, in Romania. It was designed as a multicentre, observational study that included 1213 adult patients evaluated in 75 sites in 2014. The design included 3 visits (baseline (V1); visit at 2/3

weeks (V2); visit 6/8 weeks (V3)). The scales used were: MADRS, SHAPS, CGI-I, CGI-S, PGI-I, PGI-S.

Results The MDE improvement was significant ($P < 0.001$) for all aspects evaluated. At baseline, more clinicians vs. patients considered the moderately or markedly ill as best descriptors of the state. The difference between the two assessments was even higher for V2 and V3. During V2 clinicians reported “minimally improvement” while patients reported “much improvement” in higher percentage. During V3, both, clinicians and patients reported a “very much improved” clinical status. Of the patients 42.60% reported at V3 “normal”, not at all ill’ in comparison to 34.81% of clinicians who reported the same ($P < 0.001$).

Conclusions This could mean that patients are not aware of the severity of their disease. This data could be interpreted in the way that patients are more prone to rate higher the improvements as response to treatment and the clinicians to rate as response a more than 50% decrease of symptomatology.

Rumination and primary care depression

K. Riihimäki^{1,*}, M. Vuorilehto², P. Jylhä², E. Isometsä²

¹ Health Care and Social Services, MPY, Järvenpää, Finland

² University of Helsinki and Helsinki University Hospital, Department of Psychiatry, Helsinki, Finland

* Corresponding author.

Introduction Response styles theory postulates that rumination is a central factor in occurrence, severity and maintaining of depression. High neuroticism has been associated with tendency to ruminate.

Objective To evaluate the relationships between rumination, neuroticism and depression in a naturalistic prospective cohort of primary care patients with depressive disorders with life-chart methodology.

Aims We hypothesized, that rumination would correlate with severity and duration of depression and with concurrent anxiety, gender and neuroticism.

Methods In the Vantaa Primary Care Depression Study, a stratified random sample of 1119 adult patients was screened for depression using the Prime-MD. Depressive and comorbid psychiatric disorders were diagnosed using SCID-I/P and SCID-II. Of the 137 patients with depressive disorders, 82% completed the five-year follow-up with a graphic life chart. Neuroticism was measured with the Eysenck Personality Inventory (EPI-Q). Response styles were investigated at five years using the Response Styles Questionnaire (RSQ-43).

Results Rumination correlated significantly with Hamilton Depression Rating Scale ($r = 0.54$), Beck Depression Inventory ($r = 0.61$), Beck Anxiety Inventory ($r = 0.50$), Beck Hopelessness Scale ($r = 0.51$) and Neuroticism ($r = 0.58$). Rumination correlated also with proportion of follow-up time spent depressed ($r = 0.38$). In multivariate regression, high rumination was significantly predicted by current depressive symptoms and neuroticism, but not by anxiety symptoms or preceding duration of depressive episodes.

Conclusions Rumination correlated with current severity of depression, but the association with preceding episode duration remained uncertain. The association between neuroticism and rumination was strong. The findings are consistent with rumination as a state-related phenomenon, which is also strongly intertwined with traits predisposing to depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Endocannabinoid system has been highlighted as one of the most relevant research topics by neurobiologists, pharmacists, basic scientists and clinicians. The association between endocannabinoids and its congeners and mood disorders is relatively recent. However, evidence from both clinical and preclinical studies is increasing and many researchers point out endocannabinoid system and particularly endocannabinoids and congeners as promising pharmacological targets.

Aims and objectives The main objective of this study is to compare the plasma concentrations of endocannabinoids and congeners between a sample of patients with depression and a sample of control subjects, and the influence of variables such as age, body mass index, gender, severity of symptoms, and antidepressant medication.

Method Plasma concentrations of endocannabinoids and congeners will be analyzed in 69 patients with depression from primary care and 47 controls using mass spectrometry analysis.

Results Statistically significant differences in 2-arachidonoylglycerol and monoacylglycerols were found between both samples. Somatic symptoms of depression seems to be more related to these compounds than to cognitive-affective symptoms. In addition, differences between mildly and moderately depressed patients were found in concentrations of AEA, LEA, DGLA and POEA. Patients with antidepressant medication showed higher levels of 2-AG, DGLA and OEA.

Conclusions The results of this study provide evidence supporting the hypothesis that in depression there is a dysregulation of the inflammatory signaling and, consequently the immune system. The results of this study could also support the realization of translational research to better understand the mechanisms of this widely distributed system.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Evidence indicates that manic symptoms, below the threshold for hypomania (mixed features), are common in individuals with major depressive disorder (MDD).

Objectives/aims To evaluate the effect of lurasidone on specific depressive and manic symptoms, based on Montgomery Asberg Depression Rating Scale (MADRS) and Young Mania Rating Scale (YMRS) items, in patients with MDD with mixed features.

Methods Patients meeting DSM-IV-TR criteria for MDD, who presented with 2–3 protocol-specified manic symptoms, were randomized to 6 weeks of double-blind treatment with lurasidone monotherapy 20–60 mg/d ($n=109$) or placebo ($n=100$). Change from baseline in the MADRS total, MADRS-6 core depression subscale, individual MADRS items, and total and individual items of the YMRS were analyzed by MMRM, and Cohen's d effect sizes (d) were calculated for week 6 change scores.

Results Lurasidone improved depressive symptoms at week 6 in the MADRS total score (-20.5 vs. -13.0 ; $P<0.0001$; $d=0.8$) and MADRS-6 core depression score (-13.0 vs. -8.5 ; $P<0.0001$; $d=0.7$). Significant improvement on lurasidone was observed at week 6 on all ten MADRS items ($d=0.36$ – 0.78). Effect sizes for the MADRS-6 core depression subscale items ranged from 0.36 to 0.78 at week 6. Treatment with lurasidone was associated with significantly greater week 6 improvement on the YMRS (-7.0 vs. -4.9 ; $P<0.0001$). Effect sizes for the 5 YMRS items with baseline item severity ≥ 2 ranged from 0.32 to 0.48.

Conclusions In this study of MDD with mixed features, lurasidone was effective in treating the range of depressive and manic symptoms that patients presented with.

Effect of meta-cognitive therapy on patients of depression: A case series from India

V. Sharma^{1,*}, M. Mehta², R. Sagar²

¹ New Delhi, India

² All India Institute of Medical Sciences, Department of Psychiatry, New Delhi, India

* Corresponding author.

Background Metacognitive Therapy (MCT) for depression aims at targeting attentional control, rumination, worry, and metacognitive beliefs of individuals.

Aim The purpose of this study was to examine the effects of meta-cognitive therapy (MCT) in the treatment of patients with a diagnosis of major depressive disorder.

Methods Five patients diagnosed as having major depressive disorder were recruited for the study. Each patient received 10 sessions of MCT up to 1 hour each at a frequency of once per week. All patients were assessed at baseline, which was followed by 10 weekly sessions of MCT with post-intervention assessment and follow-up assessments at 1-month post-treatment. Primary outcome measures were the reduction in symptoms of depression, worry, and rumination. Outcomes were assessed via self-report using structured psychological tests.

Data analysis Data was analyzed using individual frequency comparisons where measures of differences were obtained within each phase of assessment. Pre-intervention, post-intervention and follow-up measures were compared along with identification of within phase differences. Meticulous analysis was also performed using measures of qualitative analysis. For this purpose, following measures were used: homework assignment analysis, within ses-

sion feedbacks, change in nature of meta-cognitive beliefs, change in executive control of attention to negative thoughts, changes in beliefs related to threat monitoring, analysis of factors leading to fluctuation in symptoms and the nature of coping skills.

Results Improvements were observed between pre- and post-analyses of all primary outcome variables. In addition, the phenomenology of change in symptomatology has been explained in the light of various qualitative descriptions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Metacognitive beliefs and rumination in patients with major depressive disorder in India

V. Sharma^{1,*}, M. Mehta², R. Sagar²

¹ New Delhi, India

² All India Institute of Medical Sciences, Department of Psychiatry, New Delhi, India

* Corresponding author.

Introduction Emotional distress in patients of depression is a consequence of a particular way of responding to negative thoughts and emotions, which is influenced by attentional control, rumination, worry, and metacognitive beliefs of individuals.

Aims The present study aims to address the nature of rumination and metacognitive beliefs in patients suffering from major depressive disorder.

Methods A cross sectional study design was used to explore the symptomatology, nature of rumination and worry, and positive and negative metacognitive beliefs in patients ($n=50$) with major depressive disorder.

Measures Beck Depression Inventory (BDI-II), Anxious thoughts inventory (AnTI: Wells 1994, 2000), Metacognitive questionnaire-30 (Wells 1997), Positive beliefs about Rumination scale (Papageorgiou and Wells, 2001), and Negative beliefs about Rumination scale (Papageorgiou, Wells and Meina, 2004) were used.

Results The findings revealed that about 83% of the participants reported that they spent upto 4–6 hours of their waking time in rumination and worry. Rumination and worry had a severe detrimental impact on the activities of daily living in 79% of the participants. Maximum number of participants reported a high need to control their rumination. Most participants believed that rumination and worry could help them gain information about their illness and a possible way out of it. Participants obtained high scores on scales of health related worry and meta-worry as compared to social worry. Cognitive self-consciousness and cognitive confidence were found to be low in the overall sample. Significant correlations between depressive symptoms, rumination, and metacognitive beliefs suggest a pathological constellation operating in patients of depression.

Background Major depression is a devastating common disorder. Current pharmacotherapy centers on noradrenergic and serotonergic modulation, but effect may require up to 21. Moreover, over a third of patients remain poorly unresponsive, termed Treatment Resistant Depression (TRD). Recently, intravenous ketamine has been shown to provide rapid amelioration of TRD, but patients were followed-up for extremely short times. We aimed to assess the clinical efficacy and safety of a three-week course of oral ketamine in outpatients with TRD.

Methods In a double blind, randomized, placebo-controlled trial and 22 TRD patients received either oral ketamine or placebo as outpatients for 21 days. Patients were evaluated at pre-trial, 230 minutes after drug administration, and at 21 days. The main outcome measure was the change in Montgomery Asberg Depression Rating Scale (MADRS) score.

Result Twelve subjects were randomized to the ketamine group, and 10 to the placebo group. Four patients from the placebo group opted out due to treatment ineffectiveness. A repeated measures ANOVA showed a significant effect of time ($F(1,16)=15.12$, $P=0.001$) together with a significant interaction between group and time ($F(1,16)=7.58$, $P=0.014$). Tukey Honest significant difference (HSD) post hoc comparisons revealed a significant reduction in depression after 21 days in the ketamine group only ($P=0.0003$).

Conclusion In this study, oral ketamine in a sub-anesthetic dose caused a rapid amelioration of depressive symptoms in ambulatory TRD patients, and was well tolerated. The results of this study suggest that oral ketamine may hold significant promise in the care of outpatients with treatment resistant major depression.

A novel, very short questionnaire as a screening tool for depression

K. Pekala, T. Sobow*

Medical University of Lodz, Medical Psychology, Lodz, Poland

* Corresponding author.

Introduction Self-assessment tools are frequently used as screening tools for depression. However, they are usually long and time-consuming.

Aim of the study To assess specificity, sensitivity and overall accuracy of a novel, very short, 5 questions tool.

Subjects and methods The questionnaire consists of 3 phenomenological (based on main symptoms of depression) and 2 questions to assess functional impact of the symptoms. One hundred and ninety patients diagnosed clinically as having major depression (according to ICD-10 criteria and with the help of MINItool) filled the questionnaire in twice, during episode and remission.

Results At least two (out of three possible) “yes” answers to phenomenological questions and both two “yes” functional answers yielded 100% specificity (no person in remission). At least one “yes” answer to phenomenological questions and both “yes” answers to functional question yielded 82.8% specificity, 83.7% sensitivity and 83.3% overall accuracy. These results varied insignificantly in subgroups with different depression severity.

Conclusion A short, 5-question questionnaire may be used as a screening tool for depression. Specificity, sensitivity and overall accuracy are above 80% largely independently of depression severity.

Swedish translation and reliability of the Morningness-Eveningness Questionnaire

M. Ståleby*, S. Steingrímsson, M. Ioannou
Institute of Neuroscience and Physiology, Psychiatry and Neurochemistry, Gothenburg, Sweden

* Corresponding author.

Introduction Chronotherapy is used as an adjuvant treatment for depression in addition to pharmacological and psychological treatments. The Morningness-Eveningness Questionnaire (MEQ) is used to classify a person's sleep and activity pattern. The aim was to translate the MEQ to Swedish and evaluate the reliability. In addition, MEQ scores between a healthy study group and patient group were compared. Lastly, patient MEQ and MADRS scores were checked for correlation.

Method The MEQ was translated and back-translated. The MEQ was administered to a healthy study group ($n=285$) where a subset of these filled out the MEQ a second time. Cronbach's α was used for internal consistency and Wilcoxon signed rank test and Spearman correlation was used for test-retest reliability. Spearman correlation was used for the patient group ($n=26$) MEQ and MADRS scores.

Results Internal consistency of the MEQ was 0.903. Wilcoxon signed rank test showed small statistically significant differences between test and retest and Spearman correlation for the total score was 0.97. The MEQ scores of the healthy study group and patient group showed similar mean scores and distribution. There was no statistically significant difference between the means ($P=0.34$). There was no correlation between patient MEQ and MADRS score ($r=0.01$).

Conclusion MEQ is a reliable scale in a Swedish healthy population as well as inpatients with depression.

Ethnicity and depression among maritime university students in Canada

A. Steenbeek^{1,*}, D. Langille², K. Wilson², A. Muir²

¹ Dalhousie University, Nursing, Halifax, Canada

² Dalhousie University, Community Health and Epidemiology, Halifax, Canada

* Corresponding author.

Introduction Depression is among the most common mental illnesses in Canada. Although many factors contribute to depression, stress is among the most commonly reported. Studies suggest that marginalized groups often experience high levels of stress.

Objective To examine associations between ethnicity and depressive symptoms among university students.

Aim To identify if ethnic groups, particularly Aboriginal students, are at greater risk of depression.

Methods Online survey data were collected from students attending eight universities in the Canadian Maritime Provinces ($n=10,180$). Depressive symptoms were assessed using the 12-item version of the Center for Epidemiological Studies Depression Scale. Ethnicity was organized into five groups: Caucasian only,

Aboriginal only, Aboriginals with other ethnicities, Mixed Ethnicity (not including Aboriginal), and Other (single ethnicity not including Aboriginal or Caucasian). Unadjusted and adjusted logistic regression models were used to assess associations between ethnicity and elevated depressive symptoms. Adjusted models accounted for demographic, socioeconomic, and behavioural characteristics.

Results In adjusted analyses for men, Mixed (OR: 2.01; 95% CI: 1.12–3.63) and Other ethnic students (OR: 1.47; 95% CI: 1.11–1.96) were more likely to have elevated depressive symptoms than Caucasians. There were no differences between those who were Aboriginal and those who were Caucasian. In unadjusted and adjusted analyses for women, depressive symptoms in ethnic groups (including Aboriginals) were not significantly different from Caucasians.

Conclusion Among male university students in the Maritime, ethnicity (other than being Aboriginal) was associated with depressive symptoms in comparison to Caucasians, after adjusting for covariates. However, among women, ethnicity was not significantly associated with depressive symptoms.

EV547

Predicting symptoms in major depression after inpatient treatment: The role of alexithymia

T. Suslow^{1,*}, M. Rufer², A. Kersting¹, V. Guenther¹

¹ University of Leipzig, Psychosomatic Medicine, Leipzig, Germany

² University of Zurich, Psychiatry, Zurich, Switzerland

* Corresponding author.

Introduction Alexithymia has been considered to have a negative influence on the course of symptoms in various psychiatric disorders. Only few studies examined in depressed patients whether alexithymia predicts the outcome of therapeutic interventions or the course of symptoms in naturalistic settings.

Aims In the present prospective study, it was investigated whether alexithymia is associated with depressive symptoms after a multimodal inpatient treatment.

Methods Forty-five inpatients suffering from acute major depression were examined in the initial phase of treatment and then again after seven weeks. Patients took part in a multimodal treatment program comprising psychodynamic-interactive oriented individual and group therapy. The majority of patients were taking antidepressants during study participation. To assess alexithymia and depressive symptoms, the 20-item Toronto Alexithymia Scale (TAS-20), the Beck Depression Inventory II (BDI-II) and the Hamilton Depression Scale (HAM-D) were administered at baseline and follow-up.

Results High scores in the Externally Oriented Thinking (EOT) facet of alexithymia at baseline predicted high severity of depressive symptoms at follow-up (for self-reported as well as observer-rated scores). This relationship was not confounded by initial depressive symptoms.

Conclusions Inpatients suffering from major depression with a more pronounced external cognitive style might benefit less from multimodal inpatient treatment. Patients high on EOT could avoid reflecting on negative emotions. Psychological interventions might modify or account for alexithymic characteristics to improve the course of depressive symptoms in these patients.

Assessment of sexual dysfunctions in patients diagnosed with major depressive disorder

D. Vasile*, O. Vasiliu, D.G. Vasiliu, F. Vasile

Central University and Emergency Military Hospital "Dr. Carol Davila", Psychiatry, Bucharest, Romania

* Corresponding author.

Introduction Evaluation of sexual dysfunctions in psychiatric population is an often underestimated problem by many clinicians, and therefore, this kind of dysfunctions remain undertreated. The quality of patients' life is affected by sexual problems and addressing these issues in a comprehensive psychiatric therapy could be associated with higher rates of overall clinical improvement.

Objective To assess the incidence of sexual dysfunctions in patients diagnosed with major depressive disorder (MDD) using structured methods.

Methods A group of 55 patients (female $n = 35$, male $n = 20$) diagnosed with MDD according to DSM 5 criteria were evaluated using Sexual Dysfunctions Questionnaire (SDQ) – a self administrated instrument, UKU Side Effects Rating Scale (UKU-SERS) – clinician rated version, and Hamilton Depression Scale (HAMD). All patients received stable dose of antidepressant medication for at least 14 days.

Results A number of 16 patients (29%) reported an SDQ mean value above 45, which is considered the cut-off score, more frequently men ($n = 10$) than women ($n = 6$). The mean value of SDQ in this group was 52.3, and the most affected domains were libido (both men and women) and arousal (especially in women). UKU-SERS detected a correlation of higher scores with the use of selective serotonin reuptake inhibitors (SSRIs) (almost 48% of these patients) than with the use of other antidepressants ($P < 0.05$), while the SDQ scores correlated better with the HAMD values.

Conclusions Assessment of sexual dysfunctions in patients with major depressive disorder is needed, both due to the depression itself and to the side effects of antidepressants.

EV549

Effect of a single nights' wake followed by bright light therapy on agitationM. Widmark-Jensen^{1,*}, S. Steingrimsson², Z. Szabó¹¹ Sahlgrenska University Hospital, Clinical Department of Psychiatry, Gothenburg, Sweden² Institute of Neuroscience and Physiology, Sahlgrenska Academy, Gothenburg, Sweden

* Corresponding author.

Introduction Wake-therapy (or "Sleep deprivation") has the potential of providing a fast anti-depressive response as add-on treatment to pharmaceutical intervention. Agitation in a depressive state is well known and is often associated with interrupted sleep. Although hypomanic symptoms have been reported following a single nights wake, agitation has not been examined.

Objective To examine if agitation increases among inpatients undergoing wake-therapy compared to treatment as usual (TAU).

Methods Admitted patients suffering from a depressive episode will be randomized to either wake-therapy combined with bright light therapy in addition to TAU, including medication, or to TAU alone. Before wake-therapy, patients are assessed using PANSS-EC, aimed at measuring only agitation. The day after a single nights wake, the assessment will be repeated. Likewise, agitation will be assessed in the control group directly after randomization as well as the day after.

Results In this trial, 50 patients will be randomized for treatment. Results concerning agitation among patients that have undergone the trial will be presented.

Conclusions Agitation as a side effect of wake-therapy has been scarcely investigated and this randomized trial will contribute to the knowledge of agitation following wake-therapy.

EV550

The effects of antidepressants and the quality of low and slow reduction

O. Yakovlev

Private Practice Berlin-Schöneberg, Berlin, Germany

The depression is worldwide one of the most frequent and most serious illnesses with a raised relapse risk and a raised mortality. Besides biological psychological and social factors are also other important factors, as a conflicts and unemployment.

Four million German citizens suffer from depression. Every 5th German falls ill in the course of his life once with a depression.

Women fall ill 2–3× more often with depression than men. In Germany, 1.5 milliard euros of costs originate on the basis of depression.

The majority of 10,000 suicides and 150,000 suicide attempts per year decrease to a not optimally treated depression.

A raised mortality of depressive illnesses is to be led back on negative influence on heart illness and diabetes mellitus.

Antidepressants show a mood-lightening effect of the depressive Syndrome, and also depression-related anxiety. The average rate of the patients, with positive drug response lies in all antidepressant groups in 50–75%.

Antidepressants are also used with positive effect by pain, fear illnesses and compulsive disorder as well as stress illness. The full effect develops after some days till weeks. It is important to understand the side effects without changing the strategy because of Depression-related anxiety. In the course of a treatment are some side effects (especially vegetative symptoms) possible, without the dosage must be changed. Anxiety symptoms of depression improved in more than 90% of patients (depression-related anxiety). The slow reduction of antidepressants is the gold standard in the therapy and need a good setting and mood stability.

Structural integrity and functional connectivity of default mode network underlying the cognitive impairment in Late-onset depression

Y. Yin

Affiliated ZhongDa Hospital and Institute of Neuropsychiatry of Southeast University, Department of Psychosomatics and Psychiatry, ZhongDa Hospital, School of Medicine, Southeast University, Nanjing, China

Objective To determine the association between the functional changes and the structural lesions of the DMN underlying the cognitive impairments in Late-onset depression (LOD).

Methods Thirty-two LOD patients and thirty-nine normal controls (NCs) were recruited and underwent resting-state fMRI and DTI scans. Cognition was evaluated with MMSE and a battery of neuropsychological measurements. Seed-based correlation analysis was performed to explore the functional connectivity (FC) of the DMN. Then deterministic tractography between FC-impaired regions were calculated to examine structural connectivity (SC).

Tracts connecting FC-impaired regions were selected to count fiber number (FN) and to calculate average FA, AD and RD of all voxels along these fibers. Partial correlation analyses were applied to examine cognitive association of these altered FC and SC, controlling the effects of age and education.

Results LOD patients showed decreased FC between PCC/Pcu and dACC as well as the thalamus. Decreased FA and increased RD of these fiber tracks connecting PCC/Pcu with dACC were found in LOD patients, without significant difference in AD and FN. The FC between PCC/Pcu and dACC was positively correlated with the FA of fiber tracks connecting them. The PCC/Pcu-dACC FC and the FA of the fiber tracks between them were both positively correlated with Symbol Digit Modalities Test and Verbal Fluency Test scores which conversely displayed negative association with RD.

Conclusions The cognitive impairment in LOD, especially executive speed and semantic memory might be associated with the decreased FC in DMN which probably resulted from the demyelination of the white matter.

⁷ Moat House Clinic, General Practice, Surrey, United Kingdom

⁸ Depression Alliance, Support Group, Croydon, United Kingdom

* Corresponding author.

Introduction Cognitive dysfunction is an important aspect of depression that includes problems with thinking, concentration and memory. Research suggests that the cognitive aspect of depression is highly prevalent and has a significant impact on patient functioning. Currently, cognitive dysfunction in depression is largely unrecognised, unmonitored and untreated.

Aims We aim to define cognitive dysfunction in clinical depression (major depressive disorder) and explore its detection and management in the UK, highlighting priority areas to be addressed.

Methods A modified Delphi method was used as the process to gain consensus. A multi-stakeholder steering committee of depression experts (including psychiatrists, psychologists, primary care physicians, and representatives from occupational therapy and a depression charity) provided the key themes and, through round-table discussion, developed draft statements. The main areas of focus were burden, detection and management of cognitive dysfunction in depression. These statements formed a questionnaire to be reviewed by 150–200 health-care professionals with an involvement in the management of depression, with level of agreement noted as 'strongly disagree', 'disagree', 'don't know/uncertain', 'agree' or 'strongly agree'. Responses to the questionnaire will be analysed (very high agreement [$>66\%$] or very low agreement

[$<33\%$]) and the steering committee will revise and finalise the consensus statements, and identify priority areas for future consideration. The steering committee was initiated and supported by the pharmaceutical company Lundbeck Ltd, through an educational grant. Lundbeck Ltd did not influence content.

Results Results of the questionnaire and the evolution of the final consensus statements will be presented.

* Corresponding author.

Introduction The eating disorder (ED) are anorexia nervosa, bulimia and unspecified eating disorder behavior according to ICD-10. Currently the ED have become a social and health problem of the first kind that require specialized and interdisciplinary approach to the response of such disorders.

The growing demand observed in different assistive devices is associated with increased incidence of eating disorders in recent decades.

Case description She is a woman of 23 years old, single. It is the small two brothers. He lives with his parents and brother 25 years. It is fourth-year student of law. It is derived from primary care by their GP after significant weight loss by decreasing the intake of foods high in calories and low mood. It is defined as a very responsible person, controller and is always looking for perfection in every activity performed. He began to try to lose weight about a year that relates to start time of stress ago. She speaks that had many exams and wanted to get top marks in all. With good adherence to psychotherapy and monitoring by nurses. Aspects of body image as well as traits such as perfectionism work.

Conclusions These clinical conditions are characterized by their complexity and diversity symptomatology, which involves a significant interference in their functioning in different vital areas and clinically significant distress. After the psychotherapeutic approach, a significant reduction in the clinic that she had at the beginning and an improvement in mood was observed.

Full of nothing

E. Cortazar Alonso*, H. Guillen Rodrigo, S. Fuentes Marquez

Hospital Juan Ramón Jiménez, Salud Mental, Huelva, Spain

* Corresponding author.

The eating disorders like anorexia, bulimia nervosa, and obesity are known and described from the principles of Western civilization. Eating disorders affect a large number of people, which about the 90–95% of them are women. Not to forget is their multicausality. Though their etiology is not exactly known yet, being on a diet is the most important predictor of having an eating disorders.

We summarize here a case of R. a 30-year-old woman, who visited the Infant Mental Health Institut for the first time at the age

of 13 referred by her pediatrician and suspected to have an eating disorder. R. lived with her parents and an older sister. The patient suffered an underweight below the healthy and a distorted perception of her body among other symptoms. She has gone through several specialists and treatments including day hospital since her first entrance at the hospital.

The flexibility and cooperation between the different therapists involved in the treatment is essential for a good outcome of the patient. There are many factors that can have an influence in the treatment, like the reluctance to the treatment, the countertransference feelings that the therapy can cause and the way of relationship. These factors can often cause situations of confusion and misunderstandings between the different professionals who attend the patient, who have to be well coordinated. Not to forget is that the biggest loser of all is the patient itself.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV555

The co-occurrence of eating disorders and psychosis

C. Alves Pereira*, J.R. Silva, R. Cajão, J.P. Lourenço, T. Casanova
Centro Hospitalar Tondela Viseu, Departamento de Psiquiatria e Saúde Mental, Viseu, Portugal

* Corresponding author.

Introduction Several reviews have reported the incidence of schizophrenia in patients with eating disorders (ED) to be between 3–10% and the incidence of transient psychotic episodes to be 10–15%. On the other hand, anorexia nervosa appears to affect 1 to 4% of schizophrenia patients. Reports of psychosis and ED occurring in the same patient have led to various views as to the nature of the relationship between the two.

Objective Analysis of the literature illustrated by different clinical cases in which appears to be a relationship between ED and psychosis.

Aims Critical reflection about the hypothesis that could underlie the comorbidity of psychotic illness and ED.

Methods Non-systematic review of a literature search using the keywords: eating disorders; psychosis; comorbidity.

Results There is no consistent sequence in the co-occurrence of the two conditions – ED sometimes precede and sometimes follows the onset of psychosis. ED patients can develop psychotic symptoms, most frequently transient in the course of the disorder, while others are subsequently diagnosed with a chronic psychotic disorder. On the other hand, patients with a primary psychotic illness can develop an eating disorder. The connection between the two, however, remains speculative, considering the hypothesis that ED and psychosis can be entirely separate disorders that can, by chance, occur in the same person.

Conclusions The area of comorbidity and overlapping symptoms in psychiatry requires more deep research. Despite evidence from case series, the comorbidity between ED and psychosis is poorly understood, and firm conclusions cannot be drawn from this analysis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Anxiety, stress and depression: A comparison between anorexic, obese and healthy control women

G. Botteon

University of Trieste, Scuola di Specializzazione in Psichiatria, Trieste, Italy

Introduction Several studies have proved that people who suffer from Anorexia Nervosa (AN) experience higher levels of anxiety, stress and depression than general population; while controversial results have been found among obese people (OB); the purpose of this study is to compare levels of anxiety, stress, and depression in AN sample, in OB sample and in Healthy Control Group (HC).

Methods AN sample: 27 anorexic inpatient women in an eating disorder unit. OB sample: 27 obese women evaluated for eligibility of bariatric surgery intervention. HC group: 27 women from different countries had been recruited. DASS 21 and STAI-Y questionnaires had been administered to evaluate anxiety, stress and depression. The questionnaires had been scores and statistical analysis had been held to determine whether the differences founded in the 3 populations were significant or not (P -value < 0.05).

Results Table 1. The differences founded were significant.

Conclusion Anxiety and stress (DASS21, STAI): AN have reported higher levels than OB and HC that present similar levels. Depression (DASS21): AN have reported higher levels than OB and HC; OB higher levels than HC.

Table 1

Samples	Scores	DASS 21-Subscales			
		Depression	Stress	Anxiety	Total
AN	Mean (SD)	26.5 (12.8)	23.1 (9.8)	28.4 (8.8)	80.4 (25.3)
OB	Mean (SD)	10.8 (9.3)	8.8 (6.8)	13.7 (10.0)	33.5 (23.6)
HC	Mean (SD)	8.0 (7.4)	4.5 (4.8)	13.1 (10.3)	25.6 (20.1)
		STAI-Y			
		State		Trait	
AN	Mean (SD)	63.1 (11.8)		65.9 (10.4)	
HC	Mean (SD)	39 (14.6)		42.9 (12.5)	
OB	Mean (SD)	39 (10.0)		43.4 (9.4)

EV557

I'm really fat!

T. Carvalho

Hospitais da Universidade de Coimbra, Coimbra, Portugal

Introduction The eating disorders are changes in eating behaviour associated with distortions in the self-concept and self-image, pathological fear of getting fat, morbid motivation for thinness and changes in appetite and its control, with or without compensatory attitudes. In the DSM-5 and in the CID-10, the two fundamental diagnostics are anorexia nervosa and bulimia nervosa.

Purpose Characterization of the Portuguese population concerning eating disorders incidence.

Methods Bibliographic revision through Pubmed until 2013, using the keywords: anorexia nervosa, bulimia nervosa, eating

disorders. Psychometric instruments like the Eating Disorder Examination 12th version (Cooper and Fairburn, 1987), Eating Attitudes Test/EAT-25 (Garner e Garfinkel, 1979) and the Eating Disorder Inventory (Garner et al., 1983; Machado et al., 2001) contributed for the characterization of the Eating Disorders in the Portuguese population.

Results The Eating Disorders have a higher incidence in the young Caucasian woman, living in the urban area. The combination of the restrictive diet with intense physical exercise in the anorexia nervosa very often evolves with negative emotions. The emotional instability, namely the dysphoria, the anxiety and the sleep pattern changes are frequent. The bulimia nervosa initially manifests itself by restrictive diet, which evolves to excessive food intake episodes getting increasingly frequent and intense.

Conclusions The Eating Disorders come from the gene-environment interaction and risk premorbid biological and psychological changes may result. These are inseparable from the interaction with the social context where the epigenetic mechanisms may play an important role. The reason for thinness, limitations at the level of interoception and obsessive-compulsive character traits are predisposing factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV558

Contribution of Night Eating Syndrome to the evolution of anorexia nervosa – Case report

F. Coutinho*, I. Brandão

Centro Hospitalar de São João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction Night Eating Syndrome (NES) was described in 1955 in a subset of patients resistant to weight loss. It is characterized by morning anorexia, evening hyperphagia and sleep disturbances. It is also more prevalent among patients with another eating disorder (ED), particularly binge-eating disorder (BED) or bulimia nervosa (BN).

Objective Review of the literature about the relationship between NES and another EDs and to present a case report of a patient with a long-standing purgative anorexia nervosa (AN-BP) and comorbid NES.

Methods review of the literature using the database Medline through Pubmed, with the keywords: “night eating syndrome” and “eating disorder”.

Results NES is highly prevalent among patients with EDs, with an estimated prevalence of about 5–44%. However, most of the existent literature explores the relationship between NES and BED or BN, and it is not consensual if NES is a subtype of another ED. There is still scarce evidence about NES and AN comorbidity.

Conclusion In this case report, we present a patient with a history of AN-BP, in which the recovery of lost weight and the increase of body mass index (BMI) occurred simultaneously with a period of worsening NES symptoms, which leads the authors to question if the psychopathology of NES has contributed to the recovery of BMI at the expense of maintaining a dysfunctional eating pattern.

Effectiveness of Enhanced Cognitive Behavioral Therapy (CBT-E) in the treatment of anorexia nervosa – A prospective multidisciplinary study

Y. Danielsen^{1,*}, G. Rekkedal², S. Frostad², U. Kessler²

¹ Department of Clinical Psychology, Faculty of Psychology, Bergen, Norway

² Department of Psychosomatic Medicine, Haukeland University Hospital, Bergen, Norway

* Corresponding author.

Introduction According to the most widely influential treatment guidelines from the National Institute for Health and Clinical Excellence and the American Psychiatric Association, existing evidence for adult AN treatment is weak, and more treatment studies are needed.

Objectives/aims The primary objective of this project is to gain knowledge about the effectiveness of CBT-E in the treatment of Anorexia Nervosa (AN). Secondary objectives are to prospectively examine baseline predictors of treatment outcome/drop-out and to examine variables related to treatment process and patient engagement as predictors of outcome/drop-out. Thirdly, in a multidisciplinary approach, to focus on selected pathophysiological mechanisms including disturbed neuropsychological functioning, changes in the gut microbiota, immunological and genetic measures in patients with severe AN in different stages of the disease, and further to investigate to what extent they are related to treatment outcome.

Methods The sample consists of patients aged ≥ 16 years with AN admitted to outpatient treatment (CBT-E) at Section for Eating Disorders, Haukeland University Hospital, Bergen, Norway. Outcome measures include BMI, self-reported eating disorder symptoms (EDE-Q), depression (BDI), anxiety (BAI) general psychiatric symptomatology (SCL-90-R, M.I.N.I 6.0), health related quality of life (CIA, RAND-36), physical activity (accelerometers) and neuropsychological functioning. The main measurement points are at the start of treatment, 3 months, end of treatment and one year follow-up. Baseline predictors of treatment outcome and drop-out will be examined as well as the association between early adherence, behavioral change, therapeutic alliance and treatment outcome. In addition biochemical, genetic and bacteriological assessments will be conducted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Attachment style and cortisol response to psychosocial stress in eating disorder patients

R. Giugliano^{1,*}, A.M. Monteleone¹, F. De Riso¹, M. Nigro¹, F. Monaco¹, U. Volpe¹, P. Monteleone²

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Salerno, Neuroscience Section, Department of Medicine and Surgery, Salerno, Italy

* Corresponding author.

Introduction Stress exposure is a risk factor for both the onset and the maintenance of Eating Disorders (EDs). The attachment theory may provide a framework to explain the relationship between

social stress and EDs, since secure attachment promotes the seeking for support in order to help people to face stressful events. The endogenous stress response system, including the hypothalamus-pituitary-adrenal (HPA) axis, is likely involved in mediating the role of attachment in the subjects' coping with stressful situations.

Objectives and aims We explored cortisol responses to the Trier Social Stress Test (TSST) of patients with EDs in order to evaluate possible associations between subjects' attachment styles and HPA axis functioning.

Methods Twenty-one adult patients with EDs (7 with secure attachment and 14 with insecure attachment) filled in the Experience in Close Relationship (ECR) questionnaire, which assesses the adult attachment style, and were exposed to the TSST. Saliva samples were collected before and after the stress in order to measure cortisol levels.

Results As compared to ED patients with secure attachment, those with insecure attachment showed a significant different pattern of the HPA response to the stress test.

Discussion Present findings suggest that attachment style may influence the HPA response to stress in patients with EDs and this effect may have relevant implications for the pathophysiology of EDs.

³ University Paris 6, Medical Departement, Paris, France

⁴ University de Montpellier, Medical Departement, Montpellier, France

* Corresponding author.

Deficits in emotional processes are often observed by clinicians in anorexia nervosa and may have an impact on social functioning. Recognition of emotion was mostly investigated using visual stimuli as faces of emotional scenes. Only one study (Kucharska-Pietura et al., 2004) demonstrated impairments in emotional prosody using positive and negative valenced stimuli. However, this study did not provide a highlight for the identification of emotional bias (for example, to recognize an intense fear in a friendly voice). The aim of this study is to better understand the recognition of emotional prosody in anorexia nervosa using a wide range of positive, negative and neutral stimuli (Belin et al., 2008).

In order to test emotion recognition biases in emotional prosody, we exposed 15 patients with anorexia nervosa and 15 healthy controls (HCs) to emotional vocal tasks asking them to rate emotional intensity on visual analog scales. In addition, we assessed clinical symptomatology and cognitive functioning for all participants.

We showed that patients with anorexia nervosa provided higher intensity ratings on the non-target scales (e.g., surprise scale for fear stimuli) than HCs for sadness, fear and neutral voices. Furthermore, with the exception of neutral vocal stimuli, they provided the same intensity ratings on the target scales as the HCs.

These findings suggested a bias in the processing of emotional prosody and may impact the social functioning of patients with anorexia nervosa. The bias may result from a sensorial deficit or a high-order cognitive dysfunction and have to be investigated in future studies.

³ Hospital Universitario Santa Cristina, Unidad de Trastornos de la Conducta Alimentaria, Madrid, Spain

* Corresponding author.

Objective To describe the main characteristics of male patients suffering from anorexia in a specialized unit for eating disorders management.

Introduction As a result of a more prevalent diagnosis of eating disorders in women (including anorexia among others), male patients characteristics have been less described in current literature.

Methodology The authors retrospectively reviewed the clinical history of all male patients attending our unit of Eating Disorders in a period of one year (2015). The recorded characteristics were analyzed and classified as demographic, clinical and biographical. Finally a bibliographic review was also performed and correlated with our results.

Conclusion During our review (currently being performed) we have found that, even if in much less numbers than in women, the characteristics of male patients suffering anorexia have recognizable patterns and for instance can be used for the better understanding of this pathology in this population.

Introduction 'Dar Kenn Ghal Sahhtek' is a residential service for patients suffering from eating disorders, namely Bulimia Nervosa, Anorexia Nervosa and Obesity (Binge Eating and Non Binge Eating type). The focus will be made on the obesity services.

Objectives 1. To show that Dar Kenn Ghal Sahhtek has proved to be an effective therapeutic intervention towards obesity (with or without binge eating). 2. To show that from a recruitment of 30 obese subjects a substantial proportion met the DSM-5 criteria for Binge Eating Disorder.

Aims 1. To show that by means of questionnaires and physical testing a marked improvement was made following the therapeutic interventions offered at DKGS. 2. To highlight the high incidence of binge eating disorder in a sample of 30 obese subjects recruited via DKGS.

Methods 1. Interviewing the patient for the DSM-5 criteria of binge eating. 2. Comparing scores of questionnaires before admission and prior to discharge. 3. Evaluating the response to various treatment modalities.

Results On interviewing the group of 30 patients, 47.6% of the patients were found to be the diagnostic criteria of Binge Eating Disorder according to DSM-5 (Table 1).

Conclusion Firstly, a considerable proportions of obese subjects proved to meet the DSM-5 criteria for binge eating while Dar Kenn Ghall Sahhtek has proved to be an effective therapeutic intervention towards obesity (with and without binge eating).

Table 1

	On admission	Prior to discharge
BDI questionnaire	1.1	53.33
GAD questionnaire	4.55	400
QOL questionnaire	6.67	350
2 minute step	73 steps on average	114 steps on average
6 minute walk	440 m on average	625 m on average

The effects of shame, self-compassion and perfectionistic self-presentation of body image on eating psychopathology

A.L. Mendes¹, C. Ferreira^{2,*}, J. Marta-Simões¹, I.A. Trindade¹

¹ Faculty of Psychology and Educational Sciences, University of Coimbra, CINEICC, Cognitive, Behavioural Centre for Research and Intervention, Coimbra, Portugal

² Faculty of Psychology and Educational Sciences, University of Coimbra, CINEIC, Cognitive, Behavioral Research Centre, Coimbra, Portugal

* Corresponding author.

Shame is considered a painful emotion that emerges in social contexts when the individual perceives that others see the self as inferior, inadequate or defective. This emotion is associated with decreased levels of self-compassion and may trigger several defensive responses, such as the need to present a perfect body image. Furthermore, shame has been conceptualized as a key component of eating psychopathology.

This study aims to explore the role of external shame in the engagement in disordered eating attitudes and behaviours through the mechanisms of self-compassion and body image-related perfectionistic self-presentation. A path analysis testing a mediational model was conducted in a sample of 469 women from the general community, aged between 18 and 35 years old.

The tested model explained 49% of the eating psychopathology's variance and presented excellent fit indices. Results demonstrated that external shame has a direct effect on disordered eating behaviours and simultaneously an indirect effect through the mechanisms of self-compassion and the need to present a perfect physical appearance.

These results seem to corroborate the link between shame and eating psychopathology. Additionally, these data suggest that women who present higher levels of shame show decreased self-compassion and tend to adopt compensatory maladaptive strategies, such as striving for a perfect body. Furthermore, these findings have significant clinical implications, highlighting the importance of developing new programs focused on shame and on the promotion of adaptive emotion regulation strategies, such as self-compassion.

² Centro Hospitalar de Leiria, Psiquiatria, Leiria, Portugal

* Corresponding author.

Eating disorders (EDs) are mental illnesses, defined by abnormal eating habits. EDs are chronic, severe and difficult to treat, and cause psychological, social and physical consequences. It occurs predominantly in adolescents and young adults women (around 90%), causing severely disability, major biopsychosocial losses, and high morbidity and mortality. EDs are considered by WHO as a public health problem, affecting different ages, genres, times, regions and contexts.

Objective Case report of a patient with Anorexia Nervosa and bizarre behavior.

Methods Clinical observation in hospital.

Results Woman with 43 years old, with a peace of 65 years, who was hospitalized in Psychiatric Service – Eating Disorders, in August 2015, because of its extreme thinness, with difficulty to walk and with severe edema of the feet, ankles and legs. At the entrance, she weighed 29 kg, after 4 days her weight reduced to 23 kg, reaching a BMI of 8.5 kg/m². In the first week, she showed a high cognitive impairment, confusional state and detailed and ruminative speech about food. She had developed multiple techniques to hide food and to hide and take dietary supplements for weight loss. Furthermore, she had a bizarre behavior and marked social isolation, not interacting with other patients.

Conclusion Although the low prevalence of EDs, these have a high morbidity, and are one of the psychiatric disorders that most often leads to a fatal outcome. Treatment is lengthy and cumbersome, requiring serious investments under the personal point of view, family and clinical, yet still, these patients can have a full life and quality.

³ Università degli Studi di Torino, Scienze della Sanità Pubblica e Pediatriche, Torino, Italy

* Corresponding author.

Introduction The level of express emotion (EE) is a measure of the attitude of close relatives towards a patient and include dimensions as critical comments, hostility and emotional over-involvement. Anger and impulsivity may lead to self-injurious and aggressive behaviours, and often represent an obstacle to treatment.

Aims To compare anger expression, impulsivity and expressed emotion in ED and SCHZ, and to explore the different level of caregivers' EE in the two groups.

Methods Twenty-five female with ED diagnosis and 25 patients with schizophrenia, were recruited at the Psychiatry Ward and outpatient Service of AOU – Novara, during one year period. Patient's assessment included Global Assessment of Functioning

(GAF), Structured Clinical Interview (SCID 1-2), Level of Expressed Emotion Scale (LEE), Paykel scale, State and Trait Anxiety Inventory (STAY 1-2), State-Trait Anger Expression Inventory (STAXY), Barratt Impulsiveness Scale (BIS-11).

Results Levels of anxiety (both state and trait) are higher in the ED group than in SCHZ. As far as the STAXY is concerned, SCHZ patients score higher than ED ones on control over anger, while general index of anger expression was higher in ED patients. We did not find significant differences in EE between two groups, except for the patient's emotional response of the patient to the disease, which was greater among SCHZ. Both SCHZ and ED patients scored higher on the LEE, Paykel and STAY than their caregivers.

Conclusions SCHZ and ED patients show different patterns of anxiety and anger, but similar profile as far as EE is concerned. Implications for treatment will be discussed.

Multifactorial ethiopathogenic in eating disorders

E. García^{1,*}, M. Leon², F. Polo²

¹ Ciudad Real, Spain

² Hospital General de Ciudad Real, UTCA, Ciudad Real, Spain

* Corresponding author.

Eating Disorders is a heterogeneous group of syndromes which includes many factors in their develop. The three main syndromes, AN, BN and EDNOS has been defined in last DSM as independent entities. However is well known that a group of patients may change its presentation along time, so also been at first diagnosed of AN, lately will fulfil criteria for BN or EDNOS.

In the other hand, if we compare two patients with the same syndrome, as BN, or AN. . .

We may easily find big differences in personality, stressors. . . and in some cases the only common factor is the clinical presentation. Behind all of this is the fact that syndromic classification drives to empiric treatments that are far the most validated.

But although there is a well known evolution in this disorders, with a not so bad income as one could think initially (in some cases one third could recover without treatment), what may we do with those patients that are resistant for empiric treatments?

And it is our opinion that a deeper knowledge of all the factors that contribute to the syndrome or its presentation, as well as those related to treatments results, should be taken into account.

We have reviewed all knowledge about these issues and we have completed it with our clinical practise using a 50 patients data base, here we will show our results, that are basically that even the same factors interact in different ways in each patient, so it is not just the ingredients but the recipe.

Atypical antipsychotics use in eating disorders. Review

J.M. Hernández Sánchez^{1,*}, M.F. Molina López², M.C. Cancino Botello², M.Á. Canseco Navarro², D. Peña Serrano²

¹ Valencia, Spain

² Hospital General de Valencia, Psychiatry, Valencia, Spain

* Corresponding author.

Introduction Eating disorders often have serious medical complications, including the highest mortality rates of any psychiatric disorder. The search for an optimal therapeutic strategy during the last decades has been difficult and it has included antidepressants,

antipsychotics, anticonvulsants, benzodiazepines and mood stabilisers.

Objectives To review the medical literature related to the treatment of eating disorders with atypical antipsychotics.

Methods Medline search and ulterior review of the related literature. Keywords: "eating disorders"; "anorexia nervosa"; "bulimia nervosa"; "binge eating disorder"; "antipsychotic agents".

Results To the date, most of the studies have been with olanzapine. Olanzapine has shown effects, not only on weight gain, but also on management of other psychological features such as obsessive-compulsive symptoms, depression, aggression, persistence and interpersonal distrust. However, most of these studies have been compared to placebo, and binge-eating behaviour has also been described when using olanzapine (not with aripiprazole or ziprasidone). Recently, Marzola et al, when comparing olanzapine + SSRIs versus aripiprazol + SSRIs, described that aripiprazole (compared to olanzapine) is significantly more effective in reducing purging episodes, eating preoccupations and rituals.

Conclusions So far, aripiprazol and olanzapine have been proved to be the most effective atypical antipsychotics in eating disorders, especially in anorexia nervosa. However, most of studies were placebo-controlled and in quite small samples. Further investigation is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Patients with anorexia nervosa: Outcome inpatient care

J. Jerónimo*, J. Santos, L. Castro Nunes, S. Neves, F. Sequeira, A. Neves

Santa Maria's Hospital, CHLN, Psychiatry and Mental Health Department, Lisboa, Portugal

* Corresponding author.

Introduction Anorexia nervosa (AN) is characterized by self-induced starvation coupled with fear of gaining weight and a distorted body image. Its treatment is complex and challenging, and sometimes hospitalization is needed.

Santa Maria Hospital's Eating Disorders Unit (SMH-EDU) is a multidisciplinary team, formed in 1989, that provides both outpatient and inpatient treatment.

Objective To present and discuss SMH-EDU's AN treatment and its results.

Methods Revision and statistical analysis of all hospitalized AN' patients' clinical files, from 1 January 2014 to 31 December 2014. Treatment outcome was assessed by BMI variation.

Results A total of 45 admissions (41 patients) were analysed: 75.65% had AN restricting type and 24.45% had AN purging type. All patient were females, with median age of 27 years old (range 12–57 years). Average admission BMI was 14.51 kg/m² (ranging from 11.19 to 17.77 kg/m²). The mean lengths of stay were 39 days. Thirty-six percent of the patients had at least one previous hospitalization. Only 2 patients were readmitted at SMH-EDU: triple readmissions. The mean time between the beginning of the disorder and the admission was 111 months (ranging 2 to 408 months). Average discharged BMI was 16.32 kg/m² (ranging from 13.24 to 19.11 kg/m²).

Conclusion Inpatient treatment for AN at SMH-EDU is considered only for those patients whose disorder has not improved with appropriate outpatient treatment. Therefore, most inpatients at

SMH-EDU have disorders of high severity, as demonstrated in our results.

³ University of Medical Sciences Poznan, Department of Adult Psychiatry, Poznan, Poland

* Corresponding author.

Objective Orthorexia nervosa (ON) is an excessive fixation on the consumption of healthy food and an obsession with its biological purity. The aim of this study was to assess the prevalence of ON in a population of Polish urban adolescents and some possible contributory factors.

Method Validation and adaptation of the ORTO-15 Questionnaire was made in the group of 399 participants (15–21 years old). The validation procedure incorporated three basic methods to be applied in the reliability analysis. The reliability analysis of the ORTO-15 Questionnaire based on repeatability of the responses presents a very good (kappa: 0.81–1.00 for 5 items) and a good repeatability (kappa: 0.61–0.80 for 10 items). The reliability analysis based on the value of the Cronbach's α reached a satisfactory level (0.7–0.9). The ORTO-15 questionnaire was considered a reliable tool to identify the risk of ON in population studies in the group of urban youth aged 15–21. Assessment was made among 1899 high school students, 992 girls, and 907 boys, aged 15–21 years.

Results The mean value of the ORTO-15 was 39.2 ± 3.6 points, with no sex difference. The main factors connected with orthorexia, according to the "Orthorexia 35" definition were excess weight, sporting activities, out-of-school activities, smoking status, working parents and a high family income.

Conclusions This study, of a large number of adolescents, showed a prevalence of ON similar to that recorded in adult populations. This is a first assessment of orthorexia among adolescent population.

Anorexia nervosa and dissociative disorders in males: A case report

M.D.M. Lázaro Redondo*, F. De la Torre Brasas, A. Duque Domínguez, N. Echeverría Hernández, L. Martín Díaz, C. García Montero, M. Otálora Navarro, A. Mas Villaseñor, J.I. Bango Suárez

Complejo hospitalario de Ávila, Psychiatric unit, Ávila, Spain

* Corresponding author.

Introduction There is a low prevalence of eating disorders among men. In many cases, the disorder arises as a means of avoiding psychosocial maturation. Various psychiatric comorbidities such as depression or obsessive-compulsive disorder are frequently found in these patients.

Objectives To analyze psychiatric symptoms in relation to a case of anorexia nervosa.

Methods Pubmed revision on clinical presentation of anorexia nervosa in male. Review of patient medical records.

Results A 23-years-old male with diagnosis of restricting anorexia nervosa was treated and followed since 2012. In July 2015, the patient, who was clinically stabilized for a year, had decreased gradually intake. Suddenly he showed a decreased consciousness, followed by an absence of response and mutism that motivated hospital admission. The diagnosis was dissociative stupor. A research in women with eating disorders shows a prevalence of pathological dissociation between 4.8 and 48.6%. After recovering a normal consciousness, he presented clinical features of anorexia nervosa according DSM 5 criteria. The patient remained two months until he reached his previous BMI (17) to continue an outcome treatment. Despite of several years of specific treatment for anorexia nervosa, both parents and patient still did not accept the diagnosis. Cultural constructions of eating disorders as a "women's illness" mean that men may fail to recognise their disorder.

Conclusions There is a delay of diagnosis of anorexia nervosa in men. The lack of research on men's experiences and the cultural construction of anorexia nervosa as a female problem may contribute to underdiagnose eating disorders in men.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effect of atypical antipsychotic medications in anorexia nervosa

M. Barchiesi^{1,*}, M. Martellini¹, M.G. Oriani², B. Nardi¹

¹ Polytechnic University of Marche, Clinica di Psichiatria, Ancona, Italy

² Dipartimento di Salute Mentale Ancona ASUR Marche, Dipartimento di Salute Mentale Ancona ASUR Marche, Ancona, Italy

* Corresponding author.

Introduction Anorexia nervosa (AN) is severe and debilitating psychiatric illness characterized by destructive weight loss behaviour, refusal to maintain body weight at or above minimal normal weight for age and height, intense fear of weight gain and disturbance in experience of body shape and weight.

Objectives The purpose of this review is to investigate the state of art concerning the use of atypical antipsychotics (SGA) in the treatment of anorexia nervosa, comparing the efficacy and tolerability in female patients not selected by age.

Methods A Medline enquiry of published articles from 2005 to October 2015 was performed using the following Keywords: "anorexia nervosa; pharmacological treatment; atypical antipsychotics; olanzapine; risperidone; paliperidone; aripiprazole; quetiapine". Reviews and RCT were also analyzed.

Results No strong evidence of beneficial effects was found in using SGA in adults. The majority of studies focused on olanzapine, which seems to have, in some studies, only positive effect on body mass index, eating disorder symptoms and functional impairment. Risperidone doesn't seem to have effect on body mass index. Olanzapine and risperidone increase the mean fasting glucose and insulin levels. In a recent study the main finding is represented by the positive effects of the adjunct of aripiprazole to antidepressants on eating-related obsessive-compulsive symptomatology.

Conclusions In conclusion, in our review we observed that research in treatment with SGA of AN is still far away from finding univocal conclusions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Brain changes in anorexia nervosa

G. Gkinis, N. Ortiz*, C. Alberque, A. Canuto
HUG, Mental Health and Psychiatry, Geneva, Switzerland
* Corresponding author.

Anorexia Nervosa (AN) is a serious and frequent psychiatric condition with the highest mortality rate within psychiatric diseases. It often starts during adolescence and affects young patients whose brain maturity is still incomplete but brain changes are often under-considered although AN appears at a critical point of development. Brain regions involved in the pathophysiology of AN are still in debate. However, the illness is often associated with enlargement of the cortical sulci and ventricles as well as with deficits in grey and white matter volumes. Functional modifications have also been evidenced: mainly global hypometabolism (PET), hypoperfusions (SPECT) and recent fMRI studies have shown that the function of the insular and cingulate cortices, in particular, differ in AN.

Neuropsychological studies have also shown neurocognitive impairments concerning executive functions, episodic and working memory as well as attentional deficits.

In 1999, Geneva University Hospitals set up a medical-psychiatric unit located in the district general hospital. This structure allows dealing with severe somatic problems as medical and nursing staffs are psychiatric and somatic specialists. AN patients are over 16, often hospitalised for the first time and have very low BMI (<14). From the clinical observation of these patients who show significant attentional deficits, we explored whether cerebral abnormalities were present with structural MRI and Neuropsychological assessments.

We will describe the preliminary results of our clinical experience and consider their implication for the understanding of AN mechanisms. We will also discuss the links between psychopathology and brain impairments that could lead to more efficient treatments.

Disordered eating behaviors, perfectionism and perseverative negative thinking—Study in a clinical sample

A.T. Pereira¹, E. Monteiro¹, P. Castilho², L. Fonseca³, C. Roque^{1,3}, M. Marques^{1,3}, S. Xavier^{1,*}, A. Macedo^{1,3}

¹ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Faculty of Psychology, University of Coimbra, CINEICC, Coimbra, Portugal

³ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction In a recent study developed with a community sample, we have found that although PNT mediated the relationship between perfectionist cognitions and bulimic behavior, the effect of perfectionism on other disordered eating dimensions, such as diet, was independent of the PNT levels (Monteiro et al., 2015).

Objective To investigate if PNT mediates the relationship between perfectionism and disordered eating behaviors in a clinical sample.

Methods Fifty-two patients with eating disorders/ED (mean age = 22.54 ± 7.637; mean BMI = 20.07 ± 4.192; 14.5% Anorexia Nervosa cases; 7.8% Bulimia Nervosa and 9.0% EDNOS) were assessed with the ED section of the Diagnostic Interview for Genetic

Studies and fill in the Portuguese validated versions of Eating Attitudes Test/EAT-25 (to evaluate Bulimic behaviors/BB, Diet and Social pressure to eat), Multidimensional Perfectionism Scales (to evaluate perfectionism composite dimensions Evaluative Concerns/EC and Perfectionistic Strivings/PS) and Perseverative Thinking Questionnaire/PTQ-15 (to evaluate Repetitive Thought/RT, Cognitive interference and unproductiveness/CIU). Only variables significantly correlated with the outcomes (EAT-25.Total and its dimensions) were entered in the regression models. Mediation analyses using Preacher and Hayes bootstrapping methodology were performed.

Results EC, PS, CIU and RT were significant predictors of EAT.Total. PA, CIU and PR were significant predictors of BB. EC and PS were significant predictors of Diet. CIU partially mediated the relationship between EC and EAT.Total (95% CI = 0.0025–0.3296) and between EC and BB (95% CI = 0.0037–0.1877).

Conclusion Also in a clinical sample, CII, the most pernicious dimension of PNT, mediates the relationship between perfectionism and disordered eating behavior, particularly bulimic behavior; diet is predicted by perfectionism independently of PNT.

Introduction Overweight and obesity are considered as a pandemic disease with a worrying prevalence and still growing. According to the World Health Organization, in 2014 the 39% adults were overweight and 13% were obese. Although it is an objective fact that obesity is an abnormal or excessive accumulation of fat detrimental to health, causes that lead a person to be obese are multifactorial and not yet well known.

Objective Examine the relationship between psychopathology and obesity. Deepen in this sense, allows us to understand obesity from a broader perspective, where not only the nutritional factors are involved in these patients, but also different “emotional profiles”.

Methods The emotional aspects of overweight and the obesity study Program of the University Hospital Infanta Leonor attends to these patients from a multi-modal perspective, to offer a multidisciplinary and effective treatment that results in a permanent lost weight. Descriptive data of the first 180 patients are presented.

Results A large percentage of patients presented psychopathology, highlighting a 80.9% of patients with depressive symptomatology, a 56.39% with high anxiety trait, a 48.26% with high anxiety state, a 24.4% meet criteria for binge eating disorder, a 11.9% bulimia nervosa and a 17.3% post-traumatic stress disorder.

Conclusion Our findings support the association between obesity and psychopathology and, therefore, the conception of obesity as a bio-psycho-social problem requiring a multidisciplinary approach that go beyond the traditional nutritional guidance.

Cognitive functioning in patients suffering from anorexia nervosa: A longitudinal study

G. Rekkedal*, U. Kessler, Y. Danielsen, S. Frostad
Haukeland University Hospital, Clinic for psychosomatic medicine,
Bergen, Norway

* Corresponding author.

Introduction The majority of research concerning cognitive functioning in eating disorders has focused on the symptomatic phase of illness in patients suffering from Anorexia Nervosa. There is a lack of longitudinal studies focusing on the possible effects of cognitive functioning on treatment outcome. Further, only a subgroup of studies control for the effects of depression and depressive symptoms in this field of research.

Objective The main objective of the present study is to examine cognitive functioning in patients suffering Anorexia in a longitudinal perspective. Secondly, to examine and clarify the effects of depression on cognitive functioning in patients suffering Anorexia. Thirdly, the aim is to investigate cognitive functioning in Anorexia as a possible predictor for treatment outcome and retention.

Methods Patients aged ≥ 16 years diagnosed with Anorexia Nervosa, admitted to outpatient treatment (CBT-E) at Section for Eating Disorders, Haukeland University Hospital, will be recruited to the study. A healthy control group and a comparison group of patients diagnosed with first episode major depressive disorder will also be included. The neuropsychological assessment consists of a comprehensive test battery including well-established neuropsychological tests known to have good psychometric properties. Depressive symptoms will be measured by the Montgomery Asberg Depression Rating scale and eating disorder symptoms will be assessed with the EDE-Q. The neuropsychological assessment will be performed three times during the study: before treatment, post treatment and one year after discharge. The assessment will be performed at the Institute of biological and medical psychology, Section of clinical neuropsychology, University of Bergen.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Perfectionism is considered a multidimensional key risk factor for Eating Disorders (EDs). There are discrepancies regarding if it is mainly associated to Anorexia nervosa (AN) but not to other EDs.

Objectives To study if Perfectionism is not only related with AN, but it is present in all EDs and associated with more transdiagnostic attitudes and behaviors.

Aims To see if there were significant differences among EDs subgroups concerning Perfectionism and to study which abnormal eating attitudes were more associated with this trait.

Methods Participants were 151 outpatients with EDs. DSM-IVTR diagnoses were: 44 (29.1%) Anorexia Nervosa (AN), 55 (36.4%) Bulimia Nervosa (BN) and 52 (34.4%) Eating Disorders not Otherwise Specified (EDNOS). Perfectionism was assessed with

the Edinburg Investigatory Test (EDI-2) subscale; general psychopathology with the Beck Depression Inventory (BDI), State and Trait Anxiety Inventory (STAI), Rosenberg Self-Esteem Questionnaire (RSE). Eating psychopathology was measured with the Bulimic Investigatory Test (BITE), Eating Attitude Test (EAT-40), EDI-2 and the Body Shape Questionnaire (BSQ).

Results No significant differences were found regarding Perfectionism among the three groups. Body dissatisfaction was the variable most associated with Perfectionism ($\beta=0.330$, $F=14.2$, $P<0.001$, 10.9% of the variance) adjusting for general and eating psychopathology. Ascetism and Interoceptive awareness were the EDI-2 subscales most associated with Perfectionism.

Conclusions The findings confirm that Perfectionism is present in all EDs and there is a relationship between body dissatisfaction and Perfectionism. Interplay has been suggested between these two factors for the development of EDs.

A review on pharmacotherapy of eating disorders

E. Roohi*, F. Hashemian

Faculty of Pharmacy, Islamic Azad University, Pharmaceutical Sciences Branch, Department of Clinical Pharmacy, Tehran, Iran

* Corresponding author.

Introduction Eating disorders are identified as chronic debilitating psychiatric illnesses, which are refractory to treatment in many patients. The mortality rate associated with eating disorders is known to be the highest of any psychiatric disorder.

Aims The aim of the present article was to review pharmacological treatments available for patients with eating disorders. Moreover, mechanism of action, dosages and algorithm of use of the available treatments were discussed. Some optional new treatments undergoing clinical trials were also mentioned.

Methods Studies were identified by searching electronic databases of Medline, Cochrane Library, and Clinical Trial Registers. All eligible studies investigating efficacy and safety of the pharmacological treatments of patients with eating disorders conducted between 2000 and 2015 were included in the present article.

Results Current pharmacotherapies include Selective Serotonin Reuptake Inhibitors (SSRIs), atypical antipsychotics, mood stabilizers, androgen receptor antagonists, serotonin antagonists and antihistamines. However, level of evidence for pharmacotherapy of each category of eating disorders are not the same.

Conclusions The use of pharmacotherapy integrated with behavioral and cognitive therapies are recommended. There are still gaps in the knowledge regarding pharmacotherapy of eating disorders. Development of agents with more efficacy and better safety profiles are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Hospital Universitario de Móstoles, Psiquiatría Infanto-Juvenil, Madrid, Spain

* Corresponding author.

Introduction Anorexia nervosa is a disorder of eating behavior that is a major health problem on our society. It is characterized by three main criteria: self-induced starvation, desire for thinness or fear of obesity, and the presence of medical signs and symptoms due to improper feeding. This work is focused on its treatment. The biopsychosocial approach allows the design and application of effective therapeutic strategies and a multidisciplinary team collaboration is essential.

Objectives Research of current pharmacological and psychotherapy treatments options of the disease.

Material and methods Literature review based on articles and publications on this topic.

Results In anorexia nervosa, it is necessary to establish a therapeutic alliance between doctor and patient. Patient usually feels no motivation to improve. The different treatments options to combine, in terms of the patient status, are: nutritional rehabilitation, cognitive-behavioral, family and interpersonal psychotherapies and pharmacological treatment. It can be carried out at the ambulatory, at the day-hospital or by medical stay, even beyond patient will.

Conclusions Nowadays, the nutritional rehabilitation is the best treatment established and it is the core treatment. About the psychotherapies, the cognitive-behavioral is the most used because it has exposed better results in all different studies proved and in clinical practices, followed by the family therapy which is the responsible of the patient family's treatment. Pharmacological treatment should not be used systematically and its exclusive use is not enough to resolve anorexia nervosa as there are needed also other treatments combined.

Prevalence of depression and anxiety among over weight persons

Z. Sepehrmanesh

Kashan University of Medical Sciences, Kashan, Iran

Background and objective Today, overweight, depression and anxiety are the major diseases which are growing all over the world and threat the human health. The findings of previous studies concerning the association between overweight, obesity and psychological disorders such as depression and anxiety are conflicting. Some studies have reported a positive association and some a negative association while some found no association at all. This study evaluates depression and anxiety in people who were overweight.

Method In a cross-sectional study, 162 cases with overweight (BMI above 25 and under 30) who referred to diet clinic of Kashan University of Medical Sciences (IRAN, 2015) were selected by using simple random sampling. Depression and anxiety severity were determined by Beck Depression inventory and Beck Anxiety inventory. Data were analyzed by using descriptive statistic and *t*-test, and χ^2 .

Results The mean age of cases was 32.12 ± 7.51 and the mean score of BMI was 26.56 ± 1.31 . prevalence of anxiety in the subjects was 63.1% and 8.8% of the subjects in the study have varying degrees of depression. There was a significant correlation between mean scores of anxiety and depression in cases with overweight. There was no significant difference between sex, age, job and education incases.

Conclusion Anxiety in persons with overweight is prevalent. Detection and treatment anxiety disorders are recommended for better healthy life and prevention obesity in these cases.

Eating disorders: How can it be detected?

C.F. Silvia*, P. Cano Ruiz, A. Gómez Peinado

HNSPS, PSIQUIATRIA, Albacete, Spain

* Corresponding author.

Introduction Disorders of eating behavior can affect all people regardless of socioeconomic or cultural situation. More common in females (90-95%), has its peak incidence in adolescence. These are processes that can subtly start and go unnoticed at first.

Objective To analyze the clinical, epidemiological, diagnostic approach of the disorder, evolution and treatment of disordered eating behavior.

Methods Review of the subject and recent articles on eating behavior disorders in Psychiatric guides and magazines.

Results The eating behavior disorders arise as a result of three factors: predisposing, precipitating and perpetuating. We must take into account the genetics and family history, dissatisfaction with body weight resulting in a restriction of diet and multi-disciplinary consequences of this disorder (physical, psychological and social) as perpetuating factors. We consider the coexistence of comorbidity between disordered eating behavior and personality disorders, mood disorders (depression) and disorders of impulse control.

Conclusions Eating behavior disorders represent a major health problem that threatens the patient's life. Very important are the rapid detection of the same and the establishment of treatment. Treatment should be multidisciplinary with the patient and family, providing information on the approach to the patient, taking into account the lack of awareness of disease that often exists in patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Hopsital, Clinico San Carlos, Madrid, Spain

* Corresponding author.

Introduction The eating disorder are not only isolated power problems. They interweave issues and pathologies in patients often difficult to approach and have crimping going to reach a solution and get to the real problem of the patient. As it has been observed in studies if they have established relationships between patients with an impulsive nature and traumatized regarding the presentation of eating disorders.

Objectives Our study aims to establish the relationship between eating disorder such as anorexia and bulimia with factors such as impulsivity and suffered traumas.

Materials and methods It has used a sample ($n = 57$) and patients spent three scales "Barratt Impulsiveness Scale" (BIS-11), "Questionnaire traumatic experiences" (TQ) and the BSQ, scale measuring dissatisfaction disorders eating behavior. The aim is to see the relationship between anorexia and bulimia regarding trauma and impulsivity.

Results It is intended to check if having character traits of impulsivity or miss having lived or suffered traumatic experiences such as the unexpected death of a family member, rape, kidnapping... establishes a relationship in patients who develop conduct disorders food.

Conclusion This study aims to see if there is a correlation between eating disorder and factors such as traumatic experiences and an influential feature in this pathology such as the impulsivity through a sample of patients ($n = 57$) over 18 years.

“Reflective learning” in psychiatric education: Does it have any merit?

D. Adamis*, G. McCarthy

Sligo Mental Health Services, Psychiatry, Sligo, Ireland

* Corresponding author.

Introduction Nowadays “reflection” and “reflective practice” is nearly in every curriculum for psychiatric training. Trainees are asked to keep reflection diaries, journals, and participate in “reflection workshops”.

Aims To prove that reflection on or in action does not lead to learning.

Methods Using epistemological notation.

Results/proofs Because sciences including psychiatry are approximate, evolving and inexact, the classical definition of propositional knowledge becomes: A knows that p if:

- (a) A believes that p is an approximate true;
- (b) p is approximate truth;
- (c) A has reason to claim that p is a better approximation than its rivals on available evidence.

Condition (c) implies that A is not possible at the same time to have two mutually contradictive approximate truths.

In reflective learning we need to add two more conditions:

- (d) A knows the outcome of p;
- (e) A is satisfied in believing that p.

In cases of reflection in-action, the (e) remains even the outcome is not favourable. Similarly, in reflection on-action the condition (e) remains unchanged since this happened in the past. This leads to controversy. Is p better or worse approximation of truth than its' rival p? However, p has passed rigorous and different scientific tests and has proved scientifically superior to its rival p. Therefore subject A cannot change his knowledge despite the unfavourable outcome, but A can tests further the p. Within the former reflecting learning does not occur, within the latter “critical thinking” occurred.

Conclusions Reflection does not lead to learning but critical thinking does.

Differences in the attitudes of clinical and pre-clinical medical students to mental illness

O. Adekunle^{1,*}, C. Oliver², B. Owen¹

¹ Northumberland-Tyne and Wear NHS FT, Medical Education, Newcastle, United Kingdom

² Newcastle University, Medical School, Newcastle, United Kingdom

* Corresponding author.

Background The quality of care provided to psychiatry patients by doctors can be influenced by attitudes towards mental illness. Equally important is the attitude of medical students as future treating doctors towards mental illness. This survey compares the differences in the attitudes of pre-clinical and clinical years student to mental illness.

Aims To compare attitudes of pre-clinical and clinical medical students' to mental illness.

Methods A cross-sectional survey of 212 clinical students (CS) and pre-clinical students (PS) at Newcastle University. Each responded anonymously to an electronic questionnaire. The responses take the form of: Yes/No, free text, order of preference, and Likert scale. Results were analysed based on basic statistical analysis.

Results Little differences exist between the 2 groups in their beliefs that psychiatric patients are not difficult to like, mental illness can be a result of social adversity, psychiatry patients often recover and that people with mental illness should be offered a job with responsibility. However, 54% PS disagreed that mental illness often leads to violence, compared to 66% CS and 87% of PS identified that mental illness can be genetic in origin compared with CS of 91%.

Conclusion This survey did not identify any significant difference between the attitudes of pre-clinical and clinical students in most of the domains. However, a higher percentage of clinical students associate violence with mental illness and are unwilling to consider an elective period in psychiatry.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comparison of attitudes of pre-clinical and clinical medical students to psychiatry as a career choice: A cross sectional study

C. Oliver¹, O. Adekunle^{2,*}, O. Bruce²

¹ Newcastle University, Medical School, United Kingdom

² Northumberland-Tyne and Wear NHS FT, Medical Education, Newcastle, United Kingdom

* Corresponding author.

Background Psychiatry recruitment is currently insufficient to meet the targeted mental health service needs in the UK. Psychiatry is unpopular amongst medical students and in 2011, only 61% of junior training posts were filled by the first recruitment. RCPsych is currently working to promote psychiatry as a career choice for medical students.

Aims To compare preclinical and clinical medical students' attitudes towards psychiatry as a career choice.

Methods A cross-sectional survey of 212 clinical students (CS) and pre-clinical students (PS) at Newcastle University. Each student responded anonymously to an electronic questionnaire. The responses take the form of: Yes/No, free text, order of preference, and Likert scale. Results were analysed based on basic statistical analysis.

Results A total of 29% PS rated psychiatry in their top 3 career choices compared with 16% CS. Fifty-seven percent PS believe that psychiatry is a respected branch of medicine and 70% believes it makes good use of medical training, while CS rated these at 50% and 52% respectively. Sixty-nine percent PS believe that psychiatry is scientific evidence based compared with 63% CS. Eighty-one percent PS disagreed with the

statement that they feel negative about psychiatry compared with 61% CS.

Conclusions The outcome shows increase in negative attitude to psychiatry between pre-clinical and clinical years at the medical school. This makes psychiatry an unpopular speciality among final year students. Further research is required to ascertain the reason for this decline in interest and negative attitude.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Before and after: Effect of 4-week psychiatry attachment on medical students' attitude to psychiatry as a career choice

O. Adekunle^{1,*}, B. Owen¹, C. Oliver²

¹ Northumberland-Tyne and Wear NHS FT, Medical Education, Newcastle, United Kingdom

² Newcastle University, Medical school, United Kingdom

* Corresponding author.

Background Psychiatry is historically unpopular amongst medical students. The perception that psychiatry is remote from the rest of medicine and not evidence-based has been identified. However, there is evidence that psychiatry placement has positive effects on students. There are reports that medical students experience a positive change of attitude towards psychiatry following their undergraduate psychiatric attachment. There is evidence that medical students experience a positive change of attitude towards psychiatry following their undergraduate psychiatric attachment.

Aim To determine the effect of a four-week psychiatry placement on 3rd year medical students' attitudes towards psychiatry.

Methods Pre- and post-attachment questionnaires were administered to four cohorts of 3rd year students. Responses were anonymised and based on Yes/No, free-text, order of preference and Likert scale. Analysis was by basic statistical methods.

Results A total of 98 pre- and 81 post-placement students responded. Mean positive attitude increased by 6% and the percentage of students choosing psychiatry in their top three career choices increased from 7 to 20%. Ninety percent of students post-attachment thought that psychiatry is relevant to their future jobs, compared to 86% pre-attachment. The percentage of students who think that psychiatry makes little use of medical training decreased from 20% to 16%.

Conclusions The survey showed a period of 4 weeks psychiatry placement has a positive effect on the attitudes of medical students towards psychiatry. It also increases the number of students wanting to pursue a career in psychiatry.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evaluation of psychiatry attachment on medical students' attitude to mental illness

C. Oliver¹, O. Adekunle^{2,*}, B. Owen²

¹ Newcastle University, Medical School, United Kingdom

² Northumberland-Tyne and Wear NHS FT, Medical Education, Newcastle, United Kingdom

* Corresponding author.

Background Mental illness is subject to stigma, discrimination and prejudice by both healthcare professionals and public. Fortunately, students are still flexible in their beliefs and there is evidence that education in psychiatry may help to positively alter

these beliefs. This survey looks into how psychiatry placement positively influences attitudes of medical students to mental illness.

Aims To elicit the effect of clinical attachment in psychiatry on 3rd year medical students' attitudes toward mental illness.

Methods Questionnaires were administered to four cohorts of students pre- and post-attachment. Responses were anonymised. Responses were based on Yes/No, free text, order of preference and Likert scale. Analysis was with basic statistical analysis.

Results Ninety-eight pre- and 81 post-placement students responded. There was a 4% increase in mean positive attitude scores following the placement. There was no significant difference in the medical students' attitudes to violence in mental illness and that patients with mental illness do not want you to help them. Students post-attachment were more likely to disagree with the statement, 'Psychiatric patients are difficult to like'. However, 6% more students agreed with the statement 'Alcohol abusers have no self-control' after the placement!

Conclusions and recommendation Following the 4-week attachments, the percentage of students reporting more positive attitudes to mental illness showed only a marginal increase. A possible explanation may be insufficient contacts with patients and a feeling of not been part of the treating team.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Simulation training - pilot: Psychiatry higher trainees' mental health tribunal report writing, oral presentation and cross-examination by tribunal panel

O. Adekunle^{1,*}, B. Owen¹, C. Burrell²

¹ Northumberland-Tyne and Wear NHS FT, Medical Education, Newcastle, United Kingdom

² Northumbria University, Newcastle Upon Tyne, Northumbria Law School, Newcastle Upon Tyne, United Kingdom

* Corresponding author.

Introduction Simulation provides a non-judgemental environment where trainees learn skills without compromising patients' safety or dignity. It also provides safe environment where anxiety-provoking, real-life clinical situations can be recreated and repeatedly practiced. Mental health review tribunal is an anxiety-provoking experience for higher trainees and use of simulation can alleviate this anxiety.

Aims To develop trainees' skills in writing of tribunal reports and giving oral evidence using simulation technique (ST).

Objective To facilitate trainees' familiarisation with the process of Mental Health tribunal and improve their skills in completing report and giving oral evidence using ST.

Methods There are 2 sessions: one half-day session of interactive teaching providing fundamental details on essential elements of the tribunal process, duties and report. This is followed by 4-weeks gap to allow participants to prepare and submit anonymised patients' reports to the panel. Finally, a second full day of presentation and cross-examination by (real) tribunal panel with 25-minutes of formative feedback.

Results Six trainees participated in the pilot: A high percentage of participants strongly agreed or agreed that ST is an effective learning experience for tribunal report writing and cross-examination by the panel. Similar proportion agreed that ST helped to facilitate familiarisation with the tribunal process and that it is a satisfactory teaching method. Finally, all participants agreed that ST helped to achieve personal objectives for attending the seminar.

Conclusions Simulation in psychiatry is becoming an effective learning experience. The outcome of this pilot on report writing

and cross-examination by tribunal panels how its increasing effectiveness and relevance in psychiatry.

The attitudes towards depression of general practitioners can be improved by an educational program

M.Á. Álvarez de Mon^{1,*}, R. Manzanera², G. Lahera³, J. Saiz-Ruiz⁴, M. Alvarez de Mon⁵

¹ Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

² Imperial college, General Practice, London, United Kingdom

³ Príncipe de Asturias University Hospital, University of Alcalá, Psychiatry, Madrid, Spain

⁴ Ramón y Cajal University Hospital, University of Alcalá-, Ramón y Cajal University Hospital, Madrid, Spain

⁵ Príncipe de Asturias University Hospital, University of Alcalá-, Internal Medicine, Madrid, Spain

* Corresponding author.

Background Continuous education of physicians is critical for the quality of medical care.

Objectives To investigate the attitudes of general practitioners towards depression and to evaluate the short- and long-term impact of a specific designed postgraduate university program in depression.

Method In this prospective, interventional study participated 1322-certificated Family Practice specialist. They filled out the Depression Attitude Questionnaire (DAQ) Spanish validated version before starting the educational intervention; an official approved 12 ECTS postgraduate university program. The participant refilled the questionnaires at the end of the course and 6 months later.

Results A total of 885 females and 420 males (mean 48 years) and with a mean clinical experience of 25 years participated in this study. Short-term after training, PGs positively significant ($P < 0.05$) changed their attitudes in the management of depression in 18 out 20 items of the DAQ. There were not significant changes in only item 1 related to the number of patients presenting depressive symptoms seen in the last 5 years and the knowledge of the underlying biochemical abnormality. In the long-term, the positive effects observed in the short-term did not significantly change. However, in item 1 a significantly increase was observed. The effectiveness of the intervention was related nor to the age and sex of the physician nor to the years of medical practice.

Conclusions A specific designed educational program can improve the attitudes in depression of GPs. Years of clinical practice are not a limitation for improving the medical attitudes of General practitioners in mental health.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Violence manifestation in the university environment: Nursing undergraduate students view

Z. Scherer^{1,*}, E. Scherer²

¹ University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto - São Paulo, Brazil

² Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto - São Paulo, Brazil

* Corresponding author.

Introduction The nurses occupy the first position of victims of workplace violence in health professionals' ranking. While graduation students, are victims of different aggressions.

Objectives The goal of this study was to investigate the perception of nursing students of a Brazilian public university about violence manifestation in the university environment.

Aims Knowing the nursing students perception about violence in the university environment.

Method This is a qualitative descriptive exploratory study where a semi-structuralized interview was used.

Results The thematic content analysis allowed us to detect three categories: "interpersonal violence in the relationships established in the course", "participation as victim or perpetrator" and "reasons for the occurrence of the violence". The findings pointed out power relation inequalities and the occurrence of different types of violence and the trend in naturalize them. The results point the necessity to create a system that facilitates abuses denunciation and that offers support to the victims; investments in intervention programs that offer knowledge on this subject and improve the academic relations and prevent maltreatments; and the inclusion of the violence subject in the graduation curricula.

Conclusion The professors, as educators and models for future professionals, must search knowledge on the subject and their participation as perpetrators or victims. They must participate of qualification courses that teach them to face the violence in the academic environment. In such a way, pupils and professors are trained to identify and to deal with violence in the academic environment and out of it.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Medical students assessment from a public university considering the relevant aspects of medical practice

Á. Alves*, F. Alves, E. Melo, E. Oliva-Costa

Federal University of Sergipe, department of medicine, Aracaju, Brazil

* Corresponding author.

Introduction In traditional medicine curriculum, internship is the moment in which students experience medical practice more intensively. Attitudes can be considered predictors of behaviors and actions. Evaluate them contributes to improve medical graduation.

Objective Evaluate medical internship attitudes considering medical practice and associated factors in a Brazilian public university.

Methods Cross-sectional study with 69 students, using a structured questionnaire and an attitude scale (Colares, 2002). Descriptive statistic was carried out, classification of the attitude tendency, group analysis ('clusters') and F statistic.

Results The average age was 25.1 and 56.5% were male. Students presented positive attitudes towards four from six aspects and negative attitudes toward death.

Conclusion Results suggest the necessity of educational intervention, which follows the educational objectives.

The developmental stages of psychiatry: The role of mental health simulation across the psychiatrist's career-span

C. Attoe*, Z. Jabur, S. Cross

South London & Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

* Corresponding author.

Introduction Mental health simulation refers to training that recreates real-life scenarios in safe environments using actors and technology, followed by structured debriefs, aiming to foster professional development and improve the quality of mental healthcare. Such training can overcome many challenges faced in training psychiatrists throughout their careers; from reduced patient contact in early careers due increased community-based care, to financial and time pressures of releasing senior psychiatrists (Brown et al., 2011). This presentation conceptualises a psychiatrist's career as 5 developmental stages; infancy, childhood, adolescence, adulthood, late adulthood.

Aims To demonstrate the considerable potential of mental health simulation training in meeting training needs of psychiatrists.

Method Maudsley Simulation, London, has successfully developed and evaluated courses for psychiatrists at all stages of training. Courses have been positively received, with evaluations and outcomes highlighted in more detail.

Results Stage 1 – infancy. Specifically-designed courses to give medical students experience of mental health care.

Stage 2 – childhood. Series of courses delivered directly to focus on the key skills of core psychiatry trainees in working with mental health patients.

Stage 3 – adolescence. Various courses developed to foster core skills in experienced psychiatry trainees across community and hospital settings.

Stage 4 – adulthood. Courses tailored to specialist areas of psychiatry such as perinatal mental health, or systemic and family approaches.

Stage 5 – late adulthood. Training focused on developing skills for specific scenarios for senior psychiatrists, such as the Coroner's Court or Mental Health Tribunal.

Conclusion Mental health simulation training can meet the training needs of psychiatrists throughout their careers with positive outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

'In situ' team-based simulation training for psychiatry: Innovation in managing the medically deteriorating patient

C. Attoe^{1,*}, C. Tritschler¹, M. Lavelle², S. Cross¹

¹ South London & Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

² King's College London, Florence Nightingale Faculty of Nursing & Midwifery, London, United Kingdom

* Corresponding author.

Introduction The interconnected nature of physical and mental health has been emphasised in recent times, with eye-catching figures such as people with schizophrenia dying up to 18 years earlier than the general population, with 60% excess mortality due to physical health (Chang et al., 2011). This highlights the need to care for patients' physical health on inpatient psychiatric units, with training generally focusing on knowledge and competency. However, serious untoward incidents, including medically deteriorating patients in psychiatric settings, often evidence failings in communication, teamwork, and systems. Simulation training has the potential to develop communication and teamwork skills, as well as technical knowledge and competency.

Aims Evaluate 'in situ' simulation for managing medically deteriorating patients in psychiatric settings, evaluating knowledge, confidence, attitudes, and changes following training.

Methods Six simulation sessions were completed on one inpatient psychiatric ward over 2 months. Specifically-designed self-report measures assessed participants' ($n=35$) knowledge, confidence, and attitudes towards managing medically deteriorating patients. Open-questions, focus groups, and follow-up surveys were used to collect qualitative data on course's impact.

Results Participants' knowledge, confidence, and attitudes showed statistically significant improvements ($P < .01$), with large effect sizes (.40–.53). Thematic analyses identified the themes of confidence, teamworking, communication, and debriefing. Deficiencies in equipment and procedures were identified and rectified. Incident reporting data was also analysed.

Conclusion 'In situ' simulation training has significant potential to benefit psychiatry teams in their management of medically deteriorating patients, which is an important step for both quality and safety of care, as well as tackling the interconnected nature of mental and physical health.

What young adults know about the factors that affect fertility?

N. Carolino^{1,*}, A. Galhardo^{1,2}, M. Moura-Ramos², M. Cunha^{1,2}

¹ Instituto Superior Miguel Torga, Psicologia, Coimbra, Portugal

² Faculdade de Psicologia e Ciências da Educação da Universidade de Coimbra, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction The literature has shown that young adults reveal lack of knowledge about factors that influence fertility. Given this gap of knowledge regarding fertility, several authors indicate the need for awareness-raising and promotion of attitudes and behaviors that preserve fertility.

Objective This study aimed to assess the knowledge about factors that affect fertility as well as the impact of information transmission on this topic.

Materials and methods Five hundred and fifty-one subjects aged between 18 and 40 years old without children completed an online questionnaire specifically developed for this study. Two assessment moments were considered and participants were randomly assigned to three groups:

- video group;
- website group;
- control group.

The video and website groups accessed information on fertility-related factors such as age, weight, exercise, substance abuse, irregular menstrual cycles, pollution, etc. The control group had no access to this information.

Results Male participants revealed more knowledge about the factors that affect fertility in both moments. Participants in the groups that had access to fertility information (video group and website group) improved their level of expertise. No significant differences were found in the control group.

Discussion/conclusion Groups that watched the video or visited the website where information on fertility-related lifestyle and other factors was available increased their level of knowledge, suggesting that education on this subject should be provided to general population. The means used for the information dissemination had no impact on the improvement of knowledge.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Doctors qualified outside the UK constitute >40% workforce in psychiatry. Differential examinations' attainment and poor career progression are key issues for International Medical Graduates (IMGs). Due to increased migration, this is transversal to many countries. Varying ethical standards and values in different countries can create difficulties in the workplace and impact quality of patient-care.

Objectives To understand current support available for IMGs across countries; identify areas of best practice.

Methods We ran a preliminary open consultation to establish which initiatives were available across Europe and worldwide to address IMGs' training abroad impact on their training/work in the host country and if any support exists for supervisors of IMGs. Representatives of European trainees were contacted through European Federation of Psychiatric Trainees network and early career psychiatrists through World Psychiatric Association network. Emphasis was given to identified host countries of IMGs.

Results No specific initiatives were identified in Europe. Out of the six main host countries – Denmark, Finland, Norway, Sweden, Switzerland, UK – one did not provide information. Many countries reported specific requirements for a doctor to be accepted to work. There are courses on language and medicolegal processes. Some support is available for doctors doing short clinical placements. However, once an IMG has been accepted to work in the host country, there is no special support given by way of supervision.

Conclusions Reports suggest IMGs welcome initiatives to help them gain skills related to the system, its culture, and appreciate feedback on their performance. There is a need to help host countries better support IMGs.

Psychiatry as an option after graduating medicineL. Dehelean^{1,*}, A.M. Draghici², R.S. Romosan¹¹ "Victor Babes" University of Medicine and Pharmacy, Neuroscience, Psychiatry, Timisoara, Romania² Timisoara Psychiatric Clinic, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction Published data show that internationally, 4.5% (range 1 to 12%) of medical students consider psychiatry as a career. Psychiatric practice involves special working conditions (exposure to hostile behavior or stigma), and incentives (flexible working schedules, higher income depending on specific country regulations).

Objective The purpose of the study is to identify the students' intention to choose psychiatry after graduating medical school.

Methods Students from the terminal years of general medicine were asked to fill in a questionnaire about their future career options. We analyzed socio-demographic data, the preferred medical specialty, preferred work setting (hospital, ambulatory, mixed hospital and ambulatory), preferred country of practice (native or foreign). The study included two samples: Romanian and foreign students in general medicine.

Results Seventy-five Romanian and 37 foreign students studying medicine at Timisoara University of Medicine and Pharmacy accepted to fulfill the questionnaire. The mean age in the Romanian sample was 24.27 years, and 26.59 years in the foreign student sample. The male:female ratio was 1:3.7 in Romanian and 1.8:1 in foreign students. Psychiatry was chosen as an option by 7 (9.3%) Romanian students. None of the foreign students expressed intention for psychiatry. Foreign students come mostly from Europe 56.8% (Germany 35.1%), and the rest from Asia, Africa, and North America. Romanian students prefer non-surgical specialties and a mixed practice, while foreign students prefer surgical specialties and hospital practice.

Conclusions In Romanian students, the interest in choosing psychiatry is fairly higher than in other countries, possible due to demographic and country regulatory factors.

Educational project: Learning from the patientP. Flores^{1,*}, M. Soro², O. Orejas¹, C. Masferrer¹, A. Fernandez³, J. Renom³, M. Negrodo⁴¹ INAD, Parc de Salut Mar, Centre Forum, Barcelona, Spain² Centre Forum, Parc de Salut Mar, Servicio de atencion al usuario y comunicacion, Barcelona, Spain³ Associació Emilia BCN, Associació, Barcelona, Spain⁴ Institut Bonanova Formacion Profesional Sanitaria, Parc de Salut Mar, Barcelona, Spain

* Corresponding author.

Introduction Learning from the patient presents a pedagogical experience where patients expert in mental health participate as teachers in the teaching-learning processes.

This training activity is a pilot aimed to assess the impact and integration in the study plan of the students following the training course in auxiliary nursing care, Barcelona.

Objectives To offer a global vision on mental health problems in order to break the stigma, being the persons affected the main actors.

Stress the value of the patient voice and its particular way of living and suffering the illness in order to offer a suitable attention.

Promote the integration of expert patients as teachers in the education programs.

Methodology The training activity starts with the evaluation of the previous mental health knowledge and believes of the students. Round table with the participation of:

- 2 expert patients explain their history of life and how the illness affects their day-to-day life;

- 2 mental health professionals explain how they help patients to recover and empower them.

Four groups about the impact of illness on a personal, educational, working and social level.

Results The expert patients were very optimistic and reinforced their own self-esteem. The students show a more positive attitude towards mental illness and express that patients' are first PEOPLE, then patients'

Conclusions The expert patients collaborating with professionals are ready to become teachers in the health care academic programs and, specifically, in mental health.

Taking into account the patient voice and vision improves the technical, personal and social competences of professionals.

A quality improvement initiative – increasing cardiometabolic risk screening in adult outpatient psychiatry clinics

S. Gunturu^{1,2,*}, S. Lawler¹¹ New York, USA² USA

* Corresponding author.

In the USA, People with serious and persistent mental illness (SPMI) die 25 years earlier than the general population! Sixty percent of the increased mortality is due to cardiovascular disease. In NYS, type 2 diabetes is twice as common in people with mental illness on Medicaid compared to the general Medicaid population. In a study of over 10,000 clients with schizophrenia or depression, 52% had metabolic syndrome, and 92% had at least one risk factor. Forty-three percent of clinical antipsychotic trials of intervention effectiveness (CATIE) participants had metabolic syndrome on enrollment.

In this quality improvement project, we worked on 3348 adult outpatient psychiatry patients, used techniques like FOCUS-PDCA, brain storming, root cause analysis to address cardiometabolic risk screening and reducing the risk among these patients. We used interventions like prescriber and patient education, streamlining the cardiovascular screening process in the clinic and multidisciplinary team discussions. We collected and analyzed data regarding clinical characteristics of such patients before and after the clinical interventions. HEDIS scores were used to measure the outcomes of the project.

In this talk, we want to discuss about quality improvement projects – the methods and processes involved. Also, we wanted to give a glimpse of our project – the plan, work flow processing and the data.

Embedded mixed methods evaluation of the psycho-educational intervention impact on people diagnosed with schizophrenia and their primary caregivers: Findings from a randomized controlled trial

A.A. Hasan

University of Nottingham, Health Science, Nottingham, United Kingdom

Background Psycho-educational interventions for people diagnosed with schizophrenia (PDwS) and their primary caregivers (PC) can improve knowledge about schizophrenia, reduce PCs' burden of care, PDwSs' symptoms, and enhance PCs' quality of life. However, the majority of existing studies have significant methodological weaknesses. Also, little is known about the impact of psycho-educational interventions delivered by booklets and in developing countries like Jordan.

Objective The aim of this study was to examine the effectiveness of psycho-education delivered via a printed booklet for PDwS and their PCs' in Jordan.

Methods A single blind parallel randomized controlled trial was conducted between September 2012 and September 2013 at four mental outpatient clinics in Amman, Jordan. One hundred and twenty-one PDwS with their PCs were allocated randomly to an experimental (psycho-educational intervention plus treatment as usual in outpatient clinic) group ($n=58$) or control (treatment as usual alone) group ($n=63$). Outcomes, measured prior

randomization (pretest), immediately post-intervention (posttest 1) and at three months after intervention (posttest 2).

Results Participants receiving psycho-education and treatment as usual had better knowledge of schizophrenia, reduced positive and negative symptoms and hospitalisation at both follow-up points. PCs had reduced burden of care and experienced a better quality of life.

Conclusion Psycho-education delivered via printed booklets improves outcomes for PDwS and their PCs in Jordan better than treatment as usual. Our hypothesis is supported.

Young Psychiatrists' Network. Between past and future

A. Kanellopoulos^{1,*}, R. Psaras², N. Kokras³¹ APCHA, Child & Adolescent Psychiatry, Athens, Greece² Private Practice, Psychiatry, Athens, Greece³ National Kapodistrian University of Athens, Clinical Psychopharmacology, Athens, Greece

* Corresponding author.

The Young Psychiatrists' Network (YPN) is a rapidly growing network of Early Career Psychiatrists (till 40 years of age or 5 years since completion of specialty – unless otherwise specified in home country) and Psychiatric trainees.

Its aims include, global development of psychiatry through close collaboration of YPs worldwide, expanding knowledge and sharing experiences, and facilitating the evolution of YPs from different parts of the world and improvement of their knowledge, skills and abilities.

From 30th September – 4th October the 5th YPN Meeting was held in Porto Heli in Greece. It was the biggest Young Psychiatrists Meeting ever held with more than 150 participants from 42 world countries and it was an absolute success. The state of the art scientific program included plenary lectures by renowned psychiatrists such as Prof. Nik. Bouras and Prof. Martin Prince, symposiums and workshops.

In conjunction with the 5th YPN Meeting from 27–30 September, a leadership course directed by Prof. N. Sartorius and Prof. K.H. Wittchen was held in Athens with the participation of 16 participants from 11 world countries.

The next meeting will be in Italy on September 2016.

Future plans include research collaboration, regional meetings and promoting the best possible work and educational conditions for young psychiatrists from all over the world.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A brief survey of the impact of restructuring of clinical placement and education delivery for medical students in 5 Boroughs Partnership NHS Foundation Trust

S. Kumar^{1,*}, A. Baldwin²¹ Liverpool, United Kingdom² 5 Boroughs Partnership NHS Foundation Trust, Department of Medical Education, Warrington, United Kingdom

* Corresponding author.

Introduction In the United Kingdom, a drive has been initiated to duly attract and recruit medical student into career psychiatry. However, most medical students attending university find

the psychiatry lacks structure and organised model in teaching delivery.

As a result, many medical students put off earlier on in their studies by psychiatry.

Aim We wanted to test the above hypothesis with the introduction of structure by allocating de-centralised teaching and hands on clinical experience for medical students.

Method The collective survey tool is devised to reflect the needs of medical students with de-centralised teaching separate but to complement university studies. This included introduction of induction package, set out syllabus, structured learning sessions. The results of the feedback from the medical students were collated and the results are discussed.

Discussion The results indicate the success of the decentralized and borough based teaching, with improved interest in psychiatry and higher attendance rate. The feedback has been positive, and efforts of the tutors have been appreciated. Whether this will translate into higher recruitment rate number is to be seen.

Disclosure of interest The authors have not supplied their declaration of competing interest.

While waiting for the psychiatrist. . . the toolkit of general doctor

J. Lagræfeuil

Centre Hospitalier Tulle Cœur de Corrèze, Corrèze, Tulle, France

I am a general doctor working in a rural sector. When I need a psychiatrist to take care of my patients, I sometimes have to wait one, two three months or more. . . While waiting, what could I do before? Just prescribing some drugs and listening with empathy. . . I was not very satisfied with that so I spent two years learning medical hypnosis and brief therapy model in the Limoges medical university.

In that communication, I will describe the techniques I use, the self-hypnosis exercises I learn to patients, to permit them to become actors of their being better.

So that when they finally consult the specialist, they are much more able to precise their objective.

An audit to improve prescription writing on inpatient medication cards

H. Parvathiah^{1,*}, F.M. Osman², C. Daly²

¹ Clonmel, Ireland

² St. Lukes Hospital, Psychiatry, Kilkenny, Ireland

* Corresponding author.

Background The most common intervention performed by physicians is the writing of a prescription. All elements in the complex process of prescribing and administering drugs are susceptible to error.

Aims To measure the extent to which information recorded on prescription cards conforms to basic standards of prescription writing.

To improve prescribing, recording and staff knowledge.

To identify common prescribing errors and focus on the same to improve our standard of practice.

Methods An audit tool was designed to collect data and standard was set 100%.

Results In the initial audit, there was significant deficiency in prescription writing, which was presented at the internal teaching

to all doctors and recommendations were made. This audit was repeated after a month, which showed improvement in prescription writing and recording.

Recommendations Write all drugs in CAPITALS ensuring correct spelling, dose, route of administration and frequency.

Complete all fields on front of the prescription card legibly.

Document any change in prescription card in clinical notes.

All doctors to go through their current clients medication cards and ensure any gaps filled and errors corrected.

Audit report will be kept in audit folder as a reference for any rotating doctor to repeat the audit every six months in the services.

Conclusion Doctors should continue to improve prescription writing and reduce any adverse events or errors.

The impact of antistigma education on the attitudes of first-year medical students towards mental illness

C.A. Popescu^{1,*}, A.D. Buzoianu², S. Suciuc³, S. Armean⁴

¹ University of Medicine and Pharmacy "Iuliu Hatieganu", Social Sciences, Cluj-Napoca, Romania

² University of Medicine and Pharmacy "Iuliu Hatieganu", Pharmacology, Cluj-Napoca, Romania

³ University of Medicine and Pharmacy "Iuliu Hatieganu", Physiology, Cluj-Napoca, Romania

⁴ University of Medicine and Pharmacy "Iuliu Hatieganu", Pharmacology, Cluj-Napoca, Romania

* Corresponding author.

Introduction The stigma and prejudice surrounding mental illness exist widely throughout the world. Several surveys have shown that the general population has limited knowledge about mental illness and holds unfavorable attitudes toward people with mental disorders and that physicians endorse these negative attitudes. Medical students and their attitudes towards psychiatry and psychotherapy as well as towards the mentally ill form the foundation of their later actions as medical doctors.

Objective This study explored first-year medical students' beliefs, attitudes and desired social distance towards people with mental illness and assessed the impact of an antistigma education program in changing them. To achieve these aims a pre- and post questionnaire study design was followed.

Methods A new 2-h educational program was developed to change attitudes towards mental illness, and was conducted on first-year medical students. The study was conducted on 250 medical students from University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania (140 from Romanian section and 110 from English year).

Results At 2 months after the intervention, the authors observed positive changes in students' attitude regarding mental illness.

Conclusions According to the results of the current study, a relatively short and simple intervention could be successful in reducing the stigma of mental illness. Because the curriculum of undergraduate psychiatric training in Romania did not entail any specific antistigma training modules, one could argue that the present findings advocate for incorporation of such an orientation in undergraduate psychiatric training. Future work in this direction might shed light on the significance of such an education.

Lessons learned from leading a Canadian psychotherapy medical education program

G. Radu^{1,*}, N. Harris², G.E. Harris³

¹ Memorial University, Department of Psychiatry, St. Clare's Mercy Hospital, St. John's, Canada

² Eastern Health, Psychology, St. John's, Canada

³ Memorial University, Faculty of Education and Department of Psychology, St. John's, Canada

* Corresponding author.

Introduction Under Canadian training requirements, psychiatry residents must demonstrate proficiency in various psychotherapy modalities such as cognitive behavior therapy and psychoanalytic psychotherapy.

Objective Building from an earlier case study of the development of a comprehensive psychotherapy education program, the current presentation explores lessons learned from the ongoing delivery of this program to psychiatrists in training. Innovative strategies, opportunities, challenges and current outcomes on the delivery of this program are explored through a case study framework. The design, implementation and ongoing operation of the psychotherapy education program are based on the Royal College of Physicians of Canada specialty training requirements in psychiatry.

Methods In the context of the case study framework, a Canadian psychotherapy training program for psychiatrists in training is analysed. The psychotherapy education model is designed and operated to offer a gradual and integrated educational and clinical experience in psychotherapy over four years of training.

Results The psychotherapy education program was investigated to explore new frameworks and innovative strategies of delivery and operation. Among the lessons learned were the need to maintain formally structured, modality specific teaching and supervision, video recording of sessions in supervision, provision of additional protected psychotherapy time, access to online training resources and utilization of non-physician mental health experts.

Conclusions This presentation will investigate the ongoing insights emerging from managing delivery of different psychotherapy competencies to psychiatrists in training in a Royal College of Physicians of Canada accredited program. Implications for training, practice and future research will be discussed.

Revolutionary education: Fostering emotional intelligence and empathic imagination across the mainstream curriculum. Interdisciplinary inquiry

I. Rozentsvit

Object Relations Institute for Psychotherapy and Psychoanalysis, Parent–Child Development Program, Fresh Meadows, USA

If fostering emotional intelligence and empathic imagination and solving ethical dilemmas were discussed openly and taught methodically in K-12 mainstream (“typical”) classrooms, would we need metal detectors at the inner city schools’ entrances, and would we need special anti-bullying programs, which intend to correct bullying culture, rather than build a new one, based on kindness, openness, and consideration for others?

Will we learn lessons from the Columbine High School and the Sandy Hook Elementary School massacres, and radically change educational system, to incorporate empathic imagination and emotional intelligence into mainstream K-12 curriculum – as a mandatory discipline – instead of leaving this important part of

learning and character formatting only to the special education sphere?

This symposium represents a collaborative effort of four educators from various disciplines who crossed boundaries to emphasize and foster emotional intelligence and empathic imagination throughout the K-12 curriculum.

The following are the parts of the proposed multidisciplinary panel:

- multidisciplinary approach to revolutionary education, or paradigm shift towards fostering emotional intelligence and empathic imagination across the mainstream curriculum;
- Descartes’ error, the triune brain, and neurobiology of emotional intelligence;
- changing our consciousness: imagining the emotional experience of the other;
- teaching social skills and play therapy in schools: report from the trenches of special education;
- examining cultural artifacts, tools for personal, emotional, and academic development;
- growing kind kids: mindfulness and the whole-brained child;
- Emotional Imprint™ at the street squash: ‘If you talk, you don’t kill.’

The Japanese Society of Psychiatry and Neurology Fellowship – reflections of participation from European early career psychiatrists

H. Ryland^{1,*}, K. Scheeres²

¹ West London Mental Health Trust, Forensic Department, London, United Kingdom

² Royal College of Psychiatrists, Psychiatric Trainees’ Committee, Bristol, United Kingdom

* Corresponding author.

Introduction The Japanese Society of Psychiatry and Neurology (JSPN) fellowship is a long-running programme to support early career psychiatrists from around the world to attend the society’s annual conference in Japan.

Objectives To inform early career psychiatrists of the nature of the fellowship, disseminate learning from the experience and to encourage applications to the scheme.

Methods Each member organisation of the World Psychiatric Association can nominate up to two early career psychiatrists for consideration by the fellowship committee. Applicants must submit an abstract in one of two themes, describing how services are designed in their country. Twelve early career psychiatrists are selected to participate in the programme each year.

Results In 2015, fellows were drawn from ten countries across three continents. The fellowship programme involved several components, including the opportunity to present the nature of psychiatric services in our home nations in dedicated seminars with other international fellows. This provided an excellent platform to compare and contrast different national approaches in key areas. Each seminar was co-chaired by an eminent psychiatrist and an early career psychiatrist from Japan, increasing the possibilities for professional exchange and mentoring.

The Japanese Young Psychiatrists’ Organisation arranged a number of activities for the fellows including a guided tour of a local psychiatric facility. This enabled fellows to gain a deeper understanding of psychiatric practice in Japan, through informal discussions and interaction with clinicians.

Conclusions The JSPN fellowship is an effective mechanism for fostering improved relations and understanding between early career psychiatrists across the world.

Resource training centre as innovation didactic component of postgraduate training for doctors narcologists in Ukraine

I. Sosin*, Y. Chuev, O. Goncharova

Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

* Corresponding author.

Introduction The work presents HIV PLEDGE project cooperative results of Kharkov Medical Academy of Postgraduate Education (KhMAPE) and the United Nations Office on Drugs and Crime (UNODC) in Ukraine which correspond the Law of Ukraine "On the Higher Education" requirements.

Objectives and aims The project is aimed at the reduction of HIV-infection, tuberculosis and other comorbid disorders in drug addicts in Ukraine. The results are expected to be introduced into postgraduate training for doctors narcologists of Ukraine at the resource training centre (RTC) created under UNODC aegis according to innovation international education and technology standards criteria adapted for all forms of postgraduate training including medical residency.

Methods Clinical, laboratory, epidemiological methods, statistical monitoring were applied for modern drug addiction conditions.

Results The research allowed:

- to increase abilities of KhMAPE departments to provide up-to-date epidemiological information for narcological diseases, pathophysiology, treatment, prevention, rehabilitation, HIV-linked medical and non-medical services integration in routine practice;
- to approach renewed academic programs, distance training courses, certification, special modern software, computer technologies, internet resources;
- to increase the postgraduate education efficiency and quality;
- to apply up-to-date information concerning treatment;
- to provide tuition and online training.

RTC was equipped with special software, valid educational and diagnostic tests, e-libraries, research analytical reports, Tritnet educational and information materials, presentation setup. RTC provides monitoring system of academic efficiency "Smart Senteo", distance training module program, database server "Osvita".

Conclusions RTC efficiency and prospects of new form of postgraduate medical training for doctors narcologists in residency have been grounded.

* Corresponding author.

The impact of educational public policies in developing countries such as Brazil is determinant in the improvement of socioeconomic outcomes as well as in the increase of individual's well-being. This research aimed to study the effects of early detection and intervention in language and behavioral difficulties among 3–4-year-old preschoolers in Brazil. It was designed as a pretest–posttest model with a total of 178 subjects, 90 girls and 88 boys, divided in control ($n=94$) and experimental groups ($n=84$), with average age of 3.7 y. Children were evaluated in receptive and expressive vocabulary, central auditory processing and behavior. Subjects of the experimental group were engaged in intervention for three months for the development and refinement of language and behavior through activities developed in software used in tablets and orientation provided to their parents and teachers by a professional team composed by speech therapists, psychologists and psycho-pedagogues. The subjects improved their performance in all tests. There was a significant difference in the performance of behavioral and language tests in posttest, indicating that improvement was due to the intervention proposed. This research was supported by the Foundation for Research Support of the State of São Paulo (FAPESP) and Maria Cecilia Souto Vidigal Foundation (FMCSV) whose agreement aims to develop and support projects with potential application in society. These results are meant to guide the design of a project, which will allow the early identification of communication disorders and behavioral difficulties and the development of continuing education actions for the teachers.

Scientific research providing behavioral support for teachers on the modification of inadequate behavior among adolescents enrolled in a language course in Brazil

B. Montagni¹, C. Varanda^{2,*}

¹ Paulista University, Human Sciences, São Paulo, Brazil

² University of São Paulo, Department of Physical Therapy, Speech-Language Pathology and Audiology and Occupational Therapy, São Paulo, Brazil

* Corresponding author.

Education can benefit from psychological research concerning students' behavioral problems in order to provide teachers information on how to handle those behavioral issues, since those can predict late psychiatric disorders and interfere negatively with academic achievement. This research investigated problem behavior of students (10–12 yrs) of a language course in Brazil. Behavior was investigated through a problem behavior questionnaire considering the potential effects of peer and teacher attention. The initial hypotheses that there would be a positive correlation between problem behavior and poor academic performance was partially confirmed once correlation between some items of the problem behavior questionnaire and the performance in academic assessment was found. Among all the 15 elected problem behaviors, most of them appear to have the functionality of gaining peer attention and avoiding teacher attention; followed by gaining both teacher and peer attention and gaining teacher attention. These results were used as parameters for the suggestion of positive behavioral support, which contributed to an improved academic performance and to behavioral changes among the students. There was an increase of one point in the academic performance and reduction of 27.8% of the emission of deviant behavior. Nevertheless, a teacher training program showed to be necessary for the teachers to learn how to handle adolescent behavioral problems.

These results indicate that scientific research should be put at the service of education, especially in developing countries where lack of resources urges health and education policy makers to take into account findings which may impact a child's health and learning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Educating to legality. A tool to prevent crimes of psychiatric patients

A. Zangrando^{1,*}, F. Babici², E. Pascolo-Fabrizi¹, A. Riolo²

¹ UCO Clinica Psichiatrica, Department of Mental Health, Trieste, Italy

² CSM Domio, Department of Mental Health, Trieste, Italy

* Corresponding author.

Introduction Be a citizen means having rights but also duties and be subject to laws. Educating to legality is essential for mutual respect in the community, for the rules of social life and to exercise own rights of citizenship. A psychiatric patient can commit crimes because of mental disorders but also in absence of psychopathological problem. When a patient commits an offence, it is correct to know whether he was due and if he is actually a danger to society. The law do not allow ignorance but what patients really know about the law is not clear.

Objective In this study, we want to investigate the legal knowledge in citizens with mental disorders. Moreover, we want to build pathways to increase compliance with the law.

Methods We collected a cohort of 10 offenders and asked them if they were interested in an educational course on legality. We interviewed a sample of patients at risk of breaking the Penal code to assess their basic knowledge.

Results The reasons to undertake an educational program on compliance with the law were higher for offenders, maybe for fear of damaging sanctions. Those at risk of being sued for their behavior seemed to have more background than other group.

Conclusions It is essential to develop educational programs about crime prevention within the psychiatric field through training courses that increase the knowledge and awareness of effects of the Penal code. Moreover, citizens with mental disorders at risk of crimes should be supported by specific interventions aimed to social ethics.

Neuroleptic malignant syndrome about 14 observations

C. Aarab (Psychiatrist)*, R. Aalouane (Psychiatrist), I. Rammouz (Psychiatrist)

Hospital Ibn Alhassan, psychiatry, Fez, Morocco

* Corresponding author.

Introduction Neuroleptic malignant syndrome is potentially deadly but a rare condition occurs when taking neuroleptics. It is characterized by hyperthermia, severe extrapyramidal disorders and neuro-vegetative disturbances.

Aims and methodology We have studied retrospectively files of 14 patients hospitalized for NMS in the psychiatric department of Hassan II University Hospital of Fez in the last six years, in order to search for the causes its occurrence and planning its development.

Results Eighty-six percent of our patients are male, and the average age is 29 years. This disease usually affects young males but the risk of its development is increasing with certain factors.

According to our results, it seems that high potency neuroleptics (73%), particularly haloperidol and parenteral administration (57%) appear to be strongly associated with NMS especially in agitated patients having a psychotic disorder (78%) or if antipsychotic treatment is newly introduced (64%).

Combining several drugs is very common in our results, 50% with other antipsychotics, 81% with benzodiazepines. Physical impacts associated are somehow less frequent (42%) but also seem to have a role in the occurrence known NMS. Mortality rate was 7% (only 1 patient). These data are consistent with the majority of international works.

Conclusion Our results emphasize the necessity for rational use of antipsychotics among people at risk, the importance of early diagnosis and immediate treatment in order to have a positive development.

* Corresponding author.

Background Epidemiological studies of emergency room (ER) psychiatric settings can help monitor unmet needs and improve the quality of care.

Objectives To characterize the patients presenting to emergency department with psychiatric complaints in a medium sized health centre in oil sands region of the Northern Alberta.

Methods Information on a data assessment tool designed to capture all relevant demographic and clinical characteristics of psychiatric patients in the ER was compiled as part of a clinical audit process.

Results Overall, 477 patients were assessed by the psychiatric team over the 12 month period, comprising 230 (48.2%) males and 247 (51.8%) females. There was a fairly balanced distribution by age, ethnic background, and relationship status between the male and female patients. The majority of patients with a history of self-harm or childhood sexual abuse were female while male patients were significantly more likely to report medication non-compliance. A higher proportion of the female patients had depressive disorders and personality disorders while a higher proportion of male patients had anxiety disorders, bipolar and related disorders, schizophrenia spectrum disorders, and substance-related disorders. Approximately half of all the patients had an impaired clinical insight. Majority of the patients had a GAF score of 70 or less. Nearly one in five patients were admitted for inpatient treatment with a significantly higher proportion of male patients being admitted involuntarily.

Conclusion There are sex-specific differences in many of the demographic and clinical measures collected in our ER psychiatric sample.

Preventing self-harm and reducing suicidal ideation through an expedited regular supportive psychotherapy and assertive case management – protocol for a three-arm partial randomised controlled trial

V. Agyapong^{1,*}, T. Behre², M. Juhas¹, A. Greenshaw¹

¹ University of Alberta, Department of Psychiatry, Edmonton, Canada

² QE II Hospital, Department of Psychiatry, Grande Prairie, Canada

* Corresponding author.

Aim To conduct a three-arm partial randomised controlled trial to evaluate the effectiveness of expedited regular supportive psychotherapy and assertive case management for patients presenting with suicidal ideation or self-harm to the emergency department (ED).

Hypothesis We expect expedited regular supportive psychotherapy plus assertive case management will reduce the suicidality and/or suicidal behaviour in patients by at least 20% at 4 weeks compared to patients receiving only assertive case management or routine care and these differences will be sustained at 6 months.

Methods This will be a longitudinal, prospective, three-arm controlled single-rater-blinded partial randomized clinical trial with a recruitment period of 12 months and an observation period of 6 months for each participant. Patients in the intervention group will receive regular face-to-face or over the phone brief supportive psychotherapy during weekdays following presentation to the ED with suicidal ideation or self-harm until patients are actively enrolled in regular community mental health services with active case management by the therapist. Patients in the control and the assertive outreach arms will each receive the usual follow-up services offered routinely to regular patients and assertive outreach patients respectively who present to the ED with suicidal ideation or self-harm.

Results Recruitment will commence in February 2016 and we expect the results of the study to be available by September 2017.

Conclusion If our hypothesis is proved correct, our intervention will be a new model for caring for patients with self-harm and suicidal ideation and is expected to reduce suicide rates.

Introduction Parasomnias are a category of sleep disorders in which abnormal events occur during sleep, due to inappropriately timed activation of physiological systems.

Case report We report the case of a 41-year-old female who has no psychiatric history. The patient went to emergency department because when she was starting to sleep, in the first state of sleep, she felt a sensation of paralysis in all her body, with incapacity for

breathing, chest oppression and tactile hallucinations like something or someone was touching her entire body. Due to that, the patient awoke frightened, with high levels of anxiety, with heart palpitations, shortness of breath, trembling, choking feeling, sweating, nausea and fear of dying. When the patient arrived to the emergency department, she was suffering a panic attack, thinking that she could have some kind of neurological disease or she was suffering a heart attack. After treating the panic attack with 1 mg of lorazepam, all the symptoms subsided gradually.

Discussion In this case report, we present a patient with a new-onset parasomnia, with hypnagogic hallucinations and a panic attack at the awakening. It is known that stress factors are closely associated with parasomnias, as we can see in this case because the patient was moving and she was sleeping in a new place.

Conclusions Parasomnias are very frequently present in general population and they can trigger intense anxiety status that can lead to panic attacks.

¹ Hospital Universitario 12 de Octubre, Psychiatry, Madrid, Spain

² Hospital Dr. Rodríguez Lafora, Psychiatry, Madrid, Spain

³ Hospital Universitario 12 de Octubre, Emergency department, Madrid, Spain

* Corresponding author.

Introduction Hyperthyroidism may lead to high anxiety status, emotional lability, irritability, overactivity, exaggerated sensitivity to noise, and fluctuating mood, insomnia and hyporexia. In extreme cases, they may appear delusions and hallucinations as psychiatric symptoms.

Case report We report the case of a 53-year-old female who was diagnosed of hyperthyroidism and generalized anxiety disorder. The patient went to emergency department because of high levels of anxiety, with heart palpitations, trembling, shortness of breath and nausea. She was presenting auditory hallucinations and delusions as psychiatric symptoms. An urgent thyroid profile was made and it was observed the next results: TSH <0.005; T4:4; T3:21. Due to a severe thyroid malfunction, the patient was admitted and treated with antithyroid agent, improving the psychiatric and somatic symptoms.

Discussion In this case, a patient diagnosed of hyperthyroidism and generalized anxiety disorder presented very severe psychiatric symptoms, with hallucinations and delusions. These symptoms may be produced by primary psychiatric disorders, but is very important to look for thyroid alterations, because if they are the cause, the acute treatment of thyroid malfunction is the correct management of the patient.

Conclusions Hyperthyroidism is very common in general population, being infradiagnosed most of times. In patient with anxiety or other psychiatric symptoms, it is very important to make a thyroid function tests before the diagnosis of a psychiatric disorder. In extreme cases, hyperthyroidism status may lead to severe psychiatric and somatic complications.

* Corresponding author.

Introduction Aggressive behavior in wards is associated to poor treatment compliance and low clinical insight. Most studies focused on the clinical and cognitive dimensions of insight, while the relationship between metacognitive dimension and aggressive behaviors was not investigated. Our aim was to understand what relationship occurs between dimensions of insight (metacognitive, cognitive, clinical), and specific aggressive behaviors in acute patients.

Methods We recruited 75 acute schizophrenic patients using: AQ; MOAS; IS; PANSS; BCIS.

Results A positive correlation between the IS score and the hostility, angry and physical aggression sub-scores of the AQ was highlighted, while no correlation between the score of IS and MOAS total score was found. No correlation between the score of the PANSS G12 item and the AQ scores and MOAS was found, and no correlation between BCIS scores, MOAS and AQ scores was found.

Conclusions In our patients, a higher level of metacognitive insight, but not clinical nor cognitive insight, was associated to higher levels of hostility. We suggest that a higher ability to monitor and appraise one's own altered processes of thought and related discomfort, feeling of destabilization and loss of control, could contribute to enhance resentment and suspiciousness. Findings help develop specific therapeutic strategies to enhance metacognitive and self-monitoring abilities, helping patient's understanding of the illness, improving compliance with treatment, and patient's quality of life. Our results support the multidimensional nature of insight in schizophrenia, confirming that clinical, cognitive and metacognitive dimensions are independent though related facets of the phenomenon of insight in schizophrenia.

Loxapine for agitation in psychiatric patients who consult in emergency medical services

M.Á. Carrillo*, M.J. Martínez, P. Botías, I. Imbernón, M. Martínez-Carlón, M. Fueyo, C. Calero, N. Megias, S. Pina, M. Gavilan, M.P. Sanchez, J. Sanchez, P. Chacon

University Hospital of Murcia Virgen Arrixaca, Psychiatry, Murcia, Spain

* Corresponding author.

Introduction The DSM-5 defines psychomotor agitation as excessive motor activity associated with a feeling of inner tension. The activity is usually nonproductive and repetitious and consists of behaviors such as pacing, fidgeting, wringing of the hands, pulling of clothes, and inability to sit still. This kind of behavior occurs in up to 25% of psychiatric patients who consult in emergency medical services.

Objective The main objective was to determine the efficacy of loxapine inhalation powder in acute agitation.

Methods Ten agitated psychiatric patients scored Positive and Negative Syndrome Scale – Excited Component (PANSS-EC) baseline and ten minutes after the administration of ADASUVE®.

Results The efficacy of loxapine 10 mg in the acute treatment of agitation was established in a short-term (10 minutes).

Conclusions Loxapine is the first and only orally inhaled medication for the acute treatment of agitation associated with psychiatric disorders, which is a tool easy-to-use in emergency medical services.

* Corresponding author.

Introduction Emergency situations related to mental disorders represent a significant proportion of all medical emergencies. Over the last years we have been witness to an upturn in the incidence of psychiatry emergency service because to change of mood.

Objective To determine the profile of the patient who requires psychiatric attention with changing of mood in our area in different seasons.

Methodology This is a prevalence and prospective study in which the dependent variable is taken as change of mood and we also use three more independent variables that are age sex and seasonality. The seasonality (spring period and summer period) will be at the same time the form of divided the population in two groups to compare.

Results Out of all the consultations for changing of mood in the emergency service during the first period (113 patients), 34% were men and 66% were women. The age range of 36–50 years was more frequent for women and the age range of 51–65 years was more frequent for men. In the second period (with 162 patients), 137 women (86%) and 25 men (14%). In this case, the most common age range was 36–50 years, both for women and for men.

Conclusions The epidemiological and clinical characteristics of patients with changing of mood assessed by the emergency service are described from a naturalistic approach.

Which Chi² we will discover if the population who has been taken between woman and man is significant and with the median, we will also determine if the age ranges are enough significant to confirm our hypothesis.

Gender difference among psychiatric patient's profile in emergency department

M. Gonçalves*, J. Teixeira, R. Diana, A. Craveiro
Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrada em Psiquiatria e Saúde Mental, Coimbra, Portugal

* Corresponding author.

Introduction Over the past 40 years, services for psychiatric patients have become increasingly deinstitutionalized, shifting away from inpatient facilities. As a result, patients seek other avenues for treatment, including outpatient facilities and community resources. Unfortunately, those resources have also become increasingly constrained by widespread budget cuts, leaving patients with the health care system's last remaining safety net—the emergency department (ED).

Because EDs are seeing increasing numbers of patients, hospital administrators have recognized the importance of improving throughput and the quality of care delivered in EDs.

The aim of this report is to investigate the gender difference among patient's profile in psychiatric emergency room, assessing the socio-demographic and clinical characteristics, reasons for attendance and practices.

Methods Retrospective and observational study, conducted at Centro Hospitalar e Universitário de Coimbra, during a three month period. Statistical analysis of data with "SPSS 21".

Results During the three months period, a total of 2309 patients were admitted in Psychiatric ED, 1485 female and 824 male.

Regarding clinical data, the authors are expecting to find different psychopathology among male and female, as well as psychiatric comorbidities, diagnoses after discharge, treatment conducts, social support and different rates of psychiatric comorbidities.

Conclusions Factors such as patient's vulnerability, defined by socio-demographic elements, characteristic as the type and severity of their mental illness, social support, treatment adherence, with significant implications of prognosis, costs and care. The conducted study enabled us to outline a profile of male and female psychiatric patients in ED.

Delay in medical emergency care to patients with psychiatric symptoms

P. García González^{1,*}, E. González Martínez², S. Puerta², A. Capllonch Carrión¹

¹ Complejo Asistencial Benito Menni, Unidad Hospitalización Breve, Ciempozuelos, Madrid, Spain

² Hospital Universitario 12 de Octubre, Servicio de Psiquiatria, Madrid, Spain

* Corresponding author.

Patients with mental illness not only have a higher prevalence of physical disorders compared with the general population, but are also less likely to receive proper medical care.

We report a case of a 62-year-old woman who was hospitalized in our psychiatry hospitalization unit due to behavioural disturbances

and mild psychotic symptoms. During hospitalization, she presented a syncope with an important drop in oxygen saturation requiring continuous oxygen administration to maintain an adequate saturation. As our unit is placed in a monographic psychiatry hospital, she is derived to the medical emergency unit of a local general hospital for attention. Due to her behavioral symptoms, she was difficult to treat in the emergency department, which resulted in an approximate delay of five to six hours. Intervention of the psychiatry emergency team was necessary to encourage the general medical team to perform a full clinical examination, being finally diagnosed with bilateral pulmonary embolism and admitted to a general medicine hospitalization unit.

We review related literature regarding the delay in medical care for psychiatric patients. Patients with mental disorders are likely to not receive proper medical care. Programs addressing stigmatization of patients with mental disorders among physicians and a better coordination between medical and psychiatry emergency teams are some of the solutions proposed to address this problem.

Neuroleptic malignant syndrome. Differential diagnosis

M.J. Gordillo Montaña^{1,*}, G. Carmen², R. Ana³, G. Elena³

¹ Los Santos De Maimona, Spain

² Hospital Juan Ramón Jiménez, Spain

³ Spain

* Corresponding author.

Neuroleptic malignant syndrome is one of the most dangerous complications of antipsychotic therapy, rare but very serious, especially with first-generation neuroleptics. It is a medical emergency, an early diagnosis will be necessary and include general supportive measures and symptomatic drug therapy.

Objectives NMS is a diagnosis of exclusion that typically occurs between 24–72 hours. Rare after two weeks, except that the deposit may extend this period. The course is between 7 and 10 days.

Methods We will present a case in which we see the difficulties that arise in daily clinical practice.

Results The most characteristic symptoms are rigidity, such as stiffness ("lead pipe"), dystonia, tremor, nystagmus, opisthotonos, bradykinesia, dysphagia, dysarthria, lethargy, convulsions, trismus, oculogyric crisis. Changes the state of consciousness (confusion, delirium and stupor or coma). Hyperthermia, above 38.5 °C (up to 41). Autonomic instability (hypertension, postural hypotension and variability in blood pressure, tachycardia, tachypnea, salivation, sweating, pale skin, and urinary incontinence).

Conclusions It is particularly difficult to make the differential diagnosis with malignant catatonia, by the common features that both products, which are indistinguishable in a quarter of cases, conceptualise the NMS as a form of drug-induced malignant catatonia. This resembles by muscle rigidity, hyperthermia, and akinesia. His appearance is preceded by emotional disorders, psychotic symptoms, depressive symptoms, impaired functioning prior patient, acute anxiety and agitation, which occurs about two weeks before. Subsequently choreiform stereotypies, primitive hyperkinesias, spasms and rhythmic and cyclic arm movements. In catatonia, hyperactivity and hyperthermia typically occur prior to the administration of the neuroleptic.

⁶ Hospital Germans Tries i Pujol IGTP, Farmacologia clínica, Badalona, Spain

* Corresponding author.

Introduction New psychoactive substances (NPS) are drugs that have recently become available, are not worldwide regulated, and often intend to mimic the effect of controlled drugs. α -Pyrrolidinopentiophenone (Alpha-PVP) is a potent stimulant cathinone that is thought to act inhibiting dopamine and norepinephrine reuptake. It has been associated with hallucinations, psychosis and death.

Objectives To explore the presence of Alpha-PVP from the samples handled to, and analyzed by energy control.

To determine whether it is a new trend in recreational settings.

Methods All samples presented to energy control were analyzed. Samples in which alpha-PVP was detected using Gas Chromatography-Mass Spectrometry were selected for study.

A Google trend analysis was also performed to assess the media impact of alpha-PVP.

Results From a total of 20,062 samples, 33 contained alpha-PVP (0.16%). The samples containing alpha-PVP were mostly sold as such (40%) despite a significant proportion being sold as MDMA (15%). Google trend analysis showed an abrupt increase of alpha-PVP searches in 2015 reaching 50% of the MDMA-ones.

Conclusion Our results suggest presence of Alpha-PVP in the drug market may be increasing, especially as adulterant of other drugs. Severe side effects might be even more serious considering that a significant proportion of users may ignore which substance they are actually using. However, the total amount of alpha-PVP analyzed remains small, and does not support the alarming reports published in media.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Frequent attendance: A clinical and epidemiological study

S. López-Romeo*, G. Ledesma-Iparraguirre

Parc Sanitari Sant Joan de Déu, Psychiatry, Barcelona, Spain

* Corresponding author.

Background Frequent attenders (FA) are patients who attend a health care facility repeatedly. The frequency of frequent attendance at emergency department has been defined as 4 or more attendances/annum. FA are few in number but they produce a high number of attendances.

Aims To determine prevalence of FA, mean attendances/year generated by FA and frequency of visits by months.

Methods A retrospective study was performed on psychiatry's emergency department database from January until December

2013. FA was defined as those with ≥ 4 attendances at emergency services in a year.

Prevalence of FA, attendances' prevalence, diagnosis' prevalence, Mean attendances generated by FA and frequency of visits by months were analysed.

Results Among 4824 attendances we found 181 FAs (5.98%). Men represented 50.80% and women 49.20%. FA presented a mean of 6.33 attendances/year, while non-FA presented a mean of 1.29 attendances/year.

In accordance with frequency of visits by months, it was observed that number of attendances was increased in April and May, in both FA and non-FA.

Conclusion Prevalence of FA was 5.98%, FA generated a 23.74% of attendances. Most prevalent FA' diagnoses were: anxiety disorder, personality disorder non-specified and schizophrenia.

FA at emergency department contributes to overcrowd them. For this reason, it is important to take into account these results to develop new strategies to improve FA' attention and prevent its occurrence.

⁴ University of Medicine and Pharmacy Tg Mures, Psychiatric Department, Gh Marinescu 38, Tg Mures, Romania

* Corresponding author.

Seclusion and restraining in acute psychiatry wards is used when patients tend to harm themselves, other patients or staff members. Seclusion and restraining decision-making is a complex process based on risk of aggressivity, patient's diagnosis, history of violent incidents, staff experience, hospital internal regulations and national mental health law.

The aim of this study is to evidenciate the patients' characteristics, which could be predisposed to restraining procedure in acute psychiatric setting in Romania.

Material and method This is a two years retrospective study conducted on a total of 1000 patients (56.9 females, 43.1 males) randomly selected, admitted in acute psychiatric hospital. From these on 100 patients restraining techniques were applied.

Results and discussions Out of the restrained patients male, younger usually suffering of personality disorder were more frequent restrained. Statistical analysis of restrained group characteristics comparing with larger group of the total patients admitted showed no significant differences between these two groups. Regressive analysis on different clusters found a higher risk to be restrained for patients with agitation and recurrent depressive disorder, male, from urban area. This study draws attention to the importance of a good study design and proper methodology.

Conclusion The factors which influence the risk of being restrained in acute psychiatric setting are more related with behavior characteristics than diagnosis or demographical items.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV627

Evaluation of staff training in crisis and home treatment team in Merseyside

S. Natarajan

Warrington, United Kingdom

Introduction Home Treatment Accreditation Scheme (HTAS) is a programme published by Royal College of Psychiatrists, which reviews home treatment team with the aim of helping them to improve quality and awarding accreditation to service. Standards were focused on various domains including service provision and structure, staff appraisal, training, assessment, care planning and interventions.

Objective To evaluate whether staff received training that is required to deliver services effectively without jeopardising the needs and safety of the patients.

Methodology A tool was designed based on the recommendations from HTAS. Eighteen staffs from various backgrounds were involved in this evaluation. Each standard were categorised into type 1/2/3. In order to achieve accreditation team has to meet 100% of type 1, 80% of type 2 and majority of type 3.

Results Only 65% staffs have been trained as opposed to 100% as suggested by HTAS. Fifty-five percent of staffs have not had training as opposed to 80% for a team to be accredited. Thirty-eight percent staffs have had training compared to 50%, although they are not directly responsible for HTT.

Conclusions Would suggest all the staff to be trained in the core skills that are required to deliver good quality service. Training should be focused and specific to their roles and the teams they work, meeting the needs of the service users. Also, training should be updated on regular basis. This should be re-evaluated in 1-year time with the view of auditing across the trust in other home treatment teams.

EV628

The prevalence of the burnout syndrome among population examined at the psychiatric emergency department for attempted suicide

E. Perju^{1,*}, E. Gallois²¹ Reims, France² Psychiatry, 10, rue Corvisart, 75013 Paris, France

* Corresponding author.

Introduction The intention of this study is to show the frequency of the burnout syndrome among the population seen at psychiatric ER for the most severe complication of the burnout, the suicide attempt.

Objective (a) To demonstrate the frequency of burnout among the population examined at psychiatric ER for suicide attempt.

(b) To establish a correlation between the frequency of burnout and:

- the socio-demographic characteristics;
- the psychiatric follow-up;
- the type of personality found.

Methods Descriptive study on a sample of 92 patients examined at psychiatric ER between 01/02/2014 and 01/06/2014 after a suicide attempt, seen by a single doctor. The patients received the Maslach Burnout Inventory (MBI).

Results The frequency of burnout among the population consulted for suicide attempts is 8.7%. The limitations of this study

were: the use of MBI questionnaire only by one doctor and a collection of data carried on a certain period of time.

I managed to characterize the population seen after the suicide attempt induced by the burnout: 88% women; 25% foreign population working in a context with many responsibilities; the predominance of obsessive personality – 50%, followed by anxious personality type – 25%; the suicide attempt was done by a population without psychiatric history and without psychiatric follow-up – 75%; the studied population is divided between patients working in a high responsibility environment – 36% and patients working in the social or the public environment – 63%.

Eighty-eight percent of patients were brought in after their first suicide attempt.

Conclusion Despite the fact that until now a unanimous definition has not been formulated on the CIM-10, the burnout syndrome is one of the most popular disorders.

The problematic is real, considering that this syndrome, which starts with a psychological distress, can escalate to a self-aggressive behaviour.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Case report of autointoxication with nutmeg committed by a suicide attempter

S. Petrykiv^{1,*}, L. de Jonge², P. Michielsen³, M. Arts⁴¹ GGZ Friesland, Emergency Psychiatry, Leeuwarden, Netherlands² UMC Groningen, Epidemiology, Groningen, Netherlands³ GGZ West Noord Brabant, Psychiatry, Bergen op Zoom, Netherlands⁴ UMC Groningen, Old Age Psychiatry, Groningen, Netherlands

* Corresponding author.

Introduction Autointoxication with nutmeg in an emergency setting is a rare, but potentially a life-threatening event. Despite the low incidence of 'tentamen suicidii' (TS) with nutmeg, this substance is cheap and readily available. Early recognition of a suicide attempt with nutmeg poisoning can be extremely difficult, especially when nobody witnessed the nutmeg intake. Worldwide there are only a few cases reporting TS with nutmeg.

Objectives To present a case of TS with nutmeg committed by a suicide attempter.

Aims To review available literature on TS with nutmeg.

Methods A case report is presented and discussed, followed by a literature review.

Results Five published cases of suicide attempts with nutmeg were found while searching through PUBMED and Embase. Our case describes a 57-year-old female, diagnosed with borderline personality disorder, who has been admitted to the emergency department in a state of agitation, diminished cognition, respiratory difficulties and hemodynamic instability. Electrocardiography showed a fast sinus arrhythmia with no uschemic or hypertropic changes. Blood sampling, serum and urine toxicology did not reveal any abnormalities. In view of the complexity of her condition, she admitted to have taken a large dose of nutmeg. The patient was kept for observation, offered reassurance, and rehydration.

Conclusion The presentation of inexplicable clinical state accomplished by disturbances of central nervous, respiratory and hemodynamic systems in the population of patients with attempting suicide should alert the physician to the rare but probably underreported possibility of nutmeg autointoxication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Inhaled loxapine for the treatment of agitation in borderline personality disorder

R. Puente*, M.F. Rabito Alcon, S. García Jorge, H. Dolengevich Segal, M. Benítez Alonso, J. Gómez-Arnau Ramírez, A. Garrido Beltrán, J. Rodríguez Quirós, B. Unzeta Conde, O. Pecero García, J. Correias Lauffer
Hospital Henares, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Inhaled loxapine has shown efficiency in the treatment of the mild-moderate agitation syndrome of schizophrenia and mania patients. Its rapid response and calming effect non-sedative allow to hypothesize reasonable efficiency and tolerability in borderline personality disorder diagnosed patients.

Aims Analyze the efficiency and tolerability of inhaled loxapine as a pharmacological approach in the treatment of agitation in borderline personality disorder (BPD) clinical diagnosed patients.

Materials and method An application was administered for every agitation episode in BPD patients treated with inhaled loxapine in the emergency room or the psychiatric ward, which included BARS and CGI-S scales for the evaluation of each episode and its severity, before and after its use. Other secondary measures of efficiency were taken into account, such as requirement of physical restraint.

Results In the majority of evaluated episodes inhaled loxapine decreased notably initial BARS and CGI-S values and no serious clinical side effects attributable to this medication were observed.

Conclusion In our sample, inhaled loxapine was efficiency and well tolerated pharmacological intervention for agitation in BPD patients.

Psychiatric emergency prehospital: Incidence and management of agitation in Valladolid (Spain)

R. Rodríguez Calzada^{1,*}, M. Siesto Marcos², P. Roset Arisso³, M.A. Suarez Fuentes³, L. Delgado Alonso⁴, M. Rodríguez Calzada⁵, R. Rodríguez Calzada⁵, E. Calzada Amorrortu⁵

⁴ Gerencia Atencion Primaria Valladolid Oeste, Medical Department, Valladolid, Spain

⁵ Rc Clinic, Psychology, Valladolid, Spain

* Corresponding author.

Introduction Agitation is a frequent and complex emergency. Pre-hospital management of agitation requires appropriate measures to preserve patients' safety, stabilize the patient and alleviate suffering, and transfer to the hospital psychiatric services, including involuntary admission if needed.

Objectives To describe the incidence and management of agitation by the emergency medical service of Castilla y León (SACyL) in an area of Valladolid.

Methods Retrospective study of all psychiatric emergencies attended by a prehospital emergency medical service in 2014.

Results One hundred and twenty-one emergencies were attended over a catchment area that covered 170,000 inhabitants (1.4/1000 inhab.). Overall, 55% were men, mean age was 45

years, 60% were considered psychiatric, 29% organic and 11% mixed. However, men had a higher frequency of organic (39%) compared to psychiatric (48%) agitation than women (16% and 75%, respectively), and most of them were related to alcohol or drug use. Among patients with psychiatric or mixed agitation 81% had psychiatric history and the pharmacologic treatment most frequently used was intramuscular midazolam.

Conclusions The incidence of acute agitation accounts for almost half of the total psychiatric emergencies in the prehospital setting. Since there are different healthcare providers in charge, specific protocols as well as treatment procedures are needed to provide the most adequate management, in order to ensure the best psychiatric emergency chain.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Do we know why we indicate a mechanical restraint?

E.J. Pérez*, L. Galindo, M. Grifell, F.N. Dinamarca, V. Chavarria, P. Salgado, V. Pérez

Institut de Neuropsiquiatria i Addiccions, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction and objectives Mechanical restraint is a therapeutic procedure commonly applied in acute units in response to psychomotor agitation. Its frequency is between 21 and 59% of patients admitted. These patients represent a risk to both themselves and for health workers. There are not clinical studies that compared if there are differences of the frequency of the specific indication for the mechanical restraint.

The aim of this study is to explore the differences of frequency of each indication of mechanical restraint on patients on the psychiatry acute and dual pathology units.

Material and methods We reviewed retrospectively the informatics record of all the mechanical restraints made and the total discharges of the three acute care units and dual disorders of Neuropsychiatry and Addictions Institute of the Parc de Salut Mar de Barcelona, between January 2012 and January 2015. The episodes of mechanical restraint, the specific indications for them and the DSM-IV diagnostic were coded. Then, was calculated the frequency and proportion of mechanical restraints in the most common diagnostic groups. An ANOVA was performed:

- risk of self-aggressiveness;
- state of self-aggressiveness;
- risk of hetero-aggressiveness;
- state of aggressiveness;
- risk of psychomotor agitation;
- state of psychomotor agitation;
- acute confusional state;
- fall risk;
- risk reduction on therapeutic interventions;
- avoid pulling out of life support systems;
- facilitate administration of drug treatment;
- patient voluntarily requests it;
- high-risk of escape.

Results The number of discharges analyzed was 4659 from which 838 had an episode of mechanical restraint associated.

Neurologic and psychopathologic symptom presentation at psychiatry emergency

N. Trovão^{1,*}, A.S. Coutinho²

¹ Centro Hospitalar Vila Nova de Gaia Espinho, Psychiatry, Vila Nova de Gaia, Portugal

² Centro Hospitalar Vila Nova de Gaia/Espinho, Psychiatry, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Due to current deinstitutionalization of psychiatric patients, emergency services are assuming an important role in early intervention on acute or subacute psychopathology. At this setting, where the psychiatrist has a limited range of subsidiary tests, differential diagnosis between the symptoms of primary psychiatric illness and psychopathologic features secondary to medico-surgical pathology, especially if with systemic involvement, becomes particularly challenging.

Aims To deepen knowledge on differential diagnosis of acute episodes of behavioral disorganization.

Methods This work stands on the clinical case of a patient presenting in the emergency room with symptoms of psychomotor agitation, dysphoria and heterologous activity. Preliminary diagnostic hypothesis are of synergistic neurological and iatrogenic etiologies. We then proceed to a critical reflection on the boundaries between psychiatry and other branches of medicine, under the light of a brief literature review on the topic.

Results The patient has backgrounds of chronic kidney disease, already transplanted and treated with immunosuppressants. In addition to the psychopathological symptoms described, subacute gait impairment, sensorineural deafness on the right and important weight loss were found. She was admitted in neurology ward for diagnostic assessment. At present, we could exclude potential neoplastic and metabolic causes, confirm the presence of toxic levels of tacrolimus and important neuroimaging anomalies, leading to a possible Susac syndrome diagnosis.

Conclusions A meticulous clinical reasoning that keeps in mind the need to exclude potential medical, toxicological or iatrogenic causes is of particular relevance in emergency services where patients directly present to the psychiatrist, without prior evaluation by other specialties.

Psychiatric emergencies and admissions in Ciudad Real Area. Statistic study. A reflection on use of emergency resources and admission criteria

J. Martínez Arnaiz*, C. García Blanco, B. Vallejo-Sánchez
Santa Barbara Hospital, Mental Health Unit, Puertollano, Ciudad Real, Spain

* Corresponding author.

Introduction Ciudad Real is an area of approximately 500,000 inhabitants, with a University Hospital and several district hospitals. Psychiatric services and emergencies are centralized in the University Hospital. We analysed the totality of area admissions during 2014, establishing different categories according to ICD 10 diagnosis.

Objective We want to compare different categories of patients who are admitted to hospital (severe mental illness versus

non-severe mental illness), morbidity in different areas and readmission rates according to diagnosis.

Aims To establish a correspondence between attention and severity of psychiatric pathology, diagnostic criteria and how we manage both severe and non-severe mental illness and the repercussion in terms of assistance and pressure in psychiatric emergencies.

Methodology Initially, we made a simple statistic analysis of all admission (400 approximately) in 2014 based on ICD-10 diagnosis, socio-demographic parameters, area, admission stay, number of admissions. We compare both groups: severe and non-severe mental illness according to international criteria. We apply a Pearson correlation searching for relation between severity and attendance to psychiatric emergencies.

Results Around a 60% of admissions are not due to severe mental illness, these conditions have twice the readmission rate than severe mental illness. We did not find a correlation between attendance to psychiatric emergencies and severity of the condition. Other factors seem to have an important role in re-admissions.

Conclusions Non-severe mental illness is consuming an important part of emergency psychiatric resources. Criteria of admission need to be reviewed or apply rationally.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV635

Non-compliance in the emergency department: Is there a difference between medical and psychiatric patient's reasons and use of the emergency department

L. Zun

Mount Sinai Hospital, Emergency Medicine, Chicago, USA

Background It is estimated that on average up to 50% of patients are non-compliant with their medication, resulting in 28% emergency room visits costing about \$8.5 billion annually.

Objectives The purpose of this study was to examine, what, if any, differences there are between medical versus psychiatric non-compliant patients with regard to use of the emergency department (ED).

Methods A random sample of patients who present to the ED for medical or psychiatric illnesses and who state that they were non-compliant with their medicine were given the National Health Access Survey. They were asked about sources of medical care, drug compliance and reason for non-compliance.

Results There were a total of 300 participants in the study. There was no significant difference in the reason both medical and psychiatric patients gave for being non-compliant with their medications that resulted in their ED visit. Each group cited cost as the number one reason for not taking their medication as prescribed. The psychiatric participants who were more likely to get admitted disposition ($P = .00$), not afford mental health care ($P = .01$), were not able to get care from other places and used the ED for their psychiatric care ($P = .02$).

Conclusion There was no difference between the two populations with regards to their reasons for non-compliance that brought them to the ED. Non-compliance of the psychiatric patients compared to the medical patients lead to a higher admission rate.

EV636

Prevalence of ADHD in adult psychiatric outpatient clinics in Sligo/Leitrim Area, Ireland

D. Adamis^{1,*}, D. O'Neill¹, O. Mulligan¹, E. O'Mahony¹, S. Murthy¹, G. McCarthy¹, F. McNicholas²

¹ Sligo Mental Health Services, Psychiatry, Sligo, Ireland

² University College Dublin, Child Psychiatry, Dublin, Ireland

* Corresponding author.

Introduction The prevalence of ADHD in adult population has been estimated at 2.5%. Higher rates (23.9%) have been reported among adult mental health service (AMHS) users.

Aims To estimate the prevalence of ADHD among adult MH users in west county Ireland.

Methods All consecutive patients attending any of 5 Sligo/Leitrim AMHS were invited to participate. Participants completed the Adult ADHD Self-Report Scale (ASRS) and the Wender Utah Rating Scale (WURS). Clinical notes were reviewed to identify those with pre-existing ADHD diagnosis. Exclusion criteria applied were: age: less than 18 or above 65, illiterate, non-English speaking patients.

Results From 792 attending the clinics, $n = 59$ (47 aged above 65, 10 severe learning difficulties and 2 non-English speaking) were excluded. Ninety-three (11.7%) decline to participate, giving a total of $n = 640$ (87% eligible response rate). Mean age was 41.27 (SD: 12.8), and 336 (52.5%) were females. Three had diagnosis of ADHD. Two hundred and thirteen (33.8%) met criteria on the WURS for childhood onset ADHD and 238 (37.5%) participants met caseness on the ASRS. Applying more stringent criteria of scoring on both scales, suggested 125 (19.5%) with unrecognised ADHD.

Conclusions While recall bias (WURS) and the possibility of overlapping symptoms with other major psychiatric disorders in adulthood need to be considered, the use of both screening reduces these confounders and suggests a very high rate of ADHD. Given the low number previously identified, this becomes a clinical priority, both to offset the negative trajectories associated with untreated ADHD, but also to effect optimal treatments in comorbid conditions.

Psychological well-being among social network users of King Saud University students

D. Alateeq^{1,*}, A. Alhadi^{1,2}, F. Alateeq³, A. Alsubie¹, D. AlEesa³, S. AlShareef³, A. Omair³

¹ King Saud University, College of Medicine, Department of Psychiatry, Riyadh, Kingdom of Saudi Arabia

² King Saud University, SABIC Psychological Health Research & Applications Chair, Riyadh, Kingdom of Saudi Arabia

³ King Saud Bin Abdulaziz University for Health Sciences, College of Medicine, Riyadh, Kingdom of Saudi Arabia

* Corresponding author.

Introduction Social networks allow individuals to express themselves, and establish or maintain connections with others. Using social networks like Facebook may be associated with a sense of self-worth and may play an important role in psychological development of university students who are in emerging adulthood phase.

Objective (1) Assess the psychological well-being of Saudi university students using social networks (Facebook).

(2) Explore whether the relationship between Facebook use and bridging social capital is different for individuals with varying degrees of self-esteem and satisfaction with life.

Aim To study the psychological well-being of Saudi university students using social networks (Facebook).

Method An electronic survey was published in the community site for all students of King Saud University. In addition to the demographic information, the survey evaluates Facebook use intensity, bridging social capital and psychological well-being: self-esteem and satisfaction with life.

Results A total of 1005 students completed the survey, of which 50.5% were female. Majority of them were members in Facebook (92.1%).

Conclusions Results showed no significant correlation between the use of Facebook and psychological well-being. It could be due to the fundamental difference between Arabs and other cultures or due to the use of other social networks. There was a positive relationship between bridging social capital and psychological well-being with being in preparatory year, which is most likely because advanced years has more workload preventing students from participating in King Saud University community. A longitudinal study over a series of years and addressing other popular social networks would be the next step.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Access to mental health and immigration

S. Fuentes Márquez, R. Alonso Díaz*, E. Cortázar Alonso
Hospital Juan Ramón Jiménez, Salud Mental, Huelva, Spain

* Corresponding author.

In the present study, we certain demographic variables of immigrants accessing specialized mental health care at two points in time: 2013 and 2014. According to the National Institute of Statistics, the number of foreigners fell by 4% in 2013 and 3% in 2014 due to emigration and the acquisition of Spanish nationality. Among the objectives of the department of health is collected to ensure the right to health protection to immigrants through effective access to the health system and improve management capacity and performance of health centers in diverse contexts.

Results Despite the overall decline in foreign an increase in first consultations requested for immigrants was observed. At both time points, higher demand for foreign women is observed. With respect to age greater demand seen in middle adulthood, however in 2014 there is a greater homogeneity with respect to this variable. The greatest demand comes from Morocco, Romania and Poland, although most Latin American countries are increasingly observed.

Conclusions Better access and better quality health care to both the immigrant population and of citizens in amount from acceptance and commitment to this complex and diverse and its approach will be achieved.

Socio-demographic factors among delusional disorder: A case series register

C.M. Carrillo de Albornoz Calahorra*, M. Guerrero Jiménez,
A. Porrás Segovia, J. Cervilla Ballesteros

Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

* Corresponding author.

Introduction Delusional disorder has reached an entity of growing interest with a prevalence in developed countries between 1 and 4% of the psychiatric consultations.

Objective To describe various socio-demographic and clinical variables that characterize patients diagnosed with delusional disorder in Andalucía according to DSM-5 criteria.

Methods Reviewing common medical history digital records. First, it has been proved whether it complies DSM-5 criteria for the diagnosis of delusional disorder. Then, there have been different epidemiological variables collected: age, sex, family psychiatric history, and marital status, and employment status, age of onset of illness, number of years of follow-up by specialized care, the number of visits to your computer, and number of hospitalizations in a psychiatric inpatient unit among others.

Of the 1927 patients studied, 1452 met the criteria for diagnosis of delusional disorder. These patients live in Andalusia and come to different mental health care units, with an average follow-up period of 9 years and 1 month.

Results About half of the sample were women and half men (49% versus 51%).

Forty-seven percent of the sample are married or have a couple, and 19% are in active employment.

Thirty-two percent have a family history of psychiatric mental disorder written in his digital clinical record.

Seventy-five percent of the sample meets criteria F22, while 25% are diagnosed as other psychoses.

Conclusion This is the largest record of cases registered with delusional disorder to date, in which we describe the biopsychosocial characteristics of this group of patients in the largest Spanish region.

Socio-demographic analysis of an early psychosis intervention programme

C.M. Carrillo de Albornoz Calahorro*, J.A. Rodrigo Manzano, B. Girela Serrano

Hospital Santa Ana, Unidad de Salud Mental, Motril, Granada, Spain

* Corresponding author.

Introduction During the first 5 years of the onset of schizophrenia, the majority of the clinical and psychosocial deterioration takes place.

This period of time is critical in terms of diagnosing the illness and providing effective psychosocial and pharmacological treatment.

Objectives/aims Knowing the demographic profile of users of an Early Psychosis Intervention Program to adapt the intervention to their specific needs.

Methods A descriptive statistical analysis of the records of every patient on admission program during year 2014 was carried out. There have been various socio-demographic variables collected such as: sex, age, initial diagnosis, drug consumption, educational level, labor situation, referral source and origin.

Results We found an average age of 26, near the normal curve between 15 and 35 years distribution.

Eighty percent of our sample were men.

Eighty percent were non-affective psychosis as their initial diagnosis.

Abuse toxic in 70%, in all cases cannabis or derivatives.

Education level: 56% primary studies. Thirty percent reached secondary studies. Fourteen percent higher educational level.

In terms of job-training situation: 30% were working, 40% unemployed and 30% studying.

Sixty-five percent were referred from primary care centers, 20% from drug abuse centers and 15% from hospitalization units.

Main nationalities were Spanish 65%, 30% were Moroccan, and 5% other came from other nationalities.

Conclusion It stresses the importance of intervening on dual diagnosis, the need for greater coordination with primary care to improve the detection of cases and the development of the training-labor area in the recovery process.

It is also necessary to evaluate the different characteristics of immigrants included in the program.

Physicians' burnout: Can we make a difference?

C.A. Moreira*, G. Sobreira, J.M. Oliveira, M.A. Aleixo

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Burnout is a commonly observed syndrome in healthcare workers and it has been defined as a psychological condition involving a continuous exposure to stressful work events leading to adverse consequences both in physical and mental health. Persistent pressure can lead to exhaustion, psychological and/or physical distress and may increase the risk of medical errors and decrease job satisfaction, which incites early retirement.

Objective The authors pretend to make a brief review regarding Physicians' burnout, its prevention and management.

Aims To understand and to be capable of dealing with physicians' burnout.

Methods The review was based in papers published on PubMed using the following terms: "burnout", "risk factors", "healthcare professionals" and "physicians coaching".

Results Twenty-five to 60% of physicians report burnout across all specialties. Changes in the healthcare environment have created marked and growing external pressures. Numerous studies suggest that the difficulty that physicians face with balancing their personal and professional lives is a major contributor to distress. To reduce stress at work, one should consider two levels of intervention: the individual and the environmental. Multidisciplinary actions that include changes in the work environmental factors along with stress management programs that teach people how to cope better with stressful events showed promising solutions to manage burnout.

Discussions/conclusions Burnout among physicians is a common and serious issue with potentially devastating personal and professional consequences. More interventional research is needed in order to improve psychological well-being, professional career enjoyment as well as the quality of care provided to patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV642

Victimization of the mentally ill

A. El-Missiry

Ain Shams University, Neurology & Psychiatry, Cairo, Egypt

Background Persons with mental disorders living in the community are liable for victimization and are considered as a high-risk group.

Objective To explore the socio-demographic variables and clinical characteristics related to victimization of patients with schizophrenia in comparison to their non-victimized counterparts.

Subjects and methods One hundred patients were recruited from the inpatient wards and outpatient clinics of the Institute of Psychiatry, Ain Shams University. They were subjected to Structured Clinical Interview for DSM-IV Axis I diagnosis (clinical version);

Positive and Negative Syndrome Scale (PANSS); Global Assessment of Functioning (GAF); Clinical Global Impression (CGI); designed extensive questionnaire to elicit demographic data; inquiry about drug compliance and Victimization Questionnaire.

Results Seventy patients of the studied sample were non-victimized and 30 patients were victimized. Victimized patients were significantly younger, living mainly in urban areas, had less frequent history of bullying at school. There were exposed significantly to higher frequency of family domestic violence and childhood abuse. They scored higher for all subscales and in total PANSS scores and they were less compliant on medication than did their non-victimized counterparts.

Conclusion Studies of victimization of mentally ill did not draw the attention of researchers and clinicians in Arab world. This study proves that victimization is not uncommon among patients with schizophrenia; clinicians should include assessment for victimization of their patients as a routine work. The current study provides preliminary data for clinicians and policy makers to consider strategies to protect patients with various mental illnesses from being victimized.

Disclosure of interest The author has not supplied his declaration of competing interest.

Study of self-perceived health in a clinical sample

A. Fernandez-Quintana*, M.D.C. García-Mahía
Clinical University Hospital of La Coruña, Psychiatry, La Coruña, Spain

* Corresponding author.

Introduction The assessment of self-perceived health provides an insightful clinical tool when it comes to addressing the subjective perception of social functioning, mental and physical health.

Objective To analyze self-perceived health in patients treated in a primary care clinic and its relationship with other clinical and socio-demographic variables.

Methods A randomized sample of 130 patients, aged 18 years or over, undergoing treatment in a primary care clinic was evaluated. Patients were interviewed following a self-perceived health scale as well as a scale for other clinical and socio-demographic variables. Clinical records were reviewed for prior psychiatric and somatic diagnoses.

Results Overall, the prevalence of somatic disorders in our sample was 92.3%, whilst psychiatric disorders were present in 23% of patients. Only 6% of the sample reported their mental health to be affected to some degree, while 67% declared their physical health to be damaged. Forty-three percent of the sample follows prescribed psychopharmacological treatment. Women showed lower self-perceived health and reported more psychiatric symptoms in accordance with higher actual prevalences of psychiatric disorders. Among those patients with a psychiatric illness, only two reported the will to search for mental health care, whilst most would prefer consulting their general practitioner.

Conclusions Less than half of the patients who have been diagnosed with a psychiatric disorder consider their mental health to be affected. Among those who do report a self-perceived mental health concern, the majority would prefer consulting their general practitioner rather than a psychiatrist.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Aims To estimate the prevalence of psychostimulant use in French medical undergraduate and postgraduate students, associated consumption behaviors and motives.

Design A population-based cross-sectional study using a self-administered online survey.

Participants A total of 1718 French students and physicians (mean age 26.84 ± 7.19 years, 37.1% male).

Measurements Self-reported lifetime use, motives, socio-demographic and academic features for other the counter (OTC), medically prescribed (MPP), and Illicit (IP) psychostimulant users.

Findings Lifetime prevalence of psychostimulant use was 33% (29.7% for OTC, 6.7% for MPP and 5.2% for IP). OTC consumption mainly aimed at increasing wakefulness during competitive exams preparation and internship. OTC consumption was twice more frequent among users of other psychostimulants (MPP and/or IP). Most of OTC consumers began their consumption during exam preparation. Corticoids were the most frequently consumed MPP (4.5%) before methylphenidate and modafinil (1.5% and 0.8%, respectively). Unlike corticoids, methylphenidate and modafinil prescriptions are tightly regulated in France. Motives for MPP consumption were increased academic performance/concentration-memory and wakefulness. In that respect, restrictions on methylphenidate and modafinil prescriptions seem to be effective at limiting misuse. Corticoids were mostly consumed by interns seeking for wakefulness. Overall, 5.2% of the subjects consumed at least once IP, mostly cocaine and amphetamine derivatives. They sought euphoria and/or novelty.

Conclusions Psychostimulant use is common among French undergraduate students, interns and postgraduate physicians. The type of drug used seems to depend mainly on product availability. Increased rates of corticoids consumption for wakefulness purposes suggest another potential public health problem, as corticoids may have severe side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The assessment of social disability in persons with a diagnosis of mental disorder. Preliminary data

T.M. Gondok*, A. Królicka, B. Misiak, A. Kiejna
Wrocław Medical University, Department of Psychiatry, Wrocław, Poland

* Corresponding author.

Social disability in persons diagnosed with mental disorder is one of the factors preventing them from achieving the broadly defined well-being, even when appropriate and effective treatment is applied. Improvement in the field of social disability is therefore one of the main challenges for the mental health and social welfare

policy makers. The second version of the Groningen Social Disabilities Schedule (GSDS-II) is widely used in the assessment of social disability, however the relationship between its degree and many of the clinical and demographic factors have not been investigated thoroughly enough.

The objective of the study is to assess the degree of social disability using GSDS-II as well as to analyze the relationship between the degree of social disability and clinical, social and demographic factors, in patients with a mental disorder diagnosis of F20–F48 according to ICD-10, aged 18–65, in a day ward and an inpatient ward settings.

The paper presents the data gathered from a preliminary sample of 20 patients of both genders diagnosed with mental disorders who gave their informed consent to participate in the study, thus comprising 10% of the targeted total study sample.

Our study, performed on a larger, targeted sample, will provide a better insight into the social functioning of persons with a burden of mental disorder. A precise presentation of the social disability shall improve the model of care offered to these persons. Any possible parallel studies in other countries, employing analogical methodology, could allow for a cross-national and cross-cultural comparison of the received outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

E-mail address: marlliguerrero@gmail.com (M. Guerrero Jiménez)

Introduction Several recent epidemiological studies have reported during the last few years that the prevalence of psychotic symptoms in the community is bigger than the previously thought.

Aims Estimate the prevalence in our influence area, as there are no previous studies focused on this measure and its correlated factors in Andalusia population.

Methods Literature review was made about the prevalence reported in all continents as well as the found correlation. Then, a cross-sectional epidemiological study was designed (Granada). We present data from 809 Andalusian individuals taken from the Unified Data Base of the Andalusian Health System.

Results This poster presents a brief but updated systematic literature review of psychotic symptoms in the general population (i.e. delusions and hallucinations). We present also data from 809 individuals from our clinical catchment area. Prevalence of psychotic symptoms in Granada was of 10.3%. Hallucinations were reported in 6.1% and 7.4% reported delusions.

Conclusions The prevalence found was similar to other studies in the Spanish population such as the EsEMED Study performed in Catalonia where 11.2% of psychotic symptoms were reported, and similar to European studies like the BNS in Great Britain with a 10.9% of psychotic symptoms. Differences obtained in percentages could be due to different measure scales (PSQ, MINI, CIDI. . .) used in other studies made in the North American population such as the National Comorbidity Survey with a 28% of prevalence reported. Inter-interviewer differences and the potential risk factors for

psychotic symptoms in each population seem to be the causes of such differences and similarities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The participation of mental patients in politics

G. Hamdi^{1,*}, M. Karoui², L. Robbana², F. Elouze², F. Mrad²

¹ Razi Hospital, F, Mannouba, Tunisia

² Razi Hospital, G, Mannouba, Tunisia

* Corresponding author.

Introduction Participating in the political life is a key goal of democratic institutions. The main achievement of the Tunisian revolution has been the democratization of political life and the re-conquest of liberties that remain to consecrate and consolidate. Several studies have focused on evaluating the participation of some specific groups in political life (youth, women. . .) but none have shed a light on the mentally ill.

Objective and method Our study aims to assess the participation of patients followed in different psychiatric units of the Razi hospital in activities such as voting, attendance at political meetings, adhesion and contributions to political parties as members, political debates with their neighbors. . .

The investigation focused on 40 patients and relied on a pre-established questionnaire.

Results The study group was 40 patients followed at Razi hospital with 25 men and 15 women.

The average age of patients was 40 years (24–56).

The turnout was very low at 10% (4 male patients) versus an average of 60% of the general population.

One patient was an active member of a political party and political meetings.

Women seemed to be less interested in political issues.

Conclusion The participation of the mentally ill in politics, as in the different aspects of social life, remains very limited in a particularly vulnerable group in society that has suffered considerable discrimination.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Loneliness and mortality: A community-based prospective study

J. Henriksen^{1,*}, P.R. Kyle², P. Bech², C. Mattisson³, N. Andersson⁴

¹ Aarhus University Hospital, Psychiatric Research Academy,

Department of Affective Disorders Department Q, Risskov, Denmark

² Psychiatric Centre North Zealand, University of Copenhagen, Psychiatric Research Unit, Hillerød, Denmark

³ Lund University Hospital, Department of Clinical Sciences, Lund, Sweden

⁴ Statens Serum Institute, Department of Epidemiology Research, Copenhagen, Denmark

* Corresponding author.

Introduction Loneliness affects up to one in every third individual in the western population, and the prevalence is increasing. The literature suggests an increased mortality risk of about 26% when feeling lonely, and an association to some disorders of physical health.

Objectives To assess if loneliness increases the risk of mortality, and if so, if health indicators (hypertension, heart disease, tobacco use, alcoholism, diabetes, obesity, and depression) mediate the association.

Methods The design is a community-based prospective cohort study using data from the Swedish Lundby Study. Loneliness is measured in 1997 with a singleton question during interview of a psychiatrist. The outcome is death between 1997 and 2011. Survival analysis is used to estimate the relative risk of mortality. Stratification of potential explanatory covariates examines if any of the health indicators mediate the relationship.

Results Significant more females, unmarried, unemployed, and childless people feel lonely. Moreover, feeling lonely correlates to being smoker or alcoholic when adjusting for age and gender. The statistical work on the survival analysis is still in progress. However, we expect to find a positive correlation between loneliness and mortality corresponding to previous studies, and perhaps to reveal some of the health indicators to cause the association.

Conclusions With increasing prevalence, potential health consequences, and a neglected role in the society, loneliness is an important research area.

Disclosure of interest The authors have not supplied their declaration of competing interest.

More women are medicated while more men are talked out: Persistent gender disparities in mental health care

P. Joseph*, A. Kazanjian

UBC School of Population & Public Health, Faculty of Medicine, Vancouver, Canada

* Corresponding author.

Introduction Physician incentives have been shown in previous studies to help reduce socioeconomic disparities in health care. Its impact on gender disparities, however, has rarely been investigated.

Aim The impact of physician incentives on gender disparities in mental health care was investigated in this retrospective study.

Method De-identified health administrative data from physician claims, hospital separations, vital statistics, prescription database, and insurance plan registries were linked and examined. Monthly cohorts of individuals with depression who were residing in British Columbia, Canada were identified and their use of mental health services tracked for 12 months following receipt of initial diagnosis. Indicators that assess receipt of the following services were created:

- counseling/psychotherapy (CP);
- minimally adequate counseling/psychotherapy (MACP);
- antidepressant therapy (AT);
- minimally adequate antidepressant therapy (MAAT).

Interrupted time series analysis was used to estimate changes in these indicators before (01/2005–12/2007) and after (01/2008–12/2012) physician incentives were introduced.

Results At the beginning of the study period, the percentage of individuals diagnosed with depression who received counseling/psychotherapy was higher, on average, among men (CP: 58.4%, MACP: 13.6%) than women (CP: 57.1%, MACP: 10.9%). In contrast, the percentage who received antidepressant therapy was higher among women (AT: 57.7%, MAAT: 47.4%) than men (AT: 53.6%, MAAT: 41.9%). Levels for these indicators have changed over time but the statistically significant differences between men and women were virtually the same before and after incentives were introduced.

Conclusions Gender disparities in mental health care persist despite the introduction of physician incentives designed to enhance access to mental health services in primary care.

Chemtrails: An overview of the phenomenon

C. Llanes Álvarez^{1,*}, A. San Roman Uría¹, P. Nunes Nancabu², M. Ruiz Gippini¹, P. López Landeiro¹, M.Á. Franco Martín¹

¹ Complejo Asistencial de Zamora, Psiquiatría, Zamora, Spain

² Complejo Asistencial de Zamora, Medicina familiar y comunitaria, Zamora, Spain

* Corresponding author.

Introduction The term contrail is a contraction of condensation and trail, as chemtrail is of chemical and trail. The first one is used to name trails left in the sky by aircrafts under certain atmospheric conditions. Some people argue that when contrails do not dissipate quickly is because contain substances added and sprayed for sinister purposes undisclosed to the population (weather modification and biological and/or chemical war are the most common).

Objective Exist various versions of the chemtrail theory, most of them propagated via the Internet in discussions forums or websites, and to a lesser degree by the mass media such as TV and radio programs. The outspread popularity and diffusion of the theory has already become a reality. Scientific community has repeatedly rejected that chemtrails exist, insisting that are just contrails. We analyze this phenomenon.

Methods We made a exhaustive literature review in *Journals of Meteorology and Aviation*, about the formation of condensation trails, in *Social Psychology Journals* about the genesis and dissemination of the chemtrails theory. Finally, we will make a brief presentation of documentation built around the theory of chemtrails in the province of Zamora (Spain), where is one of the most active spots in southern Europe.

Conclusions Official statements on the non-existence of chemtrails have not discouraged the proponents of the theory of chemtrails.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence of adverse childhood experiences and socioeconomic disadvantage among Portuguese prison inmates and its relationship with current psychopathology

A. Machado*, D. Loureiro, T. Silva, J. Cerejeira
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Adverse childhood experiences such as emotional/verbal abuse, sexual abuse, physical abuse, household dysfunction and parental psychopathology play a role in the development of chronic mental and physical diseases as well as in the development of aggressive and criminal behavior.

Objectives/aims Our aim was to explore the prevalence of childhood adversity and social disadvantage among prison inmates in Portugal and its relationship with current psychopathology.

Methods We conducted a cross-sectional study among criminal offenders in a high-security prison in Portugal. Socioeconomic status was evaluated using the Graffar scale. Additionally, we inquired our sample about topics concerning education level, work experience and present social and economic situation. Childhood adversity was measured using yes or no questions evaluating sexual, physical, emotional and verbal abuse, neglect, family integrity and household dysfunction, parental psychopathology and/or drug

abuse, family, school and neighbourhood violence and economic disadvantage. General psychopathology and psychological distress were measured using the Brief Symptom Inventory. Data was analyzed using SPSS. Descriptive data is provided for all measured variables, and correlation between the number of childhood adverse events and the BSI total score were calculated using the Spearman's rho.

Results/conclusions Since the study is currently ongoing, and data collection will be completed by December 2015, we will only be able to provide final results and conclusions by the time of submission of our work presentation, in March 2016. Total sample size is expected to be in excess of 100 subjects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Central and North West London NHS Foundation Trust, Child and Adolescent Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Being able to participate in elections and to vote are important components of social inclusion; empowering people with mental illness to have a voice.

It is important that mental health professionals understand the voting rights of adults with mental illness in order to be able to provide appropriate advice and support.

Objectives To explore knowledge of the voting rights of adults living with mental illness amongst mental health professionals working in both community and inpatient settings in Westminster, London.

Aims To understand the level of knowledge amongst mental health professionals regarding the voting rights of patients with mental illness in order to identify unmet training needs.

Methods A survey, in the form of a staff quiz was undertaken in all community and inpatient teams prior to the May 2015 general election. All multidisciplinary team members were included.

Results In total, 211 surveys were completed. Ninety-eight percent of staff correctly identified that being a psychiatric inpatient does not change an individual's right to vote. Less than 50% of the staff members demonstrated correct understanding of the rights of patients detained under forensic sections, and the rights of the homeless to vote.

Conclusions It is encouraging that knowledge of voting rights amongst staff appeared higher in our survey than in some published surveys. However, despite the development of a Trust Voting Rights Policy and Educational Film prior to the 2015 general election further staff education, particularly the rights of those detained under forensic sections or who are homeless, is required.

Introduction Currently, in mental health teams there is overload in the first consultations, therefore, patients cannot be treated properly.

Objective This study tries to reflect the differences between preferential and ordinary consultations, as well as the differences in the delay in the support between them.

Methodology This is a retrospective observational study where data are collected for 3 months of the first consultations that are taken to a mental health center.

Results The study reflects that preferential or normal (ordinary) derivation has no influence when it comes to the patient going or not going to the consultation.

On the other hand, there are very significant differences statistically in the waiting time between patients with normal and preferential priority.

Conclusions According to the results observed would be advisable to use appropriate criteria to decide the priority of a patient's cares.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction To the specialized attention arrives as preferred patients with minor diagnosis.

Objective We do a relation between the type (normal/preferential) derivation of the first consultations and their corresponding diagnosis.

Methodology Retrospective observational study with data gathered during 3 months, which handle 2 variables: on the one hand, type of derivation and on the other, effected diagnosis.

Results The most frequent diagnosis found are adaptative disorders and affective disorders, corresponding to 45.45% and 9.1%, respectively of preferred leads.

Conclusions Almost half of preferential queries (consultations) could be treated in first instance by primary care physicians releasing mental health care burden.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction It often happens that primary care teams sends to specialized care any type of demand without discriminating on many times.

Objective Study of diagnoses that get to the consultations.

Methodology Retrospective observational study with data gathered during 3 months of diagnosis carried out in the first consultations.

Results The study guides that there is much minor pathology in the first consultation.

Conclusions Currently, attention on mental health is overcrowded because there is an excess of derivation from minor pathologies. So, an adequate coordination and communication with primary care could improve patients' care.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Analysis of demand in the first visit to the mental health unit

B. Mata Saenz*, E. Lopez Lavela, T. Rodríguez Cano, L. Beato Fernández
Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain
* Corresponding author.

Introduction The first visit is crucial, since it is where a treatment plan is selected and the decision to refer or not the patient to a specialized unit is made. Mental care could be improved through the centralization of demand and the identification of patients' and psychiatrists' expectations.

Objectives Analyzing patients' and psychiatrists' demands and expectations in the first visit to use them as a starting point for the planning and coordination of treatment actions.

Aims To design a record system of the Minimum Basic Data Set of the Centralized Department of our Unit.

Methods This is an epidemiological, observational, prospective study of patients referred to our department. Following variables were collected:

- referral origin;
- reason;
- demographic data;
- diagnosis impression;
- destination of referral.

The Statistical Package for Social Science version 19.0 was used to analyze the data.

Results Table 1.

Conclusions The data obtained are consistent with those reported in the literature for this population. The high rate of wrong referrals reveals the necessity of improving coordination and establishing specific referral criteria. Some initiatives have been designed and will be prospectively evaluated in the future.

Table 1

n	321
Average age	48.23
Genre	62% female
Psychiatric history	49.6%
Origin	74.4% from primary care
Did not attend	17.3%
Wrong referral	34.7% (35.2% from primary care, 53.6% from other specialties)
Main reason of wrong referral	Low intensity of the disorder (22.34%), wrong speciality (21.28%), wrong course of the disease (20.21%)
Prevalent diagnoses	Depressive disorder (24.3%), reactive depression (20.1%), anxiety (14.2%)
Destination of referral	63.4% Mental Health Unit

An evaluation of psychological distress and social support of survivors and contacts of Ebola virus disease infection and their relatives in Lagos, Nigeria – 2014

A. Mohammed^{1,*}, T. Sheikh¹, S. Gidado (Field coordinator)², P. Nguku (Resident Advisor)², A. Olayinka (Resident Advisor)², C. Oluabunwo (Resident Advisor)², W. Ndadilnasiya (Field coordinator)², A. Joseph³

¹ Federal Neuropsychiatric hospital, Clinical services, Kaduna, Nigeria

² Nigerian Field Epidemiology and Laboratory Training Program, Abuja, Nigeria

³ University of Lagos, Department of Psychiatry, Lagos, Nigeria

* Corresponding author.

Background By September 2014, an outbreak of Ebola viral disease (EVD) in West African countries had recorded over 2200 deaths. EVD, create fear and panic among patients, and other stakeholders, a risk factor for psychological distress, which could have public health implication for control of EVD. We determined factors associated with psychological distress among survivors and contacts of EVD and their relatives.

Methods In a descriptive cross-sectional study, General Health Questionnaire was used to assess psychological distress and Oslo Social Support Scale was used to assess social support factors associated with psychological distress were determined using Chi²/odds ratio and adjusted odds ratio.

Results Of the 117 participants, 78 (66.7%) were females. Most frequently occurring psychological distress were inability to concentrate (37.6%) and loss of sleep over worry (33.3%). Losing a relation to EVD outbreak (OR=6.0, 95% CI: 1.2–32.9) was significantly associated with feeling unhappy or depressed while being a health worker was protective (OR=0.4, 95% CI: 0.2–0.9). Adjusted odds ratio (AOR) showed losing a relation was a predictor of “feeling unhappy or depressed” (AOR=5.7, 95% CI: 1.2–28.0) and inability to concentrate (AOR=10.1, 95% CI: 1.7–60.7) while having no tertiary education remained protective (AOR=0.2, 95% CI: 0.1–0.6).

Conclusions Survivors and contacts of EVD and their relations develop psychological distress. Development of psychological distress was predicted by loss of family member. We recommended

mental health specialists be part of case management teams. The teams managing EVD patients should be trained on recognition of common psychological distress.

Epidemic of conversion disorder in Jاناozen, the Northern Kazakhstan

E. Molchanova

American University in Central Asia, Psychology, Bishkek, Kyrgyz Republic

Jاناozen, a small city in the Northern Kazakhstan is an oil town, where 8% of all Kazakh oil has been extracted since 1950s. Due to the harsh climate and uncomfortable living conditions on the one hand, and relatively high salaries on the other, the city became a “Mecca” for ethnic Kazakhs (oralmans), who migrated from the other countries of the former USSR. The strict division between “ours” and “oralmans” created a variety of predispositions for the existence of a recurrent intro-city conflict, which served as a background for the tragic events of December 2011. The strike of oil workers ended in a bloody carnage with long-lasting consequences. The high level of traumatic stress, secondary gain of traumatization, and relative isolation of oralmans created plausible conditions for explosion of mass conversion disorder, which in social consciousness was associated with measles vaccination.

On 16th of February, 20 teenagers were hospitalized with seizures of unknown aetiology, 60 girls got sick during the next three days, and 195 were hospitalized during the next three weeks. More than 100 were receiving an outpatient treatment. Foggy diagnosis of “post-vaccine reaction” led to panic among citizens, and a small city hospital became overcrowded by relatives of patients. The diagnosis of conversion disorder had been supported according to the criteria of ICD-10.

The results of numerous focus groups, archival research and individual interviews showed up the precise connections between oil workers' strike in 2011 and mass conversion disorder in 2015.

Disclosure of interest The author has not supplied his declaration of competing interest.

Mental and behavior disorders among combatants in Ukraine

B. Mykhaylov

Kharkov Medical Academy of Postgraduate Education, Psychotherapy, Kharkov, Ukraine

In Ukraine, the significant participants of the “anti-terroristic operation” (ATO) need to provide a system of psychiatric, psychotherapeutic assistance.

The 6 groups of disorders:

- non-pathological reaction (Z65.5);
- pathological reactions (F43.0);
- neurotic disturbances (F45);
- psychotic disturbances (F44);
- PTSD (F43.1);
- chronic personality changes (F62.0).

The system of complex assistant was provided. Step 1: emergency psychological assistance. It is carried out on the basis of crisis intervention, that is defined as the emergency and urgent medical and psychological first aid, aimed at the return of the victim to the adaptive level of functioning, preventing progredient development of mental disorders, reducing the negative impact of a traumatic event.

Step 2: medical and psychological support. The purpose is the relief of mental and behavioral disorders, prevention (secondary and tertiary), psychological maladjustment, progressive course of mental disorders, with the purpose, rational, suggestive, cognitive behavioral (CBT), and others. The aim of psychotherapy is to support the patient's assistance, processing traumatic material reevaluation of the crisis, a change of attitude, increased self-esteem, develop realistic perspectives and active life position. It is important to restore a sense of competence and design future in which you can use a good past experiences. Step 3: the primary goal of treatment is relief of anxiety and fear, stress, adaptation to the human life and activity in conditions of continuing psychogenic. The most effective method of psychotherapy in these cases is CBT. Step 4: supportive. All steps developed by multimodal model of psychotherapy.

Community mental health: Description of the patients concerning the ULS Guarda department of psychiatry and mental health area

J. Nunes*, J. Feliz, D. Brigadeiro, T. Ventura Gil, A.F. Teixeira, P. da Costa

Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital, ULS Guarda, Guarda, Portugal

* Corresponding author.

The World Health Organization (WHO, 2004) stresses the importance of home patient visiting as an answer to the epidemiologic, demographic, social and economic challenges that the world is facing.

The severe psychiatric patients are a risk group and often need domicile consultation and visiting. The domicile consultation approach favors the clinical, social and familiar support as well as promotes the integration and the recovering of the patients with mental problems, preventing the relapses and the hospital admissions of these patients.

This study, of descriptive nature, is based on the observation and consultation of 287 clinical processes of patients inserted in the domicile consultation program designed by the Department of Psychiatry and Mental Health of Sousa Martins Hospital, ULS Guarda, which covers the 7th biggest district in Portugal (in a universe of 18), between July and September 2015.

The main goal of this study is to characterize and analyze the profile of the population, which is followed by the community mental health team of our Department, namely, the socio-demographic and clinic features, in order to improve the assistance practice in the future.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Social-stress disorder. What does it mean for the people?

O. Pityk^{1,*}, M. Pityk², I. Kuzhda³

¹ *Ivano-Frankivsk National Medical University, Department of Psychiatry, Narcology and Medical Psychology, Ivano-Frankivsk, Ukraine*

² *Ivano-Frankivsk National Medical University, Department of Neurology, Ivano-Frankivsk, Ukraine*

³ *Ivano-Frankivsk Regional Children Hospital, Department of Ophthalmology, Ivano-Frankivsk, Ukraine*

* Corresponding author.

In 90th of 20 Russian psychiatrist Y.A. Alexandrovsky expressed opinion of presence the group of so-called social-stress disorders that was determined like psychogenic-actual for most people in definite social, economic and political situation.

Used the method of clinic-psychopathological interview with patients who applied outpatient psychological consultation on the chair of psychiatry.

The main changes in psychic state include following behaviors and clinical implications: loss of the value of human life, which is manifested in indifference to death in lowering caution when hazardous situations, willingness to sacrifice lives without any ideals. There is unrestrained lost for pleasure and moral promiscuity, exacerbation of personality typological traits, development of hypersthenic reactions (to self-destructive non-expedient behavior), hyposthenic disorders, panic reactions, depression, dissociative and conversive irregularities, loss of communicational plasticity, loss of the ability to adapt to what happens with the preservation prospects of targeted actions, manifestations of cynicism, the tendency to antisocial actions. Patients had complaints on increase anxiety, pessimistic attitudes, existential vacuum, sense of uselessness and loss of perspectives, tendency to irrational perception of reality with including mechanisms of autistic and archaic thinking.

Thus, psychological status of the population of Ukraine is a model of social-stress disorder and can be considered like a basis, which leads to the decreasing of the individual barrier of mental adaptation with the next manifestation of different forms of psychological maladjustment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Patients' needs as an outcome measure in schizophrenia

P. Stefanatou^{1,*}, G. Konstantakopoulos¹, E. Giannouli¹, N. Ioannidi¹, V. Mavreas²

¹ Athens University Medical School, First Department of Psychiatry, Eginition Hospital, Athens, Greece

² University Hospital of Ioannina, Department of Psychiatry, Ioannina, Greece

* Corresponding author.

Introduction Outcome assessment has been highlighted as a crucial factor in the evaluation and transformation of mental health services, providing evidences for the improvement of clinical practice.

Objective This is the first clinical study in Greece to investigate the relationship between the crucial outcome measures of needs, quality of life, disability and psychopathology for patients suffering from schizophrenia. Furthermore, service evaluation based on the assessment of the above outcome measures has never taken place in the country.

Aims To examine the associations between the patients' needs and other treatment outcome indicators:

- quality of life;
- disability;
- dimensions of schizophrenia symptomatology.

Method The CAN-R, WHOQOL-BREF, WHODAS 2.0 and PANSS scales were administered to a sample of fifty-three schizophrenia patients and the correlations between the above outcome measures were computed.

Results (1) Significant negative correlations emerged between the total number of needs and unmet needs and subjectively assessed quality of life. (2) Significant positive correlations emerged between the total number of needs and unmet needs and subjectively assessed disability. (3) Significant positive correlations were found between the dimensions of schizophrenia symptomatology

(positive/negative/general) and the total number of needs in our sample.

Conclusion According to our findings:

- as the number of unmet needs increases patients' quality of life is lowered;
- a possible relationship exists between unmet needs and subjectively assessed disability;
- a possible relationship exists between needs and all the dimensions of schizophrenia symptomatology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The relationship between insight and internalized stigma in persons with severe mental illness

D. Szczesniak^{1,*}, I. Wojciechowska², M. Kłapciński², E. Zwyrtak², J. Rymaszewska²

¹ Wroclaw, Poland

² Poland

* Corresponding author.

Introduction Stigma is a multistage process that makes person marked by the stigma to be perceived as diminished or even as “not fully human”. The internalized stigmatization is seen as one of the levels of stigma to be present in persons with mental illness. A new perspective to mediation models between internalized stigma and illness-related factors is needed.

Aim To assess the relationship between insight in mental illness and internalized stigma, as well to verify the knowledge of illness-related factors on the phenomenon of internalized stigma among patients with severe mental illnesses.

Methods A cross-sectional study design conducted among participants of both sexes between 18 years old and 65 years old with diagnosis of psychotic disorders (F20–29) and mood disorders (F30–39), who after reading the information about the study, give their written consent to participate. Among used methods were: a questionnaire of Internalized Stigma of Mental Illness (ISMI) by Ritsher [Boyed] et al. translated into Polish version and self-prepared interviews. Insight into mental illness was assessed using the Positive and Negative Syndrome Scale.

Results The preliminary results showed patients with the insight into the mental illness have significantly higher scores on the ISMI scale. Moreover, inpatient participants and those with the diagnosis of depression were characterized by higher level of stereotype endorsement compared with outpatients and psychotic patients.

Conclusions The obtained results may contribute in the clinical and therapeutic fields, assuming that insight and the type of treatment are strongly linked with the process of recovery and the internalized stigma.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Voting is an essential human right. Being able to vote and participate in elections is an important component of social inclusion; empowering people with mental illness to have a political voice and in turn reducing stigma. Previous research indicates that patients with mental illness are less likely to vote compared to the general population.

Objective This study explores knowledge and uptake of the voting rights of adults living in mental health supported accommodation in Westminster (London) in the 2015 UK general election.

Aims Understand patients' awareness of their eligibility to register and cast their vote. Identify patients' interest in engaging in the voting process and strategies to overcome potential obstacles.

Methods A staff-assisted survey was undertaken in all mental health supported accommodation across Westminster prior to the general election in May 2015.

Results A total of 142 surveys were returned. Nine out of 10 surveyed believed they were eligible to vote; over half wanted to exercise their right to vote & if registered, a third felt they required assistance to vote.

Conclusions The majority of community patients were positively aware of the impending general election and their own eligibility to vote. Only half wanted to exercise their right to vote, which is lower than the general population. As a third of the patients requested assistance for voting, this shows us that there are potential barriers impacting on their ability to exercise their right to vote. Staffs have an important role in promoting patient's right to vote by providing assistance with both the registering and voting process.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Being able to vote empowers people with mental illness to have a political voice and promotes social inclusion. Evidence shows that patients with mental illness are less likely to vote compared to the general population.

Objective This study explores the knowledge and uptake of the voting rights of adult patients in a psychiatric hospital in the 2015 UK general election.

Aims To understand patients' eligibility and intentions to vote during the 2015 UK general election. To establish what assistance patients may require in order to vote.

Methods A staff-assisted survey was undertaken in all mental health wards in the Gordon Hospital, Westminster prior to the general election in May 2015.

Results A total of 51 surveys were returned. Seventy-five percent thought they were eligible to vote, and 47% had already registered. Of those that had not yet registered, 37% wanted staff support to

do so. Fifty-seven percent of the respondents intended to vote and of those 9 out of 10 intended to vote in person. Twenty-six percent of those intending to vote identified needing assistance in this process.

Conclusions The majority of inpatients were aware of their eligibility to vote. Over half of the respondents planned to vote, which is lower than the UK average. As 1 in 4 patients intending to vote requested support, this suggests potential barriers impacting on their ability to exercise their right.

Multidisciplinary teams can provide valuable assistance to patients in the voting process in many ways, including information provision, organisation of leave and providing staff escort.

Percussions of different types of media on children's behavior

E. Zaky

Ain Shams University, Faculty of Medicine, Pediatrics, Cairo, Egypt

Background The media has been around for ages, but what we experienced growing up is worlds away from what our children are growing up with today. Media is a double ended weapon that not only can be of priceless value for children if used in moderation but also it could have a tremendous negative impact on their lives.

Objectives Highlighting the positive and negative percussions of media on children's behavior.

Summary The first 2 years of life are considered a critical time for brain development. TV and other electronic media can get in the way of exploring, playing, and interacting with parents and others, which encourages learning and healthy physical and social development. As kids get older, too much media time can interfere with their activities such as being physically active, reading, doing homework, playing with friends, and spending time with family. So, while using media in moderation could be very beneficial for education, entertainment, and communication with others of different cultures, it could be very dangerous in encouraging risky behavior as substance abuse, violence, and unhealthy eating habits.

Conclusion Because it is always a matter of quality time and not the quantity of time spent by our children using different types of media, it is so important for caregivers to monitor media content and set viewing and interacting limits for their children and share them in their healthy interests to ensure that our children will not be left on their own in an unknown and potentially risky media world.

A systematic review of the prevalence and incidence of neuropsychiatric conditions in populations with traumatic brain injury

N. Zaman*, D.R. Faruqui

St Andrews Healthcare, National Brain Injury Centre, Northampton, United Kingdom

* Corresponding author.

Introduction The relationship between traumatic brain injury and neuropsychiatric conditions has a strong clinical link. Despite significant clinical presentations, there has been a limited focus on quantifying the association between traumatic brain injury and psychiatric disorders.

Objectives To conduct a systematic review to determine the prevalence and incidence of neuropsychiatric conditions in patients with traumatic brain injury.

Aims To determine the association between traumatic brain injury and psychiatric illness.

Methods A systematic search was made of Medline, PsycINFO, EMBASE and article bibliographies. Search terms for rates of psychosis, mood disorders, anxiety conditions, organic personality disorder, neuropsychiatric disorders, neuro-behavioural disorders, aggression, dementia and frontal lobe disorder were utilised. We followed MOOSE criteria and did not apply temporal limits.

Results There were 845 relevant searches in total. After exclusion of duplicates, case reports, case series reports, letters, reviews, commentaries, systematic reviews, and editorials there were 143 relevant abstracts identified. This was further reduced to a review of 48 full text papers. We identified prevalence rates of depression between 6.9–62.5%, mania of 9–12.5%, PTSD 1.9–50%, aggression 28.4–57%, anxiety disorders 6–63% (including GAD 8–9%, agoraphobia 2–6%, panic disorder 9%, social phobia 1%) insomnia 11–29%, personality change of 33.3%, dementia 8.16% and substance use 3–8%.

Conclusions We have identified significant rates of neuropsychiatric morbidity in patients with traumatic brain injury. We have particularly identified limited research studies into psychosis, mania, dementia and personality disorders in this patient group. The review further emphasises the importance of identifying neuropsychiatric comorbidities in post-traumatic brain injury and the importance of addressing these comorbidities.

One risk factor of depression disorder in Chinese women

Y. Zhang^{1,*}, L. Feihu², D. Zunxiao¹, S. Jianguo¹, W. Qiangju¹

¹ Xi'an mental health center, pharmacy lab, Xi'an, China

² Xi'an mental health center, science and education department, Xi'an, China

* Corresponding author.

Background The prevalence of major depressive disorder (MDD) is higher in those with the unemployed and those with low social status. Most of the available data comes from studies in developed countries, and these findings may not extrapolate to developing countries. However, the extent of unemployed status cause MDD is unclear. This study seeks to determine whether depressive disorder is associated with unemployment and to further investigate the relationship between occupation, and social class in Han Chinese women with MDD.

Method Data came from Oxford and VCU Experimental Research on Genetic Epidemiology (CONVERGE) study of MDD (6017 cases, age between 30 and 60; 5983 controls, age between 40 and 60). DSM-IV depressive and anxiety disorders were assessed using the World Mental Health Composite International Diagnostic Interview. All subjects were interviewed using a computerized assessment system. All interviewers were trained by the CONVERGE team for a minimum of one week. The interview includes assessment of psychopathology, demographic and personal characteristics, and psychosocial functioning.

Results The odds ratio (OR) between employment and MDD is 0.69. An OR of less than one is protective. Lower social class is not associated with an increase in the number of episodes, or with increased rates of comorbidity with anxiety disorders.

Conclusion This study suggests that in Han Chinese women, employment is positive protect factor to MDD. Lower social status and unemployment increases the risk and severity of MDD. In

China, lower socioeconomic position is associated with increased rates of MDD, as it is elsewhere in the world.

Involuntary hospitalization in a mental health unit in 2014

A.M. Alvarez Montoya^{1,*}, C. Diago Labrador², T. Ruano Hernandez³

¹ Algeciras, Spain

² Clinica Privada, Psiquiatria, Algeciras, Spain

³ Clinica Privada, Psicologia Clinica, Malaga, Spain

* Corresponding author.

Objectives Deliver a detailed analysis of the mental distortions, which led to involuntary hospitalization in a mental health unit in 2014 and their gender distribution.

Method We analyze the total number of hospitalizations in our mental health hospital unit. From the patient registry, we extract the type of hospitalizations (voluntary or involuntary), the diagnosis and the gender.

Results In our analysis, we find a total of 315 hospitalizations. One hundred and fifty-nine (50.48%) of them are voluntary, 150 (47.62%) are involuntary and 6 (1.90%) are a result of a judicial order. From the total involuntary hospitalizations, 81 patients were diagnosed as psychotics disorders (60%), 34 (25.18%) affective disorders, 11 (8.14%) personality disorders, 3 (2.22%) adaptative disorders, 2 (1.48%) mental retardation and 2 (1.48%) autism spectrum disorders.

Conclusions According to article 763 of Spanish Procedural Law (Ley 1/2000 de Enjuiciamiento Civil) from the 7th of January: "The hospitalization of a person due to mental disorders who is not in a condition to decide for himself/herself, even should he/she be a subject to parental authority or guardianship, shall require court authorization, which shall be obtained from the court of the place of residence of the person affected by such hospitalization." For this reason the involuntary admission is considered as an exceptional and necessary measure, which is limited in time.

Ethical aspects of involuntary outpatient treatment

S. Galiano Rus^{1,*}, A. Soler Iborte², Á. López Díaz¹

¹ Servicio Andaluz de Salud, UGC Jaén Norte, Unidad de Salud Mental Hospitalaria, Úbeda, Jaén, Spain

² Servicio Andaluz de Salud, UGC Jaén Norte, Unidad de Salud Mental Comunitaria, Linares, Jaén, Spain

* Corresponding author.

Introduction Involuntary outpatient treatment (IOT) is a type of non-voluntary treatment applied in the community, which tries to ensure the therapeutic compliance of patients that have a severe mental illness.

In Spain, a specific legal regulation about this matter does not exist; however, it is a fact in clinical practice. The application of IOT is not without controversy, with advocates, who consider it a way of

achieving therapeutic compliance, and detractors, who think it is an infringement of the fundamental rights of a person.

Objectives/methodology An evaluation of the knowledge on IOT in Spain. Analyze the four ethical principles found in this treatment.

Results The protection of the patient is encompassed in the principle of beneficence. And how could we combine this with the principle of autonomy? The answer should be individualized and based on a determined disorder. Starting with non-maleficence, we ask if IOT would provoke a rejection so that the patient would distance himself further from the therapeutic environment. As for the principle of justice, the high cost by patients that do not comply with the treatment would be diminished if we are able to have them follow the treatment with higher effectiveness. This would allow a greater number of patients to access these resources.

Conclusions The proposal of IOT should be preceded by a deliberative process. This process should include a psychiatric diagnosis that includes not only psychiatric aspects, but psychological, familial and social as well. This would compel us to create a personalized design of the therapeutic needs of each patient.

Ethical issues in neuroscience

G. Grbesa*, M. Simonovic, M. Zivkovic

University of Nis, Faculty of Medicine, Psychiatry, Nis, Serbia

* Corresponding author.

Introduction The authors start from the existing conviction that all issues concerning people are ethical eventually. We would like to know if the final goal of each our action is beneficial to people. Contemporary researches in neuroscience bear certain risks, as the achievements in this field can change the way people think and behave.

Method The authors use a retrospective method to present the researches in neuroscience, especially in the plan of cognitive psychology. In the 1980s, Tonegava investigates the molecular base of learning, the role of enzymes and genes and opens the possibility of implanting false memories. Later studies reveal brain connections, which control positive and negative memories. Optogenesis changes emotional reactions. Performing genetic manipulation (Tet1), stressful emotions can be substituted by positive ones. Clinical studies involving schizophrenic patients reveal the possibility to increase cognitive skills.

Results The number of cognitive studies does not match the number of newly discovered drugs. The results of the studies remain the property of institutions, which financially support the researches. The researches set the following questions in front of the researchers: which level of risk is acceptable? Who bears the risks? Who decides? Ethical questions set in front of the researchers are: what are the consequences of the researches?

Conclusions The ordered researches are fragmented and they do not provide the researchers with the final aims of the researches. The researchers are deprived of the insight of whether the results will be applied on the population of diseased or healthy subjects with specific aims.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The burden of caregivers of patients with Alzheimer's disease

G. Jmii¹, G. Hamdi^{1,*}, L. Robbana¹, M. Karoui¹, I. Ben Ghzaïel¹, R. Rafrafi²

¹ Razi Hospital, G, Mannouba, Tunisia

² Razi Hospital, 1, Mannouba, Tunisia

* Corresponding author.

Introduction The important role of family caregivers, particularly among Alzheimer's patients is increasingly recognized. The Alzheimer's patient assistance relationship is a morally painful experience, most frequently discussed in terms of "burden" in the literature. We intended to assess the level of burden among caregivers of patients with Alzheimer's disease and to search factors associated with a high level of burden.

Methodology This is a retrospective descriptive study. Patients were recruited from neurology department of Razi hospital. The burden was measured using the Zarit inventory.

Results and discussion Thirty patients were included, the majority female. Most caregivers are descendants (60%), then, daughters-in-law (33.33%), and finally the spouses (23.33%). Eighty percent of caregivers lived in the same home as patients. The average burden in our sample is 59.9 ± 16. We observed that 3.33% have absent to light burden (score < 21), 10% have a light to moderate burden (between 21 and 40), 36.66% have moderate to severe burden (between 41 and 60) and 50% have a severe burden (> 60), according to the classification proposed by Zarit. Sex, kinship and cohabitation with the patient were not associated with a higher burden. Caregivers who support more severe patients have a higher burden. Thus, behavioral disorders are more frequent or severe and the numbers of incapacity to perform activities of daily life are more important. However, there the gravity of burden is not affected by age of the assisted person.

Conclusion The study of factors correlated with high levels of burden aims at finding ways of intervention. However, the research needs to be broadened to further analyze the causal links between these factors.

The Satanist cult of Ted heath: Ethical implications of authority compromise

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction Seven UK police forces are currently investigating the alleged involvement of the late Edward Heath (Prime Minister 1970–1974) in a child abuse ring with Operation Midland investigating specifically the alleged murder of three boys.

Objective The presentation raises international awareness of the investigation, sheds light on the suspected 'Satanist' ideology behind the cult and explores the implications for professional practice.

Aims The paper highlights the corrosive impact on society of powerful pedophile rings that are protected by compromised authority representatives and professionals.

Method Detailed accounts circulate on the Internet that name dozens of individuals allegedly active in the cult including high-ranking politicians, psychiatrists, psychologist, police officers as well as journalists and academics. Some of the alleged crimes can be corroborated with news reports or successful court prosecutions while the vast majority appear to be 'known crimes' that are successfully covered up.

Results The widespread organisational structures parallel the Marc Dutroux case in Belgium. It appears to be the case that compromised mental health professionals and authority representatives shield the cult. It becomes an ethical obligation for the silent majority to speak out against such criminality and demand from their government effective investigation and prosecution.

Conclusion Whilst an enquiry into historical allegations of institutional abuse is currently underway in the UK several cases emerged recently where satanic cults seemingly continue to be

protected by the vested interests. Mental health professionals must stand up for victims and resist ill-conceived authority attempts to persecute abuse survivors and their supporters.

Background The problems that a client presents with to therapy may be associated with his possibility of free choice.

Method Review of psychotherapeutic and cognitive behavioral literature.

Results From a psychological perspective, freedom may be either inner or outer, depending on the nature of obstacles and barriers that limit freedom. Therapy may be understood as a process through which the client is guided to actively increase his freedom. This refers to freedom from destructive habits, self-limiting attitudes, compulsive actions, symptoms etc. When creating the relationship, neither the client nor the therapist is entirely free as they bring past conscious and unconscious experiences into it. From the point of view of CBT, freedom is always relative. The idea of absolute freedom results from cognitive distortions – black and white thinking. CBT does not consider overall freedom but relatively free decision-making in particular situations that the client is in. The therapist helps the client to identify his errors in thinking and to learn a more realistic way to formulate his experiences and to use the new attitude to decide more freely. The change in attitude is realized through rehearsing freer behavior and experiments with it in one's life.

Conclusion Freedom may be either inner or outer, depending on the nature of obstacles and barriers that limit freedom. Therapy may be understood as a process through which the client is guided to actively increase his freedom.

⁷ Faculty of Social Science and Health Care, Constantine the Philosopher University, Department of Psychology Sciences, Nitra, Slovakia

* Corresponding author.

Background Values influence our thought patterns, emotions, wishes, and needs. Although individuals may be fully aware of their value systems, these often lie more or less outside the area of full consciousness. At least occasional awareness of one's priorities and set of values may be an effective means of self-regulation.

Method Literature review and description of cases.

Results Cognitive behavioral therapy is aimed at dealing with practical problems and goals in life through changes in cognitive processes, behavior, and emotional reactions. Changes to some values naturally accompany changes to these processes. Life values also underlie motivation to achieve therapeutic changes. For this reason, clarification of patients' life values is important to therapists as focusing on values aids in connecting therapeutic goals with important areas of life. In addition to a better understanding of patients' life stories and difficulties that have brought them to a psychotherapist, the identified value system may become a part of everyday CBT strategies such as time management, cognitive restructuring or accommodation of conditional assumptions.

Conclusion Identification and assessment of life values and their use in the course of therapy is a process that increases patients' motivation to face unpleasant emotions and make careful steps in CBT in order to achieve therapeutic goals. Knowing the patient's life values may help the therapist set therapeutic goals that are associated with significant areas of the patient's life. Together with other CBT techniques, this value-oriented approach increases the effectiveness of therapy and durability of its outcomes after its completion.

EV676

Issues regarding compulsory treatment in compulsory admitted mentally ill patients

C. Tsoelas

Psychiatric Hospital of Attica, 5th Dept of Acute Admissions, Athens, Greece

Introduction In psychiatric clinical practice compulsory admission to hospital is the last option of the overall care provided to mentally ill patients, justified in terms of civil and human rights because of issues of protection for patients' and society members' life and health. Usually treating psychiatrists believe that issues of compulsory admission are without doubt associated with the permission, or even obligation, to apply compulsory treatment in a routine daily base.

Aims In this review, we are exploring issues around the implementation of compulsory treatment.

Methods Thorough research of the main databases and web search engines for relevant studies, agencies and organizations, interested in compulsory treatment issues.

Results Research shows ambiguous views. Conservatives argue that delay of any substantial, even enforced, and well documented treatment, would result in delay of treatment and excess use of other potentially more enforced methods. Using laws and legislation patients' rights are guarded but we also have the obligation to treat patients. On the other hand, liberals express totally opposite views. Capacity (or incapacity) is not 'all or nothing' but specific to decision and should be respected, with the exception to emergency treatment need.

Conclusions The capacity of decision-making of the mentally ill patient, whether or not being compulsory admitted, should be assessed in a more holistic and systematic approach and become part of the standard practice, followed by dissemination of these decisions to all relevant parties. Restore decisional autonomy should be one of the main goals of any therapeutic intervention.

Disclosure of interest The author has not supplied his declaration of competing interest.

EV677

Moral obligation to acknowledge and prevent suicide in life sentence incarcerated inmates

C. Tsopelas

Psychiatric Hospital of Attica, 5th Dept of Acute Admissions, Athens, Greece

Introduction For an inmate incarcerated for life we could acknowledge factors contributing to the desire to commit suicide, as social isolation, insensitive discipline, lack of privacy, constant threat of violence, fear, guilt, hopelessness, and depression are prominent in the life imprisonment.

Aims To discuss the ethical issues of prevention suicide in inmates incarcerated for life.

Methods We performed thorough research of the main medical databases, and web search engines for relevant studies, articles and opinions and reviewed them independently.

Results Prevalence of mental illness is high among inmates and several common stressors typically herald an inmate's suicide. Suicide is often the single most common cause of death in correctional settings. Even though some suicide victims have consulted a mental health service-provider before their suicide, the majority of suicide victims were not mentally ill. The paradox, particularly for life sentence inmates is that we are trying to persuade an inmate to live within a disciplinary environment, which has as side effect the increase of suicidality of the inmates.

Conclusions Prisons' inability to protect the health and safety of inmates could raise ethical issues. We have obligation to adequate suicide prevention for all inmates, and we should be more broad minded as the will to die in mentally healthy individuals is beside a free will expression, a sign of serious lack of support and humane living conditions. We should be vigilant not to use the prevention of suicide programs as another way to increase punishment of life long imprisonment.

Critical analysis on legal capacity of the mentally retarded: The Portuguese reality in the European context

R. Cajão^{1,*}, C.A. Pereira¹, J.R. Silva¹, J.P. Lourenço¹, N.P. Gil¹, M.F. Colón²

¹ Centro Hospitalar de Tondela-Viseu, EPE, Departamento de Psiquiatria e Saúde Mental, Viseu, Portugal

² Instituto Nacional de Medicina Legal e Ciências Forenses, IT, Unidade Funcional de Clínica Forense da Delegação do Centro, Coimbra, Portugal

* Corresponding author.

Introduction Almost 50 years after the mental health reform in Europe and the deinstitutionalization of the mentally ill, there seems to be a slow change in the social concept of mental disorder. However, in the case of mental retardation, little progress has been made, since the social approach to these patients does not seem to involve the promotion of their autonomy. This is a reality with implications in medical, social and forensic psychiatry settings.

Objective We will present a statistical analysis on interdiction/inhabilitation processes in two districts of Portugal followed by a comparative analysis between Portuguese and other European countries' civil law concerning the regulation of legal capacity.

Aims Critical analysis of the means by which the concept of legal incapacity has been applied in the Portuguese social setting.

Methods Descriptive and retrospective analyses of 500 expert reports in the districts of Coimbra and Viseu regarding interdiction/disqualification processes. Research on Pubmed and legal databases; keywords used: mental disability, mental retardation, civil law, mental incapacity, legal incapacity, legal capacity, interdiction, curator.

Results The number of forensic psychiatric examinations has suffered a significant increase in the last years. The majority of these expertise concern interdiction/inhabilitation processes. Mental retardation is the more prevalent diagnosis, and the great majority of the cases were interdicted.

Conclusions In Portugal, the law has been applied in order to safeguard the economic assets of mentally retarded individuals, but not in order to promote their social integration and autonomy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV679

Patterns of long acting injectable antipsychotic prescription during criminal acts in a Portuguese psychiatric hospital

M.A. Duarte^{1,*}, F. Vieira², A. Ponte¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Clínica Psiquiátrica 6, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Regional Forensic Inpatient Unit, Lisbon, Portugal

* Corresponding author.

Introduction Under the Portuguese law, criminal offenders that are designated as non-criminal responsible – “inimputáveis”, similar those in the United States of America found “not guilty by reason of insanity”, are forced to be committed to inpatient forensic units either in psychiatric hospitals or prison hospitals for mandatory security measures.

Objectives/aims To evaluate if patients committed in a regional forensic inpatient unit (RFIU) who had a psychiatric history preceding the crime, were under long acting injectable antipsychotic (LAIA) in during the period of the crime.

Methods During September/October 2015, patients committed to the RFIU in Centro Hospitalar Psiquiátrico de Lisboa were characterized using medical and court records regarding clinical and demographic variables. The type of crime and previous number of criminal acts were also accounted for.

Results We included 33 patients in the study. During time of the crime, 25 patients (75.8%) had history of previous psychiatric appointments, with an average of 3 commitments to the psychiatric inpatient units. The majority ($n = 17$; 68%) had a diagnose of “schizophrenia, schizotypal and delusional disorders” (F20–29; ICD 10) and committed “crimes against life” ($n = 13$; 52%). They had an average of 0.8 previous criminal acts. During the crime, 7 patients (28%) were taking LAIA. Those, 16% ($n = 4$) were doing an unknown antipsychotic and 12% ($n = 3$) were doing Haloperidol.

Conclusions Despite several studies showing the clinical and rehabilitative benefit of using LAIA early in the disease course, most of the patients in our study, who were already being followed in outpatient psychiatric units, did not benefit from them.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV680

DSM-5 clinical/legal challenges regarding the USA's death penalty

L. French
Webster, USA

Introduction In May 2013, the American Psychiatric Association (APA) published the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)* in order to bring America's clinical professionals in concert with the World Health Organization's (WHO) international classifications, notably the ICD-10-CM. This effort was met with considerable resistance and changes were delayed until November 2015. Major social-cultural differences between the United States and its European and other North American partners (Canada and Mexico) poses challenges in critical forensic areas such as the clinical/legal assessment of death qualified offenders – a status unique to the USA.

Objective/aims To articulate the clinical/legal differences between the previous DSM's (III; III-R; IV) and the DSM-5 and how the new language provides greater ambiguity in defining the mental status requirements for *Mens Rea* – competence to understand one's actions.

Methods Present the major legal issues surrounding the US death penalty and brought before the US Supreme Court including: *Furman v. Georgia* (1972); *Greg v. Georgia* (1976); *Jared v. Texas* (1976); *Proffit v. Florida* (1976); *Adkins v. Virginia* (2002); *Roper v. Simmons* (2005); *Miller v. Alabama* (2012): ... and legislative actions such as Rosa's Law (Public Law 111-256; 2010).

Results/conclusions Advocacy groups pushed Rosa's Law to mental retardation with – intellectual and developmental disability. This change is reflected in the DSM-5 whereby mental retardation (MR) was once relegated to axis II, is now classified under intellectual disabilities (ID) given the impression that it is a transitory (correctable) and not a fix (organ disability) clinical condition.

Disclosure of interest The author has not supplied his declaration of competing interest.

When patients with paranoia commit medicolegal acts: A descriptive study

B. Ghajati*, S. Ghezaiel, R. Chebbi, I. Berrahal, R. Ridha
Razi Hospital, Forensic psychiatry, Tunis, Tunisia

* Corresponding author.

Patients with paranoia have always been an attractive and redoubtable group of mentally ill to mental health professionals. In fact, beyond complex psychopathology and relatively better functioning, these patients do represent a real threat to themselves and their presumed persecutors.

Objectives To explore criminological aspects of medicolegal acts committed by patients with paranoia.

Methods We conducted a retrospective and descriptive study, based on medical charts consult. Were included, patients suffering from paranoia (persistent delusional disorder: jealous/persecutory/erotomania type, DSM-IV), hospitalized in the forensic psychiatry department of Razi hospital between 1995 and 2015. This psychiatry department provides medical care for male patients not held by reason of insanity, according to article 38 of the Tunisian Criminal Code. Patients' socio-demographic characteristics were collected as well as criminological details of their acts of violence (victim, weapon type, crime scene, premeditation...).

Results We collected 23 patients. Delusional disorder types were: jealousy (17), persecution (4), erotomania (1) and claim (1). The majority was married (18), undereducated (17), with irregular work (13). Forensic acts were uxoricide (15), attempted murder (5), violence against people (2) and destruction of public properties (1). Patients used bladed weapon in most of the cases (13), in the victim's residence (19), with premeditation in (17) of the crimes. Nine patients reported their act of violence to the authorities.

Conclusion Our results do expose further data concerning potential dangerousness of patients with delusional disorders, and by that invites mental health professionals to prevent these acts with screening for violence predictors and risk factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Parricide is defined as the homicide of a father or mother by a biological or adopted child. In adults, it is generally associated to a psychotic condition. Scientific research on the subject, have been mainly interested in matricide, patricide or double parricide. Studies comparing authors of patricide to those of matricide are rare.

Objectives To compare socio-demographic and clinical profiles of patricide and matricide patients.

To compare modus operandi in matricide and patricide patients.

Methods A retrospective, descriptive and comparative study was conducted, based on medical charts' consult. Were included patients suffering from psychotic disorders (DSM-IV), hospitalized in the forensic psychiatry department of Razi hospital between 1995 and 2015, after not being held for insanity according to

article 38 of Tunisian Criminal Code. Only patients who committed patricide or matricide were included.

Results Our sample included 26 patients (13 patricides; 13 matricides). There was non-significant differences between two groups concerning: instructional level ($P=0.277$), professional status ($P=0.387$) and marital status ($P=0.790$). Committers of patricide and matricide did not differ in terms of psychiatric diagnosis ($P=0.242$) and substance abuse ($P=0.550$). A significant difference was found between the two groups in terms of schizophrenia subtypes, patricide patients suffered from a disorganized schizophrenia whereas matricide patients suffered from paranoid subtype ($P=0.05$). Patricide was more frequently associated to a conflictual relationship between son and father ($P=0.05$). We did not record a significant difference in the crime weapon or its motivations.

Conclusion Our results helps draw a profile for parricide patients in order to help identify the ones at risk.

Causes of institutionalization of children and adolescents in a shelter in Brazil

E. Guilherme^{1,*}, S. Duarte², R. Farias³, M. Steidel⁴

¹ Psychosocial Care Center, Rio Negro-PR, Prefeitura municipal de Rio Negro-PR, Mafra, Brazil

² Contestado University, Psychology, Mafra, Brazil

³ Psychosocial Care Center-Rio Negro-PR, Prefeitura municipal de Rio Negro-PR, Rio Negro, Brazil

⁴ Abrigo Institucional Mafra, Prefeitura municipal, Mafra, Brazil

* Corresponding author.

Introduction Shelters or orphanages are institutions responsible for ensuring the physical and mental integrity of children and adolescents who had their rights violated or neglected, whether from a social-levers, is at personal risk to which they were exposed or the negligence of its parents; in Brazil about 20,000 children and adolescents living in about 500 registered shelters that receive funds from the federal government.

Objectives Assess causes of institutionalization of children and adolescents in a shelter in Mafra/Santa Catarina State, Brazil.

Aims Demonstrating the causes of shelter, it is easier to point out the solutions and try to charge the responsible authorities to comply with the child and adolescent statute.

Methods We evaluated the records of institutionalized children and adolescents from the municipal shelter in Mafra/Santa Catarina State, Brazil since January/2011 to July/2015.

Results Institutionalization of the causes cited were: lack of family/guardian material resources, abandonment by parents/guardians, domestic violence, substance abuse of parents/guardians, street experience, orphans and others.

Conclusions In Brazil, poverty and extreme poverty are closely related to the institutionalization of causes of children and adolescents. Census data in 2010, the Brazilian Institute of Geography and Statistics (IBGE) indicate that 40% of Brazilians living in poverty are girls and boys up to 14 years in a total of approximately 23 million individuals. Poverty denies children and adolescents their rights, representing a vulnerability, which predisposes to some causes of shelter.

Mentally ill patients who committed sexual and physical assaults: A study about 37 cases of expertise reports

K. Hajji*, I. Marrag, R. Ben Soussia, S. Fathallah, M. Nasr

University Hospital of Mahdia, Department of Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Several studies suggest the existence of a relationship between major mental disorders and crime. However, it is important to emphasize that violent behaviors do not affect all patients and that issues of criminality among mentally ill persons only represents a small proportion.

Aims The objective of this study is to establish the general and clinical profile of perpetrators of sexual and physical assaults.

Methods This is a retrospective study of the records of forensic psychiatric expertise, conducted in the psychiatry department of the University Hospital of Mahdia during the period from May 1st 2000 to May 31st 2013.

Results The general profile of the population the study was characterized by a mean age of 39 years, a sex ratio of 8.25, unemployment in 73% of cases and by the presence of a psychiatric personal history 54% of cases. Sexual and physical assaults accounted for 54.5% of cases. It was essentially in descending order: assault and battery (65%), rape (16.2%) and incest (5.4%). As for the clinical profile, schizophrenia and epilepsy were recorded each in 13.5% of cases, major depressive disorder in 8.1% of cases, bipolar disorder in 5.4% and substance abuse in 5.4% of cases. A personality disorder was observed in 48.6% cases, essentially antisocial personality (55%). Comorbidity with addictive behavior was observed in 56.7% of cases.

Conclusion It is necessary to characterize a subgroup of patients with mental disorders, likely to commit violent crimes, in order to prevent acting out behaviors and adapt their management.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Acute psychotic disorder and forensic acts: About 25 cases

S. Younes, R. Ben Soussia, K. Hajji*, I. Marrag, L. Zarrouk,

M. Nasr

Universitary Hospital of Mahdia, Department of psychiatry, Mahdia, Tunisia

* Corresponding author.

Background The aim of this study was to identify the socio-demographic status and clinical features of patients with acute psychotic disorder and who committed a medicolegal act, seek acute psychosis implicated and raise the characteristics of this medicolegal acts.

Methods We performed a retrospective study of 25 male patients with acute psychotic disorder. They were involuntary hospitalized in the medicolegal department of Razi, according to Article 29 of Law after committing a medicolegal act because of dementia within the meaning of article 38 of the Tunisian Penal Code.

Results It was about a young person, average age of 27.32 years, family cohesion was often present (80%), with forensic history (20%), violence history (20%) and substance abuse (40%), having a personality disorder (25%), having a precipitating factor (32%), having an acute psychotic episode (72%), repetitive acute psychotic episode (16%), a first manic episode (8%) and drug-related psychotic disorder (4%). They had committed by order of frequency serious physical assault (43.5%), attempted murder, assault and injury followed by attacks against property (40%). The victim was mostly a family member (40%), without determination, under the influence

of toxic substances (16%) and motivated by delusions of persecution (51%). The acting out was recognized (68%). The majority was indifferent (92%) and does nothing (68%).

Conclusion The first-episode psychosis have a high-risk of acting out, early treatment may prevent some medicolegal acts. Preventing of acting out in the psychotic involves the identification of risk factors and an early treatment of mental disease.

Stalking and its forensic psychiatric assessment

L. Izáková^{1,*}, I. André²

¹ Comenius University Bratislava, Department of Psychiatry, Bratislava, Slovakia

² University Hospital Bratislava, Department of Psychiatry, Bratislava, Slovakia

* Corresponding author.

Introduction Stalking, a dangerous persecution, gained attention because of persecution of celebrities by fans suffering by mental disorders. In psychiatry, there is no consensus about the exact definition of stalking, because it can result from many different motivations and constellations of psychopathological symptoms.

Objective The authors provide an overview of the current state of stalking, i.e. dangerous persecution as a new crime in Slovakia. They describe the characteristics of stalkers (persecutors), victims and their interaction in their forensic psychiatric practice.

Method Search in author's expert reports were conducted on stalking. Analysis of motivations, mechanisms of persecutions and analysis of psychopathological symptoms and mental disorders in stalkers and their victims were made.

Results Stalkers and their victims are a heterogeneous group with different psychopathology and mental disorders including personality disorders and psychosis. The authors document general principles of forensic psychiatric assessment of stalkers as crime offenders.

Conclusion Stalking is problem also in forensic psychiatric practice also in Slovakia. Stalkers who suffer from mental disorders require adequate diagnostic and psychiatric treatment also in forced setting.

Forensic psychiatric aspect of battered women syndrome: The cycle of violence

M. Kachaeva

Serbsky National Research Centre for Social and Forensic Psychiatry, Moscow, Russia

Introduction Domestic violence against women is a burning problem in Russia. Forensic psychiatrists found out that domestic abuse against women is often one of the main causes of crimes of violence in women.

Aims To find out clinical and social factors contributing to aggressive crimes committed by women who are victims of intrafamily violence.

Methods Clinical, psychological, statistical. Details of background, psychiatric and offending history were extracted. Each item was assessed with the help of descriptive statistics.

Results A cohort of 12 females was examined by forensic psychiatrists. All women were victims of violence by their husbands or

partners. Domestic abuse resulted in long-term mental problems of women. Clinical assessment has revealed depression, anxiety, fear, low self-esteem, PTSD, alcohol abuse. All women had committed murders. The research has revealed two types of homicides. Women of the first subgroup displayed pathological altruistic motivation of murder of their children (4 females). Women of the second subgroup (8 females) had committed homicides of their husbands or partners.

Conclusion The research shows the necessity of domestic violence prevention by legal provisions and multidisciplinary research with the participation of psychiatrists, psychologists, social workers.

OST in forensic psychiatry – risk management: Bosnia and Herzegovina experience

S. Kasper*, J. Softić, N. Mujcinovic

Cantonal Institute for Addictions, Hospital Department, Zenica, Bosnia and Herzegovina

* Corresponding author.

This paper describes the experience of the Cantonal Institute for addiction in the implementation of OST. In analysis included patients who had been serving a prison sentence in Zenica and Busovaca. The focus of the work has focused on the possible role of the OST in preventing the commission of criminal acts and social rehabilitation of opiate addicts. The study included 296 opiate addicts (239 on methadone and 57 on buprenorphin/naloxone). Medium age was 31.3 years and 10% of the respondents were women. Criteria for inclusion in the study were clinically proven opiate addiction and involvement in some of the aspects to treatment at the Institute while the criteria for inclusion in the study were non-opioid dependence and the presence of comorbid psychiatric conditions that could affect the study results. Results of the study showed that the OST, regardless of the applied modalities have a significant effect in preventing the commission of criminal offenses, and improves results, socio-rehabilitation treatment for convicted persons who are serving a prison sentence, and those who are on parole. Improving results has contributed to the use of other therapeutic modalities (psychotherapy). Other studies with a larger number of patients and monitoring of a large number of variables could give better answers about the place and role of the OST in forensic psychiatry.

Poor quality of mental health assessment reports in UK family courts: A 'call to action'

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction Prof. Jane Ireland found that 65% of assessment reports sampled from UK family courts were 'poor' or 'very poor'.

Objective The presentation raises international awareness of the problem and explains the contextual factors that contribute to malpractice.

Aims The paper highlights typical deficiencies in family court assessments and forensic processes in order to reduce the risk of unsafe custody rulings.

Method Due to the paucity of published academic literature 'ad hoc' Internet searches were utilised to collect source material and identify advocates. A range of conferences, seminars and continued professional development (CPD) events revealed the background for some of the persistent problems.

Results The suppression of the trauma-centric approach to mental health issues and its re-emergence are central to understanding the trajectory and how to improve professional practice.

Organised Ritualised Crime Abuse Networks (ORCANs) seem to be at work infiltrating institutions that are supposed to uphold law and order.

Inadequate psychometric instruments appear to beguile some mental health professionals into wrong diagnosis and testimony.

Conclusion The standard of UK family court assessments must improve. Scrapping 'forced adoption' legislation that drives the 'child snatching' culture in UK social services department would benefit society including citizens from abroad whose governments vocally criticise the removal of their children through clandestine UK 'child protection' procedures.

Disclosure of interest The author has not supplied his declaration of competing interest.

Prevalence and nature of mental disorders among young offenders in custody and community: A meta-analysis

M. Livanou*, V. Furtado, S. Singh

University of Warwick, Warwick Medical School Division of Mental Health and Well-being, Coventry, United Kingdom

* Corresponding author.

Introduction Prevalence studies show that nearly 80% of young offenders present psychiatric comorbidity. Juvenile offenders are at 3 times higher risk of being diagnosed with a psychiatric disorder. Recent systematic reviews have mainly focused on youth in detention neglecting youth in the community. Females and ethnic minorities have been overlooked in the literature in spite of the increasing rates of psychiatric disorders striking these groups.

Objective To perform a meta-analysis on the prevalence rates of various mental disorders including depression, psychosis, PTSD, conduct disorder, ADHD, learning disabilities and personality disorders among young offenders. Self-harm and suicidal behaviour are examined too.

Aims To compare the prevalence of psychiatric disorders among young offenders across custody and community and to emphasise on gender, age, and ethnic variations.

Methods Relevant studies have been identified with computer-assisted searching and scanning of reference lists. Prevalence of mental disorders based on gender, age and ethnicity along with potential moderating factors are extracted from the included studies. Meta-regression is performed to test covariates that might have contributed to differences in prevalence rates across studies.

Results After searching the relevant literature, 99 studies were determined to be eligible for data extraction.

Conclusions Young offenders with ongoing mental health problems comprise a vulnerable group within forensic psychiatric services that needs special attention. More prevalence studies should be conducted to improve mental health provision. Ethnic, gender, and age variations across young offenders should be addressed and turn interventions into a tailored process that responds to the young person's particular treatment needs.

Co-responsibility of the victim in maintaining violent interactions in the parental couple

M. Loi^{1,*}, P. Brambilla²

¹ Private practice, Psychiatry, Milan, Italy

² Private practice, Psychology, Milan, Italy

* Corresponding author.

The few international studies that dealt with the characteristics of the victim, suggest the possibility that, in certain circumstances, psychological, psychopathological and behavioral variables, may increase the risk of violence within a couple relationship (or also inhibit the possibility that the victim falls outside the violent interaction).

We would like to better comprehend violence within a parental couple relationship, which is considered as a dynamic and two-way system, and understand how violent interactions are triggered and maintained by both partners, and, therefore, by the victim too.

Our aim is consequently pinpoint those factors, which, on several levels, make the victim become one, within a dynamic and vicious collusion with the aggressor.

We have analyzed 30 forensic court consultancies carried out in separation and divorce conflict, within which violence, acted out by one partner against the other, was detective.

The data obtained from descriptive profiles of personality (derived from biographical data, clinical observation and psychological assessment) of the victims suggest that some variables can trigger and maintain the violence within the couple. Among these are reported: masochism, learned helplessness, depression, low self-esteem, primary attachment disorders, emotional dependency, ego disorders, depression, anger, passivity, submission, lacking social and communication skills, low problem solving ability, violence in the family of origin, substance use.

The identification of these variables seems particularly useful to prevent victim's intrapsychic and interpersonal dysfunctional dynamics, and can suggest interventions aimed at correcting these dynamics, with a consequent risk reduction even in separation and divorce conflicts.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Results of forensic assertive community treatment in Belgium after 33 months

T. Marquant^{1,*}, K. Goethals^{2,3}

¹ CAPRI collaborative Antwerp Psychiatric Research Institute, forensic psychiatry, Antwerp, Belgium

² Collaborative Antwerp Psychiatric Research Institute, CAPRI University of Antwerp, Antwerp, Belgium

³ Mental Health Care Westelijk Noord-Brabant, Halsteren, the Netherlands

* Corresponding author.

Introduction Forensic adaptations of assertive community treatment (ACT) remain understudied in Europe, whereas promising results emerge from the United States. There is a need for research into the effectiveness of ForACT outside the United States, as Europe differs greatly in terms of organisation of mental health and judicial system.

Objective Investigating effectiveness of forensic adaptations of ACT in the area of Flanders, Belgium. Outcome measures are divided into forensic, like arrests or incarcerations, and non-forensic, like admissions and length of stay.

Aims Investigating effectiveness of ForACT on forensic and non-forensic outcome measures as well as factors related to outcome.

A third outcome is community tenure, which is the actual number of days divided by the potential number of days spent in the community.

Methods A controlled cohort study was designed over with first results at 33 months. The experimental group consists of a new ForACT team in the area of Flanders, Belgium ($n = 70$). Patients are admitted from prison, psychiatric hospitals or other community-based care. The control group consists of mentally ill offenders in community-based treatment after release from prison ($n = 56$).

Results Results on forensic measures and community tenure are promising in favour of the ForACT team. In contrast, clients are often, though shortly, readmitted into psychiatric residential care. Substance use emerges as the main reason for admissions.

Conclusions A local forensic adaptation of ACT reveals promising results on forensic outcome measures, yet suffers a large number of admissions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Peculiarities of mental status and criminal behavior in individuals under cannabinoid consumption

V. Martinkiene*, A. Survilaite

Forensic Psychiatry Service, Adult Department, Vilnius, Lithuania

* Corresponding author.

Introduction Substance-related mechanism may be capable of promoting brain changes in high-risk individuals [1,2]. Cannabis use reported to be associated in long-term cognitive effects.

Aim To evaluate mental status and criminal behavior in individuals under cannabinoid consumption in forensic psychiatric assessment.

Methods A retrospective analysis was conducted of forensic psychiatry examination reports in psychoactive substance consumption cases ($n = 170$) in National Service of Forensic Psychiatry 2010–2014. Offenders, which were reported with cannabinoid consumption ($n = 57$) were assessed by socio-demographic characteristics, mental state, court order and outcome.

Results Eighty-six percent offenders with cannabinoid consumption in observed period were men. The age of offenders prevailed from 18 to 35 years with basic education; 57.9% of offenders consuming cannabinoids were single (Fig. 1).

A total of 36.8% of all crimes in research group were committed against property, 31.6% – an unlawful possession of psychotropic substances, 22.8% – committed against human health, 8.8% – against public order (Fig. 2).

Conclusions Impulse control deficiency and emotion disorders were prevalent among offenders under cannabinoid consumption; 17.5% were committed irresponsible, all of them due to comorbid psychiatric disorder. More likely to offend were men, aged 18–35 years, single, who had basic or lower education.

Responsibility in offenders under cannabinoid consumption

Fig. 1 Peculiarities of mental status.

Responsibility in offenders under cannabinoid consumption

Fig. 2 Responsibility in offenders under cannabinoid consumption.

Explorations of cooperation and recalcitrance in secure mental health hospitals

M. McKeown^{1,*}, M. Chandley², F. Jones¹, K. Wright¹, J. Duxbury¹, P. Foy²

¹ University of Central Lancashire, School of Nursing, Preston, United Kingdom

² Mersey Care NHS Trust, Ashworth Hospital, Liverpool, United Kingdom

* Corresponding author.

This paper reports on the findings of three qualitative research studies undertaken within, respectively, medium and low secure units in one UK region, and a high secure mental health hospital in England (UK). The first study investigated alliance based involvement practices. The second explored service user and staff views and sense making of the notion of recovery. The third study is ongoing into service user and staff experiences of extreme coercive measures, such as forms of restraint and long-term seclusion or segregation. All studies utilised either semi-structured interviews or focus groups. All data was subject to thematic analysis. Selected and emergent themes include:

- the importance of relationships and communication; security first; involvement as pacification;
- different understandings of recovery; the importance of meaningful occupation; staff-service user relationships; recovery journeys and dialogue with the past; and recovery as personal responsibility;
- good and bad coercion; cooperation, resistance and recalcitrance; and alternatives to coercion.

Findings suggest that cooperation is largely framed by services in terms of compliance with a bio-medical model. The impact of the secure environment, whilst ever-present, is not an absolute constraint on the realisation of recovery or involvement objectives. The availability of extreme coercive measures raises some seemingly paradoxical understandings from both service user and staff perspectives. Critical social theory is drawn on to illuminate the tensions between cooperation and recalcitrance and suggest further exploration of their respective legitimacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effectiveness of paliperidone depot in seriously violent men with comorbid schizophrenia and dissocial personality disorder in a UK high-security hospital

A.M. Mortlock*, F. Larkin, C. Ross, S. Sengupta, M. Das
West London Mental Health NHS Trust, Broadmoor Hospital,
Berkshire, United Kingdom

* Corresponding author.

Introduction High-security hospital patients are often complex in presentation characterised by treatment resistance, medication non-concordance and history of violence. Paliperidone is licensed as both an oral and depot antipsychotic for the treatment of schizophrenia. Whilst there is data for the effectiveness of paliperidone palmitate (PP), there are no studies involving patients in forensic settings or those with comorbid personality disorder.

Objective To determine the effects of PP on violence, aggression and personality pathology.

Aim To evaluate the clinical effectiveness of PP.

Methods This was a retrospective service evaluation involving 11 patients. Medical records and interviews with the treating psychiatrist were used to formulate clinical global impression (CGI) and to identify incidents of violence. The effect on personality symptom domains; cognitive-perceptual, impulsive-behavioural dyscontrol and affective dysregulation was ascertained, as well as engagement with occupational and psychological therapies.

Results Six patients were being prescribed PP. All 6 showed improvement in the CGI score with benefits in the symptom domains. Two patients demonstrated a reduction in violence risk and 2 remained incident-free. There was improvement in engagement with therapies. Benefits were also seen in aspects of personality for those who had discontinued PP.

Conclusions This pragmatic study of a small but complex patient group demonstrated that PP was effective in reducing symptoms of schizophrenia. Additionally and for the first time, it was shown that PP was also effective in reducing violence as well as improving personality pathology dimensions in a comorbid patient. This could have significant implications for management of high-security patients.

⁵ Keyo Hospital, Psychiatry, Uiwang, Republic of Korea

* Corresponding author.

Introduction The systematized and proper sized research of alcohol pharmacokinetics in Korean has not reported ever.

Objectives and aim Aim of this study is to measure the β value and alcohol pharmacokinetic factors in Korean adult female and the relationship between the β value and some variables including age, smoking, total body water, drinking capacity, BMI, blood cholesterol, body fat and body fat ratio.

Methods Ninety-one subjects were randomly divided into two groups. One group was provided as much as 0.35 mg/mL/kg of alcohol and the other as much as 0.70 mg/mL/kg, and blood alcohol concentration was measured 15, 30, 45, 60, 90, 120, 180, and 240 min after the women finished drinking.

Results The subjects' mean alcohol elimination rate (β) was -0.002379 mg/100 mL·h, and there was no statistically significant difference in elimination rate between the two groups. The mean time to reach maximum blood alcohol concentration was 45 minutes, alcohol absorption rate was 0.1123 ± 0.1799 g/L/min, and the area under the concentration curve was 109.15 ± 62.95 . Among the factors that correlated with alcohol metabolism, alcohol absorption rate and follicle-stimulating hormone were statistically significant, but age, body mass index, and body fat percentage were not significantly correlated with alcohol metabolism.

Conclusions These results suggest that the β values for healthy Korean females can differ from the cut-offs that are currently used in Korea, which suggests that the legal limit for driving under intoxication should be adjusted.

The profile of the mentally incompetent patient of the local health unit of Guarda, Portugal

P. Batista*, J. Nunes, P. Da Costa

Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital, ULS Guarda, Guarda, Portugal

* Corresponding author.

Forensic psychiatry, as a specific branch of psychiatry, is the medical science that approaches mental illness and its relation with law enforcement. In this regard, medicine and justice converge in the contact with individuals that, due to the alleged assumption of acting under the effects of a psychiatric disease, have a disturbing behaviour and infringe the laws of Society. The objective of this research project, which has a retrospective nature, is to delineate the profile of the mentally incompetent patients of the Local Health Unit of Guarda, Portugal, resorting to the reports of mental faculty's examinations of, at least, 30 individuals. With this methodology, we will be able to study the characteristics of selected individuals who have committed some sort of criminal offences but are not subject to prosecution, namely with regard to the specific personal and family data, psychiatric background, diagnostic formulations, applied legal concepts, among others. Statistical analysis was carried out using the Microsoft Excel tool. The main goal of the study is to provide to the Psychiatry Department of the Local Health Unit of Guarda an analytical instrument that characterizes the respective mentally incompetent population and may, essentially, contribute positively to the contextualization and accomplishment of the future assessments on mental faculties of the individuals who are involved in judicial proceedings.

Matricide versus patricide in one Croatian psychiatric forensic inpatient unit

I. Pedisic^{1,*}, K. Radic², N. Buzina², V. Jukic²¹ General Hospital, Sibenik, Department of Psychiatry, Sibenik, Croatia² University Psychiatric Hospital Vrapče, Department of Forensic Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction Parricide (referring as parental homicide) is a rare event among homicides, yet challenging and intriguing from psychiatric point of view. Still, literature concerning parricide is sparse and most studies concern small or heterogenous samples or anecdotal cases.

Objective To analyze differences in parricide offenders among forensic psychiatric inpatients at the university psychiatric hospital Vrapče's centre for forensic psychiatry.

Aims To test some differences between parricide offenders with regard to specific type of parricide.

Methods Available retrograde data of 50 years forensic inpatients ($n=430$). We identified parricide cases of matricide and patricide included.

Results The analysis included a total of 22 parricide offenders. All parricide offenders were male adults. Matricide was more prevalent than patricide (13 vs. 9). Matricide offenders were in average younger when committed crime, had more prevalence of psychotic disorders and earlier onset of symptoms in comparison with patricide group.

Conclusion We identified differences and similarities between these two parricide offenders groups. It is important to expand

research further including different types of motives and family dynamics regarding the type of parricide victim.

A neuro-psychological model of violence propensity in schizophrenia

M. Picchioni^{1,*}, S. Harris², A. Reichenberg³, T. Fahy⁴, D. Murphy⁴¹ Institute of Psychiatry, St Andrew's Academic Department, London, United Kingdom² Institute of Psychiatry, St Andrew's Academic Department, Northampton, United Kingdom³ Mount Sinai Hospital, Icahn Medical Institute, New York, USA⁴ Institute of Psychiatry, Department of Forensic and Neurodevelopmental Science, London, United Kingdom

* Corresponding author.

Introduction Schizophrenia is associated with an increased risk of violence. The identification of the illness specific factors that contribute to that risk could lead to better risk assessment and management strategies.

Objectives/aims To identify if cognitive and emotion processing deficits are linked to violence risk in schizophrenia.

Methods Fifty male patients with DSM-IV schizophrenia and thirty-nine healthy controls were assessed across a range of intellectual, executive, emotion and social processing domains. Lifetime propensity to violence was quantified.

Results General intellectual ability and memory were not significantly associated with violence propensity. Violent patients showed significantly poorer response inhibition, after accounting for relevant clinical variables. A greater lifetime propensity to violence was associated with an attentional bias towards anger, a heightened sensitivity to the recognition of fear, with poorer complex theory of mind performance.

Conclusions Our results allow us to propose a hypothetical model of the propensity to violence in schizophrenia. We suggest that heightened sensitivity to environmental negative emotional cues and poorer understanding of complex social situations, combined with an inability both to quickly process but also inhibit responses, results in a greater propensity to violence. We propose that this model sits alongside other factors, such as drug use. These findings need replication but could have direct implications for treatment and management of our patients with schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Women 49-year-old with a history of left mastectomy for breast Ca. The patient is brought to the emergency by his family for disorderly conduct compatible with manic phase and psychotic symptoms by delirious speech mystical-religious content refusal of the patient to be evaluated by any medical decision and abandoned chemotherapy. Initial screening is performed from the emergency department of organic pathology (TAC without findings and normalcy in other PC). At the beginning of involuntary admission income that is corroborated by the commission judicial, a request of the family and given the history of abandonment IC Oncology treatment is performed as a result of which it is found that the onset of the psychiatric clinic communicates matches the decision to abandon treatment; after reassessment of the clinical status of the patient and recommendation by her oncologist to resume treatment with RT to court new authorization for further diagnosis and initiation of treatment after assessment by forensic and judge is granted a week tests requested. After screening of limbic encephalitis but positive AC. SD income it is maintained and combined treatment is performed. At discharge, the patient is stable DP vs. psychopathology with good controls over concomitant breast disease.

Results The need for medical treatment in organic pathology is justified even against the will of the patient in the context of repression

The biopsychosocial paradigm in the assessment of mental health of older persons

L. Pishchikova
Moscow, Russia

The vulnerability of patients of late age in psychiatry increases the professional and ethical requirements to the quality of psychiatric and forensic psychiatric help. It must account for the clinical and dynamic features of mental disorders in old age, biopsychosocial determinants of their formation, be based on a conceptual approach and a comprehensive understanding of the involution processes. To identify biopsychosocial determinants of mental disorders in old age and (or) involving patients to the forensic psychiatric examination, we examined 235 late age patients in criminal and civil cases. Revealed: «non-dement» mental disorders – with 45.5%, psychosis – with 7.7%, dementia – with 46.8%. The results of biopsychosocial determinants of involution are determined as follows: biological: sensory and motor deprivation, multicomorbid somatic neurological pathology, specific syndromes and disorders if late age, dementia; socio-psychological: termination of labor activity, living alone and loneliness, problematic relationship with children because of housing disputes and alcohol; legal: conclusion and contestation of legal civil acts, participation in criminal proceedings as victims and defendants, legal illiteracy, legal controversy, lack

of legal protection; victimological: physical (assault, abuse), psychological (threats of commitment into social security institutions, involuntary commitment to a psychiatric hospital and examination by a psychiatrist, hold in the psychiatric hospital), financial violence (fraud with housing for older people and deception, manipulation during conclusion of civil-legal acts), violation of rights of older person (unlawful deprivation of legal capacity).

When a man loves a woman: A case of erotomania in the 21st century

C. Rodrigues*, M. Andrade, V. Palma, C. Cardoso
Unidade Local de Saúde do Nordeste, Departamento de Psiquiatria e Saúde Mental, Bragança, Portugal

* Corresponding author.

Introduction Erotomania, or De Clerambault's Syndrome, was first described in 1921. However, cases of Insane Love were long known before. Presently, this condition is classified as a delusional disorder typically affecting women. However, in forensic samples, most of these reports relate to men with violent behaviour, associated to harassing or stalking of a woman.

Objective To present the case of a man, diagnosed with Erotomania and literature review of similar cases.

Aim To bring awareness to the infrequent diagnosis of this condition in males and the legal implications this condition may have.

Methods Consultation of the patient's clinical process and published articles focusing on Erotomania in men.

Results A 50-year-old man was referred from Court for persistently stalking a woman on the past few years. He revealed erotomanic and persecutory delusions, believing these accusations were all part of a scheme to restrain his alleged relationship.

There was a clinical improvement during hospitalization and treatment with antipsychotics. Due to the legal process in court, a forensic examination was also performed.

Conclusions On the follow-up, the patient remained stabilized. He would not verbalize any delusional content, and calmly deny any inadequate behaviour. However, some of his stalking attitude remains. As many of these patients, we believe his delusion is still present, although his behaviour is more controlled with treatment. Recognizing the characteristics and course of this disorder in our patients, grants a better chance of intervention and attentiveness towards the legal implications that may arise.

Structure of forensic psychiatric services in Iran, duties and limitations

S.M. Saberi^{1,*}, A. Ahmadi¹, G. Mirsepassi (Associate professor)²

¹ Legal Medicine Research Center, Legal Medicine Organization, Tehran, Iran

² Iranian Psychiatric Association, Tehran, Iran

* Corresponding author.

Introduction In Iran, unlike most European countries, there is not any forensic mental hospital specialized for criminal patients. Therefore, a special department of legal medicine organization is charged with the duty of clinical evaluations of patients who have legal problems.

Aim To review the structure and duties of forensic psychiatric services in Iran.

Method By analyzing activities of 15 forensic psychiatric centers in the country.

Results The duty of forensic psychiatrists in Iran is to determine mental competence of two major groups of referrals. First, people who are involved with a legal problem related to civil law, such as financial managing problems and need a guardian, doubtful mental ability for decision making, child custody, legal permission for sex reassignment surgery in cases with gender dysphoria, etc. Second, people who are involved with a criminal issue, such as criminal responsibility and/or adjustment problems in prison. According to Islamic penal code (article 149), if there is a kind of mental disorder, at the time of committing a crime, the person should be known as insane and not criminally responsible. Also, to determine the risk of dangerous behavior is one of the duties of forensic psychiatrists. Psychological evaluations, like personality inventories and projective tests, may be necessary for making a suitable decision in different cases.

Conclusion Although some facilities have been considered in the new penal code, Iranian legal system should pay more attention to the structure of forensic psychiatric services in order to improve the situation.

The relationships of clinical, socio-demographic and criminal factors in a sample of forensic psychiatric patients

A. Sileikaite^{1,*}, A. Germanavičius², I. Česniene³

¹ Rokiskis Psychiatry Hospital, Forensic Psychiatry, Vilnius, Lithuania

² Vilnius University, Psychiatry Clinic, Vilnius, Lithuania

³ Vilnius University, Department of General Psychology, Vilnius, Lithuania

* Corresponding author.

Introduction The relationship between clinical factors and both psychosocial and criminal history characteristics among forensic psychiatric patients entering treatment in Lithuania has not been well explored.

Aims The aims and objectives of this presentation are:

- to overview the clinical, socio-demographic and criminal factors in a Lithuanian sample of forensic psychiatric patients;
- to demonstrate which factors were significant to violent criminal behaviour;
- to address some main concerns and issues of risk assessment processes.

Methods Data were collected from 325 forensic psychiatric patients' files in one forensic psychiatric hospital in Lithuania. A sample consisted of 36 (11%) females and 289 (89%) males. The average age of patients was 41.7 years (SD = 14.0).

Results Psychosis was the most common psychiatric diagnosis. The substance abuse problem was common in this population as well. The results of the logistic regression show that increase in patients' substance abuse and their age was significantly associated with violent offending.

Conclusions The study stressed an urgent need for further research of forensic patients in Lithuania.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Delirium, hallucinations and criminal liability

M. Turki^{*}, N. Halouani, R. Naoui, I. Gassara, N. Hamza, J. Aloulou, O. Amami

Hedi Chaker University Hospital, Psychiatry Department, Sfax, Tunisia

* Corresponding author.

Introduction The relationship between psychotic motivation and the genesis of medico-legal acts is well documented in the literature. Delirium and hallucinations, in particular, have been widely reported in this context.

Objective The aim was to identify socio-demographic, clinical, and criminological profile of patients hospitalized for forensic acts committed in psychotic context.

Methods We conducted a descriptive retrospective study, including 7 patients committing a forensic act in psychotic context, selected among all patients hospitalized after a judgement of dismissal (Tunisian law), in psychiatry department, Hedi Chaker university hospital, Sfax, Tunisia. Socio-demographic and clinical data were collected through patients' observations.

Results The mean age was 37.7 years. Sex-ratio (M/F) was 6. The criminological act was an attack in 57.1% and homicide in 42.9% of cases. It was committed on the outside in 42.9% of cases. The tool was a bladed weapon in all cases. The victim was a family member in 71.4% of cases. The context was a delirium in 71.4% (theme: 80% persecution, 20% jealousy; mechanism: 40% hallucinatory, 60% interpretative) and hallucinations in 42.9% of cases. Among our patients, 57.1% were indifferent and 28.6% regretted the act. Psychiatric diagnosis was: schizophrenia 57.1%; delusional disorder 28.5% and brief psychotic disorder 14.2%. Personality disorder was reported in 28.6% of patients.

Conclusion The acting out in a psychotic moment in patients with mental illness remains the most formidable event, causing sometimes the problem of criminal liability. Control of attendance at psychotherapy and psychotropic treatment are preventive and curative necessary measures to avoid crossing the dangerous acts.

Continuities and discontinuities between psychopathy and narcissism among male offenders

P. Velotti^{1,*}, C. Garofalo², M. D'Aguzzo³, G. Rogier³

¹ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

² Tilburg University, Psychology, Tilburg, Netherlands

³ University La Sapienza, Psychology, Rome, Italy

* Corresponding author.

Introduction A heated and longstanding debate exists as to whether psychopathy and narcissism represent two distinct, albeit overlapping, constructs, or two different labels for the same concept. However, relatively scant attention has been dedicated to this issue in offender populations, which are likely to present elevated levels of both psychopathy and narcissism. Furthermore, the picture is complicated by the multidimensional nature of both constructs.

Objective We sought to explore the associations among psychopathy facets and pathological narcissism dimensions, comparing an offender sample with community participants.

Aims To highlight similarities and differences in clinically relevant and sub-clinical levels of psychopathy and narcissism dimensions, as well as in pattern of associations between them.

Methods A sample of male offenders incarcerated in Italian jails, and a sample of community-dwelling men, were administered the Self-Report Psychopathy Scale (SRP-4; Paulhus et al., 2015) and the Pathological Narcissism Inventory (PNI; Pincus et al., 2009).

Results As expected, levels of both narcissism and psychopathy were significantly higher in the offender sample. Narcissism and psychopathy were only partly related, with correlations ranging from low to moderate in size, and differential pattern of associations between selected dimensions emerged consistently with theoretical models and in line with prior studies.

Conclusions Psychopathy and narcissism are two separate syndromes, which share similar aspects but also present distinct features and this is likely to explain their partial overlap. Future studies should take a closer look at how facets of psychopathy and narcissism relate across different samples (e.g., also examining female offender samples).

Dealing with shame – the ‘Psychopathic Way’: Preliminary investigation for a new developmental framework of psychopathic traits

P. Velotti^{1,*}, M. D’aguanno², C. Garofalo³, G. Rogier²

¹ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

² University Sapienza, Psychology, Rome, Italy

³ Tilburg University, Psychology, Tilburg, Netherlands

* Corresponding author.

Although individuals with psychopathic traits are deemed as immune to emotional experiences, in recent year, some authors have advanced the hypothesis that a pervasive pattern of emotion dysregulation may characterize the developmental trajectories leading to a psychopathic personality structure. Shame has been proposed as crucial emotions to understand psychopathy. It has been argued that people, who often experience shame feelings during their childhood, may develop adaptive strategies to cope with them, which lead to maladaptive strategies to regulate shame feelings in adulthood. These maladaptive strategies may explain the increased likelihood for these individuals to violence when feeling ashamed. Whether these mechanisms may also explain the presence of high psychopathic traits remains a clinically valid theoretical hypothesis, which lacks empirical support.

Objective To investigate whether maladaptive strategies to cope with shame feelings were associated with psychopathic traits.

Aims To examine the association between four maladaptive shame coping were positively related with psychopathic traits.

Methods A sample of male offenders incarcerated in Italian jails completed the Self-Report Psychopathy Scale (Paulhus et al., 2015) and the Compass of Shame Scale (Elison et al., 2006).

Results As hypothesized, maladaptive shame regulation strategies did predict psychopathic traits in the offender sample examined. Specifically, significant and meaningful associations occurred between avoidance and attack other coping styles and psychopathic traits.

Conclusions The present study is among the first in providing evidence of a possible relationship between maladaptive strategies to cope with shame feelings and psychopathic traits, and such link can be informative to tailor treatment programs for these hard-to-treat patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Increasing polyvalent illicit drug abuse and increasing dropout rates in forensic in-patient treatment – is there a link?

F. Wedegaertner^{1,*}, A. Weber², M. von der Haar³

¹ Medizinische Hochschule Hannover, Psychiatry, Hannover, Germany

² MRVZN Bad Rehburg, Forensic Psychiatry, Rehburg, Germany

³ MRVZN Bad Rehburg, Forensic Psychiatry, Bad Rehburg, Germany

* Corresponding author.

For a cross-sectional survey of forensic treatment of substance use disorders in Germany, 77,220 patient records were collected between 1994 and 2012. Results show that polyvalent illicit drug abuse is an increasing phenomenon in patients referred to forensic treatment by the courts in Germany. The percentage of these patients has risen from 32 to 68%. Patients drop out of forensic treatment as not successfully treatable because of relapses or repetitive disciplinary infractions or if the maximum duration of imprisonment is reached without positive medical and/or legal prognosis. While dropout rates because of ill treatment success have risen from 34% to 47%, so has the average length of stay in cross-sectional samples from 10 to 15 months. The percentage of those released at maximum duration without positive prognosis has more than doubled. The length of parallel prison terms pronounced by the courts has risen from 31 to 44 months during the period of observation. This has led to high occupancy in forensic institutions. High occupancy poses a challenge for the individuality and thoroughness of the treatment approach and may influence success rates. Changing legislation and public pressure need to be considered when lengths of stay are interpreted. We are going to discuss the role of changing morbidity in the treatment of substance use disorders in the general population and in the forensic sample between 1994 and 2012 and how institutions prepare for the specific needs of the changing clientele.

Differential binding of CREB, USF, and c-Myc to the calreticulin human specific –220C may be linked with the evolution of higher brain functions in human

S. Farashi

University Medical Center Utrecht, Translational Neuroscience, Utrecht, Netherlands

Introduction We have previously reported a human-specific nucleotide in the promoter sequence of the calreticulin (*CALR*) gene at position –220C, which is the site of action of valproic acid.

Objectives Reversion of this nucleotide to the ancestral type, –220A, co-occurs with severe deficit in higher brain cognitive functions.

Aims In the current study, we compare the pattern of protein binding between –220C and –220A.

Methods Antibodies reactive against transcription factors CREB, USF, and c-Myc were used to identify the specific proteins involved

in complexes with DNA using electrophoretic mobility shift assay (EMSA).

Results Significant increase was observed in the overall protein complexes binding to the –220C allele vs. –220A. The transcription factors, CREB, USF, and c-Myc, were differentially bound to –220C, represented by supershifts.

Conclusions We propose that differential binding of CREB, USF, and c-Myc to CALR nucleotide –220C may be linked with the evolution of higher brain functions in human.

The epigenetic regulation of GATA4-dependent brain natriuretic peptide expression during alcohol withdrawal

A. Glahn*, S. Bleich, M. Muschler, M. Rhein, H. Frieling, T. Hillemacher

Medizinische Hochschule Hannover, Psychiatry, Psychotherapy, Social Psychiatry, Hannover, Germany

* Corresponding author.

Introduction Natriuretic peptides participate in the complex collection of metabolic effects in reaction to chronic alcohol drinking. Brain natriuretic peptide (BNP) is a specific member of this family known to be expressed in heart and brain.

Objectives Having witnessed modulation of other natriuretic peptides in a longitudinal cohort of alcohol-dependent patients undergoing detoxification treatment, we were interested how BNP methylation would be altered in correlation to protein expression and major clinical markers for craving.

Aim The epigenetic regulation of BNP in the context of alcoholism is unknown to this date.

Methods Ninety-nine male patients were subjected to a longitudinal investigation (days 1, 7 and 14 of detoxification treatment) and compared with 101 healthy controls concerning epigenetic regulation and protein expression of BNP.

Results Serum levels of BNP are significantly decreasing during withdrawal. Global OCS scores are decreasing significantly. Focusing on the two CpGs that are between GATA transcription factor binding sites, detailed statistical analysis reveals a reversely proportional methylation pattern, significantly increasing with ongoing detoxification and thereby supporting the observed serum level changes, accordingly. With BNP expression being GATA4-dependent, we observed a correlation of GATA4 binding site methylation and protein expression during alcohol withdrawal.

Conclusion Without the functional knowledge about the crucial regulation of BNP expression via the GATA transcription factor, it would have been easy to take the mean results of the global CpG data and propose a direct relationship between methylation and expression. Thus, these findings are also a voice for functionally and mechanistically approved results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pharmacogenetic technology in psychiatric practice

T. Dokukina^{1,*}, M. Makhrov¹, P. Korolevich¹, I. Gaidukevich², A. Gilep²

¹ Republican Scientific and Practical Center for Mental Health, Department of mental and behavioral disorders, Minsk, Belarus

² Institute of Bioorganic Chemistry of the National Academy of Sciences, Laboratory of Molecular Diagnostics and Biotechnology, Minsk, Belarus

* Corresponding author.

Pharmacogenetic tests allow to predict the speed and features of a metabolism of antipsychotics depending on activity of the fermental systems involved in its metabolism, proteins carriers. They are directed as on an assessment of efficiency of therapy by antipsychotics, and studying of shipping and predictive risk of formation of side effects depending on a genotype.

The studied material Tests of a buccal epithelium.

Techniques Release of nucleic acids, extraction of metabolites, PCR-analysis, release of recombinant proteins, reconstruction of fermental activity, mass and spectrometer analysis. Methods of diagnostics and additional researches include complex clinical inspection – objective survey, collecting of the anamnestic data, the analysis of experience of treatment by psychotropic medicines. Additional criteria of inclusion in research group: age from 18 to 35 years, lack of secondary resistance, absence of any associated diseases, Belarusians on a nationality, not relatives each other, with hospitalization prospect not less than 4 weeks, signed “the informed consent” to participation in the project. Neurophysiological inspection – visual and computer EEG.

Results Sixty-nine patients with schizophrenia were examined. Genomic DNA was used further for identification of mutant alleles of genes of CYP2C9 (*2/*3), CYP2C19 (*2/*3), CYP1A2, CYP2D6. Personal medical recommendations were made to all of patients. The dosage of a neuroleptic was changed depending on result of genotyping. Eighty-five percent of patients received good therapeutic effect in the form of a full reduction of psychotic symptoms. Preliminary results show efficiency and prospects of pharmacogenetic technologies in psychiatric practice.

¹ University of Turin, Department of Biological and Clinical Sciences, Orbassano, TO, Italy

² University of Turin, Department of Neurosciences “Rita Levi Montalcini”, Orbassano, TO, Italy

³ University of Turin, Department Biological and Clinical Sciences, Orbassano, TO, Italy

* Corresponding author.

Introduction Various pharmacokinetic and pharmacodynamics features have proven to be involved in the development of drug-induced side effects in psychiatry and thus pharmacogenetic profiling should be considered during drug selection to avoid the onset of side effects.

Aim To explore the usefulness of Neurofarmagen® testing in clinical practice by evaluating whether the genetic profile given by the tool could properly explain the onset of side effects during antipsychotic treatment.

Methods The pharmacogenetic profile of ten patients having a history of side effect appeared during to specific a psychopharmacologic treatment was determined by Neurofarmagen® testing tool. The relationship between genetic profile and side effects was evaluated and classified.

Results Sixty percent of the sample showed a genomic alteration related to an increased likelihood of having any side effects, one half of which presented pharmacokinetic alteration (slow or intermediate phenotype for the implicated cytochrome) whereas the other

half had a pharmacodynamic gene variant (related to dopamine or serotonin pathway).

Conclusion the Neurofarmagen® testing tool may be useful in the clinical practice in order to avoid drug-induced side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric manifestations of Niemann-Pick type C disease – two case reports

J. Rebelo*, M. Oliveira, P. Nunes

Centro Hospitalar de São João, E.P.E., Psychiatry, Porto, Portugal

* Corresponding author.

Introduction Niemann-Pick type C disease (NPCD) is a rare metabolic illness, with autosomal recessive inheritance. NPCD has a heterogeneous presentation, with non-specific psychiatric symptoms, mostly affective and psychotic features and also cognitive deficits.

Objectives and methods We present the case reports of two brothers with an adolescent-adult onset and discuss the evolution of their neuropsychiatric manifestations.

Results The patients have now 35 and 31 years old and the youngest was the first to develop clinical manifestations of the disease. From 16 years old, he developed unspecified neurological impairment with gait imbalance. In the next years, the neurologic manifestations exacerbated, with dysarthria, ataxic gait, and his academic performance declined. With 24 years old, he presented acute psychosis, with unstructured delusion and auditory hallucinations. The acute psychotic symptomatology remitted with olanzapine but he revealed social withdrawal, apathy and progressive cognitive decline that persist until now. His brother, whose diagnosis was made in the course of the family genetic study, developed the first signs of the NPCD with 19 years old. He presented neuropsychiatric compromise, with impaired learning, social isolation and insomnia. They are receiving specific treatment with miglustat and symptomatic treatment for the psychiatric manifestations.

Conclusions NPCD is a rare metabolic disease, with neuropsychiatric compromise. No general psychopathological profile has been associated to NPCD. Sometimes psychiatric symptoms dominate the initial clinical presentation, with neuro-visceral signs appearing later. An atypical psychiatric symptomatology should be extensively investigated in order to exclude organic causes, including metabolic diseases like NPCD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Azienda Ospedaliera Universitaria “Maggiore della Carità”, Traslational Medicine, Novara, Italy

* Corresponding author.

Introduction Mitochondrial disorders of energetic metabolism (MD) represent a heterogeneous group of diseases manifesting at any age and its one of a number of mitochondria syndromes that share the common characteristics of encephalopathy and myopathy. The clinical expression of MELAS (Mitochondrial Myopathy,

Encephalopathy, Lactic Acidosis and Stroke-like episodes) is highly variable and psychiatric symptoms are rarely reported in literature even if are more common in MELAS syndrome than in the general population.

Objective The first aim of the study is describing the clinically observed primary psychiatric symptoms in a patient affected by MELAS syndrome admitted to the Psychiatric ward. The second aim is to go back over the diagnostic process, which led, from the uncommon psychiatric symptoms and signs to the final genetic diagnosis of MD.

Methods and results We report the case of a 44-year-old male with MELAS in whom psychiatric symptoms preceded the establishment of the clinical diagnosis for several months. Diagnosis was initially based on the neuroimaging and metabolic findings and subsequently confirmed with genetic analysis.

Conclusions In case of aggressive and paranoid behaviour with delusions of persecution and disorganised behaviour mitochondrial disorders deserve consideration as part of the differential diagnosis, especially if there is suspected involvement of other organ groups or positive family history of MD. There is no specific consensus approach for treating MELAS syndrome. Management is largely symptomatic and should involve a multidisciplinary team.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Implications of DNA copy number variations in attention-deficit/hyperactivity disorder: An update review

M.E. Palmeira^{1,*}, L.B. De Mesquita Gouveia²

¹ Escola Bahiana de Medicina e Saúde Pública, Medicine, Salvador, Brazil

² Federal University of Alagoas, Medicine, Maceió, Brazil

* Corresponding author.

Introduction Attention deficit hyperactivity disorder (ADHD) is a highly heritable disorder. Rare genetic variants, specifically large, rare copy number variants (CNVs) play an important role in ADHD and others neurodevelopmental disorders.

Objectives Identify previous studied correlations between CNVs and ADHD, analysing physiological and genetic pathways in association with another neuropsychiatric disorders.

Aims Identify most commons CNVs variations present in ADHD; evaluate similarity between results found in researches in relation to pleiotropy and ADHD phenotypes.

Methods A scientific originals articles research was conducted on PubMed. Used keywords ‘Attention Deficit Disorder with Hyperactivity’ and ‘DNA Copy Number Variations’. Among twenty articles found, published in the last ten years, sixteen articles were selected based on relevance of information.

Results Rare CNVs were described in association with ADHD. Almost 44% of the articles reviewed screened CNV regions possibly linked with ADHD pathologic pathways, especially to metabotropic glutamate receptor and genes related to others psychiatric disorders, like *PARK2* and *SHANK3*. The case control studies also indicate some coexistence of rare and common forms ADHD. Nevertheless, there is not a consensus about relations between CNVs in ADHD samples and intellectual disability. Moreover, all articles suggest a pleiotropic effect related to CNVs in ADHD patients and others neuropsychiatric disorders.

Conclusion The relevance of CNVs in ADHD patients is clearly supported by the current findings. However, further research is necessary to analyse CNVs influence in IQ of ADHD individuals. In addition, genotype association studies to clarify the pleiotropies stated are required.

Serine racemase in inhibitory neurons at striatum and it might be involved in schizophrenia's pathophysiology with D1 and D2 receptors

S. Takagi^{1,*}, D. Balu², J. Coyle²

¹ Tokyo Medical and Dental University, Psychiatry, Tokyo, Japan

² Harvard Medical School, Department of Psychiatry, Boston, USA

* Corresponding author.

Introduction There is substantial evidence that hypofunction of the N-methyl-D-aspartate receptor (NMDAR) is a core pathophysiological mechanism underlying schizophrenia. D-serine and serine racemase (SR) (NMDAR co-agonist and its producer) are thought to be involved in schizophrenia's pathophysiology as NMDAR function moderators. Our laboratory showed that excitatory neuron specific SR knock out (SRKO) mice still have just 50% reduction of SR whereas full SRKO mice had no SR. Furthermore D-serine and SR are found in inhibitory neurons not only in excitatory neurons with immunohistochemistry methods. Because NMDAR has excitatory functions, the existence of D-serine and SR in inhibitory neurons and their functions are of interest.

Aims To elucidate the existence and roles of D-serine and SR in inhibitory neurons.

Methods Inhibitory neuron marker, GAD65, specific conditional SRKO (GAD65 SRKO) mice were made by Cre-lox recombination method. The GAD65 SRKO mice were analyzed by HPLC for D-serine concentration, western blotting for SR expression, immunohistochemistry for SR positive cell's character identification and behavioral testing.

Results GAD65 SRKO had about 50% reduction of SR in striatum but no reduction in hippocampus and frontal cortex. D-serine of GAD65 SRKO mice was not different from WT mice. Immunohistochemistry works revealed SR is in medium spiny neuron of striatum and has colocalization with DARRP-32, D1 receptor, and D2 receptor.

Conclusions SR is expressed in inhibitory neurons at least in striatum. It might be involved in schizophrenia's pathophysiology because it colocalizes with D1 and D2 receptors.

Catatonia and dementia

M. Almeida*, C. Gama Pereira

Centro Hospitalar Baixo Vouga, Departamento de Psiquiatria e Saúde Mental, Aveiro, Portugal

* Corresponding author.

Introduction Catatonia, described by Kahlbaum in 1874, is usually seen as a type of schizophrenia, but it can also occur in a wide range of other psychiatric/organic disturbances. There is a documented association between dementia and catatonia, in all phases of cognitive impairment.

Aims Literature review and discussion about Catatonia, regarding a case report.

Methods Clinical interviews and literature review in PUBMED database.

Results (case report) Female patient, 89 years old, without psychiatric history, was diagnosed with dementia 5 months prior to episode. On admission, she presents with prostration, mutism and refusal to eat/drink. Laboratory studies were normal and TC-CE shows signs of an old stroke in left temporo-parietal region and diffuse signs of ischemic leucoencephalopathy. At psychiatric evaluation, she was stuporous, unreactive to pain, mute, not following verbal commands, keeping her eyes closed and resisting attempts to open her eyelids. She had global rigidity, axial and limbs, and maintains the postures the examiner puts her into for long periods. She was already given chlorpromazine, without improvement. Then she takes diazepam 10 mg iv, with remission of the state.

Conclusions Although catatonia usually presents with drama, clinicians often forget to consider it in differential diagnosis, probably because of its traditional association with schizophrenia. A promptly diagnostic is crucial to provide adequate treatment, avoiding drugs that can worsen/perpetuate the clinical state. Some authors even support the idea that motor features associated with end-line dementias may correspond to lorazepam-responsive catatonia, in which treatment may have a tremendous impact worldwide.

Mini-Mental State (MMS) evaluation of dementia in psychiatric patients admitted to a long stay ward

N. Amel*, L.P. Isabelle, G. Aurelie, H. Marc, A. Mohammed, I. Ziad

USLD La Roseraie, EPS Maison-blanche, Seine-Saint-Denis, Neuilly-Sur-Marne, France

* Corresponding author.

Normal 0 21 false false false FR X-NONE X-NONE MicrosoftInternetExplorer4.

MMS scores for 41 psychiatric patients were analyzed at admission and regularly throughout their stay.

Results Their average age at admission was 65.7. Thirty-six patients had a diagnosis of chronic psychosis, two with bipolar disorders, one with frontotemporal dementia, two with Korsakoff syndrome.

At admission, 21 (51%) patients showed mild cognitive deterioration (score = 18–26), 12 (29%) moderate deterioration (12–17), 6 severe deterioration (0–11), 2 had normal scores (27–30). Over the following years, 28 patients were reassessed:

– 12 (42%) were stable, 7 (25%) had a fluctuating score, 5 (18%) improved;

– 4 (14%) deteriorated over their successive MMS evaluations;

– age, socio-cultural level and psychiatric diagnosis were not associated with change in MMS scores;

– average change between initial and final assessment was +6.0 points for patients with improved score, –7.75 for those showing deterioration;

– 1.28 for those with fluctuating scores, –1.0 for stable patients.

Analysis Unstable psychiatric disorders associated with somatic pathologies influenced MMS scores for all patients, particularly for those with MMS deterioration or fluctuation even if this phenomenon could also be observed to a lesser extent in stable patients. By contrast, patients whose MMS scores improved over time were more mentally stable and had no current somatic problems. Multidisciplinary teamwork is important for patients with deteriorating MMS scores.

Conclusion By illustrating the impact of somatic and psychiatric factors on dementia, the present study underlines the value of

multidisciplinary professional care, the role of the family and the importance of long-stay wards.

⁴ University Hospital of Patras, Psychiatry, Patras, Greece

* Corresponding author.

Introduction Depression is fast becoming a major public health problem with a very high prevalence rate in the 65 and over age group.

Objectives The aim of the present study was to estimate the prevalence of depression in Greeks and Cypriots older adults.

Methods A cross-sectional study was conducted among the 445 participants, 239 members of three day care centers for older people, in the municipality of Patras, West-Greece and 206 older adults (110 in the community, 65 in outpatient clinics, 31 in nursing homes) in Cyprus, aged >60 years. A questionnaire was administered including socio-demographic characteristics. Depression was assessed using the Greek version of Geriatric Depression Scale (GDS-15).

Results The overall prevalence of depression according to GDS-15 was 33% (28% moderate, 5% severe type). Depressive symptoms were more frequent in women (41,6% vs. 28,3%, $P < 0,001$), in not married (43,0% vs. 29,3%, $P < 0,001$), in elderly with chronic diseases (36,8% vs. 25,0%, $P = 0,007$), in older people dwellers of urban areas compared to rural (36,3% vs. 26,4%, $P = 0,028$) and in ages between 70 to 80 years old (38,7% vs. 31,6%, $P = 0,038$). Moreover, higher prevalence of depression was measured in Greeks compared to Cypriots (44,3% vs. 20,6%, $P < 0,001$). In a univariate analysis, the following variables were significantly associated with depression: female gender ($P < 0,001$), co-morbidity ($P = 0,004$), higher age group ($P = 0,018$), place of living ($P = 0,022$) and Greek nationality ($P < 0,001$).

Conclusions High prevalence and several risk factors are strongly associated with depression, whereas Greeks are in higher danger of developing depressive symptoms in late life, than Cypriots.

Treatment of Charles Bonnet syndrome with continuous positive airway pressure in an older adult

M. Arts^{1,*}, P. Michielsen², S. Petrykiv³, L. de Jonge¹, R. Oude Voshaar¹

¹ UMCG, Old Age Psychiatry, Groningen, Netherlands

² GGZWNB, Psychiatry, Bergen op Zoom, Netherlands

³ GGZ Friesland, Emergency Psychiatry, Leeuwarden, Netherlands

* Corresponding author.

Introduction Charles Bonnet syndrome (CBS) is a disorder in older adults, and is characterized by a triad of recurrent vivid visual hallucinations, ocular pathology causing visual impairment due to lesions in central or peripheral visual pathways, and normal cognitive status. It is often misdiagnosed as a psychosis, early dementia

or a drug related condition. Hypoxemia was anecdotally reported as a cause of CBS.

Objectives We present an older adult with CBS caused by severe obstructive sleep apnea syndrome.

Aims To report a case study, describing treatment of obstructive sleep apnea syndrome as a cause of CBS.

Methods A case study is presented and discussed.

Results An older male adult was admitted to hospital for persistent vivid visual hallucinations. There was no personal or family history of mental illness. Neurological examination was normal, except for visual impairment due to age related macular degeneration. The remainder of his physical examination was normal. Previous treatment with antipsychotics proved not to be effective. Severe hypoxemia (SaO₂ 79%) was diagnosed with overnight pulse oximetry and subsequent polysomnography revealed an obstructive sleep apnea syndrome. After three nights of nasal continuous positive airway pressure, the vivid hallucinations ceased.

Conclusion Physicians need to understand the underlying causes and mechanisms of CBS. One should be aware of the importance of a full clinical examination and sleep apnea research in elderly persons with visual impairment.

Management of late-life insomnia

S. Bravo Herrero^{1,*}, C. Moreno Menguiano², R. Martín Aragón¹, M. Gutiérrez Rodríguez², J.F. Cruz Fourcade¹, N. Rodríguez Criado¹, P. Muñoz-Calero Franco¹, B. Sánchez Sánchez¹

¹ Hospital Universitario de Móstoles, UHB Psiquiatría, Móstoles, Spain

² Hospital Universitario de Móstoles, CSM Móstoles, Móstoles, Spain

* Corresponding author.

Introduction Insomnia is the most frequent sleep disorder in late life. Forty-two percent of elderly people in the United States often complain about difficulties to get or maintain sleep, or awakening too early. Insomnia is frequent in old people greatly due to frequency of concomitant medical illnesses and polypharmacy, rather than because of age.

Objectives The objective of our research was to revise the current state of knowledge about management of insomnia in people above 65 years of age.

Methodology For that, a bibliographical search through PubMed.gov has been made. From the obtained results, the 14 which best suited for our goals were selected, 10 of them dealing with people above 65 years and the rest with people above 75 or 80 years of age.

Results Based on the literature reviewed, the current options of management of late-life insomnia are based on behavioral or pharmacological therapy. The combination of behavioral therapies shows results and is currently considered as an option, especially given the possibility of medicine interaction and the secondary effects hypnotic and sedative medicines might produce. There is a paucity of long-term safety and efficacy data for the use of non-benzodiazepine sedative-hypnotics. There are no criteria for the use of antidepressant sedatives in elderly people without diagnosed depression, although they are still used in practice.

Conclusion Possibility of using behavioral therapy as first option. In case of polymedicated or multi-pathological patients, pay special attention when starting a pharmacological treatment, choose the most suitable one and supervise it closely.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Late-life depression and dementia risk

N. Cherbuin*, S. Kim, K.J. Anstey

Australian National University, Centre for Research on Ageing-Health and Wellbeing, Canberra, Australia

* Corresponding author.

Introduction A substantial body of evidence linking late-life depression and dementia is now available. However, precise estimates of the relative risk attributable to late-life depression assessed with specific screening instruments at specified thresholds have not been previously produced.

Objective Summarise dementia risks associated with depression.

Aims Conduct a systematic review of the literature to produce precise and specific risk estimates for all cause dementia, Alzheimer's disease (AD), and vascular dementia (VaD).

Methods The PubMed, PsycInfo, and Cochrane databases were systematically searched. Studies assessing incident dementia using validated measures of clinical depression or depressive symptomatology from prospective population studies were selected. The most specific analyses were conducted using both continuous symptomatology ratings and categorical measures of clinical depression based on single instruments with defined cut-offs.

Results The literature search yielded 121,301 articles, of which 36 were eligible. Included studies provided a combined sample size of 66,532 individuals including 6593 dementia, 2797 AD, and 585 VaD cases. Random-effects summary estimates showed that the risk associated with depression did not differ by type of dementia. The most widely used instrument was the CES-D. A clinical threshold of 20 produced similar estimates for all-cause dementia (HR 1.83, 95% CI 0.95–3.52) and for AD (HR 1.97, 95% CI 0.96–4.04). Estimates based on other thresholds and continuous measures produced consistent results.

Conclusion Reliable dementia risk estimates associated with late-life depression can be produced and do not differ between dementia types. Such estimates should be used in evidence-based medicine practice to assess individual risk and to inform policy on interventions to decrease risk in the population.

The mosaic of life: Integrating attachment and trauma theory in the treatment of challenging behavior in elderly with dementia

D. D'Hooghe

Traumacentre, Brugge, Belgium

Elderly with dementia are aware people who think and feel. Suffering from dementia made them feel unsafe. This lack of safety can result in attachment behavior (e.g. proximity seeking) or challenging behavior resulting from posttraumatic symptoms, triggered by the experience of insecurity. We can use the symbol of a mosaic to illustrate that the elderly is the sum of all his different life experiences which make him a unique person. I want to emphasize the importance of a holistic assessment in which the attachment history and traumatic experiences of the person are integrated. In this workshop, I want to present a treatment model, wherein different important features such as mentalization, self-regulation, internal working model... are highlighted. The model integrates neuroscience to facilitate growth and change. By bringing together the environmental aspects with the interpersonal aspects, a safe haven is created.

The staff was trained in person-centered care, attachment and trauma theory and tailor made treatment. The blend of attachment

and trauma theory with neuroscience brings us new therapeutic possibilities in working with this specific part of the population.

Syndrome of inappropriate antidiuretic hormone secretion associated with desvenlafaxineE. García Fernández^{1,*}, D.M.I. Ramos García²¹ University Hospital, Psychiatry, Leon, Spain² San Carlos University Hospital, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Desvenlafaxine is a prescription medication approved for the treatment of major depressive disorder in adults. Hyponatremia secondary to inappropriate secretion of antidiuretic hormone (SIADH) is a possible side effect in patients receiving serotonin-norepinephrine reuptake inhibitors (SNRIS)

Method To report a case of SIADH associated with desvenlafaxine.

Results We present a 80-year-old female patient who required hospitalization due to an episode of psychotic depression. During the hospitalization, the patient developed hyponatremia after commencing treatment with desvenlafaxine. The serum sodium at this time was 117 mmol/L, serum osmolality was 249 mosmol/kg, urine osmolality 395 mosmol/kg and urine sodium 160 mmol/L, consistent with a diagnosis of SIADH. Desvenlafaxine was ceased and fluid restriction implemented. The mental status improved, and electrolyte studies 6 days later revealed serum sodium and osmolality values of 135 mEq/L during treatment with duoxetine.

Conclusions SIADH has been reported with a range of antidepressants in elderly patients. This case report suggests that desvenlafaxine might cause clinically significant hyponatremia. Close monitoring is recommended in patients starting therapy with antidepressant treatment to study and prevent possible adverse effects.

Informal caregivers of Alzheimer's patients and socio-economic burdenF. Ghali^{1,*}, M. Karoui², M. Zghal², L. Robbana², I. Ben Ghzaeil³, R. Rarafi⁴¹ Ariana, Tunisia² Razi Hospital, Psychiatry, Mannouba, Tunisia³ Razi Hospital, Neurology, Mannouba, Tunisia⁴ Mongi Slim Hospital, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Tunisia is knowing a significant increase of the elderly population, this phenomenon comes along with an increase of the incidence of degenerative pathologies "dependent on the age" as the Alzheimer's disease. The physical and psychic consequences of the disease and also the behavior of family members are an important determinant of quality of life and economic activities of both patients and informal caregivers.

Objectives and methods Our aims are to establish characteristic-60 informal caregivers of Alzheimer's patients followed in the department of neurology in Razi's Hospital and to estimate their socioeconomic burden through a descriptive study.

Results Our sample of caregivers was predominantly female with a moderate socio-economic conditions in 36,66%. The support was provided in 2/3 of cases exclusively by the informal caregivers.

22,66% ($n = 13$) of them lost their profession since the beginning of assistance's relationship. Among caregivers, 8% were forced to leave their homes to be closer to their ailing sibling.

Conclusion Our results reflect the distress of informal caregivers of Alzheimer's patients, the importance of their involvement and the adverse consequences on their quality of life and professional activities.

Mistreatment of Alzheimer's patients: Predictive factors

F. Ghali^{1,*}, L. Robbana², G. Jmii², M. Karoui², F. Medini², I. Ben Ghzaeil³, R. Rafrafi⁴

¹ Ariana, Tunisia

² Razi Hospital, Psychiatry, Mannouba, Tunisia

³ Razi Hospital, Neurology, Mannouba, Tunisia

⁴ Mongi Slim Hospital, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Violence against elderly persons is an intricate social, legal and ethic issue. Alzheimer's patients are the most vulnerable individuals to mistreatment and neglect. The aggressor can be even the main helper of the patient. We noticed a wide underestimation of this phenomenon, which remains taboo subject in our society.

Objectives and methods The aim of our study is to identify predictive factors of mistreatment of Alzheimer's patients through a prospective and descriptive study, within patients following in the department of neurology in Razi's hospital.

– We evaluate cognitive function (MMSE) and the importance of behavioural disorders.

– We explored helpers' sociodemographic characteristics and the quality of aid relationship.

– Anger and hostility within relationship were estimated through family attitude scale.

Results –Our sample accounts 60 informal caregivers predominantly female (91,7%) with an average age of 49,67 years, mostly are married (71,66%) and jobless (38,88%).

– In 78,3% of cases, caregivers spent about 12 to 24 hours per day with Alzheimer's patient.

– The average score of FAS was about 52,4% with an important emotional charge (score > 60).

– Twenty-five caregivers wished the death of the patient and 42 others admitted being sarcastic with him.

– We noticed a correlation between mistreatment and both cognitive function and behavioural disorders.

Conclusion Our results support the fact that mistreatment of people with dementia is closely related with the exhausting situation of the main caregiver.

Questions about dementia with Lewy bodies, personal beliefs and real performance for financial capacity tasks

V. Giannouli*, M. Tsolaki

Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

* Corresponding author.

Introduction Although cognitive impairment occurs early in the course of dementia with Lewy bodies, little is known about DLB and its impact on more complex civil capacities, such as financial capacity.

Method Three patients (mild DLB, severe DLB and MCI in DLB) were examined. Their total scores and (sub)scores on a financial capacity test revealed below normal (more than 1.5–2 SDs below) performance in contrast to cognitive intact elders (see Table 1).

Results This is in contrast with their personal beliefs of financial capacity, which reflect a tendency to overestimate their level of financial capacity as recorded on a Likert-scale questionnaire.

Conclusions The findings prompt a need for further research for an emerging problem in forensic psychiatry, that takes the form of the question: do all DLB patients – even in the stage of MCI – have the capacity for financial transactions?

Table 1

	Patient A	Patient B	Patient C	Healthy elders ($n = 146$)
Sex	Female	Female	Female	
Age	78	72	83	
Education	6	12	2	
MMSE or HINDI	17	27	21	> 26
FRSSD	13	1	7	< 5
GDS	6	5	2	< 6 or 7
Legal Capacity for Property Law Transactions Assessment Scale (LCPLTAS total score)	88	124	77	207.56 (13.64)
Basic monetary skills	4	12	4	13.78 (.95)
Cash transactions	1	4	0	7.84 (.54)
Bank statement management	1	4	0	7.69 (.94)
Bill payment	3	7	3	7.81 (.62)
Financial conceptual knowledge	15	27	9	31.36 (2.10)
Financial decision making	44	50	47	111.43 (7.88)
Knowledge of personal assets	20	20	14	27.62 (1.41)

Partial nephrectomy after oncocyoma causing repeated lithium poisoning with normal renal function

C. Gómez Sánchez-Lafuente^{1,*}, R. Reina Gonzalez², A. Gonzalez Moreno¹, F. Moreno de Lara¹, E. Mateos Carrasco¹, A. De Severac Cano¹

¹ Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

² Hospital Regional Universitario, General Practitioner, Málaga, Spain

* Corresponding author.

Introduction Lithium has been widely used as mood stabilizer in bipolar disease, despite its narrow therapeutic range and its side effects. Sodium levels and water consumption could affect lithium renal elimination.

Aims Describe a lithium intoxication without risk factors and normal kidney function.

Methods A 71-year-old female, diagnosed with bipolar disorder, current episode euthymic. On treatment with lithium 800 mg/day,

6 months ago she started with hematuria and urologist found a multifocal oncocytoma in left kidney. She was operated with double lumpectomy and partial nephrectomy without complications. Normal preoperative and postoperative renal function. Two months ago, she started with dysarthria, dystonia and coarse tremor, and T wave inversion on the electrocardiogram. In the blood test, lythemia was 1.67 mEq/L. Creatinine was 0.65 mg/dL. She was admitted to Internal Medicine Unit. She was treated with rehydration by serum. All psychoactive drugs were removed. Twenty days later, lithemia was undetectable in the blood analysis.

Results Two weeks ago, the patient was transferred to the mental health unit due to worsening her mood. Lithium was reintroduced 3 days ago, at doses of 200 mg per day. Today, the patient starts again with symptoms of poisoning by lithium. Lithemia was 1.78.

Conclusions On this occasion, partial nephrectomy due to oncocytoma is the most likely cause two consecutive lithium poisonings. Although creatinine and glomerular filtration are in normal range, patients after partial nephrectomy may have a reduced sodium reabsorption in proximal convoluted tubule, which may cause lithium compensatory resorption. This could cause rising in blood lithium levels.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Delusional of parasitosis in geriatric patients

M. Gutierrez Rodriguez*, C. Moreno Menguiano, F. Garcia Sanchez, R. Martin Aragon

Hospital Universitario de Móstoles, Psiquiatría, Móstoles, Spain

* Corresponding author.

Introduction Delusional of parasitosis or Ekbom's syndrome (ES) is a psychiatric disorder in which the patient has a fixed and false belief that small organisms infest the body. The belief is often accompanied by hallucinations. It is an uncommon condition that was initially studied by dermatologists, more prevalent in the elderly and typically observed in women older than 50 years although isolated cases among men have been reported.

Objective To review current knowledge about delusional of parasitosis in elderly patients through literature systematic review and the analysis of a case report.

Methodology We performed a literature search using electronic manuscripts available in PubMed database published during the last five years, following the description and discussion of a clinical case. We report a case of an 85-year-old man who presented a delusional parasitosis as a primary disorder.

Results The literature on ES consists mostly of case reports and limited series. In this paper, we analyze the etiology, demographic characteristics, clinical features and treatment in geriatric patients with delusional parasitosis.

Conclusion International classifications have included this syndrome in non-schizophrenic delusions. However, it has also been reported in schizophrenia, affective disorders, and organic or induced psychosis. Treatment is based on antipsychotic agents, psychotherapy and cooperation between dermatologists and psychiatrists.

Keywords Dermatzoic delusion; Ekbom syndrome; Infestation; Parasitosis

To investigate quality of life in elderly persons with dementia residing in assisting living facility

Y.C. Hsu^{1,*}, W.C. Ouyang², W.S. Huang³

¹ Chang Jung Christian University, Nursing, Tainan city, Taiwan

² Lutung Christian Hospital and Changhua Christian Healthcare System, Psychiatry, Changhua, Taiwan

³ Chang Jung Christian University, Health Care Administration, Tainan City, Taiwan

* Corresponding author.

Introduction With constantly increasing aged populations, quality of life (QOL) in persons with dementia has become a significant research concern. The Alzheimer's Disease Related Quality of Life (ADRQL) is a high-validated, theory-derived, and multidimensional instrument developed by Rabins et al. (1997, 2009) that has widely utilized in many countries, except in Taiwan. However, diverse results of quality of life from different countries by using the same measurement can provide the potential to help understand the impact of cultural contributor on QOL.

Objective To investigate the extent to which quality of life on older adults with dementia in Taiwan.

Methods Cross-sectional, descriptive study conducted in an assisting living facility affiliated with daycare center in southern Taiwan. A purposeful sample of 34 participants was recruited. Inclusion criteria: at least 65 years old, able to communicate, and diagnosed with mild to moderate dementia. The QOL was measured by Chinese version ADRQL. This observational instrument consists of 30 items that is divided to five subscales with the full range of each subscale scores from 0 to 100.0. Higher scores indicate better QOL.

Results The means for subscales of the Social Interaction, Awareness of Self, Feelings and Mood, Enjoyment of Activities, and Response to Surroundings were 87.9, 74.7, 91.3, 64.5, and 90.3, respectively. The overall mean for the scale of ADQOL was 0.83.

Conclusion Findings suggest that the level of enjoyment of activities is the lowest and may convey information about a need of evaluation on arrangement of facility's activities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV731

Comparative efficacy and safety of antidepressive mono- and multimodal therapy with citicoline in elderly patients with depression in psychogeriatric unit

Y. Kalyn*, S. Gavrilova, T. Safarova, E. Shipilova

Mental Health Research Center of the Russian Academy of Medical Sciences, geriatricpsychiatry, Moscow, Russia

* Corresponding author.

Introduction Citicoline is a choline donor involved in the biosynthesis of brain phospholipids and acetylcholine, used for treating neurodegenerative disorders. Several studies have shown its beneficial effects both in degenerative and vascular cognitive decline. Due to its effects on the adrenergic and dopaminergic CNS activity, citicoline can also be used as an adjuvant in depression treatment.

Objectives and aims Comparative evaluation of efficacy and safety of a multimodal antidepressive therapy with ceraxone (citicoline) plus one of the antidepressants (venlafaxine, agomelatine, or fluvoxamine) and monotherapy with the same antidepressant for the treatment of depression in the elderly. Two groups of patients were included in the study (21 patients in each group) aged from 60 to 79 years old, comparable to the main clinical characteristics.

Methods First group patients were treated with a single antidepressant, patients of the second group – with the same antidepressant and intravenous infusions of ceraxone: 10 infusions (500 mg in 100 mL isotonic sodium chloride solution) during 2 weeks, followed by transfer to the drug in solution at 3 mL per os two times a day for six weeks.

Results A multimodal therapy with ceraxone leads to more rapid and significant therapeutic response along with the reduction of adverse events compared to antidepressant monotherapy.

Conclusion Obtained data allows to recommend a multimodal antidepressive therapy with ceraxone (citicoline) for the treatment of elderly depressive patients to reduce the risk of adverse effects of antidepressants and to shorten hospitalization period.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A case report of Charles Bonnet syndrome – the silent doubt: Am I crazy?

A. Lopes*, P. Sales

Hospital Garcia de Orta, Psichiatria, Almada, Portugal

* Corresponding author.

Introduction The Charles Bonnet syndrome refers to symptoms of visual hallucinations that occur in patients with visual acuity or visual field loss. These are often called release hallucinations, reflecting the most widely accepted theory about their pathogenesis. The syndrome is most found in elderly patients, 70–85 years, and this probably reflect the mean age at which the most common underlying conditions are seen. It is probably more common than is thought and because either it is misdiagnosed as psychosis and/or dementia or it is not reported by patients because they fear that the hallucinations represent psychiatric disease.

Objective and method The authors present the clinical case of a 89-year-old woman, with no previous psychiatric disease, admitted to hospital because of visual hallucinations in form of children and animals. She experienced them during months until she told someone. No psychiatric symptoms were found. The lady had a serious cataract on the left eye with total loss of the visual acuity, as documented by ophthalmologic examination.

Results The patient initiated quetiapine 300 mg and will have period appointments with a neurologist. Further future information will be presented.

Conclusions A correct diagnosis is essential to treat these patients and explaining them the meaning of the hallucinations is generally relieving. Many author disagree with antipsychotic agents, while others report benefit.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Very late-onset schizophrenia-like psychosis: Case report and current status of the issue

R. Martín Aragón*, M. Gutiérrez Rodríguez, S. Bravo Herrero, C. Moreno Menguián, N. Rodríguez Criado, J.F. Cruz Fourcade, P. Muñoz-Calero Franco, B. Sánchez Sánchez

Hospital Universitario de Móstoles, Psichiatria, Móstoles, Spain

* Corresponding author.

Introduction Schizophrenia has traditionally been considered to strictly be an early-onset disorder. Current nosologies, including DSMV, are not restrictive with age of onset in schizophrenia and all patients that satisfy diagnostic criteria fall into the

same category. Since 1998, International Late-Onset Schizophrenia Group consensus, patients after 60 are classified as very-late onset schizophrenia-like psychosis. Female overrepresentation, low prevalence of formal thought disorder, and a higher prevalence of visual hallucinations are associated with later age at onset. Atypical antipsychotics represent the election treatment because of the reduced likelihood of EPS and tardive dyskinesias, and should be started at very low doses, with slow increases.

Objective To review the current knowledge about very late-onset schizophrenia through systematic review of the literature and the analysis of a case.

Methods Case Report. Review. Literature sources were obtained through electronic search in PubMed database of last fifteen years.

Results We present a case of a 86-year-old woman suffering from delusions and hallucinations, diagnosed with very late-onset schizophrenia-like psychosis, after differential diagnosis with other disorders. We analyze etiology, epidemiology, clinical features and treatment in geriatric patients with schizophrenia.

Conclusions Reluctance to diagnose schizophrenia in old people is still present today, probably in relation with the inconsistency in diagnostic systems and nomenclature, and consideration of medical conditions in the diagnosis. Identification of these patients is really important in order to start an appropriate treatment, which can lead to patient clinical stability.

Paliperidone palmitate in psychogeriatric patients and new criteria STOPP-START

I. Martínez Pérez^{1,*}, F. García Sánchez², M.R. Raposo Hernandez³, A. Gil Sánchez⁴, A.L. Gonzalez Galdamez³, M.D. Piqueras Acevedo³, J.M. Lujan Rico¹, A. Belmar Simo³, C.J. García Briñol³

³ Hospital Universitario Santa Lucia, Psiquiatría, Cartagena, Spain

⁴ Centro Salud Mental Vicente Campillo, Psiquiatría, Murcia, Spain

* Corresponding author.

The treatment of psychosis in the elderly should ensure effectiveness and avoid side effects from combination therapy. Long acting antipsychotic as paliperidone palmitate facilitates this work. Furthermore, STOPP-START criteria, first published in 2008 (in Spanish in 2009), are being adopted as reference criteria throughout Europe. The Spanish version of the new 2014 edition is also recently published [1]. A descriptive study of a total of 53 institutionalized patients in psychogeriatric residence (> 60 to 97 years) with psychotic disorder diagnosis and treatment with various neuroleptics is done. In total, 26.4% of the sample admitted to treatment with three different antipsychotics, and 47.1% with combination of two antipsychotics. Only 26.4% worked with antipsychotic monotherapy. In these patients, treatment with paliperidone palmitate starts or sets the previous dose. A CGI scale is applied after six months of treatment. Antipsychotic monotherapy in 66.66% of patients on neuroleptic combination therapy was achieved, so that 75% of the sample currently maintains monotherapy with paliperidone palmitate. The paliperidone palmitate has shown effectiveness in the symptomatic control and reducing the risk of inappropriate prescribing in older patients with psychosis. The paliperidone palmitate allows antipsychotic monotherapy in the psychogeriatric patient with severe mental illness polymedicated as the STOPP-START criteria recommends.

Comorbidity and polypharmacy in elderly living in nursing homes

A.R. Ferreira^{1,*}, S. Martins², L. Fernandes³

¹ PhD Program in Clinical and Health Services Research/PDICC, Health Information and Decision Sciences Department, Faculty of Medicine of University of Porto, Porto, Portugal

² Center for Health Technology and Services Research/CINTESIS, Faculty of Medicine of University of Porto, Porto, Portugal

³ Center for Health Technology and Services Research/CINTESIS, Faculty of Medicine of University of Porto, Psychiatry Service - CHSJ Porto, Porto, Portugal

* Corresponding author.

Introduction The ageing process is characterized by a high level of complexity, due to the co-occurrence of multiple chronic diseases (comorbidity) that often results in the concomitant use of multiple drug therapies (polypharmacy) for treatment and prophylaxis. Institutionalized elderly may be regarded as the paradigm of this complexity because of their multiple chronic diseases and decreased functional and cognitive functions.

Objective To explore and characterize the prevalence of comorbidity and polypharmacy in a sample of institutionalized elderly.

Methods A cross-sectional study was conducted with an elderly sample recruited from three Portuguese nursing homes. Clinical information was obtained through interview and by review of residents' medical records. The Anatomical Therapeutic Chemical/ATC classification was used to indicate the main group of medicines used, and polypharmacy was categorized into minor (2–4 medicines) or major (≥ 5). Comorbidities were coded using the individual body systems of Cumulative Illness Rating Scale for Geriatrics/CIRS-G.

Results The sample included 175 elderly with a mean age of 81 (sd = 10) years and institutionalized for an average of 7 (sd = 11) years. Residents presented a mean of 9 (sd = 4) co-morbid medical conditions, mostly psychiatric (80.8%), vascular (76.7%) and endocrine/metabolic (70.3%). Major polypharmacy was verified for 73.9% of residents. The mean number of medicines was 7 (sd = 3), most commonly for cardiovascular (86.0%) and nervous system (79.1%) and for blood and blood-forming organs (69.2%).

Conclusions As in other studies in similar settings, polypharmacy was fairly common. These results convey an important message considering that polypharmacy has been associated with negative clinical outcomes that could otherwise be preventable by reducing the number of prescribed medicines.

A case report of a Capgras' syndrome in elderly

C. Moreno Menguiano*, M. Gutierrez Rodriguez, F. Garcia Sanchez, S. Bravo Herrero

Hospital Universitario de Móstoles, Psiquiatría, Móstoles, Spain

* Corresponding author.

Introduction Capgras syndrome is the most frequent delusional misidentification syndrome (DMS) which was first described in 1923 by Capgras and Reboul-Lachaux as 'L'illusion des sosies'. Consists of believe that close relatives have been replaced by nearly identical impostors. It can occur in the context of psychiatric disorders (schizophrenia, major depression) such organic, in which

onset of delirium is usually later coinciding with neurological damage or neurodegenerative disease.

Case report Woman 73-year-old diagnosed of schizophrenia since more than thirty years ago. Her family talk about general impairment of the patient in the last two years. She needed a couple of psychiatric hospitalizations because of her psychiatric disease, and probably onset of cognitive impairment. In this context, we objectified the presence of a Capgras syndrome.

Objectives To review the literature available about Capgras syndrome in elderly and illustrate it with a clinical case.

Methods Review of literature about Capgras syndrome in elderly by searching of articles in the PubMed database of the last five years to illustrate the exposure of a single case report.

Results The etiology of this syndrome is not yet well understood. Advanced age is frequently found Capgras syndrome with or without the concomitant presence of an obvious cognitive impairment. **Conclusions** Since it is a complex process an etiological model that combines cognitive and perceptual deficits, organic impairment and psychodynamic factors should be proposed. And it is important to make a correct differential diagnosis that allows us to carry out the best possible treatment.

From the Asperger's syndrome to the Diogenes syndrome

C. Padovan^{1,*}, J. Laurent¹, Dr M. Herrmann², G. Chesnoy-Servanin¹, Dr J.M. Dorey³

¹ Centre hospitalier Le Vinatier, pôle Est, Consultation Mémoire, service du Dr Dorey, Bron, France

² Centre hospitalier Le Vinatier, pôle Est, service de psychiatrie du sujet âgé, service du Dr Dorey, Bron, France

³ Centre hospitalier Le Vinatier, pôle Est, Consultation Mémoire, service de psychiatrie du sujet âgé, service du Dr Dorey, Bron, France

* Corresponding author.

The Diogenes and Asperger's syndromes share social cognition deficits and a disturbance in social functioning. Our objective is to discuss the close relationship between these two clinical entities. In routine clinical practice of aging people, the Asperger's syndrome is rarely seen in medical consultation because symptoms may be confused with other psychiatric diseases more prevalent in aging population. The aim is to discover if Asperger's syndrome could be the comorbidity of another symptom, such as Diogenes syndrome or if it is a primary syndrome engendering other symptoms, such as Diogenes syndrome. In this perspective, the Asperger's syndrome could be seen as a misunderstood syndrome in aging people. We report the case of a patient whose Diogenes syndrome was discovered during a social intervention visit by a nurse, following a medical consultation for a breach of trust issue and behavioural disorders. The neuropsychological assessment of this patient revealed:

- normal intellectual, memory and instrumental functioning;
- a difficulty in a problem solving task only for the task involving the use of a context to answer;
- an impairment in an emotional recognition task.

During the psychiatric examination, the relationship was strange. The patient exhibited symptoms that mimic those of people having an Asperger's syndrome. In aging people, the Asperger's syndrome should be routinely screened in case of self-neglect, domestic squalor, excessive social withdrawal, hoarding, a lack of concern for one's living condition and a lack of shame.

Depression in geriatric inpatients: Correlations with nutritional state and cognitive functions

I. Bonfitto¹, G. Moniello², L. Ariano², M. Pascucci^{1,*}, M.D. Zanasi², A. Bellomo¹

¹ University of Foggia, Institute of Psychiatry, Foggia, Italy

² Ospedali Riuniti di Foggia, Department of Geriatric Medicine, Foggia, Italy

* Corresponding author.

Background Although the prevalence of malnutrition is relatively low among elderly people, the risk increases significantly among inpatients and even more in those with mental deterioration.

Aims To evaluate the possible association between the severity of depressive symptoms, the nutritional status and the cognitive decline in a sample of geriatric inpatients.

Methods Fifty-one geriatric inpatients completed the following tests:

- Hamilton Depression Rating Scale (HAM-D), to assess the severity of depressive symptoms;
- Mini Nutritional Assessment (MNA), as a nutrition screening and assessment tool;
- Mini Mental State Examination (MMSE), to assess the cognitive impairment.

Results There is a negative proportional relationship between HAM-D and MMSE scores ($P=0.001$) and between HAM-D and MNA scores ($P=0.023$). Depressed patients found to have a greater cognitive impairment and a worse nutritional status. Considering a HAM-D cut-off point of 14, distinguishing mild than moderate depression, it shows a significant correlation with the MNA scores ($P=0.008$). Patients with HAM-D scores ≥ 14 have an average MNA score of 19.8, while patients with HAM-D scores < 14 have an MNA average score of 23.6. Euthymic or mildly depressed patients are not at risk of malnutrition, while those with moderate or severe depression have an increased risk of malnutrition.

Conclusions Our study shows significant correlations between the severity of depressive symptoms and the risk of malnutrition or cognitive impairment. A mild depression state does not seem to be associated with an increased risk of malnutrition.

Neuropsychological and motivational factors of cognitive efficiency in elderly patients with essential arterial hypertension

E. Pervichko^{1,*}, Y. Zinchenko¹, O. Ostroumova²

¹ Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

² Moscow State University of Medicine and Dentistry, Faculty of General Medicine, Moscow, Russia

* Corresponding author.

Introduction The diagnostics of cognitive disorders (CD) in patients with essential arterial hypertension (EAH) is often necessary for the choice of treatment strategy.

Objective To assess the role of neuropsychological and motivational factors in cognitive efficiency of elderly EAH patients.

Materials and methods Twenty-five patients with EAH took part in the study, stage 1–2, mean age was 67.6 ± 6.1 . The assessment of cognitive functions embraced a quantitative measurement of intelligence quotient (IQ) with the Wechsler Adult Intelligence

Scale (Wechsler, 1955), and investigation into qualitative features of cognitive processes with Luria's neuropsychological assessment scheme (Luria, 1980) and Zeigarnik's procedure of pathopsychological study (Zeigarnik, 1972).

Results Within the psychological syndrome structure of CD in EAH patients the leading part is played by the neuro-dynamic factor, manifested in general lability, slowing down, and sudden exhaustion caused by reduction in energy of mental activity. The conclusion is supported by the high frequency of described symptoms among EAH patients and low dynamics of their reduction against the antihypertensive therapy (Pervichko et al., 2014, 2015). However, performance of experimental tasks makes 30% of EAH patients reveal reduced motivation. They would achieve poor results in general scoring, if compared with the group of highly motivated participants. Correlation analysis data show the interconnection between frequency disturbances in motivation and frequency in occurrence of various signs of cognitive decline, such as low efficiency in memorization and delayed recall, as well as low IQ indices.

Conclusions The data provide a strong argument to support the hypothesis of particular importance of motivational factor of cognitive efficiency in elderly EAH patients.

Case-report and review of selective serotonin reuptake inhibitors-induced delirium in older adults

S. Petrykiv^{1,*}, L. de Jonge², M. Arts³

¹ GGZ Friesland, Psychiatric Emergency, Leeuwarden, Netherlands

² UMC Groningen, Epidemiology, Groningen, Netherlands

³ UMC Groningen, Old Age Psychiatry, Groningen, Netherlands

* Corresponding author.

Introduction Selective serotonin reuptake inhibitors (SSRIs) are the most widely prescribed antidepressants with generally fewer side effects than most other types of antidepressants. However, in frail elderly, the use of SSRIs was anecdotally reported as a potential cause of a delirium.

Objectives To present a case of citalopram-induced delirium in an older adult diagnosed with late-life depression.

Aims To review available literature on SSRI-induced delirium.

Methods A case report is presented and discussed, followed by a literature review.

Results Seven published cases of SSRI-induced delirium in older adults (>60 years) were found while searching through Pubmed and Embase. Our case of a 75-year-old female is also included in this report. This patient was ambulatory treated with citalopram 20 mg per os against depressive symptoms and she developed a delirium four days after the initiation of the therapy. Blood tests were normal and CT scan showed no significant findings. No other medical evidence was found that could explain her delirium. Her symptoms finally resolved after discontinuation of citalopram.

Conclusion The on- and off-treatment side-effect correlation by a segregate oral use of citalopram strongly suggests that SSRIs may have the potential to cause a delirium, especially in frail elderly. Further research on this topic is needed.

The frequency of anxiety and depressive symptoms in Iranian older patients with serious and persistent psychiatric disorders admitted to long-term care in Razi Psychiatric Hospital

V. Rashedi^{1,*}, B. Maghsodlou-Estarabadi², S. Zamaninejad³, M. Foroughan¹

¹ University of Social Welfare and Rehabilitation Sciences, Iranian Research Center on Aging, Tehran, Iran

² University of Social Welfare and Rehabilitation Sciences, Department of Psychiatry, Tehran, Iran

³ Gorgan University of Medical Science, Department of Dentistry, Golestan, Iran

* Corresponding author.

Introduction Anxiety and depressive symptoms occur commonly in older adults and are associated with several negative outcomes including personal distress, disability burden, and increased use of health services.

Objective To determine the frequency of anxiety and depressive symptoms in Iranian older adults with persistent psychiatric disorders admitted to Razi Psychiatric Hospital.

Aims To indicate the importance of in-current prevention and therapeutic interventions in psychiatric long-term care units by giving an estimation of the frequency of depressive and anxiety symptoms in older residents.

Methods A cross-sectional, hospital-based study was performed which included male older people admitted to Razi Psychiatric Hospital, Tehran, Iran. The Hospital Anxiety and Depression Scale (HADS), Abbreviated Mental Test score (AMTs) and a demographic questionnaire were used to gather the data.

Results Ninety-four male patients were recruited into the study. The mean age of the sample was 65.65 years (SD: 3.50), mean years of hospitalization was 21.17 (SD: 10.89), and mean years of education was 5.27 (SD: 5.28). Based on the results, mean of AMT score was 6 ± 2.92 . Mean score of anxiety and depression were 8.29 (SD: 4.61) and 9.40 (SD: 3.75), and the frequency of anxiety and depressive symptoms were 29.8% and 42.6%, respectively.

Conclusions Anxiety and depressive symptoms are common in older aged care residents of psychiatric hospitals; therefore, providing hospital-based programs focused on prevention and therapeutic interventions to manage these symptoms in psychiatric older patients is needed. Using appropriate screening instruments, periodically, may help the recognition of anxiety and depression in geriatric-psychiatric population.

Differential diagnosis based on age. Diagnostic difficulties

S. Rodríguez Vargas
Almería, Spain

Introduction Following a case presented in our inpatient unit as well as various interdepartmental from internal medicine and other emergencies, we decided to conduct a literature review on the different organic causes that can trigger the onset of psychotic symptoms in elderly.

Objectives A correct differential diagnosis of psychiatric symptoms in elderly.

Aims Literature review of the literature on the presentation of psychotic symptoms in the elderly.

Methods Description of a clinical case and development of diagnostic hypotheses.

Results and conclusions For several decades are experiencing a gradual aging of the population, which means that we are at the onset of clinical symptoms not described by classical authors. Furthermore, scientific advances make infectious causes (such as neurosyphilis was our first diagnostic hypothesis) are increasingly rare. The elderly usually has multiple comorbidities, which are receiving various treatments that must be ruled out possible adverse effects.

Spousal caregiving for Parkinson's disease: Life changing dynamics

P. Seibert

Saint Alphonsus Regional Medical Center, Research Institute, Boise, USA

Although worldwide estimates of the prevalence of Parkinson's disease (PD) have been difficult to obtain, it is agreed that the frequency of cases is rising with the increase in human life expectancy. Spouses often assume the primary responsibility for individuals with PD and this considerable burden impacts all aspects of the caregivers' (CG) and their families' lives. Few have formal training in administering health care; yet they are required by necessity to undertake the CG role. We constructed two questionnaires specified for PD (84 items) and their CG (81 items). Both were either mailed or emailed to 256 people from a PD association list. We also conducted in person interviews with 8 pairs of PD and CG. The questionnaires and interviews included a wide range of topics such as health history and change, physiological health, social engagement, support availability, stressors, emotional health, sleep, financial concerns, and overall QoL. Fifty-nine participants responded to the questionnaire (PD: 20 males, mean age 73.42; 11 females, mean age 77.73; (CG: 4 males, mean age 85.25; 24 females, mean age 69.13). We analyzed data specific to CG and also made comparisons between the CD and PD groups. Findings revealed increasingly significant physiological and psychiatric issues for both the PD and CG. PD reported greater satisfaction with support systems while CG expressed concern regarding the paucity of support for themselves. The presence of PD creates a multifaceted exponential increase in challenges to QoL for both PD and their CG with the latter receiving little support.

Collaborative care between clinical pharmacists and general practitioners in patients with Alzheimer's disease in Slovenia

M. Stuhec^{1,*}, A. Premus Marusic²

¹ Ormoz's Psychiatric Hospital, Clinical Pharmacy, Ormoz, Slovenia

² General Hospital Murska Sobota, Clinical Pharmacy, Murska Sobota, Slovenia, Slovenia

* Corresponding author.

Background Alzheimer's disease (AD) patients are often treated with inadequate doses of AD's medications, which can lead to harms and additional costs.

Objective In most European countries, there is no data on inappropriate prescribing (IP) in patients with AD in terms of inadequate doses. In Slovenia, the interest for a collaborative care between

clinical pharmacists and physicians is increasing, mainly because of payer's interest to reduce several additional costs.

Aim The main aim of this paper was to present the benefits of clinical pharmacist interventions in AD patients in community health centres in Eastern Slovenia.

Methods All included outpatients with AD in 2013 were included, where clinical pharmacists' interventions were ordered by the general practitioners (GPs). All study data from the patients' records were obtained from the clinical pharmacists' reports and patients' charts. Main outcome measures were obtained from the summary of the patients' treatments and the questionnaires.

Results Six hundred and twenty-nine patients were included. Before the clinical pharmacist medications review, 39 patients were treated with AD medications (10 without established AD). In 51.0% of these cases, the suggestions to GPs were provided (mainly dose adjustment). In 70.0% of all cases, the recommendations were accepted by GPs, which led to a total reduction in the number of patients with IP (before 20 and after 6).

Conclusions A clinical pharmacist could help GPs in recognizing IP in patients with AD. These data will guide health system directors and clinical coordinators in allocating resources to establish this cooperation in more European countries.

Weathering the silver tsunami: Dementia community services in Singapore

C.H. Ting*, W.P. Lim

Tan Tock Seng Hospital, Psychological Medicine, Singapore, Singapore

* Corresponding author.

Introduction The prevalence of dementia rises with the rapidly increasing elderly population in developed world. In Singapore, 10% of the elderly population is estimated to have dementia. Other than physical and psychological needs, social welfare should also be addressed with the support of specialised geriatric care sources to improve their quality of life.

Objective To study a case of an elderly with dementia, who was identified and managed through a multi-agency approach and to describe different services involved for dementia care.

Aim To highlight the various elderly care organizations available in Singapore to address healthcare and social needs in dementia.

Method Through a case report of an elderly who presented to hospital for medical issues with dementia, the social needs were identified and multiple agencies were involved to provide holistic care in dementia.

Result A 77-year-old gentleman was brought by a community social worker to hospital as he was found ill during home visit. During admission, the concern for poor self-care and cognition decline was raised by his family. Mini-mental state examination was 16/30. He was diagnosed with vascular dementia with clinical and MRI Brain finding. With active multidisciplinary intervention, his medical issues were addressed, and family and social needs were attended by several voluntary welfare organizations. Access to memory clinic service was also arranged for. This intervention also provided opportunity for his long-term care and welfare.

Conclusion Multi-agency approach is crucial in dementia care to identify their unmet needs and plan for long-term care in Singapore.

Hostility and emotional load of Tunisian caregivers of Alzheimer patients and its impact on the patient

M. Zghal^{1,*}, L. Robbena², F. El Ghali², I. Ben Ghzael², R. Rafrafi³

¹ Tunis, Tunisia

² Hôpital Razi, Mannouba, Tunis, Tunisia

³ Hôpital Razi, Mannouba, Tunis, Tunisia

* Corresponding author.

Introduction The studies on Alzheimer disease highlight the family caregivers burden and his consequences on hostility. Few authors study the burden and the mental health of the caregivers of a demented relative.

Aims This study aims at assessing the hostility and emotional load of caregivers of Alzheimer patients and determining the relation between the burden and the psychic health caregivers and its impact on the patient.

Methods It is a descriptive cross-sectional study. Patients were recruited from the neurology department of Razi hospital Tunisia between January and June 2013. Consenting caregivers participating in the study were interviewed with a structured survey focused on their socio-demographic characteristics, the characteristics of the aid relationship and the emotional burden felt valued by the Family Attitude Scale (FAS).

Results The caregiver was in nearly 60% a child. He lived under the same roof in 78.3% of cases. In 65% of cases, it passes between 12 and 24 hours with the patient. FAS score was 52.4 ± 16.16 . Thirty-five percent of caregivers had a significant emotional burden (score > 60). FAS score was not correlated with the age of the helping relationship, cohabitation with the patient or the number of hours spent with him. The children had a greater emotional charge than spouses ($P=0.001$). The wickedness against the patient and abuse, the desire to institutionalize were related to the importance of the emotional charge ($P<0.001$).

Conclusions These hostile thoughts are mostly directed against the patient but it can also be directed against oneself causing depression and guilt.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Alcohol intoxication. Emergency management

I. Sevillano^{1,*}, P. Marqués¹, E. Mayor¹, S. Cepedello¹, A. San Román², R. Hernandez¹, S. Gómez¹, C. Noval¹, F. Uribe³

¹ Hospital Clínico Universitario Valladolid, Psiquiatría, Valladolid, Spain

² Complejo Asistencial de Zamora, Psiquiatría, Zamora, Spain

³ Hospital Clínico Universitario Valladolid, Jefe de Servicio de Psiquiatría, Valladolid, Spain

* Corresponding author.

Introduction Intoxications are very frequent in urgencies. Their gravity must be considered. Mild cases must be observed. In serious intoxications, despite the basic measures of support, complementary examinations must be realized to reject complications.

Objectives To unify criteria about general management of alcohol intoxications in urgencies. To propose a guideline that allows taking suitable decisions.

Methods Despite the treatment is individualized, we present some recommendations of action in alcohol poisoning.

General measures Clinical examination and vital signs (blood pressure, temperature, pulse and breathing rates, O₂ sat levels, capillary glycemia). In moderate or severe ones: hemogram, biochemistry, coagulation, acid-base and electrolyte status, electrocardiogram, chest X-ray, urine tox. Initial treatment of basic support (ABC) and complications control. Psychiatric evaluation is necessary when suicidal thoughts are present. Alcohol abuse produces lack of inhibition and common sense, more aggressiveness and impulsivity, and even an increased risk of suicide.

Conclusions These patients are often hostile with health personnel, but when blood alcohol level diminishes, they improve their attitude and they show hopelessness, guilty and self-hate feelings. It is necessary that emergency staff to become aware of the importance of suitable psychiatric evaluation. Psychopathological exploration must be as wide as possible; the patient must be re-evaluated when the poisoning has reverted. These patients are not self-critical and they have reduced their cognitive capacities; some of them have behavioral disturbances that usually disappear when the poisoning is in remission.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pregnancy: Challenges in psychopharmacological therapy

F. Vieira*, J. Teixeira Silva, A. Vieira Araújo
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction The pregnant psychiatric patient on or requiring psychotropic medication presents an unusual clinical dilemma. Clinicians may only rarely treat patients who are pregnant or planning to be pregnant and may be unfamiliar with the current state of the literature and what can and cannot be concluded from it. Although ethical considerations have precluded adequately controlled studies with pregnant woman, the rate of psychotropic use together with the prevalence of certain psychiatric conditions during pregnancy underscore the need for treatment guidelines to help clinicians manage pregnant patients with psychiatric disorders.

Objectives Review the safety, on the mother and fetus, of the use of psychopharmacological therapy during pregnancy.

Aims We aim to provide guidance on the psychopharmacologic treatment of pregnant women.

Methods Pubmed was used to search for relevant Portuguese and English language articles relating to psychopharmacological drug use during pregnancy up to October 2015. The search terms used were “psychopharmacological”, “psychotropic” and “pregnancy”. Reference lists of the identified articles were further used to identify other studies.

Results If treatment is deemed necessary, monotherapy at the lowest possible dose should be prescribed. More robust safety data is available for older psychotropic drugs, which, most of the times, should be employed in preference to newer agents with unestablished safety.

Conclusions Appropriate risk-benefit analysis of untreated mental illness versus medication exposure, within in the context of the available evidence, should guide clinical decision-making.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁷ Consulta privada de psicología, Psicología, Madrid, Spain

* Corresponding author.

Introduction In DSM-V, catatonia is individualized as a disease of its own. The priority is to look first for organic causes like intoxication. We present a clinical case diagnosed with intellectual disability (ID) and catatonia.

Objective To study a case of catatonia which underwent testing using Bush-Francis Catatonia rating scale (BFCS) prior/after clinical intervention. We therefore study catatonia's etiology in ID population.

Aims To study the etiology of catatonia (and its clinical complications) in ID.

Method Our patient is 48-year-old female with DI. Considering her clinical features of catatonia (using BFCS) and clinical examination (fever and hypoxia), the case orientated towards a secondary diagnosis. Work-up tests revealed pneumonia in the lower lobe of the right lung (chest radiography showed opacities and blood tests showed Leukocytosis with a left shift). The case further received a course oral levofloxacin (500 mg/day) and haloperidol was stopped. Valproic acid was also added to a dose of 600 mg/day, which led to clinical improvement. Remaining psychotropic treatment (duloxetine 60 mg/day, lorazepam 15 mg/day, diazepam 35 mg/day) was not modified.

Results After 1 month, the patient improved according to BFCS score.

Conclusions We presented a case of presence of catatonia in other psychiatric conditions and undiagnosed general medical conditions. Haloperidol is contraindicated those circumstances and it may have worsened her clinical state (it should be used cautiously in DI). Other medications (gabaergic drugs) should be considered in such settings and rare causes related to hypoxia cannot be ruled out (Table 1).

Table 1

BFCSR	Prior treatment	After treatment
First 14 items	23 points	14 points
Total score	29 points	18 points

Challenging behaviour in people with intellectual disabilities: The assessment and intervention team

K. Courtenay^{1,*}, S. Jaydeokar²

¹ UCL, Department Mental Health Sciences, London, United Kingdom

² Barnet Enfield Haringey Mental Health NHS Trust, Intellectual Disabilities, London, United Kingdom

* Corresponding author.

Objectives People with intellectual disabilities (ID) present with behaviours that challenge community services. Community models of care as alternatives to hospital care exist but are often vary in their function. Certain strategies have been developed to manage challenging behaviour in people with ID. Data from a three-year period on a community-based service for people with ID and challenging behaviour that uses an objective, multi-disciplinary approach is presented.

Methods A case note survey of adults with ID under the care of the Assessment and Intervention Team (AIT), a challenging behaviour service in the London Borough of Haringey.

Results Over the three-year period, 65 adults were managed by AIT. Forty-four were male and 21 were female. The age range was 21–64 years of age. The level of ID was mild ID 61%, moderate 39%. Diagnoses included psychotic disorder (25%); mood disorder (20%); developmental disorder (40%); dementia (10%); challenging behaviour (45%). Six people (11%) were admitted to hospital during their time with AIT. The length of care under AIT ranged from four to fourteen months.

Conclusions AIT managed effectively people with ID living in the community who presented with complex problems putting their placement at risk. The rate of hospital admission was reduced in this period compared with the previous three years. The length of stay in in-patient services was reduced. The most common reasons for the behaviours included mental illness and ‘challenging behaviour’. People with developmental disorders were a large proportion. Community alternatives are effective with positive benefits to the person.

Evaluation of DBT manual adapted for people with intellectual and developmental disabilities (IDD): First results

S. Elstner

Ev. Krankenhaus Königin Elisabeth Herzberge, Psychiatry, Psychotherapy and Psychosomatics, Berlin, Germany

Introduction In contrast to psychopharmacological treatment, the current evidence base in psychotherapy for people with IDD is limited. But psychotherapeutic approaches offer an alternative treatment modality in people with IDD.

Objectives Orientated on the “Dialectic-Behaviour-Therapy” concept, we developed an adapted manual for people with IDD and impulsive behaviour.

Aims This study presents the first results of an evaluation our adapted DBT manual.

Methods Three closed groups with 11 patients in total were prospectively included in a six-week in-patient psychotherapeutic DBT-programme. There was no randomisation or control group. Typical borderline symptoms (BS) were recorded using the “Borderline Symptom List” (BSL) and a short screening version for personality disorders (PSS-K). Impulsivity and behaviour in general were observed with the scale for impulsiveness and emotional deregulation (IES) and the German Developmental Behavioural

Checklist (VFE). Special tendencies to self-harm were assessed using the scale for self-harm behaviour (IEFAS). From these scales, the means were observed during the course of our hospital therapy program over 6 weeks.

Results There were 19 patients in total in 3 different groups. Eight dropped out for a variety of reasons. The mean scores for the remaining 11 patients in the BSL and PSS-K reduced significantly. The scores for impulsivity and self-harm improved. Overall, there was no significant change in behaviour.

Conclusion This study presents the results of a trial of a DBT manual for people with IDD and BS. In general the BS declined, the impulsivity improved. The study is limited by the small numbers in the patient sample and the absence of a control group.

EV752

Psychotherapy for ADHD in people with IDD

S. Elstner

Ev. Krankenhaus Königin Elisabeth Herzberge, Psychiatry, Psychotherapy and Psychosomatics, Berlin, Germany

Introduction Psychopharmacology and psychotherapy in children with ADHD is still well established and has been studied for many years. There has been a growing interest in treatment of ADHD in adults for some years. Whereas meanwhile the psychopharmacological treatment is well studied, the psychotherapeutic interventions are still to optimize.

Objective Since the acceptance of the diagnosis of “ADHD” in adults, there has been a growing interest in using medication as the first-line therapy. There is an established evidence base for psychopharmacological treatment in ADHD. The current therapeutic recommendations for the general population apply to people with ADHD and IDD. The study is a review of psychotherapeutic interventions in the treatment of ADHD in adults with and without IDD supported by a case study.

Methods A literature search was conducted in “Pubmed” and “PsycInfo” using the keywords “Psychotherapy”, “ADHD”, “Adults” and further “Psychotherapy”, “ADHD”, “Adults”, “intellectual”, “disabilities”. Exclusion criterion was ADHD as a sub-syndrome in the presence of other syndromes.

Results Only 2–3 publications on psychotherapy in adults with ADHD were found. Very little was found on people with IDD, and these were especially combined with the Fragile X Syndrome.

Conclusion Psychotherapy in adults with ADHD is not yet well elaborated in the scientific literature. There are some common used intervention strategies like psycho-education, cognitive behavioural therapy, and attention focusing interventions such as mindfulness-strategies. Using the principles of Easy-to-Read language and modifying the general therapeutic settings as recommended by NICE, an adaptation of these interventions in the treatment of adults with ADHD and IDD has potential.

Think fast, treat faster – a case of a treatable rapidly progressive dementia

V. Espirito Santo^{1,*}, A.R. Figueiredo², R. Almendra¹, A. Almeida³, P. Guimaraes¹, A.G. Velon¹

¹ Centro Hospitalar Trás-os-Montes e Alto Douro, Serviço de Neurologia, Vila Real, Portugal

² Centro Hospitalar Trás-os-Montes e Alto Douro, Serviço de Psiquiatria, Vila Real, Portugal

³ Centro Hospitalar Trás-os-Montes e Alto Douro, Serviço de Neurologia, Neuropsicologia,, Vila Real, Portugal

* Corresponding author.

Introduction Rapidly progressive dementias (RPD) are conditions that develop over days, weeks or months, which could be treatable if diagnosed in the acute phase.

Clinical case A 62-year-old man with personal history of type 2 diabetes, started complaining of fronto-temporal headache, nausea and sub-febrile temperature. He went to his family doctor who prescribed ciprofloxacin 500 mg bid. Later on, he had difficulty to sleep and referred complex visual hallucinations. His family noted involuntary movements of the left upper limb and that he became more clumsy needing help for daily life activities. He went to our hospital one week later. He was apyretic and hemodynamically stable. On neurological examination, he had executive and visuospatial dysfunction, left limbs bradykinesia and ipsilateral limb ataxia. Involuntary movements of his left upper limb resembled alien limb phenomena. Complete blood count, complete metabolic panel, iron, folic acid, vitamin B12, anti-neuronal antibodies were normal. HIV, hepatitis B and C serologies were negative. Cerebrospinal fluid study showed 4 cells (100% mononuclear), normal glucose and protein levels, negative bacteriological exam but positive Herpes Simplex-1 Virus (HSV) DNA. Brain CT and MRI showed signs of ischemic microangiopathic leukoencephalopathy. He started treatment with acyclovir 30 mg/kg/d IV and quetiapine 100 mg id. His symptoms improved but he remained with a mild mnemonic cognitive deficit and bradykinesia that stayed stable 3 years later.

Conclusion This case exemplifies atypical HSV-1 encephalitis, one cause of RPD, that an early recognition is essential to reduce its associated morbidity.

³ AP-HP, Cochin Hospital, Medical oncology and ethics, Paris, France

⁴ AP-HP, Coirentin-Celton Hospital, Psychiatry, Issy-les-Moulineaux, France

* Corresponding author.

Introduction Down syndrome was clinically described the first time in France by Esquirol (1838) followed by Down (England, 1866), to the identification of a chromosomal abnormality in 1959 (trisomy 21), which is the most common abnormality in neurodevelopmental disorders. Life expectancy increased from 9 years in 1929 to 55 currently. This is a common cause of mental retardation, and few tools are suitable for the care of these patients, including patients with Alzheimer's disease (prevalence of 55% between 50 and 59) or depression (prevalence 30%). No study evaluates the effectiveness of cognitive and behavioral therapy (CBT) in patients with Down syndrome but it is known to be effective in Alzheimer's patients. Some cases have been reported on the efficacy of CBT on phobias in patients with intellectual disability.

Objectives and aims To evaluate the efficacy of CBT in the treatment of a specific phobia in a patient with Down syndrome and early Alzheimer's disease.

Method Literature review and clinical case of a 51-year-old patient, hospitalized under constraints for behavioral disorders (agitation, body treatments refusals).

Results By adapting CBT techniques to the problem of intellectual disability, treatment against the phobia was effective with clinical improvement, which allowed a return home.

Conclusion The tools provided by CBT are suitable for the treatment of anxiety disorders in patients with intellectual disability, especially in patients with Down syndrome. Psychiatric disorders are under-diagnosed in these patients and under-treated. CBT is an aid to the treatment. It may allow the dismantling of symptoms and reduce behavioral problems.

Cretinism muscular hypertrophy: An unorthodox reflection

H. Mohsin*, A. Channa

Liaquat National Hospital, Psychiatry, Karachi, Pakistan

* Corresponding author.

The Kocher Debre Semelaigne Syndrome (KDSS) is also known as cretinism muscular hypertrophy. It is an unusual presentation in intellectually deficit children, commonly associated with congenital or iatrogenic hypothyroidism. The incidence of KDSS is less than 10%. It is more common in males, consanguineous marriage and age range from 18 months to 10 years [4]. The creatinine phosphokinase (CPK) is usually elevated [5]. It might be misdiagnosed particularly when other classical features of hypothyroidism are not dominant at first presentation. We present a case of 15-year-old intellectually deficit female. Her epilepsy had been managed on phenytoin for a decade. She had rigidity, leg cramps, malaise, oliguria, fever, myxedema, delayed deep tendon reflexes, calf muscle hypertrophy and agitation. Her agitation was controlled by haloperidol, which worsened the condition by altering her mental status. The patient was initially managed on line of Neuroleptic Malignant Syndrome due to raised CPK of 40,680 IU/L and mixed presentation. Nevertheless, no significant change was noticed until thyroid profile was done to exclude alternative resources. Thyroid stimulating hormone (TSH) was 74.5 IU, free T3 1.22 ng/dL, and free T4 0.43 ng/dL. Thyroxine was started along with change in anti-epileptic and recovery was observed within five days. This case report highlights the inconsistent finding from previously reported cases of KDSS. The female gender, non-consanguineous marriage, slightly delayed onset with primarily neuromuscular symptoms, and raised CPK is not the frequent demonstration in KDSS. On parallel, thyroid work-up is not routinely done, which can lead to misdiagnosis and mismanagement.

Pathologic aerophagia in patients with intellectual disability: A review of its pathophysiology, clinical features and management

S. Sajith*, W. Wong

Institute of Mental Health, General Psychiatry, Singapore, Singapore

* Corresponding author.

Background Pathologic aerophagia is characterised by excessive swallowing of air resulting in significant abdominal distension or belching. This is a relatively rare condition in general population but

has been reported in up to 8.8% of institutionalized patients with intellectual disability (ID). In severe cases, this can cause volvulus and ileus, and even intestinal perforation. Currently, there is limited information on this potentially life-threatening condition, particularly for people with ID.

Aim To review the up to date literature on the pathophysiology, clinical features and management strategies of pathologic aerophagia in relation to people with ID.

Methods A literature search of electronic database was performed using specific keywords. Review articles were selected using pre-defined criteria.

Results Apart from a few small controlled trials on pharmacotherapy, most of the studies were case series or uncontrolled studies. The understanding on pathophysiology is incomplete but is thought to involve a reflex-induced movement of upper oesophageal sphincter and may be associated with anxiety or stress. A comprehensive history and physical examination as well as an abdominal radiograph may be helpful in diagnosis. The mainstay of treatment is reassurance and behaviour therapy. Medications that are helpful include antacids, anti-reflux drugs and benzodiazepines. Surgical treatment is recommended for patients who do not respond to conservative treatment.

Conclusions Pathologic aerophagia is not uncommon in people with ID and can present with severe challenges in the assessment and management. Further studies are necessary to provide evidence-based treatment guidelines for the management of this condition particularly in patients with ID.

Real-life experience of mentally ill in the seclusion room

C. Aarab*, R. Aalouane, I. Rammouz

Psychiatrist Hospital Ibn Alhassan, Psychiatry, Fès, Morocco

* Corresponding author.

Introduction Seclusion room (SR) is part of coercive interventions in psychiatric hospitals.

Aims Describe the clinical data, and practical modalities of the seclusion room in a psychiatric inpatient unit. Evaluating the experience of patients just after, and away from their exit from the seclusion room to improve their management.

Methodology It is a cross-sectional study evaluating the experiences of patients placed in seclusion room during their hospitalization. Data were collected by interviewing patients directly and by consulting their medical records using an established farm return. The patient placed in a seclusion room was evaluated on day 1, day 7 and out.

Results Of the 120 patients, 57.7% had schizophrenia, 20% of a mood disorder, 14.2% of acute psychotic access and 4.2% a personality disorder. The average duration of the seclusion room was 3.4 days. Seventy-eight percent of patients felt that the conditions of this measure were unbearable. After exiting the room, 60% of patients maintained a good relationship with the team health care, 28% do not trust especially *vis-à-vis* the nurses and 18% experienced a feeling of hatred and resentment.

Conclusion This work has allowed us to take into consideration the experience of patients to promote the care of the mentally ill.

The quality of life of chronic mental patients

I. Adric^{1,*}, B. Dragan², M. Pavlovic², R. Babić², M. Martinac²

¹ University of Mostar, Faculty of Medicine, Mostar, Bosnia and Herzegovina

² University Clinical Hospital Mostar, Department of Psychiatry, Mostar, Bosnia and Herzegovina

* Corresponding author.

Objective Examine the quality of life (QOL) of chronic mental patients due to the socio-demographic characteristics and compare it with the QOL of chronic somatic patients.

Methods and subjects The focus group consisted of 100 chronic mental patients tested at the Department of Psychiatry at the University Clinical Hospital Mostar, and the control group made 60 chronic somatic patients tested at the Family Medicine medical clinic at the Health Center in Mostar. The survey was conducted with a socio-demographic questionnaire and a standardized questionnaire on the QOL of the World Health Organization WHOQOL-BREF.

Results In the mental patients group dominated male population of unemployed individuals, which were living in rural areas. In the somatic patients group, there were more married females of a higher economic status. More than 70% of mental patients smoked cigarettes, while in the second group, less than half of patients smoked. Drinking alcohol was more prominent in the somatic patient group. Nearly all mental patients have been hospitalized at least once, while in the other group only half of the respondents were hospitalized. The QOL of chronic mental patients was inferior to the QOL of chronic somatic patients in all sub-categories: physical health, psychological health, social relationships and environment. The lowest rated subgroup of chronic mental patients was social relations, while for chronic somatic patients that was the environment.

Conclusion The QOL of chronic mental patients was inferior to the QOL of chronic somatic patients.

Keywords Chronic mental patients; Chronic somatic patients; Quality of life

Psychosocial factors associated with frequent rehospitalization of patients with mental health disorders

T. Amirejibi*, N. Zavrashvili

Ilia State University, Faculty of Arts and Sciences, Tbilisi, Georgia

* Corresponding author.

International research, which focuses on frequent users of the psychiatric services and on the psychosocial factors that are associated with frequent rehospitalization, emphasize that the problem of revolving door patient still stands and is severe. Research concerning the above mentioned issue has not been conducted in Georgia, therefore, this study aimed to explore the revolving door patients and psychosocial factors that contribute to their relapse and frequent readmission to acute psychiatric unit. Study was conducted at psychiatric department of Ghudushauri National Medical Center. Qualitative and quantitative analysis based on medical files of 34 adult patients with psychotic disorders, rehospitalized in acute psychiatric unit 60 days after their last discharge in 2012–2014

years, was conducted. Results of the study are in line with international research findings concerning the psychosocial factors that contribute to frequent rehospitalization of patients with psychotic disorders, such as: unemployment (97%), lack of support system (76.5%), non-compliance with treatment (91.2%), emotional reactivity to stressful life events, etc. However, according to the study, family atmosphere turned out to be the central problem which influences the index of conflict and expressed aggression in the family, has impact on the size of patient's support system, on substance abuse, on patient's relapse and on their emergency rehospitalization. According to the results of the study, family atmosphere is one of the most active and multifaceted factors that contribute to patient's relapse and frequent rehospitalization in Georgia. Therefore, implementing and developing interventions discussed in the research paper that will target this factor is essential.

Social representations about the “mad” and the “madness”: Primary care professionals concepts and practices

E. Scherer^{1,*}, N. Sartory², Z. Scherer²

¹ Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, Brazil

² University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences Department, Ribeirão Preto, São Paulo, Brazil

* Corresponding author.

Introduction In Brazil, mental health care is based in asylum perspective and centered in the illness fragmenting the individual and their needs.

Objectives The goal of this study was to know the social representations of primary care health professionals about mental disorder and also the assistance provided to the mentally ill.

Methods This is an exploratory-descriptive field study, whose theoretical background of investigation was the Social Representation Theory. Twelve health professionals took part on this study.

Results We identified that social representations about the “mad” are based on discerning incapability, dangerousness, aggressiveness, incapability of interpersonal relationships. The stigmatizing and excluding view were direct and indirectly present throughout the speeches. Some professionals manage to be able to live with mental disorder patients in social environments but not private ones. Lack of autonomy has been related with the mentally disordered patient, because of their dependency, incapability of choosing and possibility of overcoming. “Madness” was represented as having a psychological, biological, spiritual, social or multiple cause background. The therapeutic approach conceived by most professionals as efficient and possible at the health centers was drug prescription. The doctors presence, medicalization, alienation of the subject, stigma and lack of capability were the weaknesses presented by the study.

Conclusion We conclude that stigma is the biggest barrier for patients to acquire autonomy and citizenship, that professional practices are grounded in our social representations being only possible to transform social process and practices when we admit that our representations recognize these people as different and marginalized.

⁶ National University of Ireland, Biostatistics Department, Galway, Ireland

* Corresponding author.

Introduction Involuntary admission and treatment is often a traumatic experience for patients and there is a wide variation in attitudes towards care even when patients are recovered.

Objectives/aims The purpose of this large prospective study was to identify clinical predictors of attitudes towards care during involuntary admission.

Methods Three hundred and ninety-one consecutively admitted involuntarily patients to three psychiatric inpatient units over a 30-month period were invited to participate in the study. Comprehensive assessments at admission and 3 months after discharge were attained including measures of symptoms, insight, functioning, attitudes towards involuntary admission and coercive experiences. Multiple linear regression modelling was used to determine the optimal explanatory variables for attitudes towards care.

Results Two hundred and sixty-three individuals participated at baseline and 156 (59%) successfully completed follow-up assessments. Individuals improved significantly over time clinically and in their attitudes towards their care. At baseline greater insight ($P < 0.001$) and less symptoms ($P = 0.02$) were associated with more positive attitudes towards care as was older age ($P = 0.001$). At follow-up, greater insight ($P < 0.001$), less symptoms ($P = 0.02$) and being older ($P = 0.04$) were associated with more positive attitudes towards care. More positive attitudes towards care at follow-up were associated with greater improvements in insight over time ($P < 0.001$) and having a diagnosis of an affective psychosis ($P = 0.0009$).

Conclusions The best predictors of positive attitudes towards care during and after involuntary admission are illness related factors, such as levels of insight and improvement in insight, rather than service or legislation related factors, such as the use of coercive measures, seclusion and restraint.

Academic burnout and hope as predictors of mental health

A.A. Bayani

Azadshahr Branch, Islamic Azad University, Psychology, Azadshahr, Iran

Introduction and objectives With increasing understanding of health concept, the importance of mental health becomes more apparent, because mental health provides effective functionality of

individuals, families, and society. This study had two major objectives:

- to examine the relationship between academic burnout, hope and mental health in an Iranian sample;
- to examine to what extent academic burnout and hope predict mental health among secondary school students.

Method Participants of this study were 250 (130 female, 120 male) students. They completed the School Burnout Inventory (BDI, Salmela-Aro et al., 2009), the General Health Questionnaire (GHQ, Goldberg, 1978) and Adult Hope Scale (AHS, Snyder et al., 1991). Correlational analyses indicated that academic burnout and hope were significantly involved in student mental health.

Results The results of multiple regression analysis indicated that mental health was affected differently from two predictor variables.

Conclusion Academic burnout and hope in students endangers their mental health. The model obtained is appropriate for explaining mental health students.

⁵ Shalvata Mental Health Center, Research Manager, Hod Hasharon, Israel

* Corresponding author.

Introduction Every theory that explains psychopathology refers to different aspects of mental pain whether it regards annihilation anxiety, fragmentation of the self or feelings of intolerable anguish. The concept of mental pain has proved to be an important symptom in mood disorders in general and suicide in particular (Orbach et al., 2004; Levi et al., 2010; Levinger et al., 2015). Combining the understanding that mental pain is as a part of all forms of psychopathology with the growing interest in assessing therapeutic processes via outcome measures has led to the assumption that the tolerance and severity of mental pain could become powerful outcome measurement. The aim of this study is to assess the Mental Pain Scale (OMMP) and Tolerance to Mental Pain Scale (TMPS) as outcome measurement and to learn about their capabilities to distinguish between different psychopathologies.

Objective The first objective would be to examine patterns of mental pain subscales in different psychopathologies. The second objective is to assess the OMMP and TMPS as outcome measurements.

Method Two hundred and thirty outpatients were administered a clinical questionnaire battery composed of eight questionnaires. The patients were to fill these questionnaires every 3 months for one year or until the end of their therapy.

Results We will present preliminary findings regarding the expressions of mental pain in different kinds of psychopathology and results of 3 months follow-up.

Conclusion Tolerance and severity of mental pain are a vital to the assessment of psychopathology and should be used as outcome measurement of therapeutic process.

Assessing medication beliefs of mental health professionals: The Portuguese version of the Medication Alliance Beliefs Questionnaire

A. Cardoso^{1,*}, P. Aguiar², M. Byrne³, M. Xavier⁴

¹ Faculty of Medical Sciences, Mental health, CEDOC, Lisbon, Portugal

² National School of Public Health, Public Health, Lisbon, Portugal

³ University of Wollongong, Psychology, Wollongong, Australia

⁴ Nova Medical School, Mental health- CEDOC, Lisbon, Portugal

* Corresponding author.

Introduction Clinician's attitudes are an important consideration in implementing adherence strategies and that these attitudes can be successfully improved as a result of training. The 22-item Medication Alliance Beliefs Questionnaire (MABQ; Byrne et al.2008) was used to assess clinician attitudes towards non-adherence. The MABQ contains five subscales reflecting the clinician's self-efficacy (adequacy), the satisfaction (work satisfaction); their appraisal of their self-worth (self-esteem), their outcome expectancies (pessimism) in relation to non-adherent patients, and the extent to which they understand the difficulties patients might experience in trying to adhere to treatment (empathy).

Aims/objectives To develop the Portuguese version of the MABQ. **Methods** The MABQ was translated and adapted for Portuguese language. The translation was done by the first author (AC). The accuracy of this translation was discussed in a two focus group of experts, providing opinion on face and content validity. After pre-testing, the final version of the Portuguese translation was produced.

Results A convenience sample of 65 mental health professionals working in a variety of settings is being collected. The average score in MABQ was 80.06 (SD 9.5). The value of internal reliability coefficient α was 0.80. The intraclass correlation coefficient of total MABQ score was 0.35. The *t*-test showed that there were no statistically significant differences between the mean values of the measurement scale at two different times (80.4 vs.76.2; $P=0.02$).

Conclusion The attitudes of mental health professionals may have a predictive relationship with treatment outcomes of patients with mental health disorders. The validation of the Portuguese version of MABQ will provide professionals with a new tool to evaluate crucial issues related to medication beliefs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessing strategies to improve antipsychotic adherence: The Portuguese version of the difficulty implementing adherence strategies

A. Cardoso^{1,*}, P. Aguiar², M. Byrne³, M. Xavier⁴

¹ Faculty of Medical Sciences, Mental health, Lisbon, Portugal

² National School of Public Health, Public Health, Lisbon, Portugal

³ University of Wollongong, Psychology, Wollongong, Australia

⁴ Nova Medical School, Mental Health, Lisbon, Portugal

* Corresponding author.

Introduction Non-adherence is a problem throughout medicine and there are many strategies that are used to improve antipsychotic adherence. A review of the literature identified 33 commonly cited strategies for enhancing consumer adherence. Three core

themes were identified: Information/Education; Behavioural strategies; and Cognitive/Motivational strategies.

Aims/objectives To develop the Portuguese version of the DIAS.

Methods The DIAS was translated and adapted for Portuguese language. The translation was done by the first author (AC). The accuracy of this translation was discussed in a two focus group of experts, providing opinion on face and content validity. The participants were asked to rate how often they had difficulties using each of the 33 strategies with consumers who were non-adherent. A four point Likert scale was used (1 = never; 4 = always) such that higher scores indicated more frequent difficulty using the strategy.

Results A convenience sample of 65 mental health professionals working in a variety of settings is being collected. The average score in DIAS was 85.0 (SD14.6). The value of internal reliability coefficient α was 0.93. The intraclass correlation coefficient of total MABQ score was 0.45. The *t*-test showed that there were no statistically significant differences between the mean values of the measurement scale at two different times (84.5 vs.90.5; $P=0.04$).

Conclusion Interventions to improve antipsychotic adherence would benefit from further research. However, it is important always to bear in mind that none of these strategies can be a substitute a positive therapeutic alliance. The Portuguese version of DIAS will provide professionals with a new tool to evaluate the frequency how strategies are implemented and the impact of each strategy in treatment adherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Atypical gender identity and eating disorder: A clinical case report

D. Celona^{1,*}, F. Sandri², E. Pascolo Fabrici³

¹ *Psychiatric clinic, Trieste, Italy*

² *Psychiatric Clinic, Unità degli Studi di Trieste, Trieste, Italy*

³ *Psychiatric Clinic, Università degli Studi di Trieste, Trieste, Italy*

* *Corresponding author.*

Gender identity disorder is a rare disorder of uncertain etiology (1:30,000 M to F; 1:100,000 F to M). The emphasis of body shape in this disorder suggests that there may be an association with anorexia nervosa. Previous research suggests that eating disorders are related to homosexuality in men although links with female sexual orientation is less clear. This report describes the case of an adolescent 19-year-old biological female transgender patient presented to a Mental Health Center in Trieste. Diagnostically, this patient presents with prominent restricting, purging anorexia that was wed by the desire to obtain and then maintain an idealized prototypical masculine shape. The failure of the realization of this project involves in a self-destructive conduct. The case offers an important opportunity to explore the comorbidity about eating disorders and gender identity disorder. The patient completed this measures: a background measure of his sexual orientation, the Millon Clinical Multiaxial Inventory III (MCMI-III), the Minnesota multiphasic personality inventory (MMPI-2), the Bem Sex Role Inventory, the Eating Disorder Inventory and the Eating Attitude test. This report suggests that the divergence of body image psychopathology may be impacted by gender role orientation, which is consistent with a developing body of research.

Epidemiological characteristics and role of socializing activities in a sample of women in Mental Health Centre

D. Celona^{1,*}, F. Sandri², D. Garino², V. Botter³, E. Pascolo Fabrici²

¹ *Psychiatric clinic, Trieste, Italy*

² *Psychiatric Clinic, Università degli Studi di Trieste, Trieste, Italy*

³ *Mental Health Center, Mental Health Centre, Trieste, Italy*

* *Corresponding author.*

Introduction From Charcot studies on Hysteria to recent analysis of the World Health Organization (WHO), mental illness seems to be a matter in which sex and gender play a non-negligible role. In the WHO data on neuropsychiatric disorders, women are prevalent in almost all types of disorder.

Objective Primary prevention can only refer to the recognition of social, educational, relational, environmental factors. Few studies have been conducted on the socio-demographic characteristics of the female population relating to psychiatric services.

Aims The aims of our research are to evaluate both the demographic and clinical characteristics of women related to mental health services in Trieste and their adherence to rehabilitation programs.

Methods The study was conducted by collecting the personal data of clinical users women from the four mental health centers in Trieste and the psychiatric service for diagnosis and treatment (SPDC). In the year 2014, the user attending the mental health department are 4952.

Results Data analysis showed that women in charge at the Department of Mental Health is 2731, representing 55% of all users. The predominant age group is between 46 and 65 years (between 17% and 23% for each CSM). The number of women taking part at rehabilitation activities is of 1332 (49%).

Conclusions It is considered necessary that the services for mental health sponsor prevention, treatment and rehabilitation around the specific needs of women.

Decisional trust and regret mediate the HRQL in work-related hand injury patients

H.H. Liao¹, S.L. Cheng², C.C. Chang^{3,*}, C.H. Lin⁴, F.C. Liu⁵, C.S. Cheng⁵

¹ *Chung Shan Medical University Hospital, Department of Surgery, Taichung, Taiwan*

² *Chung Shan Medical University Hospital, Department of Orthopedic Surgery, Taichung, Taiwan*

³ *Chung Shan Medical University & Chung Shan Medical University Hospital, School of Medical Informatics & IT Office, Taichung, Taiwan*

⁴ *Chung Shan Medical University, School of Medical Informatics, Taichung, Taiwan*

⁵ *Jen-Ai Hospital, Department of Pediatrics, Taichung, Taiwan*

* *Corresponding author.*

Background Despite mounting evidence that non-injury-related factors have an important role in recovery from injury; specific variables associated with surgery outcomes are poorly understood. This lack of knowledge complicates efforts to improve the care of work-related hand injury (WRHI) patients. However, substantial research and investigation have still not clarified these underlying relationships, which merit further attention.

Objective The purpose of this study was to evaluate the Health-Related Quality of Life (HRQL) outcome for WRHI patients after

the impact of event and to investigate the moderated mediation analysis associated with their decision trust and regret.

Methods A cross sectional study design was used to investigate the impact of event and the associated HRQL in 53 WRHI patients following severe and major hand injury. All consenting patients completed the Impact of Event Scale Revised, the Symptom Checklist-90-Revised, Decisional Trust scale, Decisional Regret scale and Short Form-36.

Anticipated achievement In the result of mediation analysis, patients affected HRQL via decisional trust and decisional regret, respectively. In addition, our data suggest that certain decisional trust and decisional regret (partial) characteristics significantly moderate this association. These findings may aid in the development of clinical interventions to enhance HRQL for WRHI patients. Overall, it is important for clinicians to consider the notion that more decisional trust or less decisional regret may sometimes, but not always, be better.

Domiciliary care service in psychiatry – who's getting our help?

I. Coelho*, G. Sobreira, J. Oliveira, F. Gomes

Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5 - Affective Disorders and OCD, Lisbon, Portugal

* Corresponding author.

Introduction Community psychiatry projects in Lisbon still do not provide the necessary response; to provide care for those who cannot reach our institution we created a domiciliary care unit, PreTrarCa.

Objectives Characterization of patients followed by PreTrarCa.

Aims Study and define our patient-type, facilitating future referrals.

Methods Selection of all active-patients followed by PreTrarCA in 2015 ($n=94$); those with social/demographic information were selected ($n=90$). Information concerning age, gender, education, marital status, family and social support, diagnosis and purpose of integration were retrospectively collected. Data analyses were performed via SPSS program.

Results Fifty-one percent of our population are male, with a mean age of 58.2 years. Although most patients are single ($n=45$), the majority does not live alone ($n=54$) or has a strong family support ($n=52$). Regarding education, most patients had only 4 years of scholarship ($n=16$). Only 31 have an active social support, usually as a day care center ($n=4$) or nursing home ($n=9$). Most patients are diagnosed with a psychotic disorder [F20–29, $n=48$], F20 (Schizophrenia) being the most common diagnosis ($n=40$). Most ($n=48$) are on LAI (long-acting injectable medication) or have supervised preparation of their weekly-fortnightly medication ($n=26$). LAI is mostly given to patients with diagnosis F20–29 ($n=37$).

Conclusions Our patient-type is a middle-age, single male with schizophrenia in need of supervision regarding medication adherence (LAI/medication preparation). By recognizing our patient-type we can more easily focus on who to help, rapidly intervening in crisis when necessary and providing a kind of support inexistent elsewhere.

An empirical study of the working conditions in the drug prevention centers of Attika, Greece: New prospects and possibilities in an era of uncertainty

I. Dritsas*, M. Theodoratou, T. Margaris, S. Christodoulidis, O. Valsami

Tei of Western Greece, Social Work, Patras, Greece

* Corresponding author.

Introduction Studies have documented that drug prevention centers in Greece have been through an era of turmoil and uncertainty (EKTEPN, 2015, Tsounis, 2012, Kiritsi and Tsiotra, 2004) underlining the staff's hard work all over Greece.

Purpose The aim of this study was to investigate the effects of the current fiscal crisis on the operating conditions as described by the staff of the Attika substance prevention centers with the emphasis on main problem areas and solutions.

Material Statistically reliable questionnaires were used by the research team investigating participants views on the aforementioned areas of enquiry.

Method Two Questionnaires were administered to 59 psychologists and social workers working at the centers of Attika, Greece during the summer of 2015.

Results The majority (85%) of those working at the centers mentioned the main problems as following:

- issues concerning the institutional role of the centers, the education and supervision of the staff;
- fiscal issues as a result of the economic austerity, which undermine the operation of the centers and the morale of the staff.

Conclusions Our empirical study is actually the first one which delves into the inner workings of the drug prevention centers in Attika, Greece:

- the extent the phenomenon of drug dependence in Greece, examining the epidemiology and the influence of the financial crisis, as well as the strategies and action plans developed in a national and EU level;
- the most significant innovative and standard European and Greek prevention programs.

Finally, research methodological issues are discussed in the light of the main findings of the empirical research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mobility in psychiatry: A personal experience in Swiss addictology

C. Feteanu

Centre hospitalo-universitaire Vaudois CHUV, service de psychiatrie communautaire, Centre Saint-Martin, Lausanne, Switzerland

Introduction Switzerland is a very attractive country for workforce brain drain in the field of psychiatry, with work, academic and financial conditions identified as pull factors; resulting in long-term migration and high level of satisfaction [1].

Objectives To enlight the phenomenon by reporting a personal experience of migration from France to Switzerland for work reasons as a psychiatrist.

Aims To describe the main characteristics of the Swiss Mental Health Care in the Canton of Vaud focused on ambulatory cares in addictology.

Methods Self-report description from the Centre Saint-Martin for drug addictions of the Community Psychiatry Department in Vaudois Teaching Hospital (CHUV) of Lausanne.

Results The Centre Saint-Martin is an ambulatory center providing cares, support, treatment and harm reduction for adult drug

addictions within a multidisciplinary team. The striking point of this model is the intense support made towards the community (general practitioners, somatic and psychiatric cares) in order to maintain and develop addiction cares in the general health system. The case management model, still rare in France, is being implemented in the center resources management. Detailed descriptions are proposed.

Lack of psychiatrists in the French speaking Canton of Vaud makes it very attractive for European specialists. Work and academic facilities, including psychotherapy training are accessible to foreign psychiatrists.

Conclusions Work migration is a unique way to experience different practices in psychiatry within Europe. Living and working conditions in Switzerland make it a country particularly attractive.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Outcomes for assertive outreach service users when the specialist team has closed – findings from a series of ‘dismantling’ studies

M. Firn*, M. Alonso-Vicente

South West London & St George's Mental Health NHS Trust, Springfield Consultancy, London, United Kingdom

* Corresponding author.

Introduction Specialist assertive outreach (AO) teams, for hard to engage patients with psychosis, are closing due to financial imperatives and a disappointing evidence base.

Objectives Compare patient outcomes, experience and service use before and for up to 4 years after closure of 3 specialised assertive outreach (AO) teams in London, UK.

Aims Flexible assertive community treatment (FACT) was adopted as the service model for the standard care community mental health team replacing AO care. We aimed to demonstrate non-inferiority in clinical effectiveness and thereby show cost efficiencies.

Method Observational mirror-image studies of the closure of 3 teams with service utilisation data, cost-consequence analysis and service user experience interviews both before and after team closure using satisfaction with services and team attachment instruments.

Results The FACT 1 study, with 112 patients, was published in 2013 and surprisingly showed a significant reduction in bed use following AO closure, with no significant change in the use of crisis services as an alternative to admission. A new 4 year pre-post analysis (in press) shows lower use of beds and crisis services is maintained despite fewer contacts and higher caseloads. We will report on the FACT2 replication study from a separate locality with the additional patient experience findings.

Conclusions AO patients are remarkably resilient to significant reductions in the intensity of care and this holds for up to 4 years. Enhancing multi-disciplinary CMHTs with FACT appears to provide a clinically effective and integrated alternative to orthodox AO teams. FACT offers a cost-effective model compared to AO.

The development of a novel, automated smartphone application for treating depression

C. Giosan*, V. Muresan, O. Cobeanu, A. Szentagotai, C. Mogoase Babe-Bolyai University, Cluj-Napoca, Romania

* Corresponding author.

In the recent years, automated CBT (interventions delivered on the computer, or online, which use no or minimal therapist support) has emerged as a solution that can, on some dimensions, be as effective as the classical CBT. However, the existing computerized interventions for depression also come with less desirable outcomes, such as high dropout rates (50–60%), limited endurance of long-term benefits, or limited improvement in functioning. We believe that these limitations characterizing the existing computerized solutions are caused by:

- reduced or non-existent personalization of the intervention (e.g., same standard intervention delivered to various people, making some unable to identify with the treatment);
- reduced immersion (and attractiveness) of the treatment experience (e.g., compared to other online activities, some intervention platforms may be perceived as uninteresting or repetitive);
- lack of a customized, personalized manner of providing feedback (most solutions present total scores for quizzes and scales).

Recognizing these shortcomings, we plan to use insights from graphic design (e.g., user interfaces), gamification theories (e.g., “serious games”) and artificial intelligence to develop an automated application aimed at both prevention and intervention for depression, which will substantially increase the quality of the user experience, thus leading to better outcomes (e.g., reduced attrition rates, more stable improvements, increased functioning).

Review of outcome domains in European Mental Healthcare

I. Großimlinghaus

LVR-Institute for Mental Healthcare Research, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

Introduction Quality in mental healthcare is a complex, multi-faceted construct. It can be categorized into structures, processes and outcomes. In the past decade, there have been many initiatives on the assurance and improvement of process quality through the development, evaluation and implementation of process indicators for several important process domains including, for example, continuity and coordination of care. Moreover, outcome measurement, focusing on the extend to which intended outcomes of mental health service provision are achieved, is receiving growing interest and should be pursued through a systematic approach.

Objectives Systematic compilation of outcome domains in mental healthcare.

Aims Identification of the full range of outcome domains in mental healthcare.

Methods Systematic literature review on outcome domains in mental healthcare.

Results A whole range of outcome domains can be identified and categorized onto a continuum ranging from ‘traditional’, objective outcome domains, such as mortality and symptomatology, to more subjective outcome domains, such as quality of life and well-being. Moreover, outcome measures in different outcome domains can be assessed taking different perspectives into account, including either the provider or the patient.

Conclusions In order to develop and implement systematic outcome measurement in mental healthcare, a first step is the

identification and systematization of outcome domains in mental healthcare. This will provide a basis for identifying important outcome domains from the perspectives of both, patients and professionals. In a next step, appropriate and important outcome measures can be identified.

Collaborative space using the andalousian integrated care process of anxiety, depression and somatization

M. Guerrero Jiménez^{1,*}, J.A. Rodrigo Manzano², C.M. Carrillo de Albornoz Calahorra², B.M. Girela Serrano²

¹ University Hospital San Cecilio, Psychiatry, Granada, Spain

² Santa Ana Hospital, Mental Health, Motril, Spain

* Corresponding author.

Introduction/objectives The Integrated Care Process of Anxiety, Depression and Somatization (ICP-ADS) lays out the cooperation between primary care (PC) and mental health (MH) as basic premises. Showing this model improves patient detection, inadequate patient referrals, adherence and response to medical treatment.

Aims The Therapeutic Program (TP) established in PC includes low intensity psychological and psychosocial interventions, pharmacological treatment, and use of collaborative space with MH combining consultations, case tracking and educational activities. Our rotation as MH residents in the Community Mental Health Unit (CMHU) has focused on this framework, encouraging the use of a collaborative space.

Methods Three training sessions were used to deal with the process as a whole. PC professionals were given self-help handbooks for low intensity interventions and clinical practice handbooks for psychopharmacological treatment. The referral space was established afterwards, where we took part in the TP founded by the PC doctor. In case the demand would continue, we opened consultation one day a week for co-therapy. With brief interventions of 3–4 sessions we continued the work with self-help guides, which also optimized psychopharmacotherapy.

Results Referrals were sufficient in many cases. Sixteen procedures were completed in co-therapy, half of which required referrals to encourage adherence. Only a referral to MH had to be done. Three months later, a follow-up showed that no patient in co-therapy had to be referred to specialized care.

Conclusions The amount of referrals was reduced in comparison to previous months, adherence to interventions of low intensity was improved and was useful in both detection and prevention of new cases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The burnout severity level was significantly higher amongst Imams in Republic of Srpska than amongst Imams in Federation of Bosnia-Herzegovina in the postwar Bosnia-Herzegovina

L. Mehmedić¹, M. Hasanovic^{2,*}, P. Izet¹, A. Isić¹

¹ University of Zenica, Department of Social Pedagogy, Islamic Pedagogical Faculty, Zenica, Bosnia and Herzegovina

² Tuzla, Bosnia and Herzegovina

* Corresponding author.

Introduction Modern researches suggested that the burnout syndrome of workers employed in the social services increased and this term is taken as a working diagnosis to indicate a particular form of psychological (mental and emotional) exhaustion due to overload at work.

Objective To investigate the differences of burnout syndrome severity amongst Imams (Islamic priests) in the Republic of Srpska (RS) and amongst Imams in the Federation of Bosnia-Herzegovina (FBH) in the postwar Bosnia-Herzegovina (BH).

Methods The sample was consisted from 148 Imams (68 from RS) of age (mean ± standard deviation) 40.2 ± 10.7 years (RS = 39.7 ± 11.1 years and FBH = 40.6 ± 10.2 years, *t*-test = 0.5, *P* = 0.6). We used the standardized – Burnout test of Archibald Hart from 2009.

Results The obtained results indicate that the level of burnout syndrome severity was significantly higher amongst Imams in the Republic of Srpska (mean ± standard deviation = 3.0 ± 1.5 on the Lickert scale 1–5) than amongst Imams in the Federation of Bosnia-Herzegovina (2.2 ± 1.3) (Student's *t*-test = 4.757, *P* < 0.001) in the postwar Bosnia-Herzegovina.

Conclusion The level of burnout syndrome severity was significantly higher amongst Imams in the Republic of Srpska than amongst Imams in the Federation of Bosnia-Herzegovina in the postwar Bosnia-Herzegovina.

Fifteen-month follow-up of an assertive community treatment program for chronic patients with mental illness

J.H. Jeong^{1,*}, K.H. Lee², D.I. Jon³

¹ St. Vincent's Hospital The Catholic University of Korea, Psychiatry, Suwon, Republic of Korea

² College of Medicine, Dongguk University, Psychiatry, Gyeongju, Republic of Korea

³ Sacred Heart Hospital, College of Medicine- Hallym University, Psychiatry, Anyang, Republic of Korea

* Corresponding author.

Objective This study was to evaluate the effect of an assertive community treatment (ACT) program on psychiatric symptoms, global functioning, life satisfaction, and recovery-promoting relationships among individuals with mental illness.

Methods Thirty-two patients were part of the ACT program and 32 patients matched for age, sex, and mental illness were in a standard case-management program and served as a control group. Follow-up with patients occurred every 3 months during the 15 months after a baseline interview. Participants completed the Brief Psychiatric Rating Scale (BPRS), Global Assessment of Functioning (GAF) Scale, Life Satisfaction Scale, and Recovery-Promoting Relationship Scale (RPRS).

Results According to the BPRS, the ACT group showed a significant reduction in symptom severity, but the ACT program was not significantly more effective at reducing psychiatric symptoms from baseline to the 15-month follow-up compared to the case-management approach. The ACT group showed more significant improvement than the control group in terms of the GAF Scale. Both groups showed no significant differences in the change of life satisfaction and in the change of recovery-promoting relationships. We observed a significant increase in recovery-promoting relationships in the control group, but the group × time interactions between groups were not statistically significant.

Conclusions In this study, we observed that ACT was significantly better at improving the GAF than case management. However, ACT did not demonstrate an absolute superiority over the standard

case-management approach in terms of the BPRS and the measures of life satisfaction and recovery-promoting relationships. ACT, however, may have some advantages over a standard-case management approach.

Can physician incentives improve continuity of care for patients receiving depression treatment in the primary care setting?

P. Joseph^{1,*}, A. Kazanjian²

¹ School of Population & Public Health, Vancouver, Canada

² School of Population & Public Health, Faculty of Medicine, Vancouver, Canada

* Corresponding author.

Introduction In 2008, the province of British Columbia, Canada introduced financial incentives to encourage general practitioners (GPs) to assume the role of major source of care for patients seeking mental health treatment in primary care. If successful, this intervention could strengthen GP–patient attachment and consequently improve continuity of care. The impact of this intervention, however, has never been investigated.

Aim To estimate the population level impact of physician incentives on continuity of care (COC).

Method This retrospective study examined linked health administrative data from physician claims, hospital separations, vital statistics, and insurance plan registries. Monthly cohorts of individuals with depression were identified and their GP visits tracked for 12 months, following receipt of initial diagnosis. COC indices were created, one for any visits (AV) and another for mental health visits (MHV) only. COC (range: 0–100) was calculated using published formula that accounts for the number of visits and number of GPs visited. Interrupted time series analysis was used to estimate the changes in COC before (01/2005–12/2007) and after (01/2008–12/2012) the introduction of physician incentives.

Results The monthly number of people diagnosed with depression ranged from 7497 to 10,575; yearly rates remained stable throughout the study period. At the start of the study period, mean COC for AV and MHV were 75.6 and 82.2 respectively, with slopes of –0.11 and –0.06. Post-intervention, the downward trend was disrupted but did not reverse.

Conclusions Physician incentives failed to enhance COC. However, results suggest that COC could have been worse without the incentives.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An innovative day centre in Athens with expertise in children neglect and abuse. A unique therapeutic intervention through the fog of economic crisis

A. Kanellopoulou^{1,*}, E. Marini², X. Antoniou², G. Nikolaidis²

¹ National Kapodistrian University of Athens, Evgenidion Therapeutirion, Mental Health Care Unit, Athens, Greece

² Smile of the Child- Athens, Day Care Centre- The House of the Child, Athens, Greece

* Corresponding author.

The Day Centre “THE HOUSE OF THE CHILD” is a unique in Greece community unit providing customized clinical mental health

services for therapeutic treatment and psychosocial rehabilitation of children and adolescents victims of abuse, neglect or domestic violence, as well as children or adolescents involved in cases of bullying. The Day Centre was founded by the non-profit voluntary organisation “THE SMILE OF THE CHILD”. The Day Centre’s services are addressed to children and adolescents up to age of 18 who live either in residential care or in the community having a documented history of exposure to violence of any kind. Services are free of charge and are expanded to the following areas:

- early intervention-evaluation-counselling;
- diagnosis and treatment of the full range of child psychiatry disorders and issues of clinical attention;
- diagnosis and treatment of specific learning deficits and provision of speech therapy, occupational therapy and special education support when needed;
- counselling for parents and carers of victimized children and adolescents;
- registering and statistical analysis of psychosocial rehabilitation needs arising from the child abuse incidents.

More general activities for raising awareness and sensitization of the wider community in order to prevent all forms of child abuse and victimization.

The Day Centre’s personnel comprises from a psychiatrist–scientific coordinator, three child psychiatrists, three clinical psychologists, a special educator, a speech therapist, a social worker, an occupational therapist and two administrators. This interdisciplinary therapeutic team undertakes a comprehensive diagnostic evaluation and therapeutic intervention scheme to address the complex disorders and wider psychosocial needs of children – victims.

Doing more than ACT: The Dutch FACT model, flexible assertive community treatment

R. Keet

GGZ, Noord-Holland -Noord, Community Mental Health Service, Heiloo, Netherlands

Background/objectives Assertive community treatment (ACT) has become the standard for integrated care for people with severe mental illnesses. Limitations of ACT are the lack of flexibility, the limited feasibility in rural areas, the limited population and the time-unlimited nature. These limitations can be overcome by flexible assertive community treatment (Flexible ACT), developed in the Netherlands and introduced in several European countries.

Methods Three studies were done between 2006 and 2015 on the results of the introduction of Flexible ACT, two in The Netherlands and one in the UK.

Results The outcomes in the Netherlands data show the effectiveness of Flexible ACT. Remission of schizophrenia increased from 19% to 31%. Bed use was reduced and quality of life increased. Effectiveness of FACT was also shown in the UK, where total patient time in hospital declined by half, even though the average time service providers spent with patients also declined. Collected data of the digitalized boards show that the board is used in accordance with the FACT model. Transition rate to primary care is 5–10% per year.

Discussion/conclusion The introduction of Flexible ACT has been shown to benefit patients with severe mental illness and indicate the ability of to allocate human resources in mental health care more efficiently. Introduction to other countries will be accompanied by research on the effectiveness and feasibility within other cultures.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

* Corresponding author.

Objective To investigate the Greek social representations towards harmful factors of health.

Design Cross-sectional questionnaire survey.

Method Two hundred and eighty healthy individuals participated to the present study from different region in Greece. The age range was 19–65 years old. The questionnaire included:

- question for the recording of social representations based on free association methods;
- The Greek version of the Revised Experiences in Close Relationships (ECRI);
- The Symptom Checklist 90-revised (SCL-90);
- question for the social-demographic parameters.

Results One factor and multifactor analysis was used for statistical analysis. Results showed significant differences in social representation of diet in terms of age and marital status. Place of region and chronic disease were found to affect the development social representations, such as exercise and disease, respectively. Exercise, night out and health were found like positive social representations, smoking and disease were characterized as negatives, whereas diet, alcohol and lifestyle were found controversial enough. Moreover, the results highlight the significant relationship between social representations towards harmful factors of health, psychopathology and attachment style ($P < .05$).

Conclusion The results of the current study highlighted the importance of studying on social representations and provided more support to the representations theory context. But more crucially, our study highlighted functional domains of them related to psychopathology.

How are you?: A culturally sensitive group therapy program for Latinos

M. Paris^{1,*}, M. Lopez¹, L. León-Quismondo², M. Silva¹, L. Añez¹

¹ Yale University School of Medicine, Department of Psychiatry, New Haven, Connecticut, USA

² "Príncipe de Asturias" University Hospital, Department of Psychiatry, Alcalá de Henares, Madrid, Spain

* Corresponding author.

Introduction An ongoing challenge for the behavioral health field in the United States is ensuring access to culturally and linguistically responsive treatments for the growing number of monolingual Spanish speakers. The limited availability of services further compromises mental health outcomes given the unique psychosocial stressors often experienced in this population, such as language barriers, family separation and inadequate social support, unemployment, trauma, and poverty.

Objective In response to the local demand for services, the authors describe a specialized group program for monolingual Spanish speaking adults with chronic and persistent mental illness.

Aims The program aims are two-fold:

- to reduce exacerbation of psychiatric symptoms for individuals presenting in an acute state of distress through the provision of recovery-oriented mental health services in a familiar setting and preferred language;
- to offer a specialized behavioral health training experience for bilingual psychology doctoral students.

Methods The group is led by the psychology fellow and is offered twice per week for a total of six hours, and includes elements of interpersonal and cognitive behavioral therapy; motivational interviewing; spirituality; coping skills training; and art/music.

Results The described mental health group program is the only one available in Spanish in the local community and has reduced utilization of the hospital emergency room. Consequently, it fills an important gap in the service system and offers care that would otherwise be unavailable for individuals in need.

Conclusions The program is a cost-effective alternative to hospitalization for Spanish speaking Latinos and a unique professional experience for psychologists in-training interested in a career in the public sector.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Perceptions of treatment and adherence during hospitalization in psychiatric patients

G. Lyrakos^{*}, G. Totorou, D. Sittas, A. Dimitriou, M. Ypofanti, V. Spinaris, I. Spyropoulos

General Hospital Nikaia "Ag. Panteleimon", Psychiatric, Nikaia, Greece

* Corresponding author.

Background Treatment adherence has a vital role in the patient's health outcome as poor adherence rates can reduce, even diminish, the effectiveness of the treatment as well as lead to a waste of the health care system's valuable resources. Previous research has shown that perceptions of treatment strongly affect adherence in psychiatric patients.

Aim To investigate how the perceptions of treatment affect adherence during hospitalization in psychiatric patients.

Method Fifty psychiatric patients participated in this research, 21 (42%) males and 29 (58%) females. Out of them, 25 (50%) had been diagnosed with depression, 15 (30%) with psychosis, 6 (12%) with psychosis and depressive symptomatology and 4 (8%) with bipolar disorder.

Results The findings showed a significant effect of psychotherapy on treatment adherence ($\chi^2 = 4.915$, $P = 0.027$), with 7 out of 11 patients who undertook psychotherapy reporting good adherence rates compared to 12 out of 39 patients who did not. Gender had a significant effect on adherence ($\chi^2 = 5.96$, $P = 0.05$), with females reporting better adherence compared to males. Perception of treatment did not correlate significantly with adherence ($\chi^2 = 0.439$, $P > 0.05$) and neither did education ($\chi^2 = 2.22$, $P > 0.05$). Also, neither age ($F(2,47) = 1.535$, $P > 0.05$) nor hospitalization time ($F(2,47) = 1.131$, $P > 0.05$) correlated significantly with adherence to treatment.

Conclusion Even though there was no significant correlation between perceptions of treatment and adherence, psychotherapy seems to improve adherence to therapy during hospitalization and is also correlated with positive perceptions of treatment, something which will be valuable for the patient even after the hospitalization.

Preserving control: Understanding people's experiences before, during and after detention under the Irish Mental Health Act 2001

D. McGuinness^{1,2,*}, A. Higgins³, B. Hallahan^{2,4}, E. Bainbridge⁴, C. McDonald^{2,4}, K. Murphy¹

* Corresponding author.

Introduction The Mental Health Act 2001 provides a legal framework for the involuntary admission and treatment of individuals deemed to have a mental disorder to psychiatric units. The perspectives of people who have been detained are relatively poorly understood.

Objective To develop a theoretical understanding of individual's experiences throughout the trajectory of their detention and to understand the psychological and social processes that individuals use to cope before, during and after detention.

Methods Fifty individuals subject to detention across three psychiatric units consented to be interviewed three months after their detention. Using a semi-structured interview people recounted their experiences. Interviews were analysed using the principles underpinning Grounded Theory.

Results The theory 'Preserving Control' encapsulates individuals' experiences and consists of three related themes: 'Losing Control', 'Regaining Control' and 'Maintaining Control'. 'Losing Control' describes individuals' experiences of losing their autonomy and liberty through the process of detention and hospitalisation. 'Regaining Control' describes the strategies individuals used in an attempt to restore their loss of autonomy and control. 'Maintaining Control' describes how individuals lived with the consequences of detention and contended with impact on discharge.

Conclusions Whilst a large variation existed in relation to the subjective experience of being detained, the characteristic process that individuals tend to experience related to identifiable phases of preserving control in the face of this loss of autonomy. Findings from this study highlight the importance of more sensitive interactions support and information during and after the detention process.

Implementation of Health of the Nation Outcome Scale (HoNOS) in Outpatient Clinic, Sligo Mental Health Services: Feasibility and Agreement with Global Assessment of Functioning Scale

O. Mulligan^{1,*}, L. Helmi², D. Adamis¹, E. O'Mahony¹, G. McCarthy¹, A. MacDonald³

³ Institute of Psychiatry, Kings College London, London, United Kingdom

* Corresponding author.

Introduction Outcome measurements in mental health services is beneficial in allowing healthcare providers in determining the effectiveness of their treatment plan. Health of the Nation Outcome Scale (HoNOS) and Global Assessment of Functioning (GAF) are two well-established instruments to measure patients' outcome.

Aims and objectives To measure the correlation of these two scales, and the feasibility of HoNOS.

Methods Prospective longitudinal study of psychiatric outpatients attending a clinic in Sligo. Patients were assessed using HoNOS and GAF by trained doctors during the consultation. Feedback from doctors using HoNOS during the research was taken as a measure for feasibility.

Results Total of 441 HoNOS and 237 GAF completed on 280 patients (53.2% female, mean age 46.23; SD=14.89). The correlation between HoNOS and GAF was ($r=-0.696$, $P<0.001$). In reassessment, we found significant reduction in HoNOS score when comparing the first assessment with the second ($t=4.590$, $df=110$, $P<0.01$) and the third ($t=2.876$, $df=37$, $P<0.01$). Using a linear mixed-effects model, it was found that patients with diagnosis of schizophrenia, mood affective disorder, neurotic disorder, personality disorder and younger in age are more likely to improve during the follow-up compared to those with organic mental disorders, alcohol related problems and older age.

Conclusions HoNOS is a feasible scale and can be potentially used as an outcome measurement in the mental health services. Can help in deciding better management plan for patient and improvement of the service. HoNOS can also be used for comparison of outcomes between services in national and international level.

Psychiatrist's mental health: A look at burnout in a psychiatry department in Portugal

S. Neves^{1,*}, F. Vieira², N. Madeira², J. Santos³, P. Garrido², A. Craveiro², F. Veiga², C.B. Saraiva²

¹ Portugal

² Coimbra Hospital and University Centre, Psychiatry Department, Coimbra, Portugal

³ Coimbra Nursing College, Coimbra Nursing College, Coimbra, Portugal

* Corresponding author.

Introduction Mental ill health is common among doctors. Fast, efficient diagnosis and treatment are needed as mentally ill doctors pose a safety risk to themselves and to patients, yet they are often reluctant to seek help. Focusing on psychiatry, it is known that psychiatrists as a professional group are prone to stress burnout and suicide. Thus, it seems relevant and current to address on the burnout in this professional group.

Objectives/aim To analyze the burnout levels and the existence of psychopathology in a Portugal psychiatry department.

Methods Anonymous self-completion questionnaire, prepared by the Suicide Prevention Consultation (also using MBI-Maslach Burnout Inventory and QIS-Suicide Ideation Questionnaire) and distributed by e-mail and online submitted for all psychiatrists in the department.

Results Forty-two percent of psychiatrists responded, mostly women. Although the percentages of responses related to fatigue/amount of work are significant, there were not high levels of emotional exhaustion and depersonalisation, but before satisfactory levels of personal fulfilment.

Conclusions High levels of "burnout" are associated with high scores of emotional exhaustion and depersonalisation, but also with low scores of personal fulfilment. Despite the preliminary results of this study, it is important to remember important

prevention strategies. Further studies directed to psychiatry trainees seem important, as this represents an important risk group, where an early intervention can make a difference.

Qualitative evaluation of a couple-based cognitive-behavioral intervention on postnatal depression

F.W. Ngai

The Hong Kong Polytechnic University, School of Nursing, Kowloon, Hong Kong, China

Introduction Postnatal depression is a significant public health problem, which has long-term sequelae on the family and the infant's psychosocial development. Cognitive behavioral therapy is one of the most effective interventions for postnatal depression. However, there is limited qualitative evaluation of the impacts of delivering couple-based cognitive behavioral therapy during the perinatal period.

Objectives/aims The purpose of this study was to explore Chinese mothers' perceptions of a couple-based cognitive-behavioral intervention at early postpartum.

Methods This study used an exploratory qualitative design. A purposeful sample of 30 first-time Chinese mothers who had participated in a couple-based cognitive-behavioral intervention was interviewed at 6 weeks postpartum. Content analysis was used to analyze the data.

Results The results revealed that Chinese mothers perceived the couple-based cognitive-behavioral intervention to be helpful in enhancing their emotional control, increasing sense of support and well-being in taking up the maternal role.

Conclusions The findings provide empirical support for the feasibility of the couple-based cognitive-behavioral intervention in facilitating maternal adaptation during the transition to parenthood. The results could be utilized to make continued improvement of perinatal services to promote maternal well-being during the transition to new parenthood.

A retrospective study of the impact of antipsychotic medication on readmission in patients followed by a domiciliary care unit

J. Oliveira^{1,*}, G. Sobreira², I. Capeto Coelho³, F. Gomes², A. Nobre³

¹ Centro Hospitalar Psiquiátrico de Lisboa, Neuropsychiatry Unit, Lisbon, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, First Psychotic Episode Unit, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Mood Disorders and OCD Unit, Lisbon, Portugal

* Corresponding author.

Introduction Domiciliary care services' patients have severe psychiatric disorders, challenging social contexts and physical comorbidities. These influence outcome but are difficult to modify. Conversely, antipsychotic medication is changeable and has been shown to be related to number of readmissions and length of stay.

Objectives To assess whether injectable or oral and first or second generation antipsychotics (FGAP and SGAP) are associated with readmission and contact with mental health services.

Aims To improve the quality of care in our domiciliary care unit (PreTrarCa) and its efficacy.

Methods Active patients in PreTrarCa in 2015 with schizophrenia, schizoaffective, delusional or bipolar disorders were included ($n = 64$). Information regarding medication and average number of hospitalizations, appointments and missed appointments per year was retrospectively collected.

Results Patients were mostly male (37), with mean age of 54, and mean follow-up of 41.20 months; 23 were prescribed injectable antipsychotics alone, 21 oral antipsychotics alone and 20 both; 36 were on injectable FGAP and 7 on SGAP. Oral medication was significantly related with missed appointments per year, but not with number of actual appointments. No other significant relation was found; although patients on SGAP had more hospitalizations (0.9 vs. 0.3 per year) and longer length of stay (21.9 vs. 6.3 days) these differences were not statistically significant.

Conclusion Type of antipsychotic was not associated with readmission rates or contact with mental health services. Confounding variables and clinical outcome measures were not included and the effect of medication changes during follow up was not addressed.

* Corresponding author.

Introduction Published rates of HIV infection among psychiatric patients are 3.1% to 23.9%, at least eight times higher than general population. (Nebhinan et al., 2013)

Aims Defects in judgment and insight in patients with psychosis is often associated with lot of anger and impulsiveness, risky behavior and lower treatment adherence. This often led to worsening of clinical status and prognosis. (Uruchurtu, 2013)

Methods A 31-year-old man diagnosed with schizophrenia and HIV four years ago. At the beginning of last year, the patient was hospitalized in the Acute Psychiatry Hospital Unit because of decompensation. Two years after diagnosis of HIV, he stopped taking his medications and was arrested several times because misdemeanors. Furthermore, patient was highly sexually active in the form of unprotected sex with multiple partners, as he had no concept of his disease. In addition to this, he made a delusional interpretation about HIV (known as VIH in Spanish) as Immortal human life (Vida Immortal Humana). He was admitted in the hospital for a month and was treated with medications and psychotherapy, which led to good stabilization, and he gained insight of both of his illnesses. At the moment, one year after this episode, the patient is stable, taking both medications regularly and followed up by his psychiatrist in the Mental Health team.

Conclusion It is of extreme importance that psychotic patients with HIV receive a good follow-up during life, as decompensation can affect the patients' health and health of others, with the implicit consequences that it carries. (Uruchurtu, 2013)

Mindfulness, self-compassion and psychological distress in pregnant women

S. Xavier^{1,*}, J. Azevedo¹, E. Bento¹, M. Marques^{1,2}, M. Soares¹, M.J. Martins^{1,3}, P. Castilho³, V. Nogueira^{1,2}, A. Macedo^{1,2}, A.T. Pereira¹

¹ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Coimbra Hospital and University Centre, Psychology, Coimbra, Portugal

³ Faculty of Psychology and Educational Sciences, University of Coimbra, CINEICC, Coimbra, Portugal

* Corresponding author.

Introduction Anxiety, depression, and stress in pregnancy are risk factors for adverse outcomes for mothers and children (Glover, 2014). There is good evidence showing a decrease in psychological distress when pregnant women participate in interventions comprising mindfulness and self-compassion practices (Dunn et al., 2012). However, there are few studies on the relationship between mindfulness, self-compassion and psychological distress variables in pregnancy, without being within the scope of intervention trials (Cohen, 2010; Zoeterman, 2014).

Objective To explore the association between mindfulness, self-compassion and psychological distress/PD in pregnant women.

Methods Four hundred and twenty-seven pregnant women (mean age: 32.56 ± 4.785 years) in their second trimester of pregnancy (17.34 ± 4.790 weeks of gestation) completed the Facets of Mindfulness Questionnaire-10 (FMQ-10; Azevedo et al., 2015; to evaluate Non-udging of experience/NJ, acting with awareness/AA and observing and describing), Self-Compassion Scale (SCS; Bento et al., 2015; to evaluate self-kindness/SK, self-judgment, common humanity, isolation, mindfulness and over-identification) and Depression Anxiety and Stress Scale-21 (DASS-21; Xavier et al., 2015). Only variables significantly correlated with the outcomes (Total DASS-21, Stress, Anxiety and Depression) were entered in the multiple regression models.

Results FMQ-10 and SCS Total scores were both significant predictors of DASS-21 ($B = -.335, -.296$). Stress predictors were NJ, AA, SK and isolation ($B = -.164; -.196; -.087; .353$); Anxiety predictors were NJ, SK and isolation ($B = -.198; -.124; .268$); depression predictors were NJ, SK and Isolation ($B = -.277; -.128; .232$) (all $P < .01$).

Conclusions Mindfulness and self-compassion dimensions, particularly non-udging of experience and self-Kindness are protective for PD in pregnancy. Isolation is a correlate of PD in pregnancy.

Primary Care Mental Health Pilot

H. Rahmanian

Sutton, United Kingdom

Improving access to mental health in primary care is a national priority A stated priority is to improve the integration between mental and physical health services and to close the gap between people

with mental health problems and the population as a whole by ensuring that mental health is treated with as much priority as physical health. Integrated working between GPs, primary and secondary care mental health services, will be key to delivering these shared priorities and to meet local commissioning objectives that will improve the health and well-being of our population, reduce inequalities and maximise value in terms of outcomes, quality and efficiency from services provided to patients. The Barnet South Primary Care Mental Health Pilot commenced on 30th June 2014 (initially for 9 months, then extended for another 3 months). The service has been commissioned to offer advice to GPs and mental health assessments in the primary care setting. The pilot provides a responsive and flexible service for the 17 practices in the South Barnet Locality. The pilot offers an assessment service for mental health referrals. People seen for assessment are aged 18 years and older and must be registered with a GP in the Barnet South Locality. They are people with diagnoses of moderate or severe depression and/or anxiety disorders, mild eating disorders who do not meet the criteria for referral to specialist services, or medically unexplained symptoms with no currently known physical cause.

* Corresponding author.

Introduction Non-attendance at initial appointments is an important problem in outpatient settings and has consequences, such as decreased efficient use of resources and delayed attention to patients who attend their visits, and that compromises quality of care.

Objectives To identify and describe the characteristics of patients who do not attend the first appointment in an adult outpatient mental health center, located in Barcelona.

Method Retrospective study. The sample was made up from all patients who had a first appointment during 2014 in our outpatient mental health centre. Socio-demographic and clinical data (type of first appointment, reason for consultation, origin of derivation, priority, history of mental health problems) were described. The results were analyzed using the SPSS statistical package.

Results A total of 272 patients were included. Twenty-six per cent did not attend their first appointment; with mean age 39.75 years and 51.4% were male. Most frequent problems were anxiety (41.7%), depression (26.4%) and psychosis and behavioural problems (11.2%). The origin was primary care (83.3%), social services (4.2%) and emergencies (2.8%). Most of them were not preferent or urgent (86.1%). The 51.4% of non-attendees had history or psychiatric problems and 13.9% nowadays are patients of our mental health centre.

Conclusions It is important to develop mechanisms that can reduce the incidence of first non-attended appointments. In our case, most of them are attended by primary care so we can establish better communication with our colleagues and try to contact to the patients prior to the date of the appointment.

The comparison of the quality of life and determination of Multidimensional Health Locus of Control (MHLC) in the healthy people and the people with hypertension

H. Sabbaghpour

Islamic Azad University Branch Amol, Clinical Psychology, Babol, Iran

The main purpose of this research is the comparison of the quality of life and determination of multidimensional health locus of control (MHLC) in the healthy people and the people with hypertension. The statistical population of this research includes of all healthy people (the fellows of patients) and patients with hypertension that have referred to Babol Cilinic and Mehregan hospitals during the first three months of 92. The volume of samples based on the Gerjci and Morgan tables including of 240 people were selected by the method of non-random sampling. The research methodology is comparative causative for data collection, the questionnaire of the quality of life (short form) and multidimensional health locus of control questionnaire were used. For data analysis and the generalization of results, *T*-test of independent samples was used. The achieved results are indicative of this matter that the quality of life in the physical and social dimension and psychological dimension and multidimensional health locus of control in the healthy people and the patients with hypertension are different but the quality of life in and the health of environment, any meaningful difference has not been observed.

V. Gutiérrez Mellado², N. Rodríguez Criado¹, R. Martín Aragón¹

¹ Hospital Universitario de Móstoles, Psiquiatría, Madrid, Spain

² Área de Salud Mental de Ibiza y Formentera, Hospital Can Misses, Ibiza, Spain

* Corresponding author.

Introduction In the 1970s emerges in Madison (United States) the assertive community treatment (ACT) and since then it has emerged as the standard model of comprehensive, intensive community treatment for patients with severe mental illness. Multiple studies support its effectiveness and efficiency reducing hospital stay and phenomena revolving door.

In 2007, it begins in Ibiza the ATC, as a form of treatment for patients who, due to a problem of geographical isolation or mental disorder, remain detached from the mental health services.

Objectives Evaluate and share the experience of the ATC in Ibiza's population as a way to improve the linkage of patients to the resources of health, their community integration and avoid abandonment of treatment and hospitalizations.

Method We compiled records from ATC activity in Ibiza since creation. This paper describes and analyzes a sample of 35 patients followed for 2014, and hospitalizations compared before and after start the ATC.

Results In the sample studied, the leading diagnoses are paranoid schizophrenia and delusional disorder. A significant decline is detected in the number and duration of hospitalizations after initiation of treatment in the ATC.

Conclusion The results observed in the sample match those reported in the literature, showing the ATC as an effective recourse for the care of patients with severe mental disorder.

Medical comorbidity related risk factors for hospital-based mortality in psychiatric disorders of ICD-10 classes F1–F4: A comparative overview of five studies in general hospital admissions

D. Schoepf^{1,*}, R. Heun²

¹ University Hospital of Bonn, Psychiatry, Bonn, Germany

² Royal Derby Hospital, Radbourne Unit, Derby, United Kingdom

* Corresponding author.

Introduction Up to 60% of the non-suicide related premature mortality of individuals with major psychiatric disorders is said to be mainly due to medical diseases.

Objectives and aims Based on five representative studies in general hospital admissions over 12.5-year observation, we will represent a comparative overview of medical comorbidity related risk factors for general hospital-based mortality in prevalent psychiatric disorders of ICD-10 major classes F1–F4.

Methods In the original studies, medical comorbidities that increased the risk for hospital-based mortality were identified using multivariate forward logistic regression analysis. In secondary analysis, independent risk factors for general hospital-based mortality were compared between studies using the OR and the 95% CI.

Results A total of fifteen medical comorbidities represented independent risk factors for general hospital-based mortality in more than one psychiatric disorder of ICD-10 major classes F1–F4. Infectious lung diseases and chronic obstructive pulmonary disease were mortality risk factors in all diagnostic classes. Type 2 diabetes mellitus represented a risk factor for general hospital-based mortality in individuals with schizophrenia (SCH), bipolar disorder (BD), and major depressive disorder (MDD). Atrial fibrillation was a mortality risk factor in individuals with MDD, anxiety disorder (ANX), and alcohol dependence (AD). In addition, nineteen medical comorbidities represented independent mortality risk factors in only one of the diagnostic classes, i.e. two in individuals with SCH, three in individuals with MDD, three in ANX, and eleven in AD.

Conclusions In general hospitals, the pattern of medical comorbidities that explain the outcome of in-hospital deaths differs considerably between psychiatric disorders of ICD-10 major classes F1–F4.

Mental health staff: To promote resilience, to reduce the risk of burnout

N. Semenova^{1,*}, A. Palin², I. Gurovich¹

¹ Moscow Research Institute of Psychiatry MoH RF, Outpatient Psychiatry, Moscow, Russia

² Psychiatric hospital No. 4 named after P.B. Gannushkin, Medico-rehabilitation Unit, Moscow, Russia

* Corresponding author.

Introduction Stress and burnout are clearly problems for mental health workers. In this paper, we present data from research study on moderators of burnout in mental health staff.

Objectives/aims The purpose of this study was to explore the phenomenon of resilience as experienced by Russian mental health clinicians working in a highly demanding, specialized and stressful environment (e.g., staff shortages, health service shortages, not being notified of changes before they occurred).

Methods The study used a range of self report questionnaires. Measures included a demographic checklist, the Hardiness Survey (Maddi 1984), and the GCOS – The General Causality Orientation Scale (Deci & Ryan 1985). The participants for this study were drawn from Medico-rehabilitation Unit, Psychiatric hospital, – the disciplines of psychiatry, clinical psychology and nursing. In all, 10 ward based mental health professionals were surveyed.

Results This paper outlines the results of these measures. This in turn allows us to develop intervention strategy to ensure an effective provision, which depends on satisfied professionals, who have a sense of ownership over what they do and an ability to shape the direction of their endeavours.

Conclusions The study's findings have the potential to inform organizations in mental health to promote resilience in clinicians, to deliver stress management interventions for staff with the potential to reduce the risk of burnout and hence staff attrition, staff retention and mental health.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depressive and anxiety symptoms in youth mental health outpatients: An observational study

J. Silva Ribeiro^{1,*}, S. Morais^{1,2}, E. Mendes¹, A. Botelho¹, G. Helena¹, V. Luísa¹, B. Aida¹, N. Madeira^{1,2}

¹ Coimbra Hospital and University Centre, Psychiatry Department, Coimbra, Portugal

² University of Coimbra, Faculty of Medicine, Coimbra, Portugal

* Corresponding author.

Introduction There is an increased risk to develop mental disorder during adolescence and early adulthood. Given this vulnerability, and in order to facilitate the transition from child and adolescent to adult mental health services, specific services for this age group have been developed in the last years, focusing on accessibility and early referral of young mental patients. Our Psychiatry Department (Coimbra Hospital and University Centre, Portugal) created a specific unit for young adults in order to provide better care, in accordance with the specificities of this subpopulation. The team consists of psychiatrists, psychiatry residents, nurses and a clinical psychologist. Referred patients are under 20 years old, presenting clinically relevant psychopathology or behavior disturbances.

Objectives/aims We aimed to characterize help-seeking outpatients regarding socio-demographic variables and its relation to depressive and anxiety symptoms.

Methods Socio-demographic characterization was undertaken with young adult psychiatric outpatients observed during eleven months (1st January to 30th November 2015). Multivariate analyses were performed to identify a relationship among socio-demographic and psychopathology variables (assessed with the Portuguese version of Brief Symptom Inventory–53 items).

Results/conclusions One hundred and sixty-two outpatients were observed: 97 females (59,9%) and 65 males (40,1%), ages between 17 and 31 years old (average: 19,9; median: 20). We found a positive correlation between depressive and anxiety symptoms and the education level. A negative correlation was found between

depressive and anxiety symptoms and male gender and presence of mental illness in the family.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Factors related to disability pensions – a cross-sectional analysis from a university hospital in Istanbul

E. Sönmez*, D. Tunca, Y. Akvardar

Marmara University Pendik Training and Research Hospital, Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Mental disorders are one of the leading reasons for disability-related retirement and payment of associated long-term benefits in many countries.

Objectives To explore the characteristics of psychiatric outpatients who apply for disability pensions and to investigate the factors associated with making an application.

Methods A four-month cross-sectional evaluation of disability pension and retirement applications to the psychiatry outpatient clinic in a university hospital in Istanbul.

Results The majority of 144 patients were male ($n = 102$, 70.8%), based in Istanbul, married, living with their families and had no occupation at the time of inquiry. Excluding applications for individuals with a diagnosis of intellectual disability ($n = 44$), most applicants were primary school graduates ($n = 31$, 32.3%). For the whole group, the median age of application was 34. 60%, ($n = 87$) had an established psychiatric diagnosis before the application, with average duration since diagnosis of approximately 8 years. The most frequent diagnoses were intellectual disability, followed by schizophrenia and depression. More than half of the patients were treated only outpatiently, with no hospitalization ($n = 55$, 58%). Thirty-two of them (22.4%) had a comorbid psychiatric diagnosis and 58 (40.3%) had at least one comorbid medical diagnosis.

Conclusions There are some similarities between our findings and findings from other countries, such as low educational level and frequent comorbid somatic diseases among patients applying for disability pension. In contrast with the literature and as an indicator of social inequality, most patients applied for disability pension were male. The results are reflecting the specificities of different health systems and cultural perceptions of disability.

Changing pattern of clinical profile of first contact patients attending outpatient Services at the General Hospital Psychiatric Units in India over the last 50 years

M. Sood*, R. Ranjan, R.K. Chadda, S. Khandelwal

All India Institute of Medical Sciences, Psychiatry, Delhi, India

* Corresponding author.

Introduction Over the last eight decades, general hospital psychiatric units (GHPUs) have become important mental health service set-ups in India. This period has seen a large number of radical changes in the Indian society. In this background, it is important to know if it had any effects on the patients attending the GHPUs.

Methodology A total of five hundred subjects, attending a GHPU were recruited prospectively for the study. The subjects were assessed using a semi-structured proforma. A comparison was

made with similar studies conducted in GHPU settings over the last 5 decades.

Results Neurotic, stress related and somatoform disorders was the commonest diagnostic group (33%) followed by psychotic disorders (17%) and mood disorders (15%). The finding is broadly similar to the studies done at different times in the last 5 decades. However, there were lesser number of patients with mental retardation, organic brain syndrome and seizure disorder.

Conclusion The study highlights the strengths of GHPU set-ups like inter-speciality referrals, fewer stigmas, patients travelling from far off places to seek treatment and involvement of family in the care of mentally ill.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Seven years of occupational psychiatry in a Portuguese university hospital

L. Sousa*, A. Antunes, L. Bastos

Hospital de Santa Maria, Lisbon Academic Medical Center, Psychiatry and Mental Health, Lisbon, Portugal

* Corresponding author.

Introduction Occupational psychiatry is the field of psychiatry that focuses on work, its importance in the lives of individuals and work organizations. It gained visibility in the 2000 decade, after the creation of the Academy of Occupational and Organizational Psychiatry. Following that trend, occupational psychiatry outpatient started in 2008 at Hospital de Santa Maria.

Objective To describe the structure and functioning of that project; to characterize the population that has been referred to this subspecialty, as well as the main motives for referral; and to highlight some paradigmatic cases that deserve special attention.

Aims Call attention to the importance of occupational psychiatry at the individual and institutional level.

Methods All the patients ever referred to the occupational psychiatry consultation were considered for the analysis. Clinical information was obtained through medical records and interviews with the patients. Bibliographic research was conducted through the PubMed in the Medline library.

Results In our hospital, the prototype patient referred to occupational psychiatry is a middle-aged woman working as a medical assistant. The most frequent motives for referral were related to difficulties in accomplishing job duties and definite psychiatric diagnosis corresponded more often to the common mental disorders (anxiety, depression and adjustment disorders). At the institutional level, the initiative was received with great enthusiasm.

Conclusions As Freud stated “To Love and work are the cornerstone of our humanness”, in line with that we consider that occupational psychiatry should be taken as a priority in what concerns to mental health policies.

Stigma and poor mental health literacy as barriers to service use among unemployed people with mental illness – a qualitative study

T. Staiger^{1,*}, T. Waldmann¹, S. Krumm², N. Rüschi¹

¹ Ulm University, Department of Psychiatry II, Ulm, Germany

² Bezirkskrankenhaus Günzburg, Department of Psychiatry II, Günzburg, Germany

* Corresponding author.

Introduction/objectives Mental health problems were shown by different studies to be both: results of and risk factors for unemployment. However, unemployed people with mental health problems often have difficulties in finding and using mental health services and therefore do not benefit from therapies. Because unemployed individuals outside the healthcare system are a hard-to-reach group, barriers to but also facilities for mental health services are poorly understood.

Aims The aim of the study is to identify barriers and facilitators of help seeking and service use, based on experiences of unemployed people with mental health strains.

Methods We conducted 15 qualitative semi-structured interviews with unemployed individuals, facing self-reported mental health problems or mental illness. Topics included individual experiences with help-seeking and mental health service use, with a focus on barriers and facilitators. Interviews were audiotaped and transcribed verbatim. Transcripts were analyzed using qualitative content analysis and major themes were identified.

Results Patients fear adverse reactions of psychiatric medication. They report to be treated as “different” by their social environment and health professionals, which leads to a lack of self-esteem and inhibits them in their help seeking efforts. Social support and desire for change on the other hand can be strong motivational factors in searching for help.

Conclusion Perception of GPs towards mental health issues of their patients, and especially unemployed patients, has to be raised. Stigmatization of mental illnesses and help seeking should be reduced in practical context.

Big data analysis for improved mental healthcare: A population-based perspective

K. Suzuki^{1,*}, J.C. Muria Tarazon², B. Hu³

¹ Japan

² Fujitsu, Business Consulting Unit, Valencia, Spain

³ Fujitsu Laboratory of Europe, Data Analytic Department, London, United Kingdom

* Corresponding author.

Introduction Mental disorder is a key public health challenge due to its high levels of disability and mortality and a leading cause of DALYs (Disability adjusted life years). Therefore, a small improvement on mental care provision and management could generate solid benefits on relieving the social burden of mental diseases.

Objective Long-term vision of collaboration between Fujitsu Laboratories, Fujitsu Spain, and Hospital Clinico San Carlos is to generate value through predictive and preventive medicine improving healthcare outcomes for every clinical area, benefiting managers, clinicians, and patients.

Aims The aim is to enable a data centric approach towards a value-based healthcare system via health informatics. The project fuses knowledge from heterogeneous sources for obtaining patterns for clinical decision-making.

Methods This project leverages a data analytic platform named HIKARI (“light” in Japanese) to deliver the “right” information, to the “right” people, at the “right” time. HIKARI consists of a data-driven and evidence-based Decision Support and Recommendation System (DSRS), facilitating identification of patterns in large-scale datasets and linking of data from different sources and types.

Results Using multiple, heterogeneous datasets, HIKARI detects correlations from data retrospectively and conducts early intervention when signs and symptoms prompt immediate actions. HIKARI also highlights resource consumption patterns and suggests future resource allocation, using real-life data.

Conclusions With the advance of ICT, especially data-intensive computing paradigm, approaches mixing individual risk assessment and environmental conditions become increasingly prevalent. HIKARI DSRS can serve as a key tool for individuals and clinicians daily management of mental disorders.

Mental health improvement through physical therapy: Polish perspective

A.R. Szczegielniak^{1,*}, J. Szczegielniak²

¹ Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

² Opole University of Technology, Faculty of Physical Education and Physiotherapy, Opole, Poland

* Corresponding author.

Among people suffering from mental conditions increased prevalence of diabetes, cardiovascular disease, hypertension and respiratory disease is observed, with considerably higher levels of morbidity and mortality. Still, mental conditions are neglected and not treated equally to other medical states in Poland. It is commonly believed that psychiatric patients are violent and unpredictable, even though they are more likely to be a victim of violence themselves. This attitude, reinforced by media coverage and observed also among health care workers, results in unwillingness to have any relations with mental patients due to fear of them being aggressive. Connection between physical well-being and mental health is well known. Physical therapists have necessary knowledge and skills to support development of individual independence, anxiety management and lifestyle control in order to keep patients healthier. It can be done by specially designed treatment programmes consisting of exercises, manual techniques and physical medicine procedures. Lack of understanding of this valuable connection results in insufficient emphasis on the presence of physiotherapist in the multidisciplinary therapeutic team on psychiatric wards nationwide. The study focuses on summary of the current situation in Poland and starts discussion on possible areas of improvements.

Experience of burnout syndrome in resident physicians

P. Cigarroa-Vázquez¹, I. Vargas-Huicochea^{2,*}

¹ National Autonomous University of Mexico UNAM, Program of Masters in Mental Health, Mexico City, Mexico

² Instituto Nacional de Psiquiatría “Ramón de la Fuente Muñiz”, Division of Clinical Research, Mexico City, Mexico

* Corresponding author.

Medical residents, as a population that is in formation and that represents the workforce in public hospitals, are in a particularly vulnerable situation for the development of burnout syndrome (BOS), defined as a psychosocial disease in response to chronic stress in the work environment. This study analyzed the impact of BOS on a personal level, residents' ways of coping, and the perceived needs to prevent it.

Objectives To analyze the experience of BOS in medical residents of Mexico City.

Methods Qualitative design with a phenomenological approach. Semi-structured interviews were conducted. Participants were medical residents in training who agreed to participate. Data analysis was based meaning categorization and condensation, as well as some elements of discourse analysis.

Results We had interviews with residents of gynaecology, otorhinolaryngology, family medicine and psychiatry. We have found that there are some specific aspects that contribute to the development BOS:

- the hidden curriculum that has become evident through unnecessary punishments;
- various roles to be met simultaneously by residents;
- the basic needs like sleeping and eating right are not being met due to excessive workload.
- impact in general health.

Conclusions It is necessary to make visible the complexity of the BOS and its impact on trainees to prevent deterioration in the quality of life and overall health status. It would be to achieve the satisfaction of basic needs as essential conditions for physical and mental well-being of all human beings, and more so for those whose task is to contribute to the health of others.

Improving Ghana's mental health care through task shifting – psychiatrists and health policy directors views

V. Agyapong^{1,*}, E. McAuliffe², C. Farren³

¹ University of Alberta, Department of Psychiatry, Fort McMurray, Canada

² University College Dublin, School of Nursing, Midwifery and Health Systems, Dublin, Ireland

³ University of Dublin, Trinity College, Department of Psychiatry, Dublin, Ireland

* Corresponding author.

Background Currently, Ghana has only twelfth psychiatrists in active service providing for the mental health needs of a population of nearly 25 million people. Ghana has therefore adopted a system of task-shifting to address the critical shortage of psychiatrists.

Aim To examine the perception of psychiatrists and health policy directors about the government's policy to expand mental health care delivery in Ghana through a system of task-shifting from psychiatrists to community mental health workers (CMHWs).

Methods A self-administered semi-structured questionnaire was developed and administered to 11 psychiatrists and 29 health policy directors.

Results Only one psychiatrist and 3 (10.3%) health policy directors reported they were not aware of task-shifting within Ghana's mental health delivery system. Ten (91.1%) psychiatrists and 23 (79.3%) health policy directors were aware of a policy of the Government of Ghana to improve on the human resource base within mental health through a system task-shifting. Overall, 5 (45.5%) of the psychiatrists and 9 (31%) health policy directors perceived there are some resistance to the implementation of a policy of task shifting including resistance from traditional and spiritual healers, some psychiatrists, some community psychiatric nurses and psychologists. The majority of psychiatrists and health policy directors were of the view that CMHWs should be allowed to assess, diagnose and treat most of the common mental disorders.

Conclusion Psychiatrists and health policy directors in Ghana support Governments policy to expand on mental health care delivery through a system of task-shifting despite their knowledge of resistance from certain professionals.

Towards new models of care: Developing a curriculum for interprofessional mental health training

C. Attoe^{1,*}, Z. Jabur¹, M. Lavelle², S. Cross¹

¹ South London & Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

² King's College London, Florence Nightingale Faculty of Nursing & Midwifery, London, United Kingdom

* Corresponding author.

Introduction Interprofessional training remains rare in mental health and psychiatry, yet this is an ideal area to benefit from this approach. Traditionally clinicians from various specialities have trained 'in silos', with knowledge expansion the focus rather than experiential team-based learning. There is no unifying mental health curriculum to meet training needs of healthcare workforces, particularly in light of New Models of Care. A move towards reducing traditional barriers between disciplines, and more collaborative patient-focused care, must be reflected in training strategies as well as service structure.

Aims To develop a comprehensive mental health curriculum relating to New Models of Care with an interprofessional focus, having recognised gaps in existing provision.

Methods A literature, strategy, and policy review identified best practice in interprofessional training for mental health. A scoping exercise collected current training plans for mental health across professions, mental health trusts, primary care and others within Community Education Provider Networks. Focus groups were held with key stakeholders across professions, trusts, and institutions to further develop the curriculum structure and pilot ideas. The curriculum was drafted and reviewed with local education leads, before being finalised.

Results The final interprofessional mental health curriculum presents a clearly structured, innovative approach to mental health training applicable to all professions and organisations, with an interprofessional focus to facilitate the transition to New Models of Care and improved patient experience and outcomes.

Conclusion We hope this curriculum will be adopted by local education leads and departments, and will have significant, wide-reaching impact on mental health training and subsequently patient care.

Task-shifting and organization of psychiatric services in a low-resource context: Using peer therapy at a mental rehabilitation center in Fès as a case study

H. Khabbache¹, N. Bragazzi^{2,*}, I. Rammouz³

¹ Faculté des lettres et des sciences humaines, Sais, laboratoire études théologiques, sciences cognitives et sociales, University of Fez Sidi Mohamed Ben Abdellah, Fès, Morocco

² University of Genoa, Department of Health Sciences DISSAL, Genoa, Italy

³ University of Fez Sidi Mohamed Ben Abdellah, Department of Psychiatry, University Hospital of Fez, centre psychiatrique

universitaire, CHU Hassan II, hôpital Ibn Alhassan, Clinical Neuroscience Laboratory, Fès, Morocco

* Corresponding author.

In this contribution, we will address the challenges that psychological and psychiatric services have to face in a low-resource context. Despite its large and young population made up of approximately thirty million inhabitants, Morocco has no more than 350 psychiatrists, 60 clinical psychologists, about 400 nurses specializing in psychiatry, and social workers. According to the World Health Organization (WHO), in Morocco there are an average of about 9 health-workers in the field of mental health per 100,000 persons. This shortage of specialized health-workers dramatically contrasts with the burden of mental disorders (which have a prevalence of 48.9% in Morocco, with depression affecting an estimated 26.5% of the general population). Psychiatric cures can be ensured, notwithstanding these hurdles, if a public health perspective is assumed. In resource limited settings, working in the field of mental health calls up for putting oneself on the line, exposing to new experiences and re-organizing one's own skills and expertise. The Italian scholar Camillo Golgi, a prominent researcher of the brain, was used to say that a poor laboratory but rich of ideas is preferable to a rich laboratory without ideas. In particular, in the present contribution we will use our clinical experience at a rehabilitation center in Fès (the association NOUR) as a case study and we will show how to use peer therapy in order to overcome the drawbacks that we daily encounter in a setting of limited resources.

Nurses in mental health – Case of Albania

A. Como^{1,*}, F. Elezi², F. Dobi³, S. Tomori⁴, E. Sotiri²

¹ University Hospital Center "Mother Teresa", Neuroscience, Tirana, Albania

² University Hospital Center "Mother Teresa", Psychiatric Service, Tirana, Albania

³ Tirana Mental Health Community Center, Community Center, Tirana, Albania

⁴ University Hospital Center "Mother Teresa", Pediatric Service, Tirana, Albania

* Corresponding author.

Human resources in mental health in Albania, a three million population LMIC, are essentially scarce as presented in a number of WHO publications over the last decade. The 'Reform' of the system of care in mental health is much spoken about during the last 20 years using 'community mental health care' as a basic keyword in national official documents describing short and long-term plans. The objective of the presentation is to describe the shortcomings in a developmental agenda when priority in building capacities is missing, pointing to nurses in mental health as a particularly important component.

Data from different WHO and other UN publications are organized to offer a contextualized picture of the situation compare to other countries in the region too. Results are presented to fuel a discussion on how to prioritize the possible education activities/strategies in the way that the huge gap is starting being filled in a meaningful way for the benefit of the existing network of mental health institutions/services and future developments considering financial constrains and massive migratory trends on educated nurses. Establishing and strengthening the system of continuing education for nurses is presented as possibly the best solution besides other paths need being taken.

Keywords Mental health nurses; LMIC; Community mental health

In France, the 5th July 2011 law changed the rights and the protection of individuals given psychiatric treatment and the conditions of their medical care

F. Cornic*, M.N. Vacheron

Sainte-Anne Hospital Center, Secteur 75G13, Paris cedex 14, France

* Corresponding author.

The principle of non-consensual care has existed in France since 1838, with significant change more than a hundred years later in 1990, triggered by advancements in medical care and the establishment of a psychiatric care in the community. The 1990 law had to evolve quickly in order to comply with European standards. The 5th July 2011 law's three main objectives were: to insure mental care accessibility and continuity, to adapt advancements in medical care to better protect the patients and their support network, and to reinforce the rights and individual freedom of patients.

The 27th September 2013 law sought to reform the previous act following feedback from both the medical and judicial sectors. The law is based on three innovative principles: control by the liberty and custody judge at the twelfth day of full hospitalisation and at the sixth month point of full hospitalisation, the possibility to arrange for the patient to have a community treatment order within the framework of an individual care plan, the possibility to section a patient without a third party, in case of clear and urgent need. As a result of these new laws, the way in which patients were looked after had to change. The choices medical staff have now, are limited by the need to respect the patients' rights in the eyes of the law and the obligation to guarantee continuous and adapted medical care. This law means that an individual's needs must be continuously assessed, substantially changing the therapeutic landscape.

Mental health systems development in UAE

A. Haque

UAE University, Psychology and Counseling, Al-Ain, United Arab Emirates

Background This paper examines the historical development of mental health services in the UAE including formation of federal laws associated with mental health and ministerial decrees. It also discusses cultural considerations in mental health practice in a society that is highly pluralistic and populated mainly by foreigners. The sharia aspects of mental health are also addressed.

Aims The aims of the paper are to familiarize readers in above areas and encourage further work in the area of mental health in UAE.

Methods The research is based on literature review.

Results All federal laws and ministerial decrees are listed and local cultural considerations and sharia laws discussed, as they are unique to his country and region.

Conclusion Although mental health is traditionally neglected in this country it is developing very fast and it is essential to keep track of and encourage such growth for the benefit of consumers and mental health professionals.

How to relate two specific concepts: Sexual health and sexual minority?

F. Jurysta^{1,2}

¹ Centres Hospitaliers Jolimont asbl, Psychiatrie, Haine-Saint-Paul, Belgium

² ULB-Hôpital Erasme, Brussels, Belgium

Introduction WHO defines Sexual Health as “a state of physical, emotional, mental and social well-being in relation to sexuality... and requires a positive and respectful approach to sexuality and sexual relationships, as well as the possibility of having pleasurable and safe sexual experiences, free of coercion, discrimination and violence”.

OCD-10 defines Transsexualism as “the desire to live and be accepted as a member of the opposite sex, usually accompanied by the wish to make his or her body as congruent as possible with the preferred sex through surgery and hormone treatment. The transsexual identity has been present persistently for at least two years. The disorder is not a symptom of another mental disorder or a chromosomal abnormality”.

Objective We developed an integrative model in 4 axes to approach Sexual Health concept and Transsexualism.

Aims Holistic and integrative model of transsexualism gives a better understanding of this disorder and ameliorates global treatment. Moreover, this model should be applied to each sexual minority.

Results 1. Etiology integrates psychological, biological and neuro-developmental aspects. 2. Clinical features for treatment imply large and multidisciplinary approach. 3. Scientific literature includes more than thousand papers on Transsexualism and numerous expertises as endocrinology, psychiatry, cardiology, sleep... 4. Social networks are developed in hospitals, associations... as well as between patients themselves.

Conclusions Holistic and integrative approach of Sexual Minority as Transsexualism could reach Sexual Health concept defined by WHO.

Mental health legislation and policy: Dignity, humanity and practice

A. Persaud

Devizes, United Kingdom

Introduction In many countries, the civil and political rights of people with mental health problems are violated: they are often subjected to serious abuse, such as chaining, and in many countries are denied fundamental human rights and protections through discriminatory laws. Too often, politicians, policy-makers, professionals and others with the authority and duty to protect and provide for them, fail to do so. Sixty-eight percent of WHO Member States have a stand-alone policy or plan for mental health; 51% have a standalone mental health law. In many countries, however, policies and laws are not fully in line with human rights instruments, implementation is weak and persons with mental disorders and family members are only partially involved; Where there has been progress, it has been slow but nevertheless welcomed; Some countries integrate legislation with policy, other have included cultural mediation into clinical practice, whilst others have developed mental health legislation alongside traditional forms of medicine.

Objective and conclusion This presentation will provide an overview of global mental health legislation, describe some practical examples where progress are being made and proposition some new progressive options where legislation can interact with policy and clinical practice to provide humane care.

The Portuguese mental health law – The criteria for compulsory internment

H. Prata-Ribeiro
Coimbra, Portugal

The Portuguese Mental Health Law is complex, aiming to ensure patients liberties and basic civil rights are respected. A specific part of this law regards the compulsory internment and its criteria, being as protective as possible, in order to prevent wrongful internments for people against their will.

The aim of this study is to analyze the mechanisms available to ensure liberty, in a law apparently about coercion.

The methods used consisted in analyzing the law and interpreting its most important details, mentioning them so they can be read and used as examples.

It can be concluded that the Portuguese law has a very strict list of mandatory criteria for the possibility of the compulsory internment, as a way of ensuring no people suffer it wrongfully. The most important being that no person can be interned compulsory if not considered to suffer from a severe mental disease, not being that enough and having to at least present risk for themselves or others, or to juridical goods of high value. Thus, reevaluation of the patient is mandatory only five days after the internment by two different doctors, being the same process assured from then on every two months. Only possible flaw lays on the fact that there is no maximum amount of time predicted for internment, being that always dependent of the revaluations made. Although, the law is considered to be good and prevent abusive use of the compulsory internments.

Preliminary evaluation of the Italian version of the INSPIRE measure of staff support for personal recovery

N. Ratti^{1,*}, B. Mattioli¹, L. Mellini¹, I. Negri², A. Mastrocola¹

¹ AUSL Romagna, Dipartimento di Salute Mentale, DSMDP, Ravenna, Italy

² Università di Bologna, Dipartimento di Psicologia, Bologna, Italy

* Corresponding author.

Introduction Supporting personal recovery has become the main aim for mental health services in many countries nowadays. In particular, the relationship between individual service users and staff members can be the key issue in supporting recovery and this requires specific measures in order to identify and evaluate the orientation of services in this process of change. INSPIRE is a standardized questionnaire developed by King's College, London that represents a service user-rated measure of staff support for personal recovery in the UK.

Objective Although there is a number of instruments aimed at monitoring recovery in the clinical and functional features, there is still lack of measures for personal recovery and recovery orientation of services in the Italian background.

Aims The aim of this study is to evaluate the psychometric properties of the Italian version of INSPIRE as it is applied in the Italian mental health services.

Methods Two rounds of data were collected from a sample of 79 inpatients and outpatients of rehabilitation centers and consultant service of the municipality of Ravenna. Analysis was undertaken using SPSS. The main issues investigated were internal consistency, test-retest reliability and exploratory factor analysis.

Results The results in the present studies indicate that the Italian version of the INSPIRE measure had a very good internal consistency and a satisfactory test-retest reliability.

Conclusions While further studies testing the instrument in larger and more diverse clinical contexts are needed, INSPIRE can be considered a relevant and feasible instrument to use in supporting the development of a recovery-oriented system in Italy.

Anxiety and depression in European immigrants in Africa: Spaniards in South Africa

L. Aguado^{1,2,*}, A. Porras¹, P. Calvo¹, A. Tomita², J. Burns², J.E. Muñoz-Negro¹

¹ San Cecilio University Hospital, Mental Health Unit, Granada, Spain

² University of kwazulu-Natal, Psychiatry, Durban, South Africa

* Corresponding author.

Introduction It is easy to find texts, in scientific literature, studying the adaptation of immigrants from developing countries in western countries. However, in these globalization times that we are living, few are the studies performed on members from developed countries emigrating to the third world.

Objectives/Aims To evaluate the factors predisposing to the onset of anxiety or depression symptoms in Spanish immigrants living in South Africa.

Methods This is an exploratory study with a sample of 51 Spanish residents in South Africa between 24 and 57 years (44% male, 56% female), 44% of which were living there for more than two years. An online survey was administered, collecting data related to reasons and conditions for their moving to the country and traumatic events living during the stay. For the screening of depression and anxiety symptoms Hopkins Symptom Scale (HSCL-25) was used. Finally, we carried about several analysis using Chi² test. For statistical analysis SPSS was utilized.

Results Thirty percent of the sample showed positive scores on anxiety symptoms scale, and 24% scored positive for depression. Job related items as being unemployed ($P < 0.001$) was associated to symptoms of depression. Insecurity/violence ($P < 0.021$) and race discrimination ($P < 0.009$) were the main factors related to anxiety symptoms.

Conclusions Factor related to employment, security and discrimination, has been significantly associated to the onset of anxiety and depression symptoms. Other factors related to the moving to the country or social relationships have shown no relations. More studies are needed to provide information about adaptation and factors related to mental health in Occidental immigrants in developing countries.

Early intervention in psychosis in hospital Santa Ana AGS. A transcultural vision

B. Girela Serrano^{1,*}, M. Guerrerón Jiménez¹,
C.M. Carrillo de Albornoz Calahorra¹, J.A. Rodrigo Manzano²,
O.B. Martínez García¹

¹ Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain

² Hospital Santa Ana Motril, Psicología, Motril, Granada, Spain

* Corresponding author.

Introduction The aim of this paper is to study the profile of Moroccan users to contextualize interventions and to identify if specific requirements are observed.

Methods A descriptive statistical analysis of sociodemographic and clinical variables are performed to acknowledge the differences between Moroccan users ($n=6$) compared to the group of Spanish users ($n=12$).

Results The following was found in the Moroccan users: the average age was 7 years higher. The percentage of Toxic abuse was slightly higher (83% vs 75%), although in comparison to the Spanish users the Moroccan users had double the percentage of patients treated in the Addictions center.

There were no significant differences in the duration of untreated psychosis (DUP) and in the duration of untreated illness (DUI). According to the referral, the Moroccan users were better detected in Primary care (50%/8%).

Regarding the PANSS negative symptoms predominated in Moroccan (45/20 percentile) and general psychopathology (65/35 percentile).

In the Social Functioning Scale (SFS), there are only differences in Autonomy Execution (T score = 104/ T = 92).

The Family Questionnaire (FQ) shows that families reported greater frequency and discomfort of symptoms and the user as less capable of controlling themselves. Finally, the Global Assessment of Functioning (GAF) offers an average of nearly 15 points lower.

Discussion The training area stands out as a handicap in the rehabilitation process. Clinically negative symptoms and general discomfort are factors that limit the overall functioning. More specific interventions are also required for the families of these users.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Transcultural approach in early psychosis interventions

M. Guerrero Jiménez^{1,*}, J.A. Rodrigo Manzano²,
C.M. Carrillo de Albornoz Calahorra², B.M. Girela Serrano²

¹ University Hospital San Cecilio, Psychiatry, Granada, Spain

² Santa Ana Hospital, Mental Health, Motril, Spain

* Corresponding author.

Introduction The Early Psychosis Intervention Programme (EPIP) in South Granada serves a population with a first psychotic episode. In 2014, 16 patients entered the program, 6 of whom were North Africans.

Aims It is justified by clinical and health care needs to adapt and contextualize care plans and interventions to the specific necessities of this population: considering its suffering meaning and interpretation.

Methods A descriptive study of the data obtained in this population with the Scale of Positive and Negative Syndrome of Schizophrenia (PANSS) arises.

Results In the positive scale, the 6 subjects score in the low range (between 6–25th percentile).

On the negative 2 score in the low range and 4 in the middle (between 26–74th percentile).

In the compound scale in 3 cases, the predominance of negative symptoms is in the low range scale, the rest is in the middle range. Finally, in general psychopathology scale, 2 subjects scored in the low range, the same who scored in the same range in the negative scale. Two subjects scored in the midrange and 2 in the high.

Conclusions According to data, positive symptoms do not stand out among this group of patients. As for negative symptoms, if the range is low, so is the measure of general psychopathology. If the range is average, general psychopathology is medium-high. Also, when the range is average in negative symptoms, means the compound profile reflects predominance of negative syndrome. This reveals the importance of emphasizing a negative symptoms approach and its relationship with general psychopathology.

Investigating physical, psychological and social wellbeing among children of Syrian refugees in Jordan

A. Hamdan-Mansour

The University of Jordan, Faculty of Nursing-community health Nursing, Amman, Jordan

Background Several man-made situations that are documented in the literature showed to jeopardize mental health of people. Amongst is war that has direct effect on mental health of children, and consequently; their health and wellbeing in future.

Objective The study aims at investigating the psychological and social wellbeing (adaptation, anxiety, perception of social support, anger, and strength and difficulties in life) among children of Syrian refugees in Jordan.

Methods A total of 250 children of Syrian refugees residing in host community been interviewed for their psychological disorders from three different areas of Jordan. Data collected in regards to adaptation, anxiety, perception of social support, psychosomatic symptoms, and.

Results About 30% ($n=77$) of children had problems in teeth and 50% had headache. Psychosocially, 25% ($n=63$) suffering loneliness, 24% ($n=59$) feeling depressed, and about 26% ($n=64$) spent times alone. Results also showed that 78.0% of children reported that they were satisfied with the ways in handling their problems, and 80.2% had a perception that the way they were managing their problems were better than their counterparts. Regarding social anxiety, the mean score was 20.2 (SD = 9.2) indicating that children suffer mild social anxiety. Also, children had mild to moderate level of anger. In particular, 75% of children had moderate score of anger subscales. Also children have moderate perception of their emotional, behavioral and social functions. About 75% of children had high score of functional disabilities.

Psychiatry trainees in Turkey considers leaving the country

O. Kilic^{1,*}, E. Sonmez², S. Guloksuz³, M. Pinto da Costa⁴

¹ Beykent University, Psychology, Istanbul, Turkey

² Marmara University School of Medicine, Psychiatry, Istanbul, Turkey

³ Yale University Medical School, Psychiatry, New Haven, CT, USA

⁴ Hospital de Magalhaes Lemos, University of Porto, Psychiatry, Porto, Portugal

* Corresponding author.

Introduction The brain drain of mental health professionals is an important issue especially for developing countries with inadequate recruitment rates. The European Federation of Psychiatric Trainees (EFPT) investigated the extent of migration among trainees across Europe by Brain Drain research project. Results from a non-EU country, with the lowest number of mental health professionals per 100 000 population across OECD countries might provide important clues.

Objective To identify attitudes towards and behaviors towards international migration among psychiatry trainees from Turkey.

Method An online survey was conducted among psychiatry trainees from Turkey in 2013, as part of the EFPT Brain Drain Research Project.

Results Of 107 trainees surveyed, 74% considered living abroad. However, the rate of having even short mobility experience was just 13%, and these were mainly educational visits. More than half of those who visited a foreign country reported to have a satisfactory experience, which might explain the positive influence of these visits on attitudes towards migration. Responders perceived academic conditions as the most important aspect of training that needs to be improved, in line with the fact that inadequate training programs were important reasons for migrating.

Conclusion Overall, psychiatry trainees in Turkey tend to remain in their country of origin, which may protect healthcare system against the detriment of workforce loss. The relatively low rate of migration may also reflect the legislative barriers (e.g. being a non-EU country) impeding migrating. Our findings also suggest that the unmet educational needs of trainees require immediate attention.

The onset of psychotic disorders and the immigration status – A look into a growing reality

L. Maia^{1,*}, I. Carvalho², D. Silva², L. Carneiro²

¹ Vila Nova de Gaia, Portugal

² Hospital Center of Vila Nova de Gaia e Espinho, Mental Health Service, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Recent studies point for an increased incidence of psychotic disorders among immigrants when compared to non-immigrant population, with a substantial risk variation being observed among different ethnic minority groups and diverse host countries/societies.

Objective This communication explores the relation between immigration and the onset of psychosis disease, namely the individual and socio-environmental factors implicated in this association.

Aims Accessing the implications of immigration in the establishment of psychotic disorders.

Methods The authors conducted a literary search on Medline and PsychInfo databases regarding the subject immigration and psychotic disorders, elaborating a bibliographic review of the topic.

Results A greater incidence of psychotic disorders in immigrants (in comparison to non-immigrant population) has been established. In actuality a range of studies carried out in different socio-demographic contexts and with different ethnic groups (of immigrants) identify ethnicity, neighbourhood characteristics (namely level ethnic density), discrimination and refugee status, as some of the probable factors that modulate the rate of psychotic disorder and influence its incidence in immigrants.

Conclusions With regard to the relationship between immigration and the development of psychosis, much is still to be understood. Future studies with focuses on different individual, social, cultural and demographic aspects need to be developed in order to better understand and address this phenomenon.

Peculiarities of depressive disorders in emigrants and re-emigrants

N.O. Maruta*, O.P. Venger, T.V. Panko, I.O. Yavdak
Institute of Neurology, Psychiatry, and Narcology of the NAMS of Ukraine, Department of Neuroses and Borderline Conditions, Kharkov, Ukraine

* Corresponding author.

Introduction Emigration and remigration are one of the greatest modern problems and considered as a factor provoking manifestation and exacerbation of mental disorders as well as pathocharacterological personality changes. In emigrants and re-emigrants peculiarities of course of depressive disorders with different genesis are not investigated, that impedes a development of adequate therapeutic methods.

Aim To study clinical-psychopathological peculiarities of depressive disorders in emigrants and re-emigrants patients with psychogenic (F43.21, F43.22) (69 non-emigrants, 68 emigrants, 67 re-emigrants), endogenous (F31.3, F31.4, F32.1, F32.2, F33.1, F33.2) (65, 66 and 63 patients, respectively) and organic depressive disorders (F06.3) (64, 62 and 61 patients, respectively) were examined.

Methods A clinical-psychopathological investigation, Standardized Personality Examination Method, Lusher's Method of Color Choices, HDRS, HARS, MADRS, and SCL-90-R.

Results The highest level of severity of depressive disorders in re-emigrants and the lowest level in non-emigrants were registered. Re-emigrants had predominantly depressive, asthenic-depressive and apathic-depressive forms, whereas emigrants had mainly anxious-depressive ones. According to SCL-90-R data, emigrants had higher indexes of somatization, obsessive-compulsive disorders, anxiety, whereas re-emigrants had higher indexes of depression and interpersonal sensitivity as well as an index of distress expression. In patients examined it was determined a predomination of dysthymic personality traits manifested in the frameworks of the leading depressive of anxious-depressive syndromes. An influence of emigration and remigration factors was the greatest in psychogenic depressions and the lowest in organic depressive disorders.

Conclusions The abovementioned regularities should be taken into account in pharmacotherapy and a social-psychological support for such patients.

Sociocultural factors in mental illness: Biopsychosocial model

S. Rodríguez Vargas*, M.J. Navarro Clemente, A.R. Ivorra Mayoral
Complejo Hospitalario Torrecárdenas, Salud Mental, Almería, Spain

* Corresponding author.

Every human being needs to acquire by interacting with peers, learning and gradually adapted to their socio-cultural environment, attitudes, group, class, gender, provided it fits the circumstances of the environment, personal values to their. They come again, a reference system which is considered to be "culture". You cannot assess psychiatric disorders in isolation, so it is essential to study the socio-cultural context in which it occurs. It is dynamic, its historic time and not everyone integrates alike. Through a case we try to show how culture influences the expression of psychiatric pathology. Specifically, in this patient it is evident that we are beings bio-psycho-social. It is a continuation and must integrate

these three areas when assessing a patient. Here we start with a family history unrelated to the Mental Health so that adherence to antipsychotic treatment is guaranteed with monthly administration depot preparation. These socio-cultural factors are the main trigger for the breakdown of the subject that cause the patient psicotización (exacerbations related to stressful situations).

⁶ Child and Adolescent Psychiatric Trainee, Gothenburg, Sweden

⁷ Psychiatric Trainee, Paris, France

* Corresponding author.

Introduction The interest in experiencing training abroad has grown and its benefits have been progressively recognized. For these reasons, several psychiatric trainees seek to extend their competencies, skills and knowledge through these exchange opportunities, such as the European Federation of Psychiatric Trainees (EFPT) Exchange Programme.

Objectives With this work we intend to describe these international experiences of being acquainted with a different health system and psychiatry training programme.

Aims Reflect on the impact of these experiences, considering on how these can be used to benefit the patient care provided across countries, further to the professional and personal individual benefits that colleagues gain.

Methods Presenting the testimonials of junior doctors from abroad that have had the opportunity to observe and collaborate in the current system of the United Kingdom.

Results The EFPT Exchange Programme is an excellent opportunity for psychiatry trainees to share experiences, knowledge and good practices. The cultural and social framework of psychiatry certainly has an impact on the approach to mental health problems, and being knowledgeable of these differences can provide benefits not only to the junior doctors who complete these exchanges abroad, but also to their colleagues working at their hosting institutions that become acquainted with different realities through their presence and feedback.

Conclusions The benefits of these exchange mobility experiences are unequivocal. Therefore, it is fundamental to share these experiences and promote these opportunities.

Where to be in 5 years? Brain drain of psychiatric trainees – Case of Albania

S. Tomori^{1,*}, M. Pinto da Costa², European Federation of Psychiatric Trainees³

¹ University Hospital Center “Mother Teresa”, Pediatric Service, Tirana, Albania

² Hospital de Magalhães Lemos, University of Porto, Porto, Portugal

³ European Federation of Psychiatric Trainees, European Federation of Psychiatric Trainees, Brussels, Belgium

* Corresponding author.

Introduction The brain drain of psychiatrists is considered as a mental health care damaging phenomenon in low- and middle-income countries. Albania currently has one of the world's highest emigration rates, relative to its population and a total emigrant population of more than 1.25 millions in 2014. More than 50% of the lecturers and researchers in Albania left the country during 1991–2005. Nevertheless, the data on healthcare workers migration is very limited.

Objectives Assessing the migration profile and migratory trends of psychiatry trainees in Albania as part of EFPT Brain Drain study in Europe.

Methods Data collection was accomplished by an anonymous online survey and hard-copy questionnaire in University Hospital Center “Mother Teresa”, to all psychiatric residents in Psychiatric Clinic in Tirana, during May–October 2013.

Results More than 2/3 respondents are very dissatisfied with their income but the main reasons for leaving the country are personal and family composition. A minority did have a short term or long term experience abroad respectively 8,3% and 16,7% during which 50% of them considered to have the same opportunities as the locals. A total of 66% of residents consider leaving the country after the residency training.

Conclusions Losing large numbers of skilled psychiatrists contributes to decreasing of quality of mental health services. Since it can be considered “brain waste” in terms of a loss of investment into human resource development, Albania needs to establish policies to promote returnees.

Psychosis and mega cisterna magna: Case report

G. Erzin^{1,*}, A. Demirci¹, D. Cılız², S. Göka¹, Ç. Aydemir¹, E. Göka¹

¹ Ministry of Health, Ankara Numune Training and Research Hospital, psychiatry, Ankara, Turkey

² Ministry of Health, Ankara Numune Training and Research Hospital, radiology, Ankara, Turkey

* Corresponding author.

Introduction Mega cisterna magna is a developmental variation of the posterior fossa characterized by the enlargement of the cisterna magna, morphologically intact vermis and cerebellar hemispheres [1]. Cerebellar structures, especially the vermis, are considered to be associated with the pathophysiology of psychiatric disorders such as schizophrenia [2]. We present a case of psychosis with in a patient with ‘mega-cisterna magna’.

Case A 21-year-old male with a three-day history of psychotic symptoms presented with disinhibited behavior, delusions of persecution and grandeur and labil affect. He neglected personal hygiene and grooming activities. He had dropped out of school a few weeks ago and functioned poorly. The patient admitted to the service. The patient's problems have regressed after 4 mg Pimozid treatment. Neurological examination and EEG were normal. CT and MRI scans disclosed ‘mega-cisterna magna’.

Conclusion This report presents a case of cerebellar lesions presenting with neuropsychiatric symptomatology. As in this case, cerebellar pathologies such as mega cisterna magna that could have a role in development psychotic symptoms should be paid attention.

* Corresponding author.

Introduction Recent studies have shown that it is important to understand the brain mechanism specifically by focusing on the common and unique functional connectivity in each disorder including depression.

Objectives To specify the biomarker of major depressive disorder (MDD), we applied the sparse machine learning algorithm to classify several types of affective disorders using the resting state fMRI data collected in multiple sites, and this study shows the results of depression as a part of those results.

Aims The aim of this study is to understand some specific pattern of functional connectivity in MDD, which would support diagnosis of depression and development of focused and personalized treatments in the future.

Methods The neuroimaging data from patients with major depressive disorder (MDD, $n = 100$) and healthy control adults (HC: $n = 100$) from multiple sites were used for the training dataset. A completely separate dataset ($n = 16$) was kept aside for testing. After all preprocessing of fMRI data, based on one hundred and forty anatomical region of interests (ROIs), 9730 functional connectivities during resting states were prepared as the input of the sparse machine-learning algorithm.

Results As results, 20 functional connectivities were selected with the classification performance of Accuracy: 83.0% (Sensitivity: 81.0%, Specificity: 85.0%). The test data, which was completely separate from the training data, showed the performance accuracy of 83.3%.

Conclusions The selected functional connectivities based on the sparse machine learning algorithm included the brain regions which have been associated with depression.

Keypy – An open source library for EEG microstate analysis

P. Milz

The KEY Institute for Brain-Mind Research, Department of Psychiatry, Psychotherapy and Psychosomatics, University Hospital of Psychiatry, Zurich, Switzerland

The brain's electric field configuration reflects its momentary, global functional state. The fluctuations of these states can be analyzed at millisecond resolution by the EEG microstate analysis. This analysis reportedly allowed the detection of brain state duration, occurrence, and sequence aberrations in psychiatric disorders such as schizophrenia, dementia, and depression. Several existing software solutions implement the microstate analysis, but they all require extensive user-interaction. This represents a major obstacle to time-efficient automated analyses and parameter exploration of large EEG datasets. Scriptable programming languages such as Python provide a means to efficiently automate such analysis workflows.

For this reason, I developed the KEY EEG Python Library keypy. This library implements all steps necessary to compute the microstate analysis based on artefact free segments of EEG. It includes functions to carry out the necessary preprocessing (data loading, filtering, average referencing), modified k-means clustering based microstate identification, principal component based mean computation (across recording runs, conditions, participants, and or participant groups), and to retrieve the microstate class based statistics necessary to compare microstate parameters between groups and/or conditions. Keypy is an open source library and freely available from <https://www.github.com/keyinst/keypy>.

Keypy provides a platform for automated microstate analysis of large-scale EEG datasets from psychiatric patient populations and their comparison to healthy controls. It is easily applicable and allows efficient identification of deviant brain states in clinical conditions.

Agenesis of the corpus callosum in a patient with bipolar disorder

J. Nogueira*, R. Ribeiro, J. Vieira, R. Sousa, S. Mendes, B. Ribeiro, M. Salta, B. Barata, A. Gamito, R. Mendes
Centro Hospitalar de Setúbal, Psiquiatria e Saúde Mental, Setúbal, Portugal

* Corresponding author.

Background The corpus callosum (CC) is the largest white matter structure in the brain, which plays a crucial role in interhemispheric communication. Agenesis of the CC is a rare development anomaly, with unknown cause. It could be asymptomatic or associated with mental retardation and neurologic symptoms. Some case reports, post-mortem studies and image studies have linked thickness reduction and agenesis of CC with psychotic symptoms, mainly in schizophrenia patients. Lately, anatomical abnormalities in the CC have been reported in patients with Bipolar Disorder (BD).
Case report A 52-year-old woman was brought to the emergency room by the authorities after being physically aggressive to her 13-year-old daughter and inappropriate behavior in public. At the emergency department her mood was elevated with emotional lability, dispersible attention, slight increase of motor activity, pressured and difficult to interrupt speech, grandious and self-referent delusional ideas.

Her past history revealed hypomanic episodes characterized by periods of excessive shopping and hyperphagia. In 2008, she had a major depressive episode.

Head CT-SCAN revealed agenesis of CC. She received the diagnosis of Manic Episode with mixed features and was treated with valproic acid, flurazepam and olanzapine.

Conclusion This case reinforces the fact that changes in CC, probably due to deficiency in myelination, could have a crucial importance in the pathophysiology of Bipolar Disorder.

Relationship between corpus callosum and anterior commissure size in brain MRI and human intelligence

R. Zareii^{1,*}, A. Alaei²

¹ Shiraz, Iran

² Mazandaran University of Medical Sciences, Department of Radiology, Sari, Iran

* Corresponding author.

Introduction and aims After Parieto-frontal integration theory of intelligence, a new area of investigations was began to examine how performance networks associate with structural networks and the results highlighted the role of brain commissures such as corpus callosum (CC) and anterior commissure (AC) in intelligence. So we investigated the relationship between CC and AC size, as the most important interhemispheric commissure, and intelligence.

Methods and materials Healthy volunteers who their MRI images lack any pathological entity were chosen. Height, length and thickness of CC and transverse, sagittal and superior-inferior diameter of AC were acquired on a 1.5-tesla MRI and a T2-weighted sequences. intelligence quotient(IQ) was measured using the Wechsler intelligence quotient scale too.

Results Our results showed that the length of the CC had a negative correlation and height of the CC had a positive correlation with IQ. However, the thickness of genu, body and splenium of CC did not show any significant correlation with IQ. Superior-inferior diameter of AC, before and after excluding the effect of age, and sagittal diameter of AC only after excluding the effect of age, showed a significant negative correlation with IQ but no significant correlation was realized between the transverse diameter of AC and IQ.

Conclusions Based on our findings, at an early age higher intelligence of the men is because of stronger intrahemispheric communication and with aging, it is due to interhemispheric communications through CC. In contrast, it seems that higher intelligence in women, resulting from stronger interactions between the hemispheres through both AC and CC.

Obsessive-compulsive disorder

EV830

Co-morbid obsessive compulsive and hypochondriac disorders complicated by tardive dyskinesia in a Nigerian man

C. Aghukwa

Bayero University Kano/Aminu Kano Teaching Hospital, Psychiatry, Kano, Nigeria

Introduction Obsessive-compulsive disorder is a group of disorders with unwanted repetition of either mind or physical acts, or both acts manifesting in an insightful sufferer. The pharmacological treatment of this group of disorders could lead to the use of more than one class of drug with resulting negative consequences such as tardive dyskinesia.

Objective The objective was to report a case of obsessive-compulsive disorder (OCD) with comorbid somatic symptoms that was complicated by movement disorders.

Method A literature search on related issues was done online with Google Scholar, followed by a chronological report of the index case.

Result This case presents a 52-year-old man who presented with intrusive, disturbing, and unreasonable thoughts at the mid adolescent time. Following these were complaints of multiple somatic symptoms, which the patient labeled with different disease terms. The illness affected his academic, occupational, social, and marital role obligations. And lately, in the illness due to underlying predispositions, developed drug-related movement problems that worsened his state of handicap.

Conclusion This case attempts to point out the importance of early detection and cautious use of medications in patients, who present with OCDs with or without other psychiatric comorbidities.

The nose – A case report of body dysmorphic disorder and a literature review

C. Agostinho^{1,*}, S. Henriques², I. Coelho²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Centro Hospitalar Psiquiátrico de Lisboa, LRS Bobadela, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Centro Hospitalar Psiquiátrico de Lisboa, Lisboa, Portugal

* Corresponding author.

Introduction Body Dysmorphic Disorder (BDD) is relatively common disorder. Patients with delusional beliefs seem to show greater morbidity (more suicidal attempts and drug abuse or dependence) and less likelihood of receiving treatment.

Objectives and aims In this study, we intended to report a case of BDD followed in psychiatric consultation from 2 years ago, and to make a review of the literature, namely presentation, treatment and prognosis of BDD.

Methods We conducted a description of a BDD case and a research using “Body Dysmorphic Disorder” keywords on Pubmed. **Results** J.F., 45 years old, unemployed, living with his father, referred to the Psychiatric consultation by his GP. The disorder started in the adolescence with an excessive preoccupation with hair loss and nose length, but in early adulthood these concerns became more important. Around 30 years old he was followed in Psychiatry but abandoned. Years later he underwent nose plastic surgery. He tried underwent other nose surgeries, but was refused. He was advised to look for psychiatric care. From the initial observation I highlight the appearance (thin, with a wig, adhesive tape connecting the tip of the nose to the forehead pulling up the nose), delusional ideas regarding the appearance of the nose, overvalued hypochondriac ideas, and no insight for the disease. The patient was reluctant in taking psychotropic drugs. He was referred to day hospital, which he attended with great irregularity.

Conclusions BDD is a disorder with poor prognosis, especially when delusional variant is present, probably in relation to the lack of insight.

Disclosure of interest The authors have not supplied their declaration of competing interest.

From obsessivity to bipolarity and vice versa. A literature review

P. Cano Ruiz^{1,*}, S. Cañas Fraile¹, A. Gómez Peinado¹, P. Sanmartín Salinas²

¹ HNSPS, Psychiatric, Albacete, Spain

² Universidad de Alcalá, Systems Biology, Alcalá de Henares, Spain

* Corresponding author.

Introduction The prevalence of obsessive symptoms in bipolar patients is currently under discussion. Last years, different cases of antidepressant-induced mania and hypomania in patients with OCD have been described.

Several authors have reported that patients with OCD and bipolar disorder have more depressive episodes than patients with only OCD.

Objective To know the relationship between OCD and other bipolar spectrum disorders.

Method Bibliographical review on comorbidity between obsessive symptoms and bipolarity.

Results Some longitudinal analysis have shown that patients firstly diagnosed with OCD have an increased risk for subsequent diagnosis of all other conditions, especially for bipolar and schizoaffective disorder, for those whose risk is of up to 13 times higher. The handling of a patient with bipolar disorder and OCD implies some difficulty, because of the main treatment of anxiety disorders, the antidepressants, alters the course of manic-depressive illness, accelerating cycles.

Conclusions OCD is etiologically related to bipolar spectrum disorders and schizophrenia. Therefore, it is necessary to continue the investigation of possible involved genes and approaches for clinical practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dual target repetitive transcranial magnetic stimulation in the treatment of comorbid obsessive-compulsive disorder in patients with anorexia nervosa: Preliminary results of two case reports

N. De Schryver*, G.M.D. Lemmens, C. Baeken, D. Van den Abbeele

Universitair Ziekenhuis Gent, Psychiatry, Gent, Belgium

* Corresponding author.

Introduction Obsessive-compulsive disorder (OCD) is a frequently reported comorbid disorder (20–30%) in patients with anorexia nervosa (AN). Increasing evidence suggests that repetitive transcranial magnetic stimulation (r-TMS) may be effective in the treatment of refractory OCD and to a lesser extent in AN. Hereby, different target areas: supplemental motor area (SMA) and orbitofrontal cortex (OFC) and dorsolateral prefrontal cortex in AN.

We report two patients with enduring AN and comorbid treatment resistant OCD treated with r-TMS.

Methods Both female patients (34 and 26 years respectively) were hospitalized at the Eating Disorder Unit at the Ghent University Hospital. Treatment responses were evaluated with Yale Brown Obsessive Compulsive Scale (Y-BOCS) and weight gain. Inhibitory continuous thurst stimulation (cTBS) of the SMA followed by cTBS of the OFC was conducted during 20 sessions, 5 sessions a week, during 4 weeks. Stimulation intensity was respectively 100% and 80% of the motor threshold.

Results After cTBS treatment Y-BOCS score of both patients decreased (31 to 24 and 31 to 23 respectively). Only one patient showed a 10% increase of weight. The treatment was well tolerated. No significant side effects were reported.

Conclusion Treatment resistant comorbid OCD in patients with AN may be successfully treated with cTBS.

Reactive anxiety to ruminations of thinking

T. Delgado Durán^{1,*}, F.J. Márquez Ligeró²

¹ Hospital Costa de la Luz, Psychiatry, Huelva, Spain

² Unidad de Gestión clínica Huelva, Psychiatry, Huelva, Spain

* Corresponding author.

The anxiety that accompanies an obsessive-compulsive disorder with predominance of ruminations of thinking, is a symptom of elevated prevalence in the population that makes up abstract labor which accesses for an opposition of hard consecution. The characteristics of the personality of such patients, like perfectionism, control, the analysis of every minimal step they take and of every decision they make, the difficulty for them to find an unexpected event, collaborates so they can have a greater accessibility to accomplish objectives they contemplate, like the case of oppositions for a position in a farm, court or education. However, as such objectives are being met, everything evolves correctly, the fact of not being able to accomplish given purposes, carry on to the appearance of the symptom. The majority of these patients, such symptom is anxiety, reaching such intensity, which limits the development of their daily activities in a correct manner, and in many cases, it obligates them to resign their position. To develop this case, I will expose the case of a 50 year old male, a justice professional, with clinical anxiety of growing intensity in the months previous to the first interview, appears with a reactive character a ruminations of thinking by the impossibility of an adequate agreement of the given working activity. The poster explains how the symptoms appear, how they are treated and what the evolution of the clinical profile is.

Skin picking – A case report

A. Fonseca*, A. Poças, A. Batista, R. Araújo
Centro Hospitalar de Leiria, Psiquiatria, Leiria, Portugal

* Corresponding author.

Introduction Compulsive skin picking and trichotillomania are both impulse control disorders, characterized by the need or urge to touch, scratch, scrub, friction, rub, bite, press or dig in the skin; it is often an answer to minimum skin defects or to mild acne. The resulting tissue damage can be moderate to severe.

Objective Case report of a woman with Skin picking resistant to treatment.

Methods Clinical observation.

Results 43-year-old woman who was admitted in emergency in June 2014 because of her skin lesions. After observation by Dermatologist she was sent to the Psychiatric due to injuries caused by her. She referring compulsion to scratch, bite and tear the skin since she was 3 years old. After introduction of psychotropic drugs, the patient was referred to the Psychiatric consultations. After 1 year consultation there is some clinical improvement.

Conclusion Despite clinical advances in psychiatry, the Skin Picking disease is still little known today, requiring more research and knowledge in terms of phenomenology and of treatment.
